salt myminion git.checkout /path/to/repo opts='--b newbranch'
```

**salt.modules.git.clone**

- Interface to `git-clone(1)`

  - `cwd`  Location of git clone

    - Changed in version 2015.8.0: If `name` is passed, then the clone will be made within this directory.

  - `url`  The URL of the repository to be cloned

    - Changed in version 2015.8.0: Argument renamed from `repository` to `url`

  - `name`  Optional alternate name for the top-level directory to be created by the clone

    - New in version 2015.8.0.

  - `opts`  Any additional options to add to the command line, in a single string

  - `user`  User under which to run the git command. By default, the command is run by the user under which the minion is running.

  - `password`  Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

    - New in version 2016.3.4.

  - `identity`  Path to a private key to use for ssh URLs

    - **Warning:** Unless Salt is invoked from the minion using `salt-call`, the key(s) must be passphraseless. For greater security with passphraseless private keys, see the `sshd(8)` manpage for information on securing the keypair from the remote side in the `authorized_keys` file.
Changed in version 2015.8.7: Salt will no longer attempt to use passphrase-protected keys unless invoked from the minion using `salt-call`, to prevent blocking waiting for user input.

Key can also be specified as a SaltStack file server URL, eg. `salt://location/identity_file`

Changed in version 2016.3.0.

**https_user** Set HTTP Basic Auth username. Only accepted for HTTPS URLs.

New in version 2015.5.0.

**https_pass** Set HTTP Basic Auth password. Only accepted for HTTPS URLs.

New in version 2015.5.0.

**ignore_recode** [False] If `True`, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

**saltenv** The default salt environment to pull sls files from

New in version 2016.3.1.

CLI Example:

```
salt myminion git.clone /path/to/repo_parent_dir git://github.com/saltstack/salt.
```

salt.modules.git.commit(cwd, message, opts='`, user=None, password=None, filename=None, ignore_recode=False)

Interface to `git-commit(1)`

**cwd** The path to the git checkout

**message** Commit message

**opts** Any additional options to add to the command line, in a single string

**user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

**password**

Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

**filename** The location of the file/directory to commit, relative to `cwd`. This argument is optional, and can be used to commit a file without first staging it.

**Note**: This argument only works on files which are already tracked by the git repository.

New in version 2015.8.0.

**ignore_recode** [False] If `True`, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:
```python
salt myminion git.commit /path/to/repo 'The commit message'
salt myminion git.commit /path/to/repo 'The commit message' filename=foo/bar.py
```

```python
salt.modules.git.config_get(key, cwd=None, user=None, password=None, ignore_retcode=False, **kwargs)
```

Get the value of a key in the git configuration file

- **key**: The name of the configuration key to get

  Changed in version 2015.8.0: Argument renamed from setting_name to key

- **cwd**: The path to the git checkout

  Changed in version 2015.8.0: Now optional if global is set to True

- **global**: [False] If True, query the global git configuration. Otherwise, only the local git configuration will be queried.

  New in version 2015.8.0.

- **all**: [False] If True, return a list of all values set for key. If the key does not exist, None will be returned.

  New in version 2015.8.0.

- **user**: User under which to run the git command. By default, the command is run by the user under which the minion is running.

- **password**: Windows only. Required when specifying user. This parameter will be ignored on non-Windows platforms.

  New in version 2016.3.4.

- **ignore_retcode**: [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

  New in version 2015.8.0.

**CLI Examples:**

```bash
salt myminion git.config_get user.name cwd=/path/to/repo
salt myminion git.config_get user.email global=True
salt myminion git.config_get core.gitproxy cwd=/path/to/repo all=True
```

```python
salt.modules.git.config_get_regexp(key, value_regex=None, cwd=None, user=None, password=None, ignore_retcode=False, **kwargs)
```

New in version 2015.8.0.

Get the value of a key or keys in the git configuration file using regexes for more flexible matching. The return data is a dictionary mapping keys to lists of values matching the `value_regex`. If no values match, an empty dictionary will be returned.

- **key**: Regex on which key names will be matched

- **value_regex**: If specified, return all values matching this regex. The return data will be a dictionary mapping keys to lists of values matching the regex.

  **Important**: Only values matching the `value_regex` will be part of the return data. So, if key matches a multivar, then it is possible that not all of the values will be returned. To get all values set for a multivar, simply omit the `value_regex` argument.

- **cwd**: The path to the git checkout

- **global**: [False] If True, query the global git configuration. Otherwise, only the local git configuration will be queried.

- **user**: User under which to run the git command. By default, the command is run by the user under which the minion is running.

- **password**
Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

**ignore_recode** [False] If `True`, do not log an error to the minion log if the git command returns a nonzero exit status.

CLI Examples:

```bash
# Matches any values for key 'foo.bar'
salt myminion git.config_get_regexp /path/to/repo foo.bar

# Matches any value starting with 'baz' set for key 'foo.bar'
salt myminion git.config_get_regexp /path/to/repo foo.bar 'baz.*'

# Matches any key starting with 'user.'
salt myminion git.config_get_regexp '^user\.' global=True
```

salt.modules.git.config_set(key, value=None, multivar=None, cwd=None, user=None, password=None, ignore_recode=False, **kwargs)

Changed in version 2015.8.0: Return the value(s) of the key being set

Set a key in the git configuration file

**cwd**
The path to the git checkout. Must be an absolute path, or the word `global` to indicate that a global key should be set.

Changed in version 2014.7.0: Made `cwd` argument optional if `is_global=True`

**key**
The name of the configuration key to set

Changed in version 2015.8.0: Argument renamed from `setting_name` to `key`

**value**
The value to set for the specified key. Incompatible with the `multivar` argument.

Changed in version 2015.8.0: Argument renamed from `setting_value` to `value`

**add** [False] Add a value to a key, creating/updating a multivar

New in version 2015.8.0.

**multivar**
Set a multivar all at once. Values can be comma-separated or passed as a Python list. Incompatible with the `value` argument.

New in version 2015.8.0.

**user**
User under which to run the git command. By default, the command is run by the user under which the minion is running.

**password**

Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

**ignore_recode** [False] If `True`, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

**global** [False] If `True`, set a global variable

**is_global** [False] If `True`, set a global variable

Depreciated since version 2015.8.0: Use `global` instead

CLI Example:

```
salt myminion git.config_set user.email me@example.com cwd=/path/to/repo
salt myminion git.config_set user.email foo@bar.com global=True
```

salt.modules.git.config_unset(key, value_regex=None, cwd=None, user=None, password=None, ignore_recode=False, **kwargs)

New in version 2015.8.0.
Unset a key in the git configuration file

**cwd** The path to the git checkout. Must be an absolute path, or the word `global` to indicate that a global key should be unset.

**key** The name of the configuration key to unset

**value_regex** Regular expression that matches exactly one key, used to delete a single value from a multivar. Ignored if `all` is set to `True`.

**all** [False] If `True` unset all values for a multivar. If `False`, and `key` is a multivar, an error will be raised.

**global** [False] If `True`, unset set a global variable. Otherwise, a local variable will be unset.

**user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

**password**

Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

**ignore_retcode** [False] If `True`, do not log an error to the minion log if the git command returns a nonzero exit status.

CLI Example:

```
salt myminion git.config_unset /path/to/repo foo.bar
salt myminion git.config_unset /path/to/repo foo.bar all=True
```

---

salt.modules.git.current_branch(cwd, user=None, password=None, ignore_retcode=False)

Returns the current branch name of a local checkout. If HEAD is detached, return the SHA1 of the revision which is currently checked out.

**cwd** The path to the git checkout

**user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

**password**

Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

**ignore_retcode** [False] If `True`, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Example:

```
salt myminion git.current_branch /path/to/repo
```

---

salt.modules.git.describe(cwd, rev='HEAD', user=None, password=None, ignore_retcode=False)

Returns the `git-describe(1)` string (or the SHA1 hash if there are no tags) for the given revision.

**cwd** The path to the git checkout

**rev** [HEAD] The revision to describe

**user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

**password**

Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

**ignore_retcode** [False] If `True`, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.
CLI Examples:

```
salt myminion git.describe /path/to/repo
salt myminion git.describe /path/to/repo develop
```

```
salt.modules.git.diff(cwd, item1=None, item2=None, opts='`, user=None, password=None, no_index=False, cached=False, paths=None)
```

New in version 2015.8.12, 2016.3.3, 2016.11.0.

Interface to `git-diff(1)`

- **cwd**: The path to the git checkout
- **item1 and item2**: Revision(s) to pass to the `git diff` command. One or both of these arguments may be ignored if some of the options below are set to `True`. When `cached` is `False`, and no revisions are passed to this function, then the current working tree will be compared against the index (i.e. unstaged changes). When two revisions are passed, they will be compared to each other.
- **opts**: Any additional options to add to the command line, in a single string

**Note**: On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with `opts=` (as in the CLI examples below) to avoid causing errors with Salt's own argument parsing.

- **user**: User under which to run the git command. By default, the command is run by the user under which the minion is running.
- **password**: Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

- **no_index**: `[False]` When it is necessary to diff two files in the same repo against each other, and not diff two different revisions, set this option to `True`. If this is left `False` in these instances, then a normal `git diff` will be performed against the index (i.e. unstaged changes), and files in the `paths` option will be used to narrow down the diff output.

**Note**: Requires Git 1.5.1 or newer. Additionally, when set to `True`, `item1` and `item2` will be ignored.

- **cached**: `[False]` If `True`, compare staged changes to `item1` (if specified), otherwise compare them to the most recent commit.

**Note**: `item2` is ignored if this option is is set to `True`.

- **paths**: File paths to pass to the `git diff` command. Can be passed as a comma-separated list or a Python list.

CLI Example:

```
# Perform diff against the index (staging area for next commit)
salt myminion git.diff /path/to/repo
# Compare staged changes to the most recent commit
salt myminion git.diff /path/to/repo cached=True
# Compare staged changes to a specific revision
salt myminion git.diff /path/to/repo mybranch cached=True
# Perform diff against the most recent commit (includes staged changes)
salt myminion git.diff /path/to/repo HEAD
# Diff two commits
salt myminion git.diff /path/to/repo abcdef1 aabbccd
# Diff two commits, only showing differences in the specified paths
```
```
salt myminion git.diff /path/to/repo abcdef1 aabbccd paths=path/to/file1,path/to/
--file2
# Diff two files with one being outside the working tree
salt myminion git.diff /path/to/repo no_index=True paths=path/to/file1,/absolute/
--path/to/file2
```

salt.modules.git.fetch(cwd, remote=None, force=False, refspecs=None, opts='', user=None, password=None, identity=None, ignore_retcode=False, saltenv='base')

Changed in version 2015.8.2: Return data is now a dictionary containing information on branches and tags that were added/updated

Interface to `git-fetch(1)`
cwd  The path to the git checkout
remote  Optional remote name to fetch. If not passed, then git will use its default behavior (as detailed in `git-fetch(1)`).

New in version 2015.8.0.

force  Force the fetch even when it is not a fast-forward.

New in version 2015.8.0.

refspecs  Override the refspec(s) configured for the remote with this argument. Multiple refspecs can be passed, comma-separated.

New in version 2015.8.0.

opts  Any additional options to add to the command line, in a single string

**Note:** On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with `opts=` (as in the CLI examples below) to avoid causing errors with Salt’s own argument parsing.

user  User under which to run the git command. By default, the command is run by the user under which the minion is running.

password

Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

identity  Path to a private key to use for ssh URLs

**Warning:** Unless Salt is invoked from the minion using `salt-call`, the key(s) must be passphrase-less. For greater security with passphraseless private keys, see the `sshd(8)` manpage for information on securing the keypair from the remote side in the `authorized_keys` file.

Changed in version 2015.8.7: Salt will no longer attempt to use passphrase-protected keys unless invoked from the minion using `salt-call`, to prevent blocking waiting for user input.

Key can also be specified as a SaltStack file server URL, eg. `salt://location/identity_file`

Changed in version 2016.3.0.

ignore_retcode  [False] If `True`, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

saltenv  The default salt environment to pull sls files from

New in version 2016.3.1.

CLI Example:
salt.myminion git.fetch /path/to/repo upstream
salt.myminion git.fetch /path/to/repo identity=/root/.ssh/id_rsa

salt.modules.git.init(cwd=None, bare=False, template=None, separate_git_dir=None, shared=None, opts='',
user=None, password=None, ignore_retcode=False)

Interface to git-init(1)

cwd  The path to the directory to be initialized
bare  [False] If True, init a bare repository

template  Set this argument to specify an alternate template directory

separate_git_dir  Set this argument to specify an alternate $GIT_DIR

shared  Set sharing permissions on git repo. See git-init(1) for more details.

opts  Any additional options to add to the command line, in a single string

Note: On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with opts=
(as in the CLI examples below) to avoid causing errors with Salt's own argument parsing.

user  User under which to run the git command. By default, the command is run by the user under which the
minion is running.

password  Windows only. Required when specifying user. This parameter will be ignored on non-Windows platforms.

new in version 2016.3.4.

ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero
exit status.

new in version 2015.8.0.

CLI Examples:
salt myminion git.init /path/to/repo
# Init a bare repo (before 2015.8.0)
salt myminion git.init /path/to/bare/repo.git \opts='--bare'
# Init a bare repo (2015.8.0 and later)
salt.myminion git.init /path/to/bare/repo.git bare=True

salt.modules.git.is_worktree(cwd=None, user=None, password=None)

new in version 2015.8.0.

This function will attempt to determine if cwd is part of a worktree by checking its .git to see if it is a file
containing a reference to another gitdir.
cwd  path to the worktree to be removed
user  User under which to run the git command. By default, the command is run by the user under which the
minion is running.

password  Windows only. Required when specifying user. This parameter will be ignored on non-Windows platforms.

new in version 2016.3.4.
CLI Example:

```
salt myminion git.is_worktree /path/to/repo
```

```
salt.modules.git.list_branches(cwd, remote=False, user=None, password=None, ignore_retcode=False)
```

New in version 2015.8.0.

Return a list of branches

**cwd** The path to the git checkout

**remote** [False] If True, list remote branches. Otherwise, local branches will be listed.

**Warning:** This option will only return remote branches of which the local checkout is aware, use `git.fetch` to update remotes.

**user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

**password**

Windows only. Required when specifying **user**. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

**ignore_retcode** [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```
salt myminion git.list_branches /path/to/repo
```

```
salt myminion git.list_branches /path/to/repo remote=True
```

```
salt.modules.git.list_tags(cwd, user=None, password=None, ignore_retcode=False)
```

New in version 2015.8.0.

Return a list of tags

**cwd** The path to the git checkout

**user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

**password**

Windows only. Required when specifying **user**. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

**ignore_retcode** [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```
salt myminion git.list_tags /path/to/repo
```

```
salt.modules.git.list_worktrees(cwd, stale=False, user=None, password=None, **kwargs)
```

New in version 2015.8.0.

Returns information on worktrees
Changed in version 2015.8.4: Version 2.7.0 added the `list` subcommand to `git-worktree(1)` which provides a lot of additional information. The return data has been changed to include this information, even for pre-2.7.0 versions of git. In addition, if a worktree has a detached head, then any tags which point to the worktree's HEAD will be included in the return data.

**Note:** By default, only worktrees for which the worktree directory is still present are returned, but this can be changed using the `all` and `stale` arguments (described below).

```bash
salt myminion git.list_worktrees /path/to/repo
salt myminion git.list_worktrees /path/to/repo all=True
salt myminion git.list_worktrees /path/to/repo stale=True
```

## `salt.modules.git.ls_remote`

Interface to `git-ls-remote(1)`. Returns the upstream hash for a remote reference.

**cwd** The path to the git checkout. Optional (and ignored if present) when `remote` is set to a URL instead of a remote name.

**remote** [origin] The name of the remote to query. Can be the name of a git remote (which exists in the git checkout defined by the `cwd` parameter), or the URL of a remote repository.

Changed in version 2015.8.0: Argument renamed from `repository` to `remote`.

**ref** The name of the ref to query. Optional, if not specified, all refs are returned. Can be a branch or tag name, or the full name of the reference (for example, to get the hash for a Github pull request number 1234, `ref` can be set to `refs/pull/1234/head`)

Changed in version 2015.8.0: Argument renamed from `branch` to `ref`.

**opts** Any additional options to add to the command line, in a single string

New in version 2015.8.0.

**user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

**password**

Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.
identity  Path to a private key to use for ssh URLs

**Warning:** Unless Salt is invoked from the minion using `salt-call`, the key(s) must be passphraseless. For greater security with passphraseless private keys, see the `sshd(8)` manpage for information on securing the keypair from the remote side in the `authorized_keys` file.

Changed in version 2015.8.7: Salt will no longer attempt to use passphrase-protected keys unless invoked from the minion using `salt-call`, to prevent blocking waiting for user input.

Key can also be specified as a SaltStack file server URL, eg. `salt://location/identity_file`

**https_user**  Set HTTP Basic Auth username. Only accepted for HTTPS URLs.

New in version 2015.5.0.

**https_pass**  Set HTTP Basic Auth password. Only accepted for HTTPS URLs.

New in version 2015.5.0.

**ignore_retcode**  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

**saltenv**  The default salt environment to pull sls files from

New in version 2016.3.1.

CLI Example:

```
salt myminion git.ls_remote /path/to/repo origin master
salt myminion git.ls_remote remote=https://mydomain.tld/repo.git ref=mytag opts='--tags'
```

salt.modules.git.merge(cwd, rev=None, opts='', user=None, password=None, ignore_retcode=False, **kwargs)

Interface to `git-merge(1)`

**cwd**  The path to the git checkout

New in version 2015.8.0.

**rev**  Revision to merge into the current branch. If not specified, the remote tracking branch will be merged.

New in version 2015.8.0.

**branch**  The remote branch or revision to merge into the current branch

Deprecated since version 2015.8.0: Use `rev` instead.

**opts**  Any additional options to add to the command line, in a single string

**Note:** On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with `opts=` (as in the CLI examples below) to avoid causing errors with Salt’s own argument parsing.

**user**  User under which to run the git command. By default, the command is run by the user under which the minion is running.

**password**

Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

**ignore_retcode**  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.
New in version 2015.8.0.

CLI Example:

```bash
# Fetch first...
salt myminion git.fetch /path/to/repo
# ... then merge the remote tracking branch
salt myminion git.merge /path/to/repo
# ... or merge another rev
salt myminion git.merge /path/to/repo rev=upstream/foo
```

```
salt.modules.git.merge_base(cwd, refs=None, octopus=False, is_ancestor=False, independent=False, fork_point=None, opts='`, user=None, password=None, ignore_retcode=False, **kwargs)
```

New in version 2015.8.0.

Interface to `git-merge-base(1)`.

- **cwd** The path to the git checkout
- **refs** Any refs/commits to check for a merge base. Can be passed as a comma-separated list or a Python list.
- **all** [False] Return a list of all matching merge bases. Not compatible with any of the below options except for `octopus`.
- **octopus** [False] If `True`, then this function will determine the best common ancestors of all specified commits, in preparation for an n-way merge. See [here](#) for a description of how these bases are determined.
  
  Set all to `True` with this option to return all computed merge bases, otherwise only the ```best``` will be returned.
- **is_ancestor** [False] If `True`, then instead of returning the merge base, return a boolean telling whether or not the first commit is an ancestor of the second commit.

**Note:** This option requires two commits to be passed.

Changed in version 2015.8.2: Works properly in git versions older than 1.8.0, where the `--is-ancestor` CLI option is not present.

- **independent** [False] If `True`, this function will return the IDs of the refs/commits passed which cannot be reached by another commit.
- **fork_point** If passed, then this function will return the commit where the commit diverged from the ref specified by `fork_point`. If no fork point is found, `None` is returned.

**Note:** At most one commit is permitted to be passed if a `fork_point` is specified. If no commits are passed, then `HEAD` is assumed.

- **opts** Any additional options to add to the command line, in a single string

  **Note:** On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with `opts=` (as in the CLI examples below) to avoid causing errors with Salt's own argument parsing.

  This option should not be necessary unless new CLI arguments are added to `git-merge-base(1)` and are not yet supported in Salt.

- **user** User under which to run the git command. By default, the command is run by the user under which the minion is running.
- **password**

  Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.
New in version 2016.3.4.

**ignore_recode**  [False] if True, do not log an error to the minion log if the git command returns a nonzero exit status.

CLI Examples:

```
salt myminion git.merge_base /path/to/repo HEAD upstream/mybranch
salt myminion git.merge_base /path/to/repo 8f2e542,4ad8cab,cdc9886 octopus=True
salt myminion git.merge_base /path/to/repo refs=8f2e542,4ad8cab,cdc9886 independent=True
salt myminion git.merge_base /path/to/repo refs=8f2e542,4ad8cab is_ancestor=True
salt myminion git.merge_base /path/to/repo fork_point=upstream/master
salt myminion git.merge_base /path/to/repo refs=mybranch fork_point=upstream/master
```

```
salt myminion git.merge_base /path/to/repo HEAD upstream/dev
salt myminion git.merge_base /path/to/repo HEAD upstream/dev base=aaf3c3d
```

`salt.modules.git.merge_tree(cwd, ref1, ref2, base=None, user=None, password=None, ignore_recode=False)`

New in version 2015.8.0.

Interface to *git-merge-tree(1)*, shows the merge results and conflicts from a 3-way merge without touching the index.

cwd  The path to the git checkout

ref1  First ref/commit to compare

ref2  Second ref/commit to compare

base  The base tree to use for the 3-way-merge. If not provided, then *git.merge_base* will be invoked on ref1 and ref2 to determine the merge base to use.

user  User under which to run the git command. By default, the command is run by the user under which the minion is running.

password  

Windows only. Required when specifying user. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

**ignore_recode**  [False] if True, do not log an error to the minion log if the git command returns a nonzero exit status.

CLI Examples:

```
salt myminion git.merge_tree /path/to/repo HEAD upstream/dev
salt myminion git.merge_tree /path/to/repo HEAD upstream/dev base=aaf3c3d
```

`salt.modules.git.pull(cwd, opts='', user=None, password=None, identity=None, ignore_recode=False, saltenv='base')`

Interface to *git-pull(1)*

cwd  The path to the git checkout

opts  Any additional options to add to the command line, in a single string

**Note:** On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with opts= (as in the CLI examples below) to avoid causing errors with Salt's own argument parsing.

user  User under which to run the git command. By default, the command is run by the user under which the minion is running.

password  

Windows only. Required when specifying user. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.
identity  Path to a private key to use for ssh URLs

Warning: Unless Salt is invoked from the minion using salt-call, the key(s) must be passphrase-less. For greater security with passphraseless private keys, see the sshd(8) manpage for information on securing the keypair from the remote side in the authorized_keys file.

Changed in version 2015.8.7: Salt will no longer attempt to use passphrase-protected keys unless invoked from the minion using salt-call, to prevent blocking waiting for user input.

Key can also be specified as a SaltStack file server URL, eg. salt://location/identity_file

Changed in version 2016.3.0.

ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

saltenv  The default salt environment to pull sls files from

New in version 2016.3.1.

CLI Example:

```
salt myminion git.pull /path/to/repo opts='--rebase origin master'
```

salt.modules.git.push(cwd, remote=None, ref=None, opts=' ', user=None, password=None, identity=None, ignore_retcode=False, saltenv='base', **kwargs)

Interface to git-push(1)

cwd  The path to the git checkout

remote  Name of the remote to which the ref should be pushed

New in version 2015.8.0.

ref  [master] Name of the ref to push

Note: Being a refspec, this argument can include a colon to define local and remote ref names.

branch  Name of the ref to push

Depreciated since version 2015.8.0: Use ref instead

opts  Any additional options to add to the command line, in a single string

Note: On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with opts= (as in the CLI examples below) to avoid causing errors with Salt’s own argument parsing.

user  User under which to run the git command. By default, the command is run by the user under which the minion is running.

password  Windows only. Required when specifying user. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

identity  Path to a private key to use for ssh URLs
Warning: Unless Salt is invoked from the minion using `salt-call`, the key(s) must be passphraseless. For greater security with passphraseless private keys, see the `sshd(8)` manpage for information on securing the keypair from the remote side in the `authorized_keys` file.

Changed in version 2015.8.7: Salt will no longer attempt to use passphrase-protected keys unless invoked from the minion using `salt-call`, to prevent blocking waiting for user input.

Key can also be specified as a SaltStack file server URL, eg. `salt://location/identity_file`

Changed in version 2016.3.0.

`ignore_retcode` [False] If `True`, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

`saltenv` The default salt environment to pull sls files from

New in version 2016.3.1.

CLI Example:

```
# Push master as origin/master
salt myminion git.push /path/to/repo origin master
# Push issue21 as upstream/develop
salt myminion git.push /path/to/repo upstream issue21:develop
# Delete remote branch 'upstream/temp'
salt myminion git.push /path/to/repo upstream :temp
```

`salt.modules.git.rebase(cwd, rev='master', opts='`, user=None, password=None, ignore_retcode=False)`

Interface to `git-rebase(1)`

- `cwd` The path to the git checkout
- `rev` [master] The revision to rebase onto the current branch
- `opts` Any additional options to add to the command line, in a single string

Note: On the Salt CLI, if the `opts` are preceded with a dash, it is necessary to precede them with `opts=` (as in the CLI examples below) to avoid causing errors with Salt’s own argument parsing.

- `user` User under which to run the git command. By default, the command is run by the user under which the minion is running.
- `password` Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

`ignore_retcode` [False] If `True`, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Example:

```
salt myminion git.rebase /path/to/repo master
salt myminion git.rebase /path/to/repo 'origin master'
salt myminion git.rebase /path/to/repo origin/master opts='--onto newbranch'
```

`salt.modules.git.remote_get(cwd, remote='origin', user=None, password=None, redact_auth=True, ignore_retcode=False)`

Get the fetch and push URL for a specific remote
cwd  The path to the git checkout
remote [origin] Name of the remote to query
user  User under which to run the git command. By default, the command is run by the user under which the
minion is running.
password
      Windows only. Required when specifying user. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.
redact_auth [True] Set to False to include the username/password if the remote uses HTTPS Basic Auth. Otherwise, this information will be redacted.

Warning: Setting this to False will not only reveal any HTTPS Basic Auth that is configured, but the return data will also be written to the job cache. When possible, it is recommended to use SSH for authentication.

New in version 2015.5.6.
ignore_retcode [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.
CLI Examples:
salt myminion git.remote_get /path/to/repo
salt myminion git.remote_get /path/to/repo upstream

salt.modules.git.remote_refs(url, heads=False, tags=False, user=None, password=None, identity=None, https_user=None, https_pass=None, ignore_retcode=False, saltenv='base')

New in version 2015.8.0.
Return the remote refs for the specified URL
url  URL of the remote repository
heads [False] Restrict output to heads. Can be combined with tags.
tags  [False] Restrict output to tags. Can be combined with heads.
user  User under which to run the git command. By default, the command is run by the user under which the
minion is running.
password
      Windows only. Required when specifying user. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.
identity  Path to a private key to use for ssh URLs

Warning: Unless Salt is invoked from the minion using salt-call, the key(s) must be passphrase-less. For greater security with passphraseless private keys, see the sshd(8) manpage for information on securing the keypair from the remote side in the authorized_keys file.

Changed in version 2015.8.7: Salt will no longer attempt to use passphrase-protected keys unless invoked from the minion using salt-call, to prevent blocking waiting for user input.

Key can also be specified as a SaltStack file server URL, eg. salt://location/identity_file

Changed in version 2016.3.0.
https_user | Set HTTP Basic Auth username. Only accepted for HTTPS URLs.
https_pass | Set HTTP Basic Auth password. Only accepted for HTTPS URLs.
ignore_retcode | [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.
saltenv | The default salt environment to pull sls files from

New in version 2016.3.1.

CLI Example:
```
salt myminion git.remote_refs https://github.com/saltstack/salt.git
```

```
salt.modules.git.remote_set(cwd, url, remote='origin', user=None, password=None,
                           https_user=None, https_pass=None, push_url=None,
                           push_https_user=None, push_https_pass=None, ignore_retcode=False)
```

cwd | The path to the git checkout
url | Remote URL to set
remote | [origin] Name of the remote to set
push_url | If unset, the push URL will be identical to the fetch URL.

New in version 2015.8.0.

user | User under which to run the git command. By default, the command is run by the user under which the minion is running.
password | Windows only. Required when specifying user. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

https_user | Set HTTP Basic Auth username. Only accepted for HTTPS URLs.

New in version 2015.5.0.

https_pass | Set HTTP Basic Auth password. Only accepted for HTTPS URLs.

New in version 2015.5.0.

push_https_user | Set HTTP Basic Auth user for push_url. Ignored if push_url is unset. Only accepted for HTTPS URLs.

New in version 2015.8.0.

push_https_pass | Set HTTP Basic Auth password for push_url. Ignored if push_url is unset. Only accepted for HTTPS URLs.

New in version 2015.8.0.

ignore_retcode | [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:
```
salt myminion git.remote_set /path/to/repo git@github.com:user/repo.git
salt myminion git.remote_set /path/to/repo git@github.com:user/repo.git
   →remote=upstream
salt myminion git.remote_set /path/to/repo https://github.com/user/repo.git
   →remote=upstream push_url=git@github.com:user/repo.git
```

```
salt.modules.git.remotes(cwd, user=None, password=None, redact_auth=True, ignore_retcode=False)
```

Get fetch and push URLs for each remote in a git checkout

cwd | The path to the git checkout
user  User under which to run the git command. By default, the command is run by the user under which the
minion is running.

password

Windows only. Required when specifying user. This parameter will be ignored on non-
Windows platforms.

New in version 2016.3.4.

redact_auth [True] Set to False to include the username/password for authenticated remotes in the return
data. Otherwise, this information will be redacted.

Warning: Setting this to False will not only reveal any HTTPS Basic Auth that is configured, but
the return data will also be written to the job cache. When possible, it is recommended to use SSH
for authentication.

New in version 2015.5.6.

ignore_retcode [False] If True, do not log an error to the minion log if the git command returns a nonzero
exit status.

New in version 2015.8.0.

CLI Example:

```
salt myminion git.remotes /path/to/repo
```

```
salt.modules.git.reset(cwd, opts='', user=None, password=None, ignore_retcode=False)
```

Interface to `git-reset(1)`, returns the stdout from the git command

- **cwd** The path to the git checkout
- **opts** Any additional options to add to the command line, in a single string

Note: On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with `opts=`
as in the CLI examples below to avoid causing errors with Salt’s own argument parsing.

user  User under which to run the git command. By default, the command is run by the user under which the
minion is running.

password

Windows only. Required when specifying user. This parameter will be ignored on non-
Windows platforms.

New in version 2016.3.4.

ignore_retcode [False] If True, do not log an error to the minion log if the git command returns a nonzero
exit status.

New in version 2015.8.0.

CLI Examples:

```
# Soft reset to a specific commit ID
salt myminion git.reset /path/to/repo ac3ee5c
# Hard reset
salt myminion git.reset /path/to/repo opts='--hard origin/master'
```

```
salt.modules.git.rev_parse(cwd, rev=None, opts='', user=None, password=None, ignore_retcode=False)
```

New in version 2015.8.0.

```
Interface to `git-rev-parse(1)`
```

cwd  The path to the git checkout
**rev** Revision to parse. See the SPECIFYING REVISIONS section of the git-rev-parse(1) manpage for details on how to format this argument.

This argument is optional when using the options in the Options for Files section of the git-rev-parse(1) manpage.

**opts** Any additional options to add to the command line, in a single string

**user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

**password**

Windows only. Required when specifying **user**. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

**ignore_retcode** [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

CLI Examples:

```
# Get the full SHA1 for HEAD
salt myminion git.rev_parse /path/to/repo HEAD
# Get the short SHA1 for HEAD
salt myminion git.rev_parse /path/to/repo HEAD opts='--short'
# Get the develop branch's upstream tracking branch
salt myminion git.rev_parse /path/to/repo 'develop{upstream}' opts='--abbrev-ref'
# Get the SHA1 for the commit corresponding to tag v1.2.3
salt myminion git.rev_parse /path/to/repo v1.2.3^{commit}'
# Find out whether or not the repo at /path/to/repo is a bare repository
salt myminion git.rev_parse /path/to/repo opts='--is-bare-repository'
```

**salt.modules.git.revision**(**cwd**, **rev**='HEAD', **short**=False, **user**=None, **password**=None, **ignore_retcode**=False)

Returns the SHA1 hash of a given identifier (hash, branch, tag, HEAD, etc.)

**cwd** The path to the git checkout

**rev** [HEAD] The revision

**short** [False] If True, return an abbreviated SHA1 git hash

**user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

**password**

Windows only. Required when specifying **user**. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

**ignore_retcode** [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Example:

```
salt myminion git.revision /path/to/repo mybranch
```

**salt.modules.git.rm**(**cwd**, **filename**, **opts**=''', **user**=None, **password**=None, **ignore_retcode**=False)

Interface to git-rm(1)

**cwd** The path to the git checkout

**filename** The location of the file/directory to remove, relative to **cwd**

---

**Note:** To remove a directory, `-r` must be part of the **opts** parameter.
**opts**  Any additional options to add to the command line, in a single string

*Note:* On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with `opts=` (as in the CLI examples below) to avoid causing errors with Salt’s own argument parsing.

**user**  User under which to run the git command. By default, the command is run by the user under which the minion is running.

**password**

Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

**ignore_retcode**  [False] If `True`, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```
salt myminion git.rm /path/to/repo foo/bar.py
salt myminion git.rm /path/to/repo foo/bar.py opts='--dry-run'
salt myminion git.rm /path/to/repo foo/baz opts='--'
```

**salt.modules.git.stash**( `cwd`, `action`='save', `opts`='', `user`=None, `password`=None, `ignore_retcode`=False )

Interface to `git-stash(1)`, returns the stdout from the git command

**cwd**  The path to the git checkout

**opts**  Any additional options to add to the command line, in a single string. Use this to complete the `git stash` command by adding the remaining arguments (i.e. 'save <stash comment>', 'apply stash@{2}', 'show', etc.). Omitting this argument will simply run `git stash`.

**user**  User under which to run the git command. By default, the command is run by the user under which the minion is running.

**password**

Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

**ignore_retcode**  [False] If `True`, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```
salt myminion git.stash /path/to/repo save opts='work in progress'
salt myminion git.stash /path/to/repo apply opts='stash@{1}'
salt myminion git.stash /path/to/repo drop opts='stash@{1}'
salt myminion git.stash /path/to/repo list
```

**salt.modules.git.status**( `cwd`, `user`=None, `password`=None, `ignore_retcode`=False )

Changed in version 2015.8.0: Return data has changed from a list of lists to a dictionary

Returns the changes to the repository

**cwd**  The path to the git checkout

**user**  User under which to run the git command. By default, the command is run by the user under which the minion is running.

**password**
Windows only. Required when specifying user. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

ignore_retcode [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Example:

```
salt myminion git.status /path/to/repo
```

**salt.modules.git.submodule**(cwd, command, opts='`, user=None, password=None, identity=None, ignore_retcode=False, saltenv='base', **kwargs)

Changed in version 2015.8.0: Added the command argument to allow for operations other than update to be run on submodules, and deprecated the init argument. To do a submodule update with init=True moving forward, use command=update opts='--init'

Interface to `git-submodule(1)`

cwd The path to the submodule

command Submodule command to run, see `git-submodule(1) <git submodule>` for more information. Any additional arguments after the command (such as the URL when adding a submodule) must be passed in the opts parameter.

New in version 2015.8.0.

opts Any additional options to add to the command line, in a single string

**Note:** On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with opts=(as in the CLI examples below) to avoid causing errors with Salt's own argument parsing.

init [False] If True, ensures that new submodules are initialized

Deprecated since version 2015.8.0: Pass init as the command parameter, or include --init in the opts param with command set to update.

user User under which to run the git command. By default, the command is run by the user under which the minion is running.

password

Windows only. Required when specifying user. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

identity Path to a private key to use for ssh URLs

**Warning:** Unless Salt is invoked from the minion using `salt-call`, the key(s) must be passphrase-less. For greater security with passphraseless private keys, see the `sshd(8)` manpage for information on securing the keypair from the remote side in the authorized_keys file.

Changed in version 2015.8.7: Salt will no longer attempt to use passphrase-protected keys unless invoked from the minion using `salt-call`, to prevent blocking waiting for user input.

Key can also be specified as a SaltStack file server URL, eg. `salt://location/identity_file`

Changed in version 2016.3.0.

ignore_retcode [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.
New in version 2015.8.0.
saltenv  The default salt environment to pull sls files from

New in version 2016.3.1.

CLI Example:

```bash
# Update submodule and ensure it is initialized (before 2015.8.0)
salt myminion git.submodule /path/to/repo/sub/repo init=True
# Update submodule and ensure it is initialized (2015.8.0 and later)
salt myminion git.submodule /path/to/repo/sub/repo update opts='--init'
# Rebase submodule (2015.8.0 and later)
salt myminion git.submodule /path/to/repo/sub/repo update opts='--rebase'
# Add submodule (2015.8.0 and later)
salt myminion git.submodule /path/to/repo/sub/repo add opts='https://mydomain.tld/repo.git'
# Unregister submodule (2015.8.0 and later)
salt myminion git.submodule /path/to/repo/sub/repo deinit
```

```
salt.modules.git.symbolic_ref(cwd, ref, value=None, opts='', user=None, password=None, ignore_retcode=False)
```

New in version 2015.8.0.

Interface to `git-symbolic-ref(1)`

cwd  The path to the git checkout
ref  Symbolic ref to read/modify
value  If passed, then the symbolic ref will be set to this value and an empty string will be returned.

If not passed, then the ref to which ref points will be returned, unless `--delete` is included in opts
(in which case the symbolic ref will be deleted).

opts  Any additional options to add to the command line, in a single string
user  User under which to run the git command. By default, the command is run by the user under which the

minion is running.

password

Windows only. Required when specifying user. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero

exit status.

New in version 2015.8.0.

CLI Examples:

```
# Get ref to which HEAD is pointing
salt myminion git.symbolic_ref /path/to/repo HEAD
# Set/overwrite symbolic ref 'FOO' to local branch 'foo'
salt myminion git.symbolic_ref /path/to/repo FOO refs/heads/foo
# Delete symbolic ref 'FOO'
salt myminion git.symbolic_ref /path/to/repo FOO opts='--delete'
```

```
salt.modules.git.version(versioninfo=False)
```

New in version 2015.8.0.

Returns the version of Git installed on the minion

versioninfo  [False] If True, return the version in a versioninfo list (e.g. [2,5,0])

13.6. execution modules 1085
CLI Example:

```
salt myminion git.version
```

```
salt.modules.git.worktree_add(cwd, worktree_path, ref=None, reset_branch=None, force=None, detach=False, opts='`', user=None, password=None, ignore_retcode=False, **kwargs)
```

New in version 2015.8.0.

Interface to `git-worktree(1)`, adds a worktree

cwd  The path to the git checkout

worktree_path  Path to the new worktree. Can be either absolute, or relative to cwd.

branch  Name of new branch to create. If omitted, will be set to the basename of the worktree_path. For example, if the worktree_path is `/foo/bar/baz`, then branch will be `baz`.

ref  Name of the ref on which to base the new worktree. If omitted, then HEAD is use, and a new branch will be created, named for the basename of the worktree_path. For example, if the worktree_path is `/foo/bar/baz` then a new branch `baz` will be created, and pointed at HEAD.

reset_branch  [False] If False, then `git-worktree(1)` will fail to create the worktree if the targeted branch already exists. Set this argument to True to reset the targeted branch to point at ref, and checkout the newly-reset branch into the new worktree.

force  [False] By default, `git-worktree(1)` will not permit the same branch to be checked out in more than one worktree. Set this argument to True to override this.

opts  Any additional options to add to the command line, in a single string

Note: On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with opts= to avoid causing errors with Salt's own argument parsing.

All CLI options for adding worktrees as of Git 2.5.0 are already supported by this function as of Salt 2015.8.0, so using this argument is unnecessary unless new CLI arguments are added to `git-worktree(1)` and are not yet supported in Salt.

user  User under which to run the git command. By default, the command is run by the user under which the minion is running.

password

Windows only. Required when specifying user. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```
salt myminion git.worktree_add /path/to/repo/main ../hotfix ref=origin/master
salt myminion git.worktree_add /path/to/repo/main ../hotfix ref=origin/master branch=hotfix21
```

salt.modules.git.worktree_prune(cwd, dry_run=False, verbose=True, expire=None, opts='`, user=None, password=None, ignore_retcode=False)

New in version 2015.8.0.

Interface to `git-worktree(1)`, prunes stale worktree administrative data from the gitdir

cwd  The path to the main git checkout or a linked worktree

dry_run  [False] If True, then this function will report what would have been pruned, but no changes will be made.

verbose  [True] Report all changes made. Set to False to suppress this output.
**expire**  Only prune unused worktree data older than a specific period of time. The date format for this parameter is described in the documentation for the `gc.pruneWorktreesExpire` config param in the `git-config(1)` manpage.

**opts**  Any additional options to add to the command line, in a single string

---

**User**  User under which to run the git command. By default, the command is run by the user under which the minion is running.

**password**

Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

**ignore_recode**  [False] If `True`, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```
salt myminion git.worktree_prune /path/to/repo
salt myminion git.worktree_prune /path/to/repo dry_run=True
salt myminion git.worktree_prune /path/to/repo expire=1.day.ago
```

salt.modules.git.worktree_rm(cwd, user=None)

New in version 2015.8.0.

Recursively removes the worktree located at `cwd`, returning `True` if successful. This function will attempt to determine if `cwd` is actually a worktree by invoking `git.is_worktree`. If the path does not correspond to a worktree, then an error will be raised and no action will be taken.

**Warning:** There is no undoing this action. Be **VERY** careful before running this function.

**cwd**  Path to the worktree to be removed

**user**  Used for path expansion when `cwd` is not an absolute path. By default, when `cwd` is not absolute, the path will be assumed to be relative to the home directory of the user under which the minion is running. Setting this option will change the home directory from which path expansion is performed.

CLI Examples:

```
salt myminion git.worktree_rm /path/to/worktree
```

**13.6.103  salt.modules.github module**

Module for interacting with the GitHub v3 API.

New in version 2016.3.0.

**depends**  PyGithub python module
Configuration

Configure this module by specifying the name of a configuration profile in the minion config, minion pillar, or master config. The module will use the `github` key by default, if defined.

For example:

```json
github:
  token: abc1234
  org_name: my_organization
  # optional: only some functions, such as 'add_user',
  # require a dev_team_id
  dev_team_id: 1234
```

```python
salt.modules.github.add_user(name, profile='github')
Add a GitHub user.
name The user for which to obtain information.
profile The name of the profile configuration to use. Defaults to github.
CLI Example:
```
```
salt myminion github.add_user github-handle
```

```python
salt.modules.github.get_user(name, profile='github', user_details=False)
Get a GitHub user by name.
name The user for which to obtain information.
profile The name of the profile configuration to use. Defaults to github.
user_details Prints user information details. Defaults to False. If the user is already in the organization and user_details is set to False, the get_user function returns True. If the user is not already present in the organization, user details will be printed by default.
CLI Example:
```
```
salt myminion github.get_user github-handle
salt myminion github.get_user github-handle user_details=true
```

```python
salt.modules.github.list_users(profile='github')
List all users within the organization.
profile The name of the profile configuration to use. Defaults to github.
CLI Example:
```
```
salt myminion github.list_users
salt myminion github.list_users profile='my-github-profile'
```

```python
salt.modules.github.remove_user(name, profile='github')
Remove a Github user by name.
name The user for which to obtain information.
profile The name of the profile configuration to use. Defaults to github.
CLI Example:
```
```
salt myminion github.remove_user github-handle
```

13.6.104 salt.modules.glance

Module for handling openstack glance calls.

optdepends
• glanceclient Python adapter

**configuration** This module is not usable until the following are specified either in a pillar or in the minion's config file:

```python
keystone.user: admin
keystone.password: verybadpass
keystone.tenant: admin
keystone.insecure: False  #(optional)
keystone.auth_url: 'http://127.0.0.1:5000/v2.0/
```

If configuration for multiple openstack accounts is required, they can be set up as different configuration profiles: For example:

```python
openstack1:
  keystone.user: admin
  keystone.password: verybadpass
  keystone.tenant: admin
  keystone.auth_url: 'http://127.0.0.1:5000/v2.0/

openstack2:
  keystone.user: admin
  keystone.password: verybadpass
  keystone.tenant: admin
  keystone.auth_url: 'http://127.0.0.2:5000/v2.0/
```

With this configuration in place, any of the glance functions can make use of a configuration profile by declaring it explicitly. For example:

```python
salt '*' glance.image_list profile=openstack1
```

**salt.modules.glance.image_create**

Create an image (glance image-create)

CLI Example, old format:

```python
salt '*' glance.image_create
name=f16-jeos
is_public=true
  disk_format=qcow2
  container_format=ovf
  copy_from=http://berrange.fedorapeople.org/
  images/2012-02-29/f16-x86_64-openstack-sda.qcow2
```

CLI Example, new format resembling Glance API v2:

```python
salt '*' glance.image_create
name=f16-jeos
visibility=public
  disk_format=qcow2
  container_format=ovf
  copy_from=http://berrange.fedorapeople.org/
  images/2012-02-29/f16-x86_64-openstack-sda.qcow2
```

The parameter `visibility` defaults to `public` if neither `visibility` nor `is_public` is specified.

**salt.modules.glance.image_delete**

Delete an image (glance image-delete)

CLI Examples:

```python
salt '*' glance.image_delete c2eb2eb0-53e1-4a80-b990-8ec887eae7df
salt '*' glance.image_delete id=c2eb2eb0-53e1-4a80-b990-8ec887eae7df
salt '*' glance.image_delete name=f16-jeos
```
salt.modules.glance.image_list(id=None, profile=None, name=None)
    Return a list of available images (glance image-list)
    CLI Example:
    salt '*' glance.image_list

salt.modules.glance.image_schema(profile=None)
    Returns names and descriptions of the schema `image`'s properties for this profile's instance of glance
    CLI Example:
    salt '*' glance.image_schema

salt.modules.glance.image_show(id=None, name=None, profile=None)
    Return details about a specific image (glance image-show)
    CLI Example:
    salt '*' glance.image_show

salt.modules.glance.image_update(id=None, name=None, profile=None, **kwargs)
    Update properties of given image. Known to work for: - min_ram (in MB) - protected (bool) - visibility ('public' or 'private')
    CLI Example:
    salt '*' glance.image_update id=c2eb2eb0-53e1-4a80-b990-8ec887eae7df
    salt '*' glance.image_update name=f16-jeos

salt.modules.glance.schema_get(name, profile=None)
    Known valid names of schemas are:
    - image
    - images
    - member
    - members
    CLI Example:
    salt '*' glance.schema_get name=f16-jeos

13.6.105 salt.modules.glusterfs

Manage a glusterfs pool
salt.modules.glusterfs.add_volume_bricks(name, bricks)
    Add brick(s) to an existing volume
    name  Volume name
    bricks List of bricks to add to the volume

salt.modules.glusterfs.create(name, bricks, stripe=False, replica=False, device_vg=False, transport='tcp', start=False, force=False)
    Create a glusterfs volume.
    name  Name of the gluster volume
bricks  Bricks to create volume from, in `<peer>`:<brick path> format. For multiple bricks use list format:
  `['<peer1>:=<brick1>', '<peer2>:=<brick2>']`

stripe  Stripe count, the number of bricks should be a multiple of the stripe count for a distributed striped volume
replica  Replica count, the number of bricks should be a multiple of the replica count for a distributed replicated volume
device_vg  If true, specifies volume should use block backend instead of regular posix backend. Block device backend volume does not support multiple bricks
transport  Transport protocol to use, can be `tcp`, `rdma` or `tcp,rdma`
start  Start the volume after creation
force  Force volume creation, this works even if creating in root FS

CLI Example:

```
salt host1 glusterfs.create newvolume host1:/brick
salt gluster1 glusterfs.create vol2
  '[["gluster1:/export/vol2/brick",
    "gluster2:/export/vol2/brick"]]
replica=2 start=True
```

salt.modules.glusterfs.delete(target, stop=True)
Delete a gluster volume
target  Volume to delete
stop  Stop volume before delete if it is started, True by default

salt.modules.glusterfs.info(name)
Return the gluster volume info.
name  Volume name

CLI Example:

```
salt '*' glusterfs.info myvolume
```

salt.modules.glusterfs.list_peers()
Return a list of gluster peers

CLI Example:

```
salt '*' glusterfs.list_peers
```

GLUSTER direct CLI example (to show what salt is sending to gluster):
```
$ gluster peer status
GLUSTER CLI 3.4.4 return example (so we know what we are parsing):
  Number of Peers: 2
  Hostname: ftp2 Port: 24007 Uuid: cbcb256b-e66e-4ec7-a718-21082d396c24 State: Peer in Cluster (Connected)
  Hostname: ftp3 Uuid: 5ea10457-6cb2-427b-a770-7897509625e9 State: Peer in Cluster (Connected)
```

salt.modules.glusterfs.list_volumes()
List configured volumes

CLI Example:

```
salt '*' glusterfs.list_volumes
```

salt.modules.glusterfs.peer(name)
Add another node into the peer list.
name  The remote host to probe.
CLI Example:

```python
salt 'one.gluster.*' glusterfs.peer two
```

GLUSTER direct CLI example (to show what salt is sending to gluster):

```
$ gluster peer probe ftp2
```

GLUSTER CLI 3.4.4 return example (so we know what we are parsing):

- if the `peer` is the local host:
  - peer probe: success: on localhost not needed
- if the peer was just added:
  - peer probe: success
- if the peer was already part of the cluster:
  - peer probe: success: host ftp2 port 24007 already in peer list

### `salt.modules.glusterfs.start_volume(name, force=False)`
Start a gluster volume.

- **name** Volume name
- **force** Force the volume start even if the volume is started. .. versionadded:: 2015.8.4

CLI Example:

```python
salt '*' glusterfs.start mycluster
```

### `salt.modules.glusterfs.status(name)`
Check the status of a gluster volume.

- **name** Volume name

CLI Example:

```python
salt '*' glusterfs.status myvolume
```

### `salt.modules.glusterfs.stop_volume(name, force=False)`
Stop a gluster volume.

- **name** Volume name
- **force** Force stop the volume. .. versionadded:: 2015.8.4

CLI Example:

```python
salt '*' glusterfs.stop_volume mycluster
```

### 13.6.106 `salt.modules.gnomedesktop`

#### GNOME implementations

### `salt.modules.gnomedesktop.get(schema=None, key=None, user=None, **kwargs)`
Get key in a particular GNOME schema

CLI Example:

```python
salt 'user=<username> schema=org.gnome.desktop.screensaver key=idle-activation-enabled
```

### `salt.modules.gnomedesktop.getClockFormat(**kwargs)`
Return the current clock format, either 12h or 24h format.

CLI Example:

```python
salt 'user=<username>' gnome.getClockFormat
```

### `salt.modules.gnomedesktop.getClockShowDate(**kwargs)`
Return the current setting, if the date is shown in the clock
salt modules.gnomedesktop.getIdleActivation(**kwargs)
Get whether the idle activation is enabled

CLI Example:
```
salt '*' gnome.getIdleActivation user=<username>
```

salt modules.gnomedesktop.getIdleDelay(**kwargs)
Return the current idle delay setting in seconds

CLI Example:
```
salt '*' gnome.getIdleDelay user=<username>
```

salt modules.gnomedesktop.ping(**kwargs)
A test to ensure the GNOME module is loaded

CLI Example:
```
salt '*' gnome.ping user=<username>
```

salt modules.gnomedesktop.setClockFormat(clockFormat, **kwargs)
Set the clock format, either 12h or 24h format.

CLI Example:
```
salt '*' gnome.setClockFormat <12h|24h> user=<username>
```

salt modules.gnomedesktop.setClockShowDate(kvalue, **kwargs)
Set whether the date is visible in the clock

CLI Example:
```
salt '*' gnome.setClockShowDate <True|False> user=<username>
```

salt modules.gnomedesktop.setIdleActivation(kvalue, **kwargs)
Set whether the idle activation is enabled

CLI Example:
```
salt '*' gnome.setIdleActivation <True|False> user=<username>
```

salt modules.gnomedesktop.setIdleDelay(delaySeconds, **kwargs)
Set the current idle delay setting in seconds

CLI Example:
```
salt '*' gnome.setIdleDelay <seconds> user=<username>
```

salt modules.gnomedesktop.set(schema=None, key=None, user=None, value=None, **kwargs)
Set key in a particular GNOME schema

CLI Example:
```
salt '*' gnome.set user=<username> schema=org.gnome.desktop.screensaver key=idle-activation-enabled value=False
```
13.6.107 salt.modules.gpg

Manage a GPG keychains, add keys, create keys, retrieve keys from keyservers. Sign, encrypt and sign plus encrypt text and files.

New in version 2015.5.0.

Note: The python-gnupg library and gpg binary are required to be installed.

salt.modules.gpg.create_key(*args, **kwargs)

Create a key in the GPG keychain

Note: GPG key generation requires a lot of entropy and randomness. Difficult to do over a remote connection, consider having another process available which is generating randomness for the machine. Also especially difficult on virtual machines, consider the rng-tools package.

The create_key process takes awhile so increasing the timeout may be necessary, e.g. -t 15.

key_type The type of the primary key to generate. It must be capable of signing. `RSA' or `DSA'.
key_length The length of the primary key in bits.
name_real The real name of the user identity which is represented by the key.
name_comment A comment to attach to the user id.
name_email An email address for the user.
subkey_type The type of the secondary key to generate.
subkey_length The length of the secondary key in bits.
expire_date The expiration date for the primary and any secondary key. You can specify an ISO date, A number of days/weeks/months/years, an epoch value, or 0 for a non-expiring key.
use_passphrase Whether to use a passphrase with the signing key. Passphrase is received from Pillar.
user Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the /etc/salt/gpgkeys.
gnupghome Specify the location where GPG keyring and related files are stored.

CLI Example:

```
salt -t 15 '*' gpg.create_key
```

salt.modules.gpg.decrypt(user=None, text=None, filename=None, output=None, use_passphrase=False, gnupghome=None, bare=False)

Decrypt a message or file

user Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the /etc/salt/gpgkeys.
text The encrypted text to decrypt.
filename The filename to decrypt.
output The filename where the decrypted data will be written, default is standard out.
use_passphrase Whether to use a passphrase with the signing key. Passphrase is received from Pillar.
gnupghome Specify the location where GPG keyring and related files are stored.
bare If True, return the (armored) decrypted block as a string without the standard comment/res dict.

CLI Example:

```
salt '*' gpg.decrypt filename='/path/to/important.file.gpg'
salt '*' gpg.decrypt filename='/path/to/important.file.gpg' use_passphrase=True
```
**salt.modules.gpg.delete_key**

Get a key from the GPG keychain

- **keyid** (Default: None) The keyid of the key to be deleted.
- **fingerprint** (Default: None) The fingerprint of the key to be deleted.
- **delete_secret** (Default: False) Whether to delete a corresponding secret key prior to deleting the public key. Secret keys must be deleted before deleting any corresponding public keys.
- **user** (Default: None) Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the `/etc/salt/gpgkeys`.
- **gnupghome** (Default: None) Specify the location where GPG keyring and related files are stored.

**CLI Example**:

```
salt '*' gpg.delete_key keyid=3FAD9F1E
salt '*' gpg.delete_key fingerprint=53C96788253E58416D20BCD352952C84C3252192
salt '*' gpg.delete_key keyid=3FAD9F1E user=username
salt '*' gpg.delete_key keyid=3FAD9F1E user=username delete_secret=True
```

**salt.modules.gpg.encrypt**

Encrypt a message or file

- **user** (Default: None) Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the `/etc/salt/gpgkeys`.
- **recipients** (Default: None) The fingerprints for those recipient whom the data is being encrypted for.
- **text** (Default: None) The text to encrypt.
- **filename** (Default: None) The filename to encrypt.
- **output** (Default: None) The filename where the signed file will be written, default is standard out.
- **sign** (Default: None) Whether to sign, in addition to encrypt, the data. True to use default key or fingerprint to specify a different key to sign with.
- **use_passphrase** (Default: False) Whether to use a passphrase with the signing key. Passphrase is received from Pillar.
- **gnupghome** (Default: None) Specify the location where GPG keyring and related files are stored.
- **bare** (Default: False) If True, return the (armored) encrypted block as a string without the standard comment/res dict.

**CLI Example**:

```
salt '*' gpg.encrypt text='Hello there. How are you?'
salt '*' gpg.encrypt filename='/path/to/important.file'
salt '*' gpg.encrypt filename='/path/to/important.file' use_passphrase=True
```

**salt.modules.gpg.export_key**

Export a key from the GPG keychain

- **keyids** (Default: None) The key ID(s) of the key(s) to be exported. Can be specified as a comma separated string or a list. Anything which GnuPG itself accepts to identify a key - for example, the key ID or the fingerprint could be used.
- **secret** (Default: False) Export the secret key identified by the keyids information passed.
- **user** (Default: None) Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the `/etc/salt/gpgkeys`.
- **gnupghome** (Default: None) Specify the location where GPG keyring and related files are stored.

**CLI Example**:

```
salt '*' gpg.export_key keyids=3FAD9F1E
salt '*' gpg.export_key keyids=3FAD9F1E secret=True
```

13.6. execution modules
salt '*' gpg.export_key keyids="['3FAD9F1E','3FBD8F1E']" user=username

salt.modules.gpg.get_key(keyid=None, fingerprint=None, user=None, gnupghome=None)
Get a key from the GPG keychain
keyid  The key ID (short or long) of the key to be retrieved.
fingerprint  The fingerprint of the key to be retrieved.
user  Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the /etc/salt/gpgkeys.
gnupghome  Specify the location where GPG keyring and related files are stored.
CLI Example:
salt '*' gpg.get_key keyid=3FAD9F1E
salt '*' gpg.get_key fingerprint=53C96788253E58416D20BCD352952C84C3252192
salt '*' gpg.get_key keyid=3FAD9F1E user=username

salt.modules.gpg.get_secret_key(keyid=None, fingerprint=None, user=None, gnupghome=None)
Get a key from the GPG keychain
keyid  The key ID (short or long) of the key to be retrieved.
fingerprint  The fingerprint of the key to be retrieved.
user  Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the /etc/salt/gpgkeys.
gnupghome  Specify the location where GPG keyring and related files are stored.
CLI Example:
salt '*' gpg.get_secret_key keyid=3FAD9F1E
salt '*' gpg.get_secret_key fingerprint=53C96788253E58416D20BCD352952C84C3252192
salt '*' gpg.get_secret_key keyid=3FAD9F1E user=username

salt.modules.gpg.import_key(*args, **kwargs)
Import a key from text or file
text  The text containing to import.
filename  The filename containing the key to import.
user  Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the /etc/salt/gpgkeys.
gnupghome  Specify the location where GPG keyring and related files are stored.
CLI Example:
salt '*' gpg.import_key text='-----BEGIN PGP PUBLIC KEY BLOCK-----\n... -----END PGP PUBLIC KEY BLOCK-----'
salt '*' gpg.import_key filename='path/to/public-key-file'

salt.modules.gpg.list_keys(user=None, gnupghome=None)
List keys in GPG keychain
user  Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the /etc/salt/gpgkeys.
gnupghome  Specify the location where GPG keyring and related files are stored.
CLI Example:
salt '*' gpg.list_keys
salt.modules.gpg.list_secret_keys(user=None, gnupghome=None)

List secret keys in GPG keychain

user Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the /etc/salt/gpgkeys.

gnupghome Specify the location where GPG keyring and related files are stored.

CLI Example:

```shell
salt '*' gpg.list_secret_keys
```

salt.modules.gpg.receive_keys(*args, **kwargs)

Receive key(s) from keyserver and add them to keychain

keyserver Keyserver to use for searching for GPG keys, defaults to pgp.mit.edu

keys The keyID(s) to retrieve from the keyserver. Can be specified as a comma separated string or a list.

user Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the /etc/salt/gpgkeys.

gnupghome Specify the location where GPG keyring and related files are stored.

CLI Example:

```shell
salt '*' gpg.receive_keys keys='3FAD9F1E'
salt '*' gpg.receive_keys keys='[3FAD9F1E,3FBD9F2E]'
salt '*' gpg.receive_keys keys=3FAD9F1E user=username
```

salt.modules.gpg.search_keys(text, keyserver=None, user=None)

Search keys from keyserver

text Text to search the keyserver for, e.g. email address, keyID or fingerprint.

keyserver Keyserver to use for searching for GPG keys, defaults to pgp.mit.edu.

user Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the /etc/salt/gpgkeys.

CLI Example:

```shell
salt '*' gpg.search_keys user@example.com
salt '*' gpg.search_keys user@example.com keyserver=keyserver.ubuntu.com
salt '*' gpg.search_keys user@example.com keyserver=keyserver.ubuntu.com user=username
```

salt.modules.gpg.sign(user=None, keyid=None, text=None, filename=None, output=None, use_passphrase=False, gnupghome=None)

Sign message or file

user Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the /etc/salt/gpgkeys.

keyid The keyid of the key to set the trust level for, defaults to first key in the secret keyring.

text The text to sign.

filename The filename to sign.

output The filename where the signed file will be written, default is standard out.

use_passphrase Whether to use a passphrase with the signing key. Passphrase is received from Pillar.

gnupghome Specify the location where GPG keyring and related files are stored.

CLI Example:

```shell
salt '*' gpg.sign text='Hello there. How are you?'
salt '*' gpg.sign filename='/path/to/important.file'
```
salt.modules.gpg.sign(filename='/path/to/important.file' use_passphrase=True)

salt.modules.gpg.trust_key(keyid=None, fingerprint=None, trust_level=None, user=None)
Set the trust level for a key in GPG keychain

- **keyid** The keyid of the key to set the trust level for.
- **fingerprint** The fingerprint of the key to set the trust level for.
- **trust_level** The trust level to set for the specified key, must be one of the following: expired, unknown, not_trusted, marginally, fully, ultimately
- **user** Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt` will set the GnuPG home directory to the `/etc/salt/gpgkeys`.

CLI Example:

```
salt '*' gpg.trust_key keyid='3FAD9F1E' trust_level='marginally'
salt '*' gpg.trust_key fingerprint='53C96788253E58416D20BCD352952C84C3252192' trust_level='not_trusted'
salt '*' gpg.trust_key keys='3FAD9F1E' trust_level='ultimately' user='username'
```

salt.modules.gpg.verify(text=None, user=None, filename=None, gnupghome=None)
Verify a message or file

- **text** The text to verify.
- **filename** The filename to verify.
- **user** Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt` will set the GnuPG home directory to the `/etc/salt/gpgkeys`.
- **gnupghome** Specify the location where GPG keyring and related files are stored.

CLI Example:

```
salt '*' gpg.verify text='Hello there. How are you?'
salt '*' gpg.verify filename='/path/to/important.file'
```

13.6.108 salt.modules.grains

Return/control aspects of the grains data

salt.modules.grains.append(key, val, convert=False, delimiter=':')
New in version 0.17.0.

- **key** The grain key to be appended to
- **val** The value to append to the grain key
- **convert** If convert is True, convert non-list contents into a list. If convert is False and the grain contains non-list contents, an error is given. Defaults to False.
- **delimiter** The key can be a nested dict key. Use this parameter to specify the delimiter you use, instead of the default ':'. You can now append values to a list in nested dictionary grains. If the list doesn't exist at this level, it will be created.

New in version 2014.7.6.

CLI Example:

```
salt '*' grains.append key val
```
salt.modules.grains.delval(key, destructive=False)

New in version 0.17.0.
Delete a grain from the grains config file
key The grain key from which to delete the value.
destructive Delete the key, too. Defaults to False.

CLI Example:
```
salt '*' grains.delval key
```

salt.modules.grains.fetch(key, default='`', delimiter=': ')

Attempts to retrieve the named value from grains, if the named value is not available return the passed default.
The default return is an empty string.
The value can also represent a value in a nested dict using a ":" delimiter for the dict. This means that if a dict in
grains looks like this:
```
{'pkg': {'apache': 'httpd'}}
```
To retrieve the value associated with the apache key in the pkg dict this key can be passed:
```
pkg:apache
```

Parameters

delimiter -- Specify an alternate delimiter to use when traversing a nested dict.
This is useful for when the desired key contains a colon. See CLI example below for usage.

New in version 2014.7.0.

CLI Example:
```
salt '*' grains.get pkg:apache
salt '*' grains.get abc::def|ghi delimiter='|'
```

salt.modules.grains.filter_by(lookup_dict, grain='os_family', merge=None, default='default', base=None)

New in version 0.17.0.

Look up the given grain in a given dictionary for the current OS and return the result
Although this may occasionally be useful at the CLI, the primary intent of this function is for use in Jinja to make short work of creating lookup tables for OS-specific data. For example:
```
{% set apache = salt['grains.filter_by']({
    'Debian': {'pkg': 'apache2', 'srv': 'apache2'},
    'RedHat': {'pkg': 'httpd', 'srv': 'httpd'},
}, default='Debian') %}
myapache:
  pkg.installed:
    - name: {{ apache.pkg }}
service.running:
    - name: {{ apache.srv }}
```
Values in the lookup table may be overridden by values in Pillar. An example Pillar to override values in the
example above could be as follows:
```
apache:
  lookup:
    pkg: apache_13
    srv: apache
```

13.6. execution modules
The call to `filter_by()` would be modified as follows to reference those Pillar values:

```python
{% set apache = salt['grains.filter_by']({
    ...
}, merge=salt['pillar.get']('apache:lookup')) %}
```

### Parameters

- **lookup_dict** -- A dictionary, keyed by a grain, containing a value or values relevant to systems matching that grain. For example, a key could be the grain for an OS and the value could be the name of a package on that particular OS.

- **grain** -- The name of a grain to match with the current system’s grains. For example, the value of the `''os_family''` grain for the current system could be used to pull values from the `lookup_dict` dictionary.

- **merge** -- A dictionary to merge with the results of the grain selection from `lookup_dict`. This allows Pillar to override the values in the `lookup_dict`. This could be useful, for example, to override the values for non-standard package names such as when using a different Python version from the default Python version provided by the OS (e.g., `python26-mysql` instead of `python-mysql`).

- **default** -- default `lookup_dict``s key used if the grain does not exists or if the grain value has no match on `lookup_dict`. If unspecified the value is `''default''`.

  New in version 2014.1.0.

- **base** -- A `lookup_dict` key to use for a base dictionary. The grain-selected `lookup_dict` is merged over this and then finally the `merge` dictionary is merged. This allows common values for each case to be collected in the base and overridden by the grain selection dictionary and the merge dictionary. Default is unset.

  New in version 2015.5.0.

### CLI Example:

```
salt '*' grains.filter_by '{Debian: Debheads rule, RedHat: I love my hat}'
# this one will render {D: {E: I, G: H}, J: K}
# next one renders {A: {B: G}, D: J}
salt '*' grains.filter_by '{default: {A: {B: C}, D: E}, F: {A: {B: G}}, H: {D: I}}
  'xxx' '{D: J}''F' 'default'
# next same as above when default='H' instead of 'F' renders {A: {B: C}, D: J}
```

### Salt.modules.grains.get(key, default='', delimiter=':')

Attempt to retrieve the named value from grains, if the named value is not available return the passed default. The default return is an empty string.

The value can also represent a value in a nested dict using a `''`` delimiter for the dict. This means that if a dict in grains looks like this:

```
{'pkg': {'apache': 'httpd'}}
```

To retrieve the value associated with the `apache` key in the `pkg` dict this key can be passed:

```
pkg:apache
```

### Parameters delimiter -- Specify an alternate delimiter to use when traversing a nested dict.

This is useful for when the desired key contains a colon. See CLI example below for usage.

New in version 2014.7.0.
CLI Example:

```
salt '*' grains.get pkg:apache
salt '*' grains.get abc::def|ghi delimiter='|'
```

**salt.modules.grains.get_or_set_hash**

```
salt.modules.grains.get_or_set_hash(name, length=8, chars='abcdefghijklmnopqrstuvwxyz0123456789!@#$%^&*(-_=+)')
```

Perform a one-time generation of a hash and write it to the local grains. If that grain has already been set, return the value instead.

This is useful for generating passwords or keys that are specific to a single minion that don't need to be stored somewhere centrally.

State Example:

```yaml
some_mysql_user:
  mysql_user:
    - present
    - host: localhost
    - password: {{ salt['grains.get_or_set_hash']('mysql:some_mysql_user') }}
```

CLI Example:

```
salt '*' grains.get_or_set_hash 'django:SECRET_KEY' 50
```

**Warning:** This function could return strings which may contain characters which are reserved as directives by the YAML parser, such as strings beginning with `%`. To avoid issues when using the output of this function in an SLS file containing YAML+Jinja, surround the call with single quotes.

**salt.modules.grains.has_value**

Determine whether a named value exists in the grains dictionary.

Given a grains dictionary that contains the following structure:

```
{'pkg': {'apache': 'httpd'}}
```

One would determine if the apache key in the pkg dict exists by:

```
pkg:apache
```

CLI Example:

```
salt '*' grains.has_value pkg:apache
```

**salt.modules.grains.item**

```
salt.modules.grains.item('args', 'kwargs')
```

Return one or more grains

CLI Example:

```
salt '*' grains.item os
salt '*' grains.item os osrelease oscodename
```

Sanitized CLI Example:

```
salt '*' grains.item host sanitize=True
```

---

13.6. execution modules

1101
salt.modules.grains.items(sanitize=False)
Return all of the minion’s grains

CLI Example:
```
salt '*' grains.items
```
Sanitized CLI Example:
```
salt '*' grains.items sanitize=True
```

salt.modules.grains.ls()
Return a list of all available grains

CLI Example:
```
salt '*' grains.ls
```

salt.modules.grains.remove(key, val, delimiter=':)
New in version 0.17.0.
Remove a value from a list in the grains config file
key The grain key to remove.
val The value to remove.
delimiter The key can be a nested dict key. Use this parameter to specify the delimiter you use, instead of the default :. You can now append values to a list in nested dictionary grains. If the list doesn’t exist at this level, it will be created.

New in version 2015.8.2.
CLI Example:
```
salt '*' grains.remove key val
```

salt.modules.grains.set(key, val='`, force=False, destructive=False, delimiter=':)
Set a key to an arbitrary value. It is used like setval but works with nested keys.
This function is conservative. It will only overwrite an entry if its value and the given one are not a list or a dict. The force parameter is used to allow overwriting in all cases.

New in version 2015.8.0.
Parameters

- **force** -- Force writing over existing entry if given or existing values are list or dict. Defaults to False.
- **destructive** -- If an operation results in a key being removed, delete the key, too. Defaults to False.
- **delimiter** -- Specify an alternate delimiter to use when traversing a nested dict, the default being :

CLI Example:
```
salt '*' grains.set 'apps:myApp:port' 2209
salt '*' grains.set 'apps:myApp' '{port: 2209}'
```

salt.modules.grains.setval(key, val, destructive=False)
Set a grains value in the grains config file
key The grain key to be set.
val The value to set the grain key to.
destructive If an operation results in a key being removed, delete the key, too. Defaults to False.
CLI Example:
```
salt '*' grains.setval key val
salt '*' grains.setval key "{'sub-key': 'val', 'sub-key2': 'val2'}"
```

```
salt.modules.grains.setvals(grains, destructive=False)
```
Set new grains values in the grains config file

**destructive** If an operation results in a key being removed, delete the key, too. Defaults to False.

CLI Example:
```
salt '*' grains.setvals "{'key1': 'val1', 'key2': 'val2'}"
```

## 13.6.109 salt.modules.groupadd
Manage groups on Linux, OpenBSD and NetBSD

**Important:** If you feel that Salt should be using this module to manage groups on a minion, and it is using a different module (or gives an error similar to `group.info` is not available), see [here](#).

```
salt.modules.groupadd.add(name, gid=None, system=False, root=None)
```
Add the specified group

CLI Example:
```
salt '*' group.add foo 3456
```

```
salt.modules.groupadd.adduser(name, username, root=None)
```
Add a user in the group.

CLI Example:
```
salt '*' group.adduser foo bar
```
Verifies if a valid username `bar` as a member of an existing group `foo`, if not then adds it.

```
salt.modules.groupadd.chgid(name, gid, root=None)
```
Change the gid for a named group

CLI Example:
```
salt '*' group.chgid foo 4376
```

```
salt.modules.groupadd.delete(name, root=None)
```
Remove the named group

CLI Example:
```
salt '*' group.delete foo
```

```
salt.modules.groupadd.deluser(name, username, root=None)
```
Remove a user from the group.

CLI Example:
```
salt '*' group.deluser foo bar
```
Removes a member user `bar` from a group `foo`. If group is not present then returns True.
**salt.modules.groupadd.getent**(refresh=False)
Return info on all groups

CLI Example:
```
salt '*' group.getent
```

**salt.modules.groupadd.info**(name)
Return information about a group

CLI Example:
```
salt '*' group.info foo
```

**salt.modules.groupadd.members**(name, members_list, root=None)
Replaces members of the group with a provided list.

CLI Example:
```
salt '*' group.members foo `user1,user2,user3,...`
```
Replaces a membership list for a local group `foo'.

---

### 13.6.110 salt.modules.grub_legacy

Support for GRUB Legacy

**salt.modules.grub_legacy.conf()**
Parse GRUB conf file

CLI Example:
```
salt '*' grub.conf
```

**salt.modules.grub_legacy.version()**
Return server version from grub --version

CLI Example:
```
salt '*' grub.version
```

---

### 13.6.111 salt.modules.guestfs

Interact with virtual machine images via libguestfs

**depends**
- libguestfs

**salt.modules.guestfs.mount**(location, access='rw', root=None)
Mount an image

CLI Example:
```
salt '*' guest.mount /srv/images/fedora.qcow
```
13.6.112 salt.modules.hadoop

Support for hadoop

maintainer Yann Jouanin <yann.jouanin@intelunix.fr>
maturity new
depends
platform linux

salt.modules.hadoop dfs(command=None, *args)
Execute a command on DFS

CLI Example:
```
salt '*' hadoop.dfs ls /
```

salt.modules.hadoop dfs_absent(path)
Check if a file or directory is absent on the distributed FS.

CLI Example:
```
salt '*' hadoop.dfs_absent /some_random_file
```

Returns True if the file is absent

salt.modules.hadoop dfs_present(path)
Check if a file or directory is present on the distributed FS.

CLI Example:
```
salt '*' hadoop.dfs_present /some_random_file
```

Returns True if the file is present

salt.modules.hadoop namenode_format(force=None)
Format a name node

```
salt '*' hadoop.namenode_format force=True
```

salt.modules.hadoop version()
Return version from hadoop version

```
salt '*' hadoop.version
```

13.6.113 salt.modules.haproxyconn

Support for haproxy

New in version 2014.7.0.

salt.modules.haproxyconn disable_server(name, backend, socket='/var/run/haproxy.sock')
Disable server in haproxy.
name Server to disable
backend haproxy backend, or all backends if '*' is supplied
socket haproxy stats socket
CLI Example:
```
salt '*' haproxy.disable_server db1.example.com mysql
```

salt.modules.haproxyconn.enable_server(name, backend, socket='/var/run/haproxy.sock')
Enable Server in haproxy

- **name**: Server to enable
- **backend**: haproxy backend, or all backends if '*' is supplied
- **socket**: haproxy stats socket

CLI Example:
```
salt '*' haproxy.enable_server web1.example.com www
```

salt.modules.haproxyconn.get_weight(name, backend, socket='/var/run/haproxy.sock')
Get server weight

- **name**: Server name
- **backend**: haproxy backend
- **socket**: haproxy stats socket

CLI Example:
```
salt '*' haproxy.get_weight web1.example.com www
```

salt.modules.haproxyconn.list_servers(backend, socket='/var/run/haproxy.sock', objectify=False)
List servers in haproxy backend.

- **backend**: haproxy backend
- **socket**: haproxy stats socket

CLI Example:
```
salt '*' haproxy.list_servers mysql
```

salt.modules.haproxyconn.set_weight(name, backend, weight=0, socket='/var/run/haproxy.sock')
Set server weight

- **name**: Server name
- **backend**: haproxy backend
- **weight**: Server Weight
- **socket**: haproxy stats socket

CLI Example:
```
salt '*' haproxy.set_weight web1.example.com www 13
```

salt.modules.haproxyconn.show_backends(socket='/var/run/haproxy.sock')
Show HaProxy Backends

- **socket**: haproxy stats socket

CLI Example:
```
salt '*' haproxy.show_backends
```

salt.modules.haproxyconn.show_frontends(socket='/var/run/haproxy.sock')
Show HaProxy frontends

- **socket**: haproxy stats socket

CLI Example:
```
salt '*' haproxy.show_frontends
```
13.6.114 `salt.modules.hashutil`

A collection of hashing and encoding functions

`salt.modules.hashutil.base64_b64decode(instr)`
Decode a base64-encoded string using the "modern" Python interface

New in version 2016.3.0.

CLI Example:

```bash
salt '*' hashutil.base64_b64decode 'Z2V0IHNhbHRlZA=='
```

`salt.modules.hashutil.base64_b64encode(instr)`
Encode a string as base64 using the "modern" Python interface.

Among other possible differences, the "modern" encoder does not include newline ('n') characters in the encoded output.

New in version 2016.3.0.

CLI Example:

```bash
salt '*' hashutil.base64_b64encode 'get salted'
```

`salt.modules.hashutil.base64_decodefile(instr, outfile)`
Decode a base64-encoded string and write the result to a file

New in version 2015.2.0.

CLI Example:

```bash
salt '*' hashutil.base64_decodefile instr='Z2V0IHNhbHRlZAo=' outfile='/path/to/binary_file'
```

`salt.modules.hashutil.base64_decodestring(instr)`
Decode a base64-encoded string using the "legacy" Python interface

New in version 2014.7.0.

CLI Example:

```bash
salt '*' hashutil.base64_decodestring instr='Z2V0IHNhbHRlZAo='
```

`salt.modules.hashutil.base64_encodefile(fname)`
Read a file from the file system and return as a base64 encoded string

New in version 2016.3.0.

Pillar example:

```yaml
path: to:
  data: |
    {{ salt.hashutil.base64_encodefile('/path/to/binary_file') | indent(6) }}
```

The `file.decode` state function can be used to decode this data and write it to disk.

CLI Example:

```bash
salt '*' hashutil.base64_encodefile /path/to/binary_file
```
salt.modules.hashutil.base64_encodestring(instr)
Encode a string as base64 using the `"legacy" Python interface.

Among other possible differences, the `"legacy" encoder includes a newline (`n') character after every 76 characters and always at the end of the encoded string.

New in version 2014.7.0.

CLI Example:

```
salt '*' hashutil.base64_encodestring 'get salted'
```

salt.modules.hashutil.digest(instr, checksum='md5')
Return a checksum digest for a string

`instr` A string

CLI Example:

```
salt '*' hashutil.digest 'get salted'
```

salt.modules.hashutil.digest_file(infile, checksum='md5')
Return a checksum digest for a file

`infile` A file path
`checksum` [md5] The hashing algorithm to use to generate checksums. Wraps the `hashutil.digest` execution function.

CLI Example:

```
salt '*' hashutil.digest_file /path/to/file
```

salt.modules.hashutil.hmac_signature(string, shared_secret, challenge_hmac)
Verify a challenging hmac signature against a string / shared-secret

New in version 2014.7.0.

Returns a boolean if the verification succeeded or failed.

CLI Example:

```
salt '*' hashutil.hmac_signature 'get salted' 'shared secret'
```

salt.modules.hashutil.md5_digest(instr)
Generate an md5 hash of a given string

New in version 2014.7.0.

CLI Example:

```
salt '*' hashutil.md5_digest 'get salted'
```

salt.modules.hashutil.sha256_digest(instr)
Generate an sha256 hash of a given string

New in version 2014.7.0.

CLI Example:

```
salt '*' hashutil.sha256_digest 'get salted'
```

salt.modules.hashutil.sha512_digest(instr)
Generate an sha512 hash of a given string
New in version 2014.7.0.

CLI Example:
```
salt '*' hashutil.sha512_digest 'get salted'
```

13.6.115 `salt.modules.hg`

Support for the Mercurial SCM

`salt.modules.hg.archive(cwd, output, rev='tip', fmt=None, prefix=None, user=None)`

- Export a tarball from the repository
- `cwd` The path to the Mercurial repository
- `output` The path to the archive tarball
- `rev: tip` The revision to create an archive from
- `fmt: None` Format of the resulting archive. Mercurial supports: tar, tbz2, tgz, zip, uzip, and files formats.
- `prefix` [None] Prepend `<prefix>/` to every filename in the archive
- `user` [None] Run hg as a user other than what the minion runs as
- If `prefix` is not specified it defaults to the basename of the repo directory.

CLI Example:
```
salt '*' hg.archive /path/to/repo output=/tmp/archive.tgz fmt=tgz
```

`salt.modules.hg.clone(cwd, repository, opts=None, user=None, identity=None)`

- Clone a new repository
- `cwd` The path to the Mercurial repository
- `repository` The hg URI of the repository
- `opts` [None] Any additional options to add to the command line
- `user` [None] Run hg as a user other than what the minion runs as
- `identity` [None] Private SSH key on the minion server for authentication (ssh://)

New in version 2015.5.0.

CLI Example:
```
salt '*' hg.clone /path/to/repo https://bitbucket.org/birkenfeld/sphinx
```

`salt.modules.hg.describe(cwd, rev='tip', user=None)`

- Mimic git describe and return an identifier for the given revision
- `cwd` The path to the Mercurial repository
- `rev: tip` The path to the archive tarball
- `user` [None] Run hg as a user other than what the minion runs as

CLI Example:
```
salt '*' hg.describe /path/to/repo
```

`salt.modules.hg.pull(cwd, opts=None, user=None, identity=None, repository=None)`

- Perform a pull on the given repository
- `cwd` The path to the Mercurial repository
- `repository` [None] Perform pull from the repository different from .hg/hgrc:[paths]:default
- `opts` [None] Any additional options to add to the command line
- `user` [None] Run hg as a user other than what the minion runs as
- `identity` [None] Private SSH key on the minion server for authentication (ssh://)

New in version 2015.5.0.

CLI Example:
salt 'devserver1' hg.pull /path/to/repo opts=-u

salt.modules.hg.revision(cwd, rev='tip', short=False, user=None)
Returns the long hash of a given identifier (hash, branch, tag, HEAD, etc)
cwd  The path to the Mercurial repository
rev: tip  The revision
short: False  Return an abbreviated commit hash
user [None]  Run hg as a user other than what the minion runs as
CLI Example:
salt 'devserver1' hg.revision /path/to/repo mybranch

salt.modules.hg.status(cwd, opts=None, user=None)
Show changed files of the given repository
cwd  The path to the Mercurial repository
opts [None]  Any additional options to add to the command line
user [None]  Run hg as a user other than what the minion runs as
CLI Example:
salt 'devserver1' hg.status /path/to/repo

salt.modules.hg.update(cwd, rev, force=False, user=None)
Update to a given revision
cwd  The path to the Mercurial repository
rev  The revision to update to
force [False]  Force an update
user [None]  Run hg as a user other than what the minion runs as
CLI Example:
salt devserver1 hg.update /path/to/repo somebranch

13.6.116  salt.modules.hipchat
Module for sending messages to hipchat.
New in version 2015.5.0.

classification  This module can be used by either passing an api key and version directly or by specifying both in a configuration profile in the salt master/minion config.

For example:

```toml
[hipchat]
  api_key: peWcBiMOS9HzG15peWcBiMOS9HzG15
  api_version: v1
```

salt.modules.hipchat.find_room(name, api_key=None, api_version=None)
Find a room by name and return it.

- param name: The room name.
- param api_key: The HipChat admin api key.
- param api_version: The HipChat api version, if not specified in the configuration.

- return: The room object.

CLI Example:
salt '*' hipchat.find_room name="Development Room"
salt '*' hipchat.find_room name="Development Room" api_key=peWcBiMOS9HzG15peWcBiMOS9HzG15 api_version=v1
salt.modules.hipchat.find_user(name, api_key=None, api_version=None)

Find a user by name and return it. :param name: The user name. :param api_key: The HipChat admin api key. :param api_version: The HipChat api version, if not specified in the configuration. :return: The user object.

CLI Example:

```
salt '*' hipchat.find_user name="Thomas Hatch"
salt '*' hipchat.find_user name="Thomas Hatch" api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15 api_version=v1
```

salt.modules.hipchat.list_rooms(api_key=None, api_version=None)

List all HipChat rooms.

Parameters

- **api_key** -- The HipChat admin api key.
- **api_version** -- The HipChat api version, if not specified in the configuration.

Returns The room list.

CLI Example:

```
salt '*' hipchat.list_rooms
salt '*' hipchat.list_rooms api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15 api_version=v1
```

salt.modules.hipchat.list_users(api_key=None, api_version=None)

CLI Example:

```
salt '*' hipchat.list_users
salt '*' hipchat.list_users api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15 api_version=v1
```

salt.modules.hipchat.send_message(room_id, message, from_name, api_key=None, api_version=None, color='yellow', notify=False)

Send a message to a HipChat room. :param room_id: The room id or room name, either will work. :param message: The message to send to the HipChat room. :param from_name: Specify who the message is from. :param api_key: The HipChat api key, if not specified in the configuration. :param api_version: The HipChat api version, if not specified in the configuration. :param color: The color for the message, default: yellow. :param notify: Whether to notify the room, default: False. :return: Boolean if message was sent successfully.

CLI Example:

```
salt '*' hipchat.send_message room_id="Development Room" message="Build is done" from_name="Build Server"
salt '*' hipchat.send_message room_id="Development Room" message="Build failed" from_name="Build Server" color="red" notify=True
```

**13.6.117** salt.modules.hosts

Manage the information in the hosts file

**13.6. execution modules** 1111
salt.modules.hosts.add_host(ip, alias)
Add a host to an existing entry, if the entry is not in place then create it with the given host

CLI Example:
salt '*' hosts.add_host <ip> <alias>

salt.modules.hosts.get_alias(ip)
Return the list of aliases associated with an ip

Aliases (host names) are returned in the order in which they appear in the hosts file. If there are no aliases associated with the IP, an empty list is returned.

CLI Example:
salt '*' hosts.get_alias <ip addr>

salt.modules.hosts.get_ip(host)
Return the ip associated with the named host

CLI Example:
salt '*' hosts.get_ip <hostname>

salt.modules.hosts.has_pair(ip, alias)
Return true if the alias is set

CLI Example:
salt '*' hosts.has_pair <ip> <alias>

salt.modules.hosts.list_hosts()
Return the hosts found in the hosts file in this format:

```
{['<ip addr>': ['alias1', 'alias2', ...]]}
```

CLI Example:
salt '*' hosts.list_hosts

salt.modules.hosts.rm_host(ip, alias)
Remove a host entry from the hosts file

CLI Example:
salt '*' hosts.rm_host <ip> <alias>

salt.modules.hosts.set_host(ip, alias)
Set the host entry in the hosts file for the given ip, this will overwrite any previous entry for the given ip

Changed in version 2016.3.0: If alias does not include any host names (it is the empty string or contains only whitespace), all entries for the given IP address are removed.

CLI Example:
salt '*' hosts.set_host <ip> <alias>
13.6.118 salt.modules.htpasswd

Support for htpasswd command. Requires the apache2-utils package for Debian-based distros.

New in version 2014.1.0.

The functions here will load inside the webutil module. This allows other functions that don’t use htpasswd to use the webutil module name.

salt.modules.htpasswd.useradd(pwfile, user, password, opts='`, runas=None)

Add a user to htpasswd file using the htpasswd command. If the htpasswd file does not exist, it will be created.

- **pwfile** Path to htpasswd file
- **user** User name
- **password** User password
- **opts** Valid options that can be passed are:
  - **n** Don’t update file; display results on stdout.
  - **m** Force MD5 encryption of the password (default).
  - **d** Force CRYPT encryption of the password.
  - **p** Do not encrypt the password (plaintext).
  - **s** Force SHA encryption of the password.
- **runas** The system user to run htpasswd command with

CLI Examples:
```
salt '*' webutil.useradd /etc/httpd/htpasswd larry badpassword
salt '*' webutil.useradd /etc/httpd/htpasswd larry badpass opts=ns
```

salt.modules.htpasswd.useradd_all(pwfile, user, password, opts='`, runas=None)

Add a user to htpasswd file using the htpasswd command. If the htpasswd file does not exist, it will be created.

Deprecated since version 2016.3.0.

- **pwfile** Path to htpasswd file
- **user** User name
- **password** User password
- **opts** Valid options that can be passed are:
  - **n** Don’t update file; display results on stdout.
  - **m** Force MD5 encryption of the password (default).
  - **d** Force CRYPT encryption of the password.
  - **p** Do not encrypt the password (plaintext).
  - **s** Force SHA encryption of the password.
- **runas** The system user to run htpasswd command with

CLI Examples:
```
salt '*' webutil.useradd /etc/httpd/htpasswd larry badpassword
salt '*' webutil.useradd /etc/httpd/htpasswd larry badpass opts=ns
```

salt.modules.htpasswd.userdel(pwfile, user, runas=None)

Delete a user from the specified htpasswd file.

- **pwfile** Path to htpasswd file
- **user** User name
- **runas** The system user to run htpasswd command with

CLI Examples:
salt '*' webutil.userdel /etc/httpd/htpasswd larry

13.6.119 salt.modules.http

Module for making various web calls. Primarily designed for webhooks and the like, but also useful for basic http testing.

New in version 2015.5.0.

salt.modules.http.query(url, **kwargs)
Query a resource, and decode the return data

New in version 2015.5.0.

CLI Example:
```bash
salt '*' http.query http://somelink.com/
salt '*' http.query http://somelink.com/ method=POST params='key1=val1&key2=val2'
salt '*' http.query http://somelink.com/ method=POST data='<xml>'
```

salt.modules.http.update_ca_bundle(target=None, source=None, merge_files=None)
Update the local CA bundle file from a URL

New in version 2015.5.0.

CLI Example:
```bash
salt '*' http.update_ca_bundle
salt '*' http.update_ca_bundle target=/path/to/cacerts.pem
salt '*' http.update_ca_bundle source=https://example.com/cacerts.pem
```

If the target is not specified, it will be pulled from the ca_cert configuration variable available to the minion. If it cannot be found there, it will be placed at $<<FILE_ROOTS>>/cacerts.pem.

If the source is not specified, it will be pulled from the ca_cert_url configuration variable available to the minion. If it cannot be found, it will be downloaded from the cURL website, using an http (not https) URL. USING THE DEFAULT URL SHOULD BE AVOIDED!

merge_files may also be specified, which includes a string or list of strings representing a file or files to be appended to the end of the CA bundle, once it is downloaded.

CLI Example:
```bash
salt '*' http.update_ca_bundle merge_files=/path/to/mycert.pem
```

13.6.120 salt.modules.ifttt

Support for IFTTT

New in version 2015.8.0.

Requires an api_key in /etc/salt/minion:

salt.modules.ifttt.trigger_event(event=None, **kwargs)
Trigger a configured event in IFTTT.

Parameters event -- The name of the event to trigger.
Returns A dictionary with status, text, and error if result was failure.

13.6.121 salt.modules.ilo

Manage HP ILO

depends hponcfg (SmartStart Scripting Toolkit Linux Edition)
salt.modules.ilo.change_password(username, password)
Reset a users password
CLI Example:
```bash
salt '*' ilo.change_password damianMyerscough
```
salt.modules.ilo.change_username(old_username, new_username)
Change a username
CLI Example:
```bash
salt '*' ilo.change_username damian diana
```
salt.modules.ilo.configure_network(ip, netmask, gateway)
Configure Network Interface
CLI Example:
```bash
salt '*' ilo.configure_network [IP ADDRESS] [NETMASK] [GATEWAY]
```
salt.modules.ilo.configure_snmp(community, snmp_port=161, snmp_trapport=161)
Configure SNMP
CLI Example:
```bash
salt '*' ilo.configure_snmp [COMMUNITY STRING] [SNMP PORT] [SNMP TRAP PORT]
```
salt.modules.ilo.create_user(name, password, *privileges)
Create user
CLI Example:
```bash
salt '*' ilo.create_user damian secretagent VIRTUAL_MEDIA_PRIV
```
If no permissions are specify the user will only have a read-only account.

Supported privileges:
• ADMIN_PRIV Enables the user to administer user accounts.
• REMOTECONS_PRIV Enables the user to access the Remote Console functionality.
• RESET_SERVER_PRIV Enables the user to remotely manipulate the server power setting.
• VIRTUAL_MEDIA_PRIV Enables the user permission to access the virtual media functionality.
• CONFIG_ILO_PRIV Enables the user to configure iLO settings.
salt.modules.ilo.delete_ssh_key(username)
Delete a users SSH key from the ILO
CLI Example:
```bash
salt '*' ilo.delete_user_sshkey damian
```
salt.modules.ilo.delete_user(username)
Delete a user
    CLI Example:
    ```
salt '*' ilo.delete_user damian
    ```

salt.modules.ilo.disable_dhcp()
Disable DHCP
    CLI Example:
    ```
salt '*' ilo.disable_dhcp
    ```

salt.modules.ilo.disable_ssh()
Disable the SSH daemon
    CLI Example:
    ```
salt '*' ilo.disable_ssh
    ```

salt.modules.ilo.enable_dhcp()
Enable DHCP
    CLI Example:
    ```
salt '*' ilo.enable_dhcp
    ```

salt.modules.ilo.enable_ssh()
Enable the SSH daemon
    CLI Example:
    ```
salt '*' ilo.enable_ssh
    ```

salt.modules.ilo.get_user(username)
Returns local user information, excluding the password
    CLI Example:
    ```
salt '*' ilo.get_user damian
    ```

salt.modules.ilo.global_settings()
Show global settings
    CLI Example:
    ```
salt '*' ilo.global_settings
    ```

salt.modules.ilo.list_users()
List all users
    CLI Example:
    ```
salt '*' ilo.list_users
    ```

salt.modules.ilo.list_users_info()
List all users in detail
    CLI Example:
salt '*' ilo.list_users_info

salt.modules.ilo.network()
   Grab the current network settings
   CLI Example:
   salt '*' ilo.network

salt.modules.ilo.set_http_port(port=80)
   Configure the port HTTP should listen on
   CLI Example:
   salt '*' ilo.set_http_port 8080

salt.modules.ilo.set_https_port(port=443)
   Configure the port HTTPS should listen on
   CLI Example:
   salt '*' ilo.set_https_port 4334

salt.modules.ilo.set_ssh_key(public_key)
   Configure SSH public keys for specific users
   CLI Example:
   salt '*' ilo.set_ssh_key "ssh-dss AAAAB3NzaC1kc3MAAACBA... damian"

   The SSH public key needs to be DSA and the last argument in the key needs to be the username (case-sensitive) of the ILO username.

salt.modules.ilo.set_ssh_port(port=22)
   Enable SSH on a user defined port
   CLI Example:
   salt '*' ilo.set_ssh_port 2222

13.6.122 salt.modules.img

Virtual machine image management tools
Deprecation since version 2016.3.0.

salt.modules.img.bootstrap(location, size, fmt)
   HIGHLY EXPERIMENTAL Bootstrap a virtual machine image
   location: The location to create the image
   size: The size of the image to create in megabytes
   fmt: The image format, raw or qcow2
   CLI Example:
   salt '*' img.bootstrap /srv/salt-images/host.qcow 4096 qcow2

salt.modules.img.mount_image(location)
   Mount the named image and return the mount point
CLI Example:
```
salt '*' img.mount_image /tmp/foo
```

**salt.modules.img.umount_image**(mnt)
Unmount an image mountpoint

CLI Example:
```
salt '*' img.umount_image /mnt/foo
```

13.6.123 **salt.modules.incron**

Work with incron

**salt.modules.incron.list_tab**(user)
Return the contents of the specified user's incrontab

CLI Example:
```
salt '*' incron.list_tab root
```

**salt.modules.incron.ls**(user)
This function is an alias of `list_tab`.
Return the contents of the specified user's incrontab

CLI Example:
```
salt '*' incron.list_tab root
```

**salt.modules.incron.raw_incron**(user)
Return the contents of the user's incrontab

CLI Example:
```
salt '*' incron.raw_incron root
```

**salt.modules.incron.raw_system_incron()**
Return the contents of the system wide incrontab

CLI Example:
```
salt '*' incron.raw_system_incron
```

**salt.modules.incron.rm**(user, path, mask, cmd)
This function is an alias of `rm_job`.
Remove a incron job for a specified user. If any of the day/time params are specified, the job will only be removed if the specified params match.

CLI Example:
```
salt '*' incron.rm_job root /path
```

**salt.modules.incron.rm_job**(user, path, mask, cmd)
Remove a incron job for a specified user. If any of the day/time params are specified, the job will only be removed if the specified params match.

CLI Example:
```python
salt '*' incron.rm_job root /path
```

```python
salt.modules.incron.set_job(user, path, mask, cmd)
Sets an incron job up for a specified user.
CLI Example:
```
```
salt '*' incron.set_job root '/root' 'IN_MODIFY' 'echo "$$ $@ $$ $% $$ $&''
```

```python
salt.modules.incron.write_incron_file(user, path)
Writes the contents of a file to a user's incrontab
CLI Example:
```
```
salt '*' incron.write_incron_file root /tmp/new_incron
```

```python
salt.modules.incron.write_incron_file_verbose(user, path)
Writes the contents of a file to a user's incrontab and return error message on error
CLI Example:
```
```
salt '*' incron.write_incron_file_verbose root /tmp/new_incron
```

### 13.6.124 salt.modules.influx

InfluxDB - A distributed time series database

Module to provide InfluxDB compatibility to Salt (compatible with InfluxDB version 0.5+)

New in version 2014.7.0.

**depends**
- influxdb Python module

**configuration** This module accepts connection configuration details either as parameters or as configuration settings in /etc/salt/minion on the relevant minions:

```python
influxdb.host: 'localhost'
influxdb.port: 8086
influxdb.user: 'root'
influxdb.password: 'root'
```

This data can also be passed into pillar. Options passed into opts will overwrite options passed into pillar.

```python
salt.modules.influx.db_create(name, user=None, password=None, host=None, port=None)
Create a database
name Database name to create
user The user to connect as
password The password of the user
host The host to connect to
port The port to connect to
CLI Example:
```
```
salt '*' influxdb.db_create <name>
salt '*' influxdb.db_create <name> <user> <password> <host> <port>
```

13.6. execution modules
salt.modules.influx.db_exists(name, user=None, password=None, host=None, port=None)
Checks if a database exists in InfluxDB
name Database name to create
user The user to connect as
password The password of the user
host The host to connect to
port The port to connect to
CLI Example:
```
salt '*' influxdb.db_exists <name>
salt '*' influxdb.db_exists <name> <user> <password> <host> <port>
```

salt.modules.influx.db_list(user=None, password=None, host=None, port=None)
List all InfluxDB databases
user The user to connect as
password The password of the user
host The host to connect to
port The port to connect to
CLI Example:
```
salt '*' influxdb.db_list
salt '*' influxdb.db_list <user> <password> <host> <port>
```

salt.modules.influx.db_remove(name, user=None, password=None, host=None, port=None)
Remove a database
name Database name to remove
user The user to connect as
password The password of the user
host The host to connect to
port The port to connect to
CLI Example:
```
salt '*' influxdb.db_remove <name>
salt '*' influxdb.db_remove <name> <user> <password> <host> <port>
```

salt.modules.influx.login_test(name, password, database=None, host=None, port=None)
Checks if a credential pair can log in at all.
If a database is specified: it will check for database user existence. If a database is not specified: it will check for cluster admin existence.
name The user to connect as
password The password of the user
database The database to try to log in to
host The host to connect to
port The port to connect to
CLI Example:
```
salt '*' influxdb.login_test <name>
salt '*' influxdb.login_test <name> <database>
salt '*' influxdb.login_test <name> <database> <user> <password> <host> <port>
```

salt.modules.influx.query(database, query, time_precision='s', chunked=False, user=None, password=None, host=None, port=None)
Querying data
database The database to query
query Query to be executed
**time_precision**  Time precision to use (`s`, `m`, or `u`)
**chunked**  Whether is chunked or not
**user**  The user to connect as
**password**  The password of the user
**host**  The host to connect to
**port**  The port to connect to

CLI Example:

```bash
salt '*' influxdb.query <database> <query>
salt '*' influxdb.query <database> <query> <time_precision> <chunked> <user> ...
```

```bash
salt.modules.influx.retention_policy_add(database, name, duration, replication, default=False, user=None, password=None, host=None, port=None)
```

Add a retention policy.
**database**  The database to operate on.
**name**  Name of the policy to modify.
**duration**  How long InfluxDB keeps the data.
**replication**  How many copies of the data are stored in the cluster.
**default**  Whether this policy should be the default or not. Default is False.

CLI Example:

```bash
salt '*' influxdb.retention_policy_add metrics default 1d 1
```

```bash
salt.modules.influx.retention_policy_alter(database, name, duration, replication, default=False, user=None, password=None, host=None, port=None)
```

Modify an existing retention policy.
**database**  The database to operate on.
**name**  Name of the policy to modify.
**duration**  How long InfluxDB keeps the data.
**replication**  How many copies of the data are stored in the cluster.
**default**  Whether this policy should be the default or not. Default is False.

CLI Example:

```bash
salt '*' influxdb.retention_policy_modify metrics default 1d 1
```

```bash
salt.modules.influx.retention_policy_exists(database, name, user=None, password=None, host=None, port=None)
```

Check if a retention policy exists.
**database**  The database to operate on.
**name**  Name of the policy to modify.

CLI Example:

```bash
salt '*' influxdb.retention_policy_exists metrics default
```

```bash
salt.modules.influx.retention_policy_get(database, name, user=None, password=None, host=None, port=None)
```

Get an existing retention policy.
**database**  The database to operate on.
**name**  Name of the policy to modify.

CLI Example:

```bash
salt '*' influxdb.retention_policy_get metrics default
```
salt.modules.influx.user_chpass(name, passwd, database=...}

Change password for a cluster admin or a database user.

If a database is specified: it will update database user password. If a database is not specified: it will update
cluster admin password.

name User name for whom to change the password
passwd New password
database The database on which to operate
user The user to connect as
password The password of the user
host The host to connect to
port The port to connect to

CLI Example:

```
salt '*' influxdb.user_chpass <name> <passwd>
salt '*' influxdb.user_chpass <name> <passwd> <database>
salt '*' influxdb.user_chpass <name> <passwd> <database> <user> <password> <host> ←<port>
```

salt.modules.influx.user_create(name, passwd, database=...}

Create a cluster admin or a database user.

If a database is specified: it will create database user. If a database is not specified: it will create a cluster
admin.

name User name for the new user to create
passwd Password for the new user to create
database The database to create the user in
user The user to connect as
password The password of the user
host The host to connect to
port The port to connect to

CLI Example:

```
salt '*' influxdb.user_create <name> <passwd>
salt '*' influxdb.user_create <name> <passwd> <database>
salt '*' influxdb.user_create <name> <passwd> <database> <user> <password> <host> ←<port>
```

salt.modules.influx.user_exists(name, database=...}

Checks if a cluster admin or database user exists.

If a database is specified: it will check for database user existence. If a database is not specified: it will check
for cluster admin existence.

name User name
database The database to check for the user to exist
user The user to connect as
password The password of the user
host The host to connect to
port The port to connect to

CLI Example:

```
salt '*' influxdb.user_exists <name>
salt '*' influxdb.user_exists <name> <database>
salt '*' influxdb.user_exists <name> <database> <user> <password> <host> <port>
```
salt.modules.influx.user_list(database=None, user=None, password=None, host=None, port=None)

List cluster admins or database users.

If a database is specified: it will return database users list. If a database is not specified: it will return cluster admins list.

- **database** The database to list the users from
- **user** The user to connect as
- **password** The password of the user
- **host** The host to connect to
- **port** The port to connect to

CLI Example:

```
salt '*' influxdb.user_list
salt '*' influxdb.user_list <database>
salt '*' influxdb.user_list <database> <user> <password> <host> <port>
```

salt.modules.influx.user_remove(name, database=None, user=None, password=None, host=None, port=None)

Remove a cluster admin or a database user.

If a database is specified: it will remove the database user. If a database is not specified: it will remove the cluster admin.

- **name** User name to remove
- **database** The database to remove the user from
- **user** User name for the new user to delete
- **user** The user to connect as
- **password** The password of the user
- **host** The host to connect to
- **port** The port to connect to

CLI Example:

```
salt '*' influxdb.user_remove <name>
salt '*' influxdb.user_remove <name> <database>
salt '*' influxdb.user_remove <name> <database> <user> <password> <host> <port>
```

13.6.125 salt.modules.infoblox

Module for managing Infoblox

Will look for pillar data infoblox:server, infoblox:user, infoblox:password if not passed to functions

New in version 2016.3.0.

**depends**

- requests

salt.modules.infoblox.add_record(name, value, record_type, dns_view, infoblox_server=None, infoblox_user=None, infoblox_password=None, infoblox_api_version='v1.4.2', sslVerify=True)

add a record to an infoblox dns view

- **name** the record name
- **value**

  the value for the entry can make use of infoblox functions for next available IP, like 'func:nextavailableip:10.1.0.0/24'
- **record_type** the record type (cname, a, host, etc)
**dns_view**  the DNS view to add the record to
**infoblox_server**  the infoblox server hostname (can also use the infoblox:server pillar)
**infoblox_user**  the infoblox user to connect with (can also use the infoblox:user pillar)
**infoblox_password**  the infoblox user's password (can also use the infoblox:password pillar)
**infoblox_api_version**  the infoblox api version to use

**sslVerify**  should ssl verification be done on the connection to the Infoblox REST API

CLI Example:
```bash
salt 'myminion' infoblox.add_record alias.network.name canonical.network.name
```

**salt.modules.infoblox.delete_record**(name, dns_view, record_type, infoblox_server=None, infoblox_user=None, infoblox_password=None, infoblox_api_version='v1.4.2', sslVerify=True)

delete a record

**name**  name of the record
**dns_view**  the DNS view to remove the record from
**record_type**  the record type (a, cname, host, etc)
**infoblox_server**  the infoblox server hostname (can also use the infoblox:server pillar)
**infoblox_user**  the infoblox user to connect with (can also use the infoblox:user pillar)
**infoblox_password**  the infoblox user's password (can also use the infoblox:password pillar)
**infoblox_api_version**  the infoblox api version to use

**sslVerify**  should ssl verification be done on the connection to the Infoblox REST API

CLI Example:
```bash
salt my-minion infoblox.delete_record some.dns.record MyInfobloxView A;
```

**salt.modules.infoblox.get_network**(network_name, network_view=None, infoblox_server=None, infoblox_user=None, infoblox_password=None, infoblox_api_version='v1.4.2', sslVerify=True)

get a network from infoblox

**network_name**  The name of the network in IPAM
**network_view**  The name of the network view the network belongs to
**infoblox_server**  the infoblox server hostname (can also use the infoblox:server pillar)
**infoblox_user**  the infoblox user to connect with (can also use the infoblox:user pillar)
**infoblox_password**  the infoblox user's password (can also use the infoblox:password pillar)
**infoblox_api_version**  the infoblox api version to use

**sslVerify**  should ssl verification be done on the connection to the Infoblox REST API

CLI Example:
```bash
salt myminion infoblox.get_network '10.0.0.0/8'
```

**salt.modules.infoblox.get_record**(record_name, record_type='host', infoblox_server=None, infoblox_user=None, infoblox_password=None, dns_view=None, infoblox_api_version='v1.4.2', sslVerify=True)

get a record from infoblox

**record_name**  name of the record to search for
**record_type**  type of record to search for (host, cname, a...defaults to host)
**infoblox_server**  the infoblox server hostname (can also use the infoblox:server pillar)
**infoblox_user**  the infoblox user to connect with (can also use the infoblox:user pillar)
**infoblox_password**  the infoblox user's password (can also use the infoblox:password pillar)
**dns_view**  the infoblox DNS view to search, if not specified all views are searched
**infoblox_api_version**  the infoblox api version to use

**sslVerify**  should ssl verification be done on the connection to the Infoblox REST API
CLI Example:

```bash
salt myminion infoblox.get_record some.host.com A sslVerify=False
```

```
salt.modules.infoblox.update_record(name, value, dns_view, record_type, infoblox_server=None, infoblox_user=None, infoblox_password=None, infoblox_api_version='v1.4.2', sslVerify=True)
```

update an entry to an infoblox dns view

- **name**: the dns name
- **value**: the value for the record
- **record_type**: the record type (a, cname, etc)
- **dns_view**: the DNS view to add the record to
- **infoblox_server**: the infoblox server hostname (can also use the infoblox:server pillar)
- **infoblox_user**: the infoblox user to connect with (can also use the infoblox:user pillar)
- **infoblox_password**: the infoblox user's password (can also use the infoblox:password pillar)
- **infoblox_api_version**: the infoblox api version to use
- **sslVerify**: should ssl verification be done on the connection to the Infoblox REST API

CLI Example:

```
salt '*' infoblox.update_record alias.network.name canonical.network.name
        -->MyInfobloxView cname sslVerify=False
```

13.6.126 salt.modules.ini_manage

Edit ini files

- **maintainer**: <akilesh1597@gmail.com>
- **maturity**: new
- **depends**: re
- **platform**: all

(for example /etc/sysctl.conf)

```
salt.modules.ini_manage.get_option(file_name, section, option)
```

Get value of a key from a section in an ini file. Returns None if no matching key was found.

API Example:

```python
import salt
sc = salt.client.get_local_client()
sc.cmd('target', 'ini.get_option',
       [path_to_ini_file, section_name, option])
```

CLI Example:

```
salt '*' ini.get_option /path/to/ini section_name option_name
```

```
salt.modules.ini_manage.get_section(file_name, section)
```

Retrieve a section from an ini file. Returns the section as dictionary. If the section is not found, an empty dictionary is returned.

API Example:
```python
import salt
sc = salt.client.get_local_client()
sc.cmd('target', 'ini.get_section',
       [path_to_ini_file, section_name])
```

**CLI Example:**
```
salt '*' ini.get_section /path/to/ini section_name
```

salt.modules.ini_manage.remove_option(file_name, section, option)
Remove a key/value pair from a section in an ini file. Returns the value of the removed key, or None if nothing was removed.

**API Example:**
```python
import salt
sc = salt.client.get_local_client()
sc.cmd('target', 'ini.remove_option',
       [path_to_ini_file, section_name, option])
```

**CLI Example:**
```
salt '*' ini.remove_option /path/to/ini section_name option_name
```

salt.modules.ini_manage.remove_section(file_name, section)
Remove a section in an ini file. Returns the removed section as dictionary, or None if nothing was removed.

**API Example:**
```python
import salt
sc = salt.client.get_local_client()
sc.cmd('target', 'ini.remove_section',
       [path_to_ini_file, section_name])
```

**CLI Example:**
```
salt '*' ini.remove_section /path/to/ini section_name
```

salt.modules.ini_manage.set_option(file_name, sections=None)
Edit an ini file, replacing one or more sections. Returns a dictionary containing the changes made.

**file_name** path of ini file

**sections** [None] A dictionary representing the sections to be edited ini file. The keys are the section names and the values are the dictionary containing the options. If the ini file does not contain sections the keys and values represent the options.

**API Example:**
```python
import salt
sc = salt.client.get_local_client()
sc.cmd('target', 'ini.set_option',
       [path_to_ini_file, '{section_foo: {key: value}}'])
```

**CLI Example:**
```
salt '*' ini.set_option /path/to/ini '{section_foo: {key: value}}'
```
13.6.127 salt.modules.inspectlib package

Submodules

salt.modules.inspectlib.collector module

class salt.modules.inspectlib.collector.Inspector(cachedir=None, piddir=None, pidfile-name=None)

DEFAULT_MINION_CONFIG_PATH = '/etc/salt/minion'
IGNORE_FS_TYPES = ['autofs', 'cifs', 'nfs', 'nfs4']
IGNORE_MOUNTS = ['proc', 'sysfs', 'devtmpfs', 'tmpfs', 'fuse.gvfs-fuse-daemon']
IGNORE_PATHS = ['/tmp', '/var/tmp', '/lost+found', '/var/run', '/var/lib/rpm', '/snapshots', '/.zfs', '/etc/ssh', '/root', '/home'
MODE = ['configuration', 'payload', 'all']

build(format='qcow2', path='/tmp')
    Build an image using Kiwi.

Parameters
  • format --
  • path --

Returns

export(description, local=False, path='/tmp', format='qcow2')
    Export description for Kiwi.

Parameters
  • local --
  • path --

Returns

request_snapshot(mode, priority=19, **kwargs)
    Take a snapshot of the system.

snapshot(mode)
    Take a snapshot of the system.

salt.modules.inspectlib.collector.is_alive(pidfile)
    Check if PID is still alive.

salt.modules.inspectlib.collector.main(dbfile, pidfile, mode)
    Main analyzer routine.

salt.modules.inspectlib.dbhandle module

class salt.modules.inspectlib.dbhandle.DBHandle(path)

class salt.modules.inspectlib.dbhandle.DBHandleBase(path)
    Handle for the volatile database, which serves the purpose of caching the inspected data. This database can be destroyed or corrupted, so it should be simply re-created from scratch.

    close()
        Close the database connection.
**flush**(table)
Flush the table.

**open**(new=False)
Init the database, if required.

**purge**()
Purge whole database.

```python
salt.modules.inspectlib.exceptions module
```

exception salt.modules.inspectlib.exceptions.InspectorKiwiProcessorException
Kiwi builder/exporter exception.

exception salt.modules.inspectlib.exceptions.InspectorQueryException
Exception that is only for the inspector query.

exception salt.modules.inspectlib.exceptions.InspectorSnapshotException
Snapshot exception.

exception salt.modules.inspectlib.exceptions.SIException
System information exception.

```python
salt.modules.inspectlib.query module
```

class salt.modules.inspectlib.query.Query(scope, cachedir=None)
Query the system. This class is actually puts all Salt features together, so there would be no need to pick it from various places.

**SCOPES** = ['changes', 'configuration', 'identity', 'system', 'software', 'services', 'payload', 'all']

class salt.modules.inspectlib.query.SysInfo(systype)
System information.

**Module contents**

class salt.modules.inspectlib.EnvLoader(cachedir=None, piddir=None, pidfilename=None)
Load environment.

  **DB_FILE** = `._minion_collector.db`
  **DEFAULT_CACHE_PATH** = `/var/cache/salt`
  **DEFAULT_PID_PATH** = `/var/run`
  **PID_FILE** = `._minion_collector.pid`

13.6.128 salt.modules.introspect

Functions to perform introspection on a minion, and return data in a format usable by Salt States

salt.modules.introspect.enabled_service_owners()
Return which packages own each of the services that are currently enabled.

  CLI Example:
  
salt myminion introspect.enabled_service_owners
salt.modules.introspect.running_service_owners(exclude=('/dev', '/home', '/media', '/proc', '/run', '/sys', '/tmp', '/var'))

Determine which packages own the currently running services. By default, excludes files whose full path starts with /dev, /home, /media, /proc, /run, /sys, /tmp and /var. This can be overridden by passing in a new list to exclude.

CLI Example:
    salt myminion introspect.running_service_owners

salt.modules.introspect.service_highstate(requires=True)

Return running and enabled services in a highstate structure. By default also returns package dependencies for those services, which means that package definitions must be created outside this function. To drop the package dependencies, set requires to False.

CLI Example:
    salt myminion introspect.service_highstate
    salt myminion introspect.service_highstate requires=False

13.6.129 salt.modules.ipmi

Support IPMI commands over LAN. This module does not talk to the local systems hardware through IPMI drivers. It uses a python module pyghmi.

depends Python module pyghmi. You can install pyghmi using pip:

    pip install pyghmi

configuration The following configuration defaults can be define (pillar or config files):

    ipmi.config:
        api_host: 127.0.0.1
        api_user: admin
        api_pass: apassword
        api_port: 623
        api_kg: None

Usage can override the config defaults:

    salt-call ipmi.get_user api_host=myipmienabled.system
        api_user=admin api_pass=password
        uid=1

salt.modules.ipmi.create_user(uid, name, password, channel=14, callback=False, link_auth=True, ipmi_msg=True, privilege_level='administrator', **kwargs)

create/ensure a user is created with provided settings.

Parameters

- privilege_level -- User Privilege Limit. (Determines the maximum privilege level that the user is allowed to switch to on the specified channel.) * callback * user * operator * administrator * proprietary * no_access

- kwargs --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
Salt Documentation, Release 2016.3.6

- api_kg=None

CLI Examples:

```
salt-call ipmi.create_user uid=2 name=steverweber api_host=172.168.0.7 api_pass=nevertell
```

salt.modules.ipmi.fast_connect_test(**kwargs)

Returns True if connection success. This uses an aggressive timeout value!

Parameters **kwargs --

- api_host=127.0.0.1
- api_user=admin
- api_pass=example
- api_port=623
- api_kg=None

CLI Examples:

```
salt-call ipmi.fast_connect_test api_host=172.168.0.9
```

salt.modules.ipmi.get_bootdev(**kwargs)

Get current boot device override information.

Provides the current requested boot device. Be aware that not all IPMI devices support this. Even in BMCs that claim to, occasionally the BIOS or UEFI fail to honor it. This is usually only applicable to the next reboot.

Parameters **kwargs --

- api_host=127.0.0.1
- api_user=admin
- api_pass=example
- api_port=623
- api_kg=None

CLI Example:

```
salt-call ipmi.get_bootdev api_host=127.0.0.1 api_user=admin api_pass=pass
```

salt.modules.ipmi.get_channel_access(channel=14, read_mode='non_volatile', **kwargs)

:param kwargs: api_host='127.0.0.1' api_user='admin' api_pass='example' api_port=623

Parameters

- **channel** -- number [1:7]
- **read_mode** --
  - non_volatile = get non-volatile Channel Access
  - volatile = get present volatile (active) setting of Channel Access
- **kwargs** --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
- api_kg=None

return A Python dict with the following keys/values:

```python
{
    'alerting':
    'per_msg_auth':
    'user_level_auth':
    'access_mode': { (ONE OF)
        0: 'disabled',
        1: 'pre_boot',
        2: 'always',
        3: 'shared'
    }
    'privilege_level': { (ONE OF)
        1: 'callback',
        2: 'user',
        3: 'operator',
        4: 'administrator',
        5: 'proprietary',
    }
}
```

CLI Examples:

```bash
salt-call ipmi.get_channel_access channel=1
```

```
salt.modules.ipmi.get_channel_info(channel=14, **kwargs)
Get channel info

Parameters

- **channel** -- number [1:7]
- **kwargs** --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

return channel session supports:

- no_session: channel is session-less
- single: channel is single-session
- multi: channel is multi-session
- auto: channel is session-based (channel could alternate between single- and multi-session operation, as can occur with a serial/modem channel that supports connection mode auto-detect)

CLI Examples:

```bash
salt-call ipmi.get_channel_info
```

```
salt.modules.ipmi.get_channel_max_user_count(channel=14, **kwargs)
Get max users in channel

Parameters
```
**channel** -- number [1:7]

**kwargs** --
- api_host=127.0.0.1
- api_user=admin
- api_pass=example
- api_port=623
- api_kg=None

Returns int -- often 16

CLI Examples:

```
salt-call ipmi.get_channel_max_user_count
```

salt.modules.ipmi.get_health(**kwargs)
Get Summarize health

This provides a summary of the health of the managed system. It additionally provides an iterable list of
reasons for warning, critical, or failed assessments.

good health: {'badreadings': [], 'health': 0}

Parameters **kwargs** --
- api_host=127.0.0.1
- api_user=admin
- api_pass=example
- api_port=623
- api_kg=None

CLI Example:

```
salt-call ipmi.get_health api_host=127.0.0.1 api_user=admin api_pass=pass
```

salt.modules.ipmi.get_power(**kwargs)
Get current power state

The response, if successful, should contain `powerstate` key and either `on` or `off` to indicate current state.

Parameters **kwargs** --
- api_host=127.0.0.1
- api_user=admin
- api_pass=example
- api_port=623
- api_kg=None

CLI Example:

```
salt-call ipmi.get_power api_host=127.0.0.1 api_user=admin api_pass=pass
```

salt.modules.ipmi.get_sensor_data(**kwargs)
Get sensor readings

Iterates sensor reading objects

Parameters **kwargs** --
• api_host=127.0.0.1
• api_user=admin
• api_pass=example
• api_port=623
• api_kg=None

CLI Example:

```
salt-call ipmi.get_sensor_data api_host=127.0.0.1 api_user=admin api_pass=pass
```

salt.modules.ipmi.**get_user**(uid, channel=14, **kwargs)

Get user from uid and access on channel

**Parameters**

• **uid** -- user number [1:16]
• **channel** -- number [1:7]
• **kwargs** --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

**return**

```
name: (str)
uid: (int)
channel: (int)
access:
  - callback (bool)
  - link_auth (bool)
  - ipmi_msg (bool)
  - privilege_level: (str)[callback, user, operator, administrator, proprietary, no_access]
```

CLI Examples:

```
salt-call ipmi.get_user uid=2
```

salt.modules.ipmi.**get_user_access**(uid, channel=14, **kwargs)

Get user access

**Parameters**

• **uid** -- user number [1:16]
• **channel** -- number [1:7]
• **kwargs** --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
- api_kg=None

return

```
channel_info:
- max_user_count = maximum number of user IDs on this channel
- enabled_users = count of User ID slots presently in use
- users_with_fixed_names = count of user IDs with fixed names

access:
- callback
- link_auth
- ipmi_msg
- privilege_level: [reserved, callback, user, operator
  administrator, proprietary, no_access]
```

CLI Examples:

```
salt-call ipmi.get_user_access uid=2
```

```
salt.modules.ipmi.get_user_name(uid, return_none_on_error=True, **kwargs)
```

Get user name

**Parameters**

- **uid** -- user number [1:16]
- **return_none_on_error** -- return None on error
- **kwargs**
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

**CLI Examples:**

```
salt-call ipmi.get_user_name uid=2
```

```
salt.modules.ipmi.get_users(channel=14, **kwargs)
```

get list of users and access information

**Parameters**

- **channel** -- number [1:7]
- **kwargs**
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

**Returns**

- name: (str)
- uid: (int)
- channel: (int)
• access:
  – callback (bool)
  – link_auth (bool)
  – ipmi_msg (bool)
  – privilege_level: (str) [callback, user, operator, administrator, proprietary, no_access]

CLI Examples:
salt-call ipmi.get_users api_host=172.168.0.7

```
salt.modules.ipmi.raw_command(netfn, command, bridge_request=None, data=(), retry=True, delay_xmit=None, **kwargs)
```

Send raw ipmi command

This allows arbitrary IPMI bytes to be issued. This is commonly used for certain vendor specific commands.

Parameters

• **netfn** -- Net function number
• **command** -- Command value
• **bridge_request** -- The target slave address and channel number for the bridge request.
• **data** -- Command data as a tuple or list
• **kwargs** --
  – api_host=127.0.0.1
  – api_user=admin
  – api_pass=example
  – api_port=623
  – api_kg=None

Returns
dict -- The response from IPMI device

CLI Examples:
salt-call ipmi.raw_command netfn=0x06 command=0x46 data=[0x02]
# this will return the name of the user with id 2 in bytes

```
salt.modules.ipmi.set_bootdev(bootdev='default', persist=False, uefiboot=False, **kwargs)
```

Set boot device to use on next reboot

Parameters

• **bootdev** --
  – network: Request network boot
  – hd: Boot from hard drive
  – safe: Boot from hard drive, requesting `safe mode`
  – optical: boot from CD/DVD/BD drive
  – setup: Boot into setup utility
  – default: remove any IPMI directed boot device request
- **persist** -- If true, ask that system firmware use this device beyond next boot. Be aware many systems do not honor this

- **uefiboot** -- If true, request UEFI boot explicitly. Strictly speaking, the spec suggests that if not set, the system should BIOS boot and offers no "don't care" option. In practice, this flag not being set does not preclude UEFI boot on any system I've encountered.

- **kwargs** --
  - `api_host=127.0.0.1`
  - `api_user=admin`
  - `api_pass=example`
  - `api_port=623`
  - `api_kg=None`

Returns dict or True -- If callback is not provided, the response

CLI Examples:

```
salt-call ipmi.set_bootdev bootdev=network persist=True
```

```python
salt.modules.ipmi.set_channel_access(channel=14, access_update_mode='non_volatile',
    alerting=False, per_msg_auth=False, user_level_auth=False, access_mode='always',
    privilege_update_mode='non_volatile', privilege_level='administrator', **kwargs)
```

Set channel access

Parameters

- **channel** -- number [1:7]

- **access_update_mode** --
  - 'don't_change' = don't set or change Channel Access
  - 'non_volatile' = set non-volatile Channel Access
  - 'volatile' = set volatile (active) setting of Channel Access

- **alerting** --
  PEF Alerting Enable/Disable
  - True = enable PEF Alerting
  - False = disable PEF Alerting on this channel

  (Alert Immediate command can still be used to generate alerts)

- **per_msg_auth** --
  Per-message Authentication
  - True = enable
  - False = disable Per-message Authentication. [Authentication required to activate any session on this channel, but authentication not used on subsequent packets for the session.]

- **user_level_auth** --
  User Level Authentication Enable/Disable.
- True = enable User Level Authentication. All User Level commands are to be authenticated per the Authentication Type that was negotiated when the session was activated.

- False = disable User Level Authentication. Allow User Level commands to be executed without being authenticated. If the option to disable User Level Command authentication is accepted, the BMC will accept packets with Authentication Type set to None if they contain user level commands. For outgoing packets, the BMC returns responses with the same Authentication Type that was used for the request.

- **access_mode** -- Access Mode for IPMI messaging (PEF Alerting is enabled/disabled separately from IPMI messaging)
  - disabled = disabled for IPMI messaging
  - pre_boot = pre-boot only channel only available when system is in a powered down state or in BIOS prior to start of boot.
  - always = channel always available regardless of system mode. BIOS typically dedicates the serial connection to the BMC.
  - shared = same as always available, but BIOS typically leaves the serial port available for software use.

- **privilege_update_mode** -- Channel Privilege Level Limit. This value sets the maximum privilege level that can be accepted on the specified channel.
  - dont_change = don’t set or change channel Privilege Level Limit
  - non_volatile = non-volatile Privilege Level Limit according
  - volatile = volatile setting of Privilege Level Limit

- **privilege_level** --
  Channel Privilege Level Limit
  - reserved = unused
  - callback
  - user
  - operator
  - administrator
  - proprietary = used by OEM

- **kwargs** --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

CLI Examples:

```
salt-call ipmi.set_channel_access privilege_level='administrator'
```
salt.modules.ipmi.set_identify(on=True, duration=600, **kwargs)
Request identify light

Request the identify light to turn off, on for a duration, or on indefinitely. Other than error exceptions,

Parameters

- on -- Set to True to force on or False to force off
- duration -- Set if wanting to request turn on for a duration in seconds, None = indefinitely.
- kwargs --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

CLI Examples:
salt-call ipmi.set_identify

salt.modules.ipmi.set_power(state='power_on', wait=True, **kwargs)
Request power state change

Parameters

- name --
  - power_on -- system turn on
  - power_off -- system turn off (without waiting for OS)
  - shutdown -- request OS proper shutdown
  - reset -- reset (without waiting for OS)
  - boot -- If system is off, then `on', else `reset'
- ensure -- If (bool True), do not return until system actually completes requested state change for 300 seconds. If a non-zero (int), adjust the wait time to the requested number of seconds
- kwargs --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

Returns dict -- A dict describing the response retrieved

CLI Examples:
salt-call ipmi.set_power state=shutdown wait=True

salt.modules.ipmi.set_user_access(uid, channel=14, callback=True, link_auth=True, ipmi_msg=True, privilege_level='administrator', **kwargs)
Set user access

1138 Chapter 13. Salt Module Reference
Parameters

- **uid** -- user number [1:16]
- **channel** -- number [1:7]
- **callback** --

  User Restricted to Callback

  - False = User Privilege Limit is determined by the User Privilege Limit parameter, below, for both callback and non-callback connections.
  - True = User Privilege Limit is determined by the User Privilege Limit parameter for callback connections, but is restricted to Callback level for non-callback connections. Thus, a user can only initiate a Callback when they `call in' to the BMC, but once the callback connection has been made, the user could potentially establish a session as an Operator.

- **link_auth** -- User Link authentication enable/disable (used to enable whether this user's name and password information will be used for link authentication, e.g. PPP CHAP) for the given channel. Link authentication itself is a global setting for the channel and is enabled/disabled via the serial/modem configuration parameters.

- **ipmi_msg** -- User IPMI Messaging: (used to enable/disable whether this user’s name and password information will be used for IPMI Messaging. In this case, `IPMI Messaging' refers to the ability to execute generic IPMI commands that are not associated with a particular payload type. For example, if IPMI Messaging is disabled for a user, but that user is enabled for activating the SOL payload type, then IPMI commands associated with SOL and session management, such as Get SOL Configuration Parameters and Close Session are available, but generic IPMI commands such as Get SEL Time are unavailable.)

- **privilege_level** -- User Privilege Limit. (Determines the maximum privilege level that the user is allowed to switch to on the specified channel.)

  - callback
  - user
  - operator
  - administrator
  - proprietary
  - no_access

- **kwargs** --

  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

CLI Examples:

```
salt-call ipmi.set_user_access uid=2 privilege_level='operator'
salt.modules.ipmi.set_user_name(uid, name, **kwargs)
```

Set user name
Parameters

• **uid** -- user number [1:16]
• **name** -- username (limit of 16 bytes)
• **kwargs** --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

CLI Examples:

```python
salt-call ipmi.set_user_name uid=2 name='steverweber'
```

```
salt.modules.ipmi.set_user_password(uid, mode='set_password', password=None, **kwargs)
```

Set user password and (modes)

Parameters

• **uid** -- id number of user. see: get_names_uid()['name']
• **mode** --
  - disable = disable user connections
  - enable = enable user connections
  - set_password = set or ensure password
  - test_password = test password is correct
• **password** -- max 16 char string (optional when mode is [disable or enable])
• **kwargs** --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

**Returns** True on success when mode = test_password, return False on bad password

CLI Example:

```python
salt-call ipmi.set_user_password api_host=127.0.0.1 api_user=admin api_pass=pass uid=1 password=newPass
salt-call ipmi.set_user_password uid=1 mode=enable
```

```
salt.modules.ipmi.user_delete(uid, channel=14, **kwargs)
```

Delete user (helper)

Parameters

• **uid** -- user number [1:16]
• **channel** -- number [1:7]
• **kwargs** --
- api_host=127.0.0.1
- api_user=admin
- api_pass=example
- api_port=623
- api_kg=None

CLI Examples:

```
salt-call ipmi.user_delete uid=2
```  

### 13.6.130 salt.modules.ipset

Support for ipset

**salt.modules.ipset.add** *(set=None, entry=None, family='ipv4', **kwargs)*

Append an entry to the specified set.

CLI Example:

```
salt '*' ipset.add setname 192.168.1.26
```

**salt.modules.ipset.check** *(set=None, entry=None, family='ipv4')*

Check that an entry exists in the specified set.

- **set** The ipset name
- **entry** An entry in the ipset. This parameter can be a single IP address, a range of IP addresses, or a subnet block. Example:
  
  ```
  192.168.0.1
  192.168.0.2-192.168.0.19
  192.168.0.0/25
  ```

- **family** IP protocol version: ipv4 or ipv6

CLI Example:

```
salt '*' ipset.check setname '192.168.0.1 comment "Hello"'
```

**salt.modules.ipset.check_set** *(set=None, family='ipv4')*

Check that given ipset set exists.

New in version 2014.7.0.

CLI Example:

```
salt '*' ipset.check_set setname
```

**salt.modules.ipset.delete** *(set=None, entry=None, family='ipv4', **kwargs)*

Delete an entry from the specified set.

CLI Example:

```
```

**salt.modules.ipset.delete_set** *(set=None, family='ipv4')*

New in version 2014.7.0.
Delete ipset set.

CLI Example:

```python
salt '*' ipset.delete_set custom_set
```

IPv6:
```
salt '*' ipset.delete_set custom_set family=ipv6
```

**salt.modules.ipset.flush**(set=None, family='ipv4')
Flush entries in the specified set, Flush all sets if set is not specified.

CLI Example:

```python
salt '*' ipset.flush
salt '*' ipset.flush set
```

IPv6:
```
salt '*' ipset.flush
salt '*' ipset.flush set
```

**salt.modules.ipset.list_sets**(family='ipv4')
New in version 2014.7.0.
List all ipset sets.

CLI Example:

```
salt '*' ipset.list_sets
```

**salt.modules.ipset.long_range**(start, end)

**salt.modules.ipset.new_set**(set=None, set_type=None, family='ipv4', comment=False, **kwargs)
New in version 2014.7.0.
Create new custom set

CLI Example:

```python
salt '*' ipset.new_set custom_set list:set
salt '*' ipset.new_set custom_set list:set comment=True
```

IPv6:
```
salt '*' ipset.new_set custom_set list:set family=ipv6
```

**salt.modules.ipset.rename_set**(set=None, new_set=None, family='ipv4')
New in version 2014.7.0.
Delete ipset set.

CLI Example:

```python
salt '*' ipset.rename_set custom_set new_set=new_set_name
```

IPv6:
```
salt '*' ipset.rename_set custom_set new_set=new_set_name family=ipv6
```
salt.modules.ipset.test
(set=None, entry=None, family='ipv4', **kwargs)

Test if an entry is in the specified set.

CLI Example:

```
salt '*' ipset.test setname 192.168.0.2
IPv6:
salt '*' ipset.test setname fd81:fc56:9ac7::/48
```

salt.modules.ipset.version()

Return version from ipset --version

CLI Example:

```
salt '*' ipset.version
```

13.6.131 salt.modules.iptables

Support for iptables

salt.modules.iptables.append(table='filter', chain=None, rule=None, family='ipv4')

Append a rule to the specified table/chain.

This function accepts a rule in a standard iptables command format, starting with the chain. Trying to
force users to adapt to a new method of creating rules would be irritating at best, and we already have
a parser that can handle it.

CLI Example:

```
salt '*' iptables.append filter INPUT \n  rule=': -m state --state RELATED,ESTABLISHED -j ACCEPT'
IPv6:
salt '*' iptables.append filter INPUT \n  rule=': -m state --state RELATED,ESTABLISHED -j ACCEPT' \n  family=ipv6
```

salt.modules.iptables.build_rule(table='filter', chain=None, command=None, position=", full=None, family='ipv4', **kwargs)

Build a well-formatted iptables rule based on kwargs. A table and chain are not required, unless full is True.

If full is True, then table, chain and command are required. command may be specified as either a short option
(’I’) or a long option (’--insert’). This will return the iptables command, exactly as it would be used from the
command line.

If a position is required (as with -I or -D), it may be specified as position. This will only be useful if full is True.

If connstate is passed in, it may be automatically be changed to state.

To pass in jump options that doesn't take arguments, pass in an empty string.

CLI Examples:

```
salt '*' iptables.build_rule match=state \n  connstate=RELATED,ESTABLISHED jump=ACCEPT
salt '*' iptables.build_rule filter INPUT command=I position=3 \n  full=True match=state state=RELATED,ESTABLISHED jump=ACCEPT
salt '*' iptables.build_rule filter INPUT command=A \n```
.. Invert Rules

salt '* iptables.build_rule filter INPUT command=A \ 
  full=True match=state state=RELATED,ESTABLISHED \ 
  source='127.0.0.1' jump=ACCEPT

IPv6:
salt '* iptables.build_rule filter INPUT command=A \ 
  full=True match=state state=RELATED,ESTABLISHED \ 
  destination='! 127.0.0.1' jump=ACCEPT

salt.modules.iptables.check(table='filter', chain=None, rule=None, family='ipv4')
Check for the existence of a rule in the table and chain
This function accepts a rule in a standard iptables command format, starting with the chain. Trying to
force users to adapt to a new method of creating rules would be irritating at best, and we already have
a parser that can handle it.

CLI Example:
salt '* iptables.check filter INPUT \ 
  rule='-m state --state RELATED,ESTABLISHED -j ACCEPT'

IPv6:
salt '* iptables.check filter INPUT \ 
  rule='-m state --state RELATED,ESTABLISHED -j ACCEPT' \ 
  family=ipv6

salt.modules.iptables.check_chain(table='filter', chain=None, family='ipv4')
New in version 2014.1.0.
Check for the existence of a chain in the table

CLI Example:
salt '* iptables.check_chain filter INPUT
IPv6:
salt '* iptables.check_chain filter INPUT family=ipv6

salt.modules.iptables.delete(table, chain=None, position=None, rule=None, family='ipv4')
Delete a rule from the specified table/chain, specifying either the rule in its entirety, or the rule's position
in the chain.
This function accepts a rule in a standard iptables command format, starting with the chain. Trying to
force users to adapt to a new method of creating rules would be irritating at best, and we already have
a parser that can handle it.

CLI Examples:
salt '* iptables.delete filter INPUT position=3
salt '* iptables.delete filter INPUT \ 
  rule='-m state --state RELATED,ESTABLISHED -j ACCEPT'
IPv6:
salt '*' iptables.delete filter INPUT position=3 family=ipv6
salt '*' iptables.delete filter INPUT \
   rule='-m state --state RELATED,ESTABLISHED -j ACCEPT' \
   family=ipv6

salt.modules.iptables.delete_chain(table='filter', chain=None, family='ipv4')
New in version 2014.1.0.
Delete custom chain to the specified table.
CLI Example:
salt '*' iptables.delete_chain filter CUSTOM_CHAIN
IPv6:
salt '*' iptables.delete_chain filter CUSTOM_CHAIN family=ipv6

salt.modules.iptables.flush(table='filter', chain='*', family='ipv4')
Flush the chain in the specified table, flush all chains in the specified table if not specified chain.
CLI Example:
salt '*' iptables.flush filter INPUT
IPv6:
salt '*' iptables.flush filter INPUT family=ipv6

salt.modules.iptables.get_policy(table='filter', chain=None, family='ipv4')
Return the current policy for the specified table/chain
CLI Example:
salt '*' iptables.get_policy filter INPUT
IPv6:
salt '*' iptables.get_policy filter INPUT family=ipv6

salt.modules.iptables.get_rules(family='ipv4')
Return a data structure of the current, in-memory rules
CLI Example:
salt '*' iptables.get_rules
IPv6:
salt '*' iptables.get_rules family=ipv6

salt.modules.iptables.get_saved_policy(table='filter', chain=None, conf_file=None, family='ipv4')
Return the current policy for the specified table/chain
CLI Examples:
salt '*' iptables.get_saved_policy filter INPUT
salt '*' iptables.get_saved_policy filter INPUT \
   conf_file=/etc/iptables.saved
salt.modules.iptables.get_saved_policy(filter='INPUT', family='ipv6')

Return a data structure of the rules in the conf file.

CLI Example:
```
salt '*' iptables.get_saved_policy filter INPUT family=ipv6
```

salt.modules.iptables.get_saved_rules(
    conf_file=None, family='ipv4'
)

Return a data structure of the rules in the conf file.

CLI Example:
```
salt '*' iptables.get_saved_rules
```

salt.modules.iptables.insert(
    table='filter', chain=None, position=None, rule=None, family='ipv4'
)

Insert a rule into the specified table/chain, at the specified position.

This function accepts a rule in a standard iptables command format, starting with the chain. Trying to
force users to adapt to a new method of creating rules would be irritating at best, and we already have
a parser that can handle it.

If the position specified is a negative number, then the insert will be performed counting from the end of
the list. For instance, a position of -1 will insert the rule as the second to last rule. To insert a rule in the
last position, use the append function instead.

CLI Examples:
```
salt '*' iptables.insert filter INPUT position=3 \
    rule='-m state --state RELATED,ESTABLISHED -j ACCEPT'
```

salt.modules.iptables.new_chain(
    table='filter', chain=None, family='ipv4'
)

Create new custom chain to the specified table.

CLI Example:
```
salt '*' iptables.new_chain filter CUSTOM_CHAIN
```

salt.modules.iptables.save(
    filename=None, family='ipv4'
)

Save the current in-memory rules to disk.

CLI Example:
```
salt '*' iptables.save /etc/sysconfig/iptables
```

salt.modules.iptables.set_policy(
    table='filter', chain=None, policy=None, family='ipv4'
)

Set the current policy for the specified table/chain.

CLI Example:
salt.modules.iptables.version(family='ipv4')
    Return version from iptables --version
    CLI Example:
        salt '*' iptables.version
IPv6:
    salt '*' iptables.version family=ipv6

13.6.132 salt.modules.iwtools module

Support for Wireless Tools for Linux

salt.modules.iwtools.list_interfaces(style=None)
    List all of the wireless interfaces
    CLI Example:
        salt minion iwtools.list_interfaces

salt.modules.iwtools.scan(iface, style=None)
    List networks on a wireless interface
    CLI Examples:
        salt minion iwtools.scan wlp3s0
        salt minion iwtools.scan wlp3s0 list

salt.modules.iwtools.set_mode(iface, mode)
    List networks on a wireless interface
    CLI Example:
        salt minion iwtools.set_mode wlp3s0 Managed

13.6.133 salt.modules.jboss7

Module for managing JBoss AS 7 through the CLI interface.

New in version 2015.5.0.

In order to run each function, jboss_config dictionary with the following properties must be passed:

- cli_path: the path to jboss-cli script, for example: '/opt/jboss/jboss-7.0/bin/jboss-cli.sh'
- controller: the IP address and port of controller, for example: 10.11.12.13:9999
- cli_user: username to connect to jboss administration console if necessary
- cli_password: password to connect to jboss administration console if necessary

Example:

```python
jboss_config:
    cli_path: '/opt/jboss/jboss-7.0/bin/jboss-cli.sh'
    controller: 10.11.12.13:9999
```
salt.modules.jboss7.create_datasource(jboss_config, name, datasource_properties, profile=None)

Create datasource in running jboss instance

jboss_config Configuration dictionary with properties specified above.
name Datasource name
datasource_properties

A dictionary of datasource properties to be created:

- driver-name: mysql
- connection-url: `jdbc:mysql://localhost:3306/sampleDatabase`
- jndi-name: `java:jboss/datasources/sampleDS`
- user-name: sampleuser
- password: secret
- min-pool-size: 3
- use-java-context: True

profile The profile name (JBoss domain mode only)

CLI Example:

```bash
```

class=jboss7
name=deploy

salt.modules.jboss7.create_simple_binding(jboss_config, binding_name, value, profile=None)

Create a simple jndi binding in the running jboss instance

jboss_config Configuration dictionary with properties specified above.
binding_name Binding name to be created
value Binding value
profile The profile name (JBoss domain mode only)

CLI Example:

```bash
salt '*' jboss7.create_simple_binding '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_docs", "controller": "10.11.12.13:9999", "cli_user": "jbossadm", "cli_password": "jbossadm"} my_binding_name my_binding_value
```

class=jboss7
name=deploy

salt.modules.jboss7.deploy(jboss_config, source_file)

Deploy the application on the jboss instance from the local file system where minion is running.

jboss_config Configuration dictionary with properties specified above.
source_file Source file to deploy from

CLI Example:

```bash
```
salt.modules.jboss7.list_deployments(jboss_config)
List all deployments on the jboss instance

jboss_config
Configuration dictionary with properties specified above.

CLI Example:
```
salt '*' jboss7.list_deployments '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_docs", "controller": "10.11.12.9999", "cli_user": "jbossadm", "cli_password": "jbossadm"}'
```

salt.modules.jboss7.read.datasource(jboss_config, name, profile=None)
Read datasource properties in the running jboss instance.

jboss_config Configuration dictionary with properties specified above.
name Datasource name
profile Profile name (JBoss domain mode only)

CLI Example:
```
salt '*' jboss7.read_datasource '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_docs", "controller": "10.11.12.9999", "cli_user": "jbossadm", "cli_password": "jbossadm"}'
```

salt.modules.jboss7.read_simple_binding(jboss_config, binding_name, profile=None)
Read jndi binding in the running jboss instance

jboss_config Configuration dictionary with properties specified above.
binding_name Binding name to be created
profile The profile name (JBoss domain mode only)

CLI Example:
```
salt '*' jboss7.read_simple_binding '{cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_docs", "controller": "10.11.12.9999", "cli_user": "jbossadm", "cli_password": "jbossadm"}' my_binding_name
```

salt.modules.jboss7.reload(jboss_config, host=None)
Reload running jboss instance

jboss_config Configuration dictionary with properties specified above.
host The name of the host. JBoss domain mode only - and required if running in domain mode. The host name is the "name" attribute of the "host" element in host.xml

CLI Example:
```
salt '*' jboss7.reload '{cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_docs", "controller": "10.11.12.9999", "cli_user": "jbossadm", "cli_password": "jbossadm"}'
```

salt.modules.jboss7.remove_datasource(jboss_config, name, profile=None)
Remove an existing datasource from the running jboss instance.

jboss_config Configuration dictionary with properties specified above.
name Datasource name
profile The profile (JBoss domain mode only)

CLI Example:
```
salt '*' jboss7.remove_datasource '{cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_docs", "controller": "10.11.12.9999", "cli_user": "jbossadm", "cli_password": "jbossadm"}' my_datasource_name
```

13.6. execution modules
salt.modules.jboss7.status(jboss_config, host=None, server_config=None)

Get status of running jboss instance.

**jboss_config** Configuration dictionary with properties specified above.

**host** The name of the host. JBoss domain mode only - and required if running in domain mode. The host name is the `"name"` attribute of the `"host"` element in host.xml

**server_config** The name of the Server Configuration. JBoss Domain mode only - and required if running in domain mode.

CLI Example:

```
```

salt.modules.jboss7.stop_server(jboss_config, host=None)

Stop running jboss instance

**jboss_config** Configuration dictionary with properties specified above.

**host** The name of the host. JBoss domain mode only - and required if running in domain mode. The host name is the `"name"` attribute of the `"host"` element in host.xml

CLI Example:

```
```

salt.modules.jboss7.undeploy(jboss_config, deployment)

Undeploy the application from jboss instance

**jboss_config** Configuration dictionary with properties specified above.

**deployment** Deployment name to undeploy

CLI Example:

```
```

salt.modules.jboss7.update_datasource(jboss_config, name, new_properties, profile=None)

Update an existing datasource in running jboss instance. If the property doesn't exist if will be created, if it does, it will be updated with the new value

**jboss_config** Configuration dictionary with properties specified above.

**name** Datasource name

**new_properties**

A dictionary of datasource properties to be updated. For example:

- driver-name: mysql
- connection-url: `jdbc:mysql://localhost:3306/sampleDatabase`
- jndi-name: `java:jboss/datasources/sampleDS`
- user-name: sampleuser
- password: secret
- min-pool-size: 3
- use-java-context: True

**profile** The profile name (JBoss domain mode only)

CLI Example:

salt.modules.jboss7.update_simple_binding(jboss_config, binding_name, value, profile=None)

Update the simple jndi binding in the running jboss instance
jboss_config Configuration dictionary with properties specified above.
binding_name Binding name to be updated
value New binding value
profile The profile name (JBoss domain mode only)
CLI Example:
salt '*' jboss7.update_simple_binding '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_docs", "controller": "10.11.12.13:9999", "cli_user": "$jbossadm", "cli_password": "$jbossadm"}' my_binding_name my_binding_value

13.6.134 salt.modules.jboss7_cli

Module for low-level interaction with JbossAS7 through CLI.
This module exposes two ways of interaction with the CLI, either through commands or operations.

Note: Following JBoss documentation (https://developer.jboss.org/wiki/CommandLineInterface): "Operations are considered a low level but comprehensive way to manage the AS controller, i.e. if it can't be done with operations it can't be done in any other way. Commands, on the other hand, are more user-friendly in syntax, although most of them still translate into operation requests and some of them even into a few composite operation requests, i.e. commands also simplify some management operations from the user's point of view."

The difference between calling a command or operation is in handling the result. Commands return a zero return code if operation is successful or return non-zero return code and print an error to standard output in plain text, in case of an error.

Operations return a json-like structure, that contain more information about the result. In case of a failure, they also return a specific return code. This module parses the output from the operations and returns it as a dictionary so that an execution of an operation can then be verified against specific errors.

In order to run each function, jboss_config dictionary with the following properties must be passed:
  - cli_path: the path to jboss-cli script, for example: '/opt/jboss/jboss-7.0/bin/jboss-cli.sh'
  - controller: the IP address and port of controller, for example: 10.11.12.13:9999
  - cli_user: username to connect to jboss administration console if necessary
  - cli_password: password to connect to jboss administration console if necessary

Example:

jboss_config:
  cli_path: '/opt/jboss/jboss-7.0/bin/jboss-cli.sh'
  controller: 10.11.12.13:9999
  cli_user: '$jbossadm'
  cli_password: '$jbossadm'
salt.modules.jboss7_cli.run_command(jboss_config, command, fail_on_error=True)

Execute a command against jboss instance through the CLI interface.

- **jboss_config**: Configuration dictionary with properties specified above.
- **command**: Command to execute against jboss instance
- **fail_on_error (default=True)**: Is true, raise CommandExecutionException exception if execution fails. If false, 'success' property of the returned dictionary is set to False

CLI Example:

```
salt '*' jboss7_cli.run_command '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_docs", "controller": "10.11.12.13:9999", "cli_user": "jbossadm", "cli_password": "jbossadm"}' my_command
```

salt.modules.jboss7_cli.run_operation(jboss_config, operation, fail_on_error=True, retries=1)

Execute an operation against jboss instance through the CLI interface.

- **jboss_config**: Configuration dictionary with properties specified above.
- **operation**: An operation to execute against jboss instance
- **fail_on_error (default=True)**: Is true, raise CommandExecutionException exception if execution fails. If false, 'success' property of the returned dictionary is set to False
- **retries**: Number of retries in case of 'JBAS012144: Could not connect to remote' error.

CLI Example:

```
salt '*' jboss7_cli.run_operation '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_docs", "controller": "10.11.12.13:9999", "cli_user": "jbossadm", "cli_password": "jbossadm"}' my_operation
```

### 13.6.135 salt.modules.jenkins module

Module for controlling Jenkins

New in version 2016.3.0.

- **depends**: python-jenkins Python module (not to be confused with jenkins)
- **configuration**: This module can be used by either passing an api key and version directly or by specifying both in a configuration profile in the salt master/minion config.

For example:

```
jenkins:
  api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

salt.modules.jenkins.build_job(name=None, parameters=None)

Initiate a build for the provided job.

- **Parameters**
  - **name** -- The name of the job is check if it exists.
  - **parameters** -- Parameters to send to the job.

- **Returns**: True is successful, otherwise raise an exception.

CLI Example:

```
salt '*' jenkins.build_job jobname
```

salt.modules.jenkins.create_job(name=None, config_xml=None, saltenv='base')

Return the configuration file.
Parameters

- **name** -- The name of the job is check if it exists.
- **config_xml** -- The configuration file to use to create the job.
- **saltenv** -- The environment to look for the file in.

**Returns**  The configuration file used for the job.

CLI Example:

```bash
salt '*' jenkins.create_job jobname
salt '*' jenkins.create_job jobname config_xml='salt://jenkins/config.xml'
```

```bash
salt.modules.jenkins.delete_job(name=None)
```

Return true is job is deleted successfully.

**Parameters**  **name** -- The name of the job to delete.

**Returns**  Return true if job is deleted successfully.

CLI Example:

```bash
salt '*' jenkins.delete_job jobname
```

```bash
salt.modules.jenkins.disable_job(name=None)
```

Return true is job is disabled successfully.

**Parameters**  **name** -- The name of the job to disable.

**Returns**  Return true if job is disabled successfully.

CLI Example:

```bash
salt '*' jenkins.disable_job jobname
```

```bash
salt.modules.jenkins.enable_job(name=None)
```

Return true is job is enabled successfully.

**Parameters**  **name** -- The name of the job to enable.

**Returns**  Return true if job is enabled successfully.

CLI Example:

```bash
salt '*' jenkins.enable_job jobname
```

```bash
salt.modules.jenkins.get_job_config(name=None)
```

Return the current job configuration for the provided job.

**Parameters**  **name** -- The name of the job to return the configuration for.

**Returns**  The configuration for the job specified.

CLI Example:

```bash
salt '*' jenkins.get_job_config jobname
```

```bash
salt.modules.jenkins.get_job_info(name=None)
```

Return information about the Jenkins job.

**Parameters**  **name** -- The name of the job is check if it exists.

**Returns**  Information about the Jenkins job.

CLI Example:

```bash
salt '*' jenkins.get_job_info jobname
```
salt.modules.jenkins.get_jobs()
Return the currently configured jobs.

Returns The currently configured jobs.

CLI Example:

```
salt '*' jenkins.get_jobs
```

salt.modules.jenkins.get_version()
Return version of Jenkins

Returns The version of Jenkins

CLI Example:

```
salt '*' jenkins.get_version
```

salt.modules.jenkins.job_exists(name=None)
Check whether the job exists in configured Jenkins jobs.

Parameters name -- The name of the job is check if it exists.

Returns True if job exists, False if job does not exist.

CLI Example:

```
salt '*' jenkins.job_exists jobname
```

salt.modules.jenkins.job_status(name=None)
Return the current status, enabled or disabled, of the job.

Parameters name -- The name of the job to return status for

Returns Return true if enabled or false if disabled.

CLI Example:

```
salt '*' jenkins.job_status jobname
```

salt.modules.jenkins.update_job(name=None, config_xml=None, saltenv='base')
Return the updated configuration file.

Parameters

- name -- The name of the job is check if it exists.
- config_xml -- The configuration file to use to create the job.
- saltenv -- The environment to look for the file in.

Returns The configuration file used for the job.

CLI Example:

```
salt '*' jenkins.update_job jobname
```

```
salt '*' jenkins.update_job jobname config_xml='salt://jenkins/config.xml'
```

13.6.136 salt.modules.junos

Module for interfacing to Junos devices

ALPHA QUALITY code.

salt.modules.junos.call_rpc()
salt.modules.junos.commit()
salt.modules.junos.diff()
salt.modules.junos.facts_refresh()
    Reload the facts dictionary from the device. Usually only needed if the device configuration is changed by
    some other actor.
salt.modules.junos.ping()
salt.modules.junos.rollback()
salt.modules.junos.set_hostname(hostname=None, commit_change=True)

13.6.137 salt.modules.kerberos

Manage Kerberos KDC

   configuration In order to manage your KDC you will need to generate a keytab that can authenticate
without requiring a password.

```
# ktadd -k /root/secure.keytab kadmin/admin kadmin/changepw
```

On the KDC minion you will need to add the following to the minion configuration file so Salt knows what keytab
to use and what principal to authenticate as.

```
auth_keytab: /root/auth.keytab
auth_principal: kadmin/admin
```

salt.modules.kerberos.create_keytab(name, keytab, enctypes=None)
    Create keytab
    CLI Example:
    salt 'kdc.example.com' kerberos.create_keytab host1.example.com host1.example.com.keytab

salt.modules.kerberos.create_principal(name, enctypes=None)
    Create Principal
    CLI Example:
    salt 'kdc.example.com' kerberos.create_principal host/example.com

salt.modules.kerberos.delete_principal(name)
    Delete Principal
    CLI Example:
    salt 'kdc.example.com' kerberos.delete_principal host1.example.com@EXAMPLE.COM

salt.modules.kerberos.get_policy(name)
    Get policy details
    CLI Example:
    salt 'kdc.example.com' kerberos.get_policy my_policy

salt.modules.kerberos.get_principal(name)
    Get principal details
CLI Example:

```bash
salt 'kdc.example.com' kerberos.get_principal root/admin
```

salt.modules.kerberos.get_prives()
Current privileges
CLI Example:

```bash
salt 'kdc.example.com' kerberos.get_prives
```

salt.modules.kerberos.list_policies()
List policies
CLI Example:

```bash
salt 'kdc.example.com' kerberos.list_policies
```

salt.modules.kerberos.list_principals()
Get all principals
CLI Example:

```bash
salt 'kdc.example.com' kerberos.list_principals
```

13.6.138 salt.modules.key

Functions to view the minion's public key information
salt.modules.key.finger()
Return the minion's public key fingerprint
CLI Example:

```bash
salt '*' key.finger
```

salt.modules.key.finger_master()
Return the fingerprint of the master's public key on the minion.
CLI Example:

```bash
salt '*' key.finger_master
```

13.6.139 salt.modules.keyboard

Module for managing keyboards on supported POSIX-like systems using systemd, or such as Redhat, Debian and Gentoo.

salt.modules.keyboard.get_sys()
Get current system keyboard setting
CLI Example:

```bash
salt '*' keyboard.get_sys
```
salt.modules.keyboard.get_x()
   Get current X keyboard setting
   CLI Example:
   ```
salt '*' keyboard.get_x
   ```

salt.modules.keyboard.set_sys(layout)
   Set current system keyboard setting
   CLI Example:
   ```
salt '*' keyboard.set_sys dvorak
   ```

salt.modules.keyboard.set_x(layout)
   Set current X keyboard setting
   CLI Example:
   ```
salt '*' keyboard.set_x dvorak
   ```

13.6.140 salt.modules.keystone

Module for handling openstack keystone calls.

optdepends
   • keystoneclient Python adapter

configuration This module is not usable until the following are specified either in a pillar or in the
   minion's config file:

   ```
   keystone.user: admin
   keystone.password: verybadpass
   keystone.tenant: admin
   keystone.tenant_id: f80919baedab48ec8931f200c65a50df
   keystone.auth_url: 'http://127.0.0.1:5000/v2.0/
   ```

OR (for token based authentication)

   ```
   keystone.token: 'ADMIN'
   keystone.endpoint: 'http://127.0.0.1:35357/v2.0'
   ```

If configuration for multiple openstack accounts is required, they can be set up as different configuration profiles. For example:

   ```
   openstack1:
      keystone.user: admin
      keystone.password: verybadpass
      keystone.tenant: admin
      keystone.tenant_id: f80919baedab48ec8931f200c65a50df
      keystone.auth_url: 'http://127.0.0.1:5000/v2.0/
   ```

   ```
   openstack2:
      keystone.user: admin
      keystone.password: verybadpass
      keystone.tenant: admin
      keystone.tenant_id: f80919baedab48ec8931f200c65a50df
      keystone.auth_url: 'http://127.0.0.2:5000/v2.0/
   ```
With this configuration in place, any of the keystone functions can make use of a configuration profile by declaring it explicitly. For example:

```
salt '*' keystone.tenant_list profile=openstack1
```

`salt.modules.keystone.auth(profile=None, **connection_args)`

Set up keystone credentials. Only intended to be used within Keystone-enabled modules.

CLI Example:

```
salt '*' keystone.auth
```

`salt.modules.keystone.ec2_credentials_create(user_id=None, name=None, tenant_id=None, tenant=None, profile=None, **connection_args)`

Create EC2-compatible credentials for user per tenant

CLI Examples:

```
salt '*' keystone.ec2_credentials_create name=admin tenant=admin
salt '*' keystone.ec2_credentials_create user_id=c965f79c4f864eaaa9c3b41904e67082
  tenant_id=722787eb54084915866370dc627ec5f
```

`salt.modules.keystone.ec2_credentials_delete(user_id=None, name=None, access_key=None, profile=None, **connection_args)`

Delete EC2-compatible credentials

CLI Examples:

```
salt '*' keystone.ec2_credentials_delete 860f8c2c38ca4fab989f9bc56a61a64 access_key=5f66d2fd24f604b8bb9cd28886106f442
salt '*' keystone.ec2_credentials_delete name=admin access_key=5f66d2fd24f604b8bb9cd28886106f442
```

`salt.modules.keystone.ec2_credentials_get(user_id=None, name=None, access=None, profile=None, **connection_args)`

Return ec2_credentials for a user (keystone ec2-credentials-get)

CLI Examples:

```
salt '*' keystone.ec2_credentials_get c965f79c4f864eaaa9c3b41904e67082
  access=722787eb54084915866370dc627ec5f
salt '*' keystone.ec2_credentials_get user_id=c965f79c4f864eaaa9c3b41904e67082
  access=722787eb54084915866370dc627ec5f
salt '*' keystone.ec2_credentials_get name=nova
  access=722787eb54084915866370dc627ec5f
```

`salt.modules.keystone.ec2_credentials_list(user_id=None, name=None, profile=None, **connection_args)`

Return a list of ec2_credentials for a specific user (keystone ec2-credentials-list)

CLI Examples:

```
salt '*' keystone.ec2_credentials_list 298ce377245c4ec9b70e1c639c89e654
salt '*' keystone.ec2_credentials_list user_id=298ce377245c4ec9b70e1c639c89e654
salt '*' keystone.ec2_credentials_list name=jack
```
salt.modules.keystone.endpoint_create(service, publicurl=None, internalurl=None, adminurl=None, region=None, profile=None, **connection_args)

Create an endpoint for an Openstack service

CLI Examples:

```
salt '*' keystone.endpoint_create nova 'http://public/url'
'http://internal/url' 'http://adminurl/url' region
```

salt.modules.keystone.endpoint_delete(service, profile=None, **connection_args)

Delete endpoints of an Openstack service

CLI Examples:

```
salt '*' keystone.endpoint_delete nova
```

salt.modules.keystone.endpoint_get(service, profile=None, **connection_args)

Return a specific endpoint (keystone endpoint-get)

CLI Example:

```
salt '*' keystone.endpoint_get nova
```

salt.modules.keystone.endpoint_list(profile=None, **connection_args)

Return a list of available endpoints (keystone endpoints-list)

CLI Example:

```
salt '*' keystone.endpoint_list
```

salt.modules.keystone.role_create(name, profile=None, **connection_args)

Create a named role.

CLI Example:

```
salt '*' keystone.role_create admin
```

salt.modules.keystone.role_delete(role_id=None, name=None, profile=None, **connection_args)

Delete a role (keystone role-delete)

CLI Examples:

```
salt '*' keystone.role_delete c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.role_delete role_id=c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.role_delete role_id=c965f79c4f864eaaa9c3b41904e67082
```

salt.modules.keystone.role_get(role_id=None, name=None, profile=None, **connection_args)

Return a specific roles (keystone role-get)

CLI Examples:

```
salt '*' keystone.role_get c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.role_get role_id=c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.role_get name=admin
```

salt.modules.keystone.role_list(profile=None, **connection_args)

Return a list of available roles (keystone role-list)

CLI Example:
salt '*' keystone.role_list

salt.modules.keystone.service_create(name, service_type, description=None, profile=None, **connection_args)
Add service to Keystone service catalog
CLI Examples:
salt '*' keystone.service_create nova compute 'OpenStack Compute Service'

salt.modules.keystone.service_delete(service_id=None, name=None, profile=None, **connection_args)
Delete a service from Keystone service catalog
CLI Examples:
salt '*' keystone.service_delete c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.service_delete name=nova

salt.modules.keystone.service_get(service_id=None, name=None, profile=None, **connection_args)
Return a specific services (keystone service-get)
CLI Examples:
salt '*' keystone.service_get c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.service_get service_id=c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.service_get name=nova

salt.modules.keystone.service_list(profile=None, **connection_args)
Return a list of available services (keystone services-list)
CLI Example:
salt '*' keystone.service_list

salt.modules.keystone.tenant_create(name, description=None, enabled=True, profile=None, **connection_args)
Create a keystone tenant
CLI Examples:
salt '*' keystone.tenant_create nova description='nova tenant'
salt '*' keystone.tenant_create test enabled=False

salt.modules.keystone.tenant_delete(tenant_id=None, name=None, profile=None, **connection_args)
Delete a tenant (keystone tenant-delete)
CLI Examples:
salt '*' keystone.tenant_delete c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.tenant_delete tenant_id=c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.tenant_delete name=demo

salt.modules.keystone.tenant_get(tenant_id=None, name=None, profile=None, **connection_args)
Return a specific tenants (keystone tenant-get)
CLI Examples:
salt.modules.keystone.tenant_list(profile=None, **connection_args)
    Return a list of available tenants (keystone tenants-list)
    CLI Example:
    ```
salt '*' keystone.tenant_list
    ```

salt.modules.keystone.tenant_update(tenant_id=None, name=None, description=None, enabled=None, profile=None, **connection_args)
    Update a tenant's information (keystone tenant-update) The following fields may be updated: name, email, enabled. Can only update name if targeting by ID
    CLI Examples:
    ```
salt '*' keystone.tenant_update name=admin enabled=True
salt '*' keystone.tenant_update tenant_id=c965f79c4f864eaa9c3b41904e67082 name=admin
    ```

salt.modules.keystone.token_get(profile=None, **connection_args)
    Return the configured tokens (keystone token-get)
    CLI Example:
    ```
salt '*' keystone.token_get
    ```

salt.modules.keystone.user_create(name, password, email, tenant_id=None, enabled=True, profile=None, **connection_args)
    Create a user (keystone user-create)
    CLI Examples:
    ```
salt '*' keystone.user_create name=jack password=zero email=jack@halloweentown.
    ```

salt.modules.keystone.user_delete(user_id=None, name=None, profile=None, **connection_args)
    Delete a user (keystone user-delete)
    CLI Examples:
    ```
salt '*' keystone.user_delete c965f79c4f864eaa9c3b41904e67082
salt '*' keystone.user_delete user_id=c965f79c4f864eaa9c3b41904e67082
salt '*' keystone.user_delete name=nova
    ```

salt.modules.keystone.user_get(user_id=None, name=None, profile=None, **connection_args)
    Return a specific users (keystone user-get)
    CLI Examples:
    ```
salt '*' keystone.user_get c965f79c4f864eaa9c3b41904e67082
salt '*' keystone.user_get user_id=c965f79c4f864eaa9c3b41904e67082
salt '*' keystone.user_get name=nova
    ```

salt.modules.keystone.user_list(profile=None, **connection_args)
    Return a list of available users (keystone user-list)
CLI Example:

```bash
salt '*' keystone.user_list
```

**salt.modules.keystone.user_password_update**

Update a user's password (keystone user-password-update)

CLI Examples:

```
salt '*' keystone.user_password_update user_id=c965f79c4f864eaaa9c3b41904e67082 password=12345
salt '*' keystone.user_password_update user_id=c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.user_password_update name=nova password=12345
```

**salt.modules.keystone.user_role_add**

Add role for user in tenant (keystone user-role-add)

CLI Examples:

```
salt '*' keystone.user_role_add user_id=298ce377245c4ec9b70e1c639c89e654 tenant_id=7167a092e84bae8ceed4bf9d15bb3b role_id=ce377245c4ec9b70e1c639c89e8ceed4
salt '*' keystone.user_role_add user=admin tenant=admin role=admin
```

**salt.modules.keystone.user_role_list**

Return a list of available user_roles (keystone user-roles-list)

CLI Examples:

```
salt '*' keystone.user_role_list user_id=298ce377245c4ec9b70e1c639c89e654 tenant_id=7167a092e84bae8ceed4bf9d15bb3b user_name=admin tenant_name=admin
```

**salt.modules.keystone.user_role_remove**

Remove role for user in tenant (keystone user-role-remove)

CLI Examples:

```
salt '*' keystone.user_role_remove user_id=298ce377245c4ec9b70e1c639c89e654 tenant_id=7167a092e84bae8ceed4bf9d15bb3b role_id=ce377245c4ec9b70e1c639c89e8ceed4
salt '*' keystone.user_role_remove user=admin tenant=admin role=admin
```

**salt.modules.keystone.user_update**

Update a user's information (keystone user-update) The following fields may be updated: name, email, enabled, tenant. Because the name is one of the fields, a valid user id is required.

CLI Examples:

```
salt '*' keystone.user_update user_id=c965f79c4f864eaaa9c3b41904e67082 name=newname
salt '*' keystone.user_update c965f79c4f864eaaa9c3b41904e67082 name=newname
```
salt.modules.keystone.user_verify_password(*\(user_id=None, name=None, password=None,\)
\[profile=None, **connection_args\])
Verify a user's password

CLI Examples:
salt '*' keystone.user_verify_password name=test password=foobar
salt '*' keystone.user_verify_password user_id=c965f79c4f864eaa89c3b41904e67082\[password=foobar

13.6.141 salt.modules.kmod
Module to manage Linux kernel modules

salt.modules.kmod.available()
Return a list of all available kernel modules

CLI Example:
salt '*' kmod.available

salt.modules.kmod.check_available(mod)
Check to see if the specified kernel module is available

CLI Example:
salt '*' kmod.check_available kvm

salt.modules.kmod.is_loaded(mod)
Check to see if the specified kernel module is loaded

CLI Example:
salt '*' kmod.is_loaded kvm

salt.modules.kmod.load(mod, persist=False)
Load the specified kernel module
*mod* Name of module to add
*persist* Write module to /etc/modules to make it load on system reboot

CLI Example:
salt '*' kmod.load kvm

salt.modules.kmod.lsmod()
Return a dict containing information about currently loaded modules

CLI Example:
salt '*' kmod.lsmod

salt.modules.kmod.mod_list(only_persist=False)
Return a list of the loaded module names
*only_persist* Only return the list of loaded persistent modules

CLI Example:
salt '*' kmod.mod_list
salt.modules.kmod.remove(mod, persist=False, comment=True)

Remove the specified kernel module

- **mod** Name of module to remove
- **persist** Also remove module from /etc/modules
- **comment** If persist is set don’t remove line from /etc/modules but only comment it

CLI Example:

```
salt '*' kmod.remove kvm
```

13.6.142 salt.modules.launchctl

Module for the management of MacOS systems that use launchd/launchctl

**Important:** If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `service.start` is not available), see [here](#).

- **depends**
  - plistlib Python module

salt.modules.launchctl.available(job_label)

Check that the given service is available.

CLI Example:

```
salt '*' service.available com.openssh.sshd
```

salt.modules.launchctl.disabled(job_label, runas=None)

Return True if the named service is disabled, false otherwise

CLI Example:

```
salt '*' service.disabled <service label>
```

salt.modules.launchctl.enabled(job_label, runas=None)

Return True if the named service is enabled, false otherwise

CLI Example:

```
salt '*' service.enabled <service label>
```

salt.modules.launchctl.get_all()

Return all installed services

CLI Example:

```
salt '*' service.get_all
```

salt.modules.launchctl.missing(job_label)

The inverse of service.available Check that the given service is not available.

CLI Example:

```
salt '*' service.missing com.openssh.sshd
```
salt.modules.launchctl.restart(job_label, runas=None)
    Restart the named service
    
    CLI Example:
    
    ```
    salt '*' service.restart <service label>
    ```

salt.modules.launchctl.start(job_label, runas=None)
    Start the specified service
    
    CLI Example:
    
    ```
    salt '*' service.start <service label>
    salt '*' service.start org.ntp.ntpd
    salt '*' service.start /System/Library/LaunchDaemons/org.ntp.ntpd.plist
    ```

salt.modules.launchctl.status(job_label, runas=None)
    Return the status for a service, returns a bool whether the service is running.
    
    CLI Example:
    
    ```
    salt '*' service.status <service label>
    ```

salt.modules.launchctl.stop(job_label, runas=None)
    Stop the specified service
    
    CLI Example:
    
    ```
    salt '*' service.stop <service label>
    salt '*' service.stop org.ntp.ntpd
    salt '*' service.stop /System/Library/LaunchDaemons/org.ntp.ntpd.plist
    ```

13.6.143 salt.modules.layman

Support for Layman

salt.modules.layman.add(overlay)
    Add the given overlay from the cached remote list to your locally installed overlays. Specify `ALL' to add all overlays from the remote list.
    
    Return a list of the new overlay(s) added:
    
    CLI Example:
    
    ```
    salt '*' layman.add <overlay name>
    ```

salt.modules.layman.delete(overlay)
    Remove the given overlay from the your locally installed overlays. Specify `ALL' to remove all overlays.
    
    Return a list of the overlays(s) that were removed:
    
    CLI Example:
    
    ```
    salt '*' layman.delete <overlay name>
    ```

salt.modules.layman.list_all()
    List all overlays, including remote ones.
    
    Return a list of available overlays.
Salt Documentation, Release 2016.3.6

CLI Example:
```
salt '*' layman.list_all
```

salt.modules.layman.list_local()

List the locally installed overlays.

Return a list of installed overlays:

CLI Example:
```
salt '*' layman.list_local
```

salt.modules.layman.sync(overlay='ALL')

Update the specified overlay. Use `ALL` to synchronize all overlays. This is the default if no overlay is specified.

**Parameters**
- **overlay** Name of the overlay to sync. (Defaults to `ALL`)

CLI Example:
```
salt '*' layman.sync
```

### 13.6.144 salt.modules.ldap3

Query and modify an LDAP database (alternative interface)

New in version 2016.3.0.

This is an alternative to the ldap interface provided by the ldapmod execution module.

**depends**
- ldap Python module

**exception**
salt.modules.ldap3.LDAPError(message=`None`)

Base class of all LDAP exceptions raised by backends.

This is only used for errors encountered while interacting with the LDAP server; usage errors (e.g., invalid backend name) will have a different type.

**Variables**
- **cause** -- backend exception object, if applicable

salt.modules.ldap3.add(connect_spec, dn, attributes)

Add an entry to an LDAP database.

**Parameters**
- **connect_spec** -- See the documentation for the connect_spec parameter for connect().
- **dn** -- Distinguished name of the entry.
- **attributes** -- Non-empty dict mapping each of the new entry's attributes to a non-empty iterable of values.

**Returns**
True if successful, raises an exception otherwise.

CLI example:
```
salt '*' ldap3.add "{
    'url': 'ldaps://ldap.example.com/,'
    'bind': {
        'method': 'simple',
        'password': 'secret',
```
salt.modules.ldap3.change(connect_spec, dn, before, after)
Modify an entry in an LDAP database.

This does the same thing as modify(), but with a simpler interface. Instead of taking a list of directives, it
takes a before and after view of an entry, determines the differences between the two, computes the directives,
and executes them.

Any attribute value present in before but missing in after is deleted. Any attribute value present in after
but missing in before is added. Any attribute value in the database that is not mentioned in either before
or after is not altered. Any attribute value that is present in both before and after is ignored, regardless
of whether that attribute value exists in the database.

Parameters

* connect_spec -- See the documentation for the connect_spec parameter for
  connect() .
* dn -- Distinguished name of the entry.
* before -- The expected state of the entry before modification. This is a dict mapping
each attribute name to an iterable of values.
* after -- The desired state of the entry after modification. This is a dict mapping each
  attribute name to an iterable of values.

Returns True if successful, raises an exception otherwise.

CLI example:

```python
salt '*' ldap3.change "{
  'url': 'ldaps://ldap.example.com/','
  'bind': {
    'method': 'simple',
    'password': 'secret'
  }
}" dn='cn=admin,dc=example,dc=com' "attributes={'example': 'values'}"
```

salt.modules.ldap3.connect(connect_spec=None)
Connect and optionally bind to an LDAP server.

Parameters connect_spec -- This can be an LDAP connection object returned by a previous
call to connect() (in which case the argument is simply returned), None (in which case
an empty dict is used), or a dict with the following keys:

* 'backend' Optional; default depends on which Python LDAP modules are in-
stalled. Name of the Python LDAP module to use. Only 'ldap' is supported
at the moment.
* 'url' Optional; defaults to 'ldapi:///'. URL to the LDAP server.
* 'bind' Optional; defaults to None. Describes how to bind an identity to the LDAP
  connection. If None, an anonymous connection is made. Valid keys:
    * 'method' Optional; defaults to None. The authentication method to
      use. Valid values include but are not necessarily limited to 'simple',
      'sasl', and None. If None, an anonymous connection is made. Available
      methods depend on the chosen backend.

13.6. execution modules 1167
- 'mechanism' Optional; defaults to 'EXTERNAL'. The SASL mechanism to use. Ignored unless the method is 'sasl'. Available methods depend on the chosen backend and the server's capabilities.

- 'credentials' Optional; defaults to None. An object specific to the chosen SASL mechanism and backend that represents the authentication credentials. Ignored unless the method is 'sasl'.

For the 'ldap' backend, this is a dictionary. If None, an empty dict is used. Keys:
  
  * 'args' Optional; defaults to an empty list. A list of arguments to pass to the SASL mechanism constructor. See the SASL mechanism constructor documentation in the `ldap.sasl` Python module.
  
  * 'kwargs' Optional; defaults to an empty dict. A dict of keyword arguments to pass to the SASL mechanism constructor. See the SASL mechanism constructor documentation in the `ldap.sasl` Python module.

- 'dn' Optional; defaults to an empty string. The distinguished name to bind.

- 'password' Optional; defaults to an empty string. Password for binding. Ignored if the method is 'sasl'.

- 'tls' Optional; defaults to None. A backend-specific object containing settings to override default TLS behavior.

  For the 'ldap' backend, this is a dictionary. Not all settings in this dictionary are supported by all versions of python-ldap or the underlying TLS library. If None, an empty dict is used. Possible keys:

  * 'starttls' If present, initiate a TLS connection using StartTLS. (The value associated with this key is ignored.)
  
  * 'cacertdir' Set the path of the directory containing CA certificates.
  
  * 'cacertfile' Set the pathname of the CA certificate file.
  
  * 'certfile' Set the pathname of the certificate file.
  
  * 'cipher_suite' Set the allowed cipher suite.
  
  * 'crlcheck' Set the CRL evaluation strategy. Valid values are 'none', 'peer', and 'all'.
  
  * 'crlfile' Set the pathname of the CRL file.
  
  * 'dhfile' Set the pathname of the file containing the parameters for Diffie-Hellman ephemeral key exchange.
  
  * 'keyfile' Set the pathname of the certificate key file.
  
  * 'newctx' If present, instruct the underlying TLS library to create a new TLS context. (The value associated with this key is ignored.)
  
  * 'protocol_min' Set the minimum protocol version.
  
  * 'random_file' Set the pathname of the random file when /dev/random and /dev/urandom are not available.
  
  * 'require_cert' Set the certificate validation policy. Valid values are 'never', 'hard', 'demand', 'allow', and 'try'.

1168 Chapter 13. Salt Module Reference
Salt Documentation, Release 2016.3.6

• 'opts' Optional; defaults to None. A backend-specific object containing options for the backend.

  For the 'ldap' backend, this is a dictionary of OpenLDAP options to set. If None, an empty dict is used. Each key is a the name of an OpenLDAP option constant without the 'LDAP_OPT_' prefix, then converted to lower case.

Returns

an object representing an LDAP connection that can be used as the connect_spec argument to any of the functions in this module (to avoid the overhead of making and terminating multiple connections).

This object should be used as a context manager. It is safe to nest with statements.

CLI example:

```
salt '*' ldap3.connect "{
    'url': 'ldaps://ldap.example.com/',
    'bind': {
        'method': 'simple',
        'dn': 'cn=admin,dc=example,dc=com',
        'password': 'secret'
    }
}"
```

salt.modules.ldap3.delete(connect_spec, dn)
Delete an entry from an LDAP database.

Parameters

• connect_spec -- See the documentation for the connect_spec parameter for connect().
• dn -- Distinguished name of the entry.

Returns True if successful, raises an exception otherwise.

CLI example:

```
salt '*' ldap3.delete "{
    'url': 'ldaps://ldap.example.com/',
    'bind': {
        'method': 'simple',
        'password': 'secret'
    }
}" dn='cn=admin,dc=example,dc=com'
```

salt.modules.ldap3.modify(connect_spec, dn, directives)
Modify an entry in an LDAP database.

Parameters

• connect_spec -- See the documentation for the connect_spec parameter for connect().
• dn -- Distinguished name of the entry.
• directives -- Iterable of directives that indicate how to modify the entry. Each directive is a tuple of the form (op, attr, vals), where:
  - op identifies the modification operation to perform. One of:
    * 'add' to add one or more values to the attribute
    * 'delete' to delete some or all of the values from the attribute. If no values are specified with this operation, all of the attribute's values are deleted. Otherwise, only the named values are deleted.
'replace' to replace all of the attribute's values with zero or more new values

- **attr** names the attribute to modify
- **vals** is an iterable of values to add or delete

**Returns** True if successful, raises an exception otherwise.

CLI example:

```python
salt '*' ldap3.modify "{
    'url': 'ldaps://ldap.example.com/',
    'bind': {
        'method': 'simple',
        'password': 'secret'
    }
}"

dn='cn=admin,dc=example,dc=com'
directives="('add', 'example', ['example_val'])"
```

salt.modules.ldap3.search(connect_spec, base, scope='subtree', filterstr='(objectClass=*)', attrlist=None, attrsonly=0)

Search an LDAP database.

**Parameters**

- **connect_spec** -- See the documentation for the connect_spec parameter for `connect()`.
- **base** -- Distinguished name of the entry at which to start the search.
- **scope** -- One of the following:
  - 'subtree' Search the base and all of its descendants.
  - 'base' Search only the base itself.
  - 'onelevel' Search only the base's immediate children.
- **filterstr** -- String representation of the filter to apply in the search.
- **attrlist** -- Limit the returned attributes to those in the specified list. If None, all attributes of each entry are returned.
- **attrsonly** -- If non-zero, don’t return any attribute values.

**Returns** a dict of results. The dict is empty if there are no results. The dict maps each returned entry’s distinguished name to a dict that maps each of the matching attribute names to a list of its values.

CLI example:

```python
salt '*' ldap3.search "{
    'url': 'ldaps://ldap.example.com/',
    'bind': {
        'method': 'simple',
        'dn': 'cn=admin,dc=example,dc=com',
        'password': 'secret',
    }
}"

"base='dc=example,dc=com'"
```

13.6.145 salt.modules.ldapmod

Salt interface to LDAP commands

**depends**
ldap Python module

**configuration** In order to connect to LDAP, certain configuration is required in the minion config on the LDAP server. The minimum configuration items that must be set are:

```
ldap.basedn: dc=acme,dc=com (example values, adjust to suit)
```

If your LDAP server requires authentication then you must also set:

```
ldap.anonymous: False
ldap.binddn: admin
ldap.bindpw: password
```

In addition, the following optional values may be set:

```
ldap.server: localhost (default=localhost, see warning below)
ldap.port: 389 (default=389, standard port)
ldap.tls: False (default=False, no TLS)
ldap.no_verify: False (default=False, verify TLS)
ldap.anonymous: True (default=True, bind anonymous)
ldap.scope: 2 (default=2, ldap.SCOPE_SUBTREE)
ldap.attrs: [saltAttr] (default=None, return all attributes)
```

**Warning:** At the moment this module only recommends connection to LDAP services listening on localhost. This is deliberate to avoid the potentially dangerous situation of multiple minions sending identical update commands to the same LDAP server. It’s easy enough to override this behavior, but badness may ensue - you have been warned.

**salt.modules.ldapmod.search**

Run an arbitrary LDAP query and return the results.

CLI Example:

```
salt 'ldaphost' ldap.search "filter=cn=myhost"
```

Return data:

```
{
    'myhost': {
        'count': 1,
        'results': [[
            'saltKeyValue': ['ntpserver=ntp.acme.local',
                            'foo=myfoo'],
            'saltState': ['foo', 'bar']
        ]],
        'time': {'human': '1.2ms', 'raw': '0.00123'}
    }
}
```

Search and connection options can be overridden by specifying the relevant option as key=value pairs, for example:

```
salt 'ldaphost' ldap.search filter=cn=myhost dn=ou=hosts,o=acme,c=gb scope=1 attrs='' server='localhost' port='7393' tls=True bindpw='ssh'
```

**13.6.146 salt.modules.linux_acl**

Support for Linux File Access Control Lists
salt.modules.linux_acl.delfacl(acl_type, acl_name=``, *args, **kwargs)

Remove specific FACL from the specified file(s)

CLI Examples:

```
salt '*' acl.delfacl user myuser /tmp/house/kitchen
salt '*' acl.delfacl default:group mygroup /tmp/house/kitchen
salt '*' acl.delfacl d:u myuser /tmp/house/kitchen
salt '*' acl.delfacl g myuser /tmp/house/kitchen /tmp/house/livingroom
salt '*' acl.delfacl user myuser /tmp/house/kitchen recursive=True
```

salt.modules.linux_acl.getfacl(*args, **kwargs)

Return (extremely verbose) map of FACLs on specified file(s)

CLI Examples:

```
salt '*' acl.getfacl /tmp/house/kitchen
salt '*' acl.getfacl /tmp/house/kitchen /tmp/house/livingroom
salt '*' acl.getfacl /tmp/house/kitchen /tmp/house/livingroom recursive=True
```

salt.modules.linux_acl.modfacl(acl_type, acl_name=``, perms=``, *args, **kwargs)

Add or modify a FACL for the specified file(s)

CLI Examples:

```
salt '*' acl.modfacl user myuser rwx /tmp/house/kitchen
salt '*' acl.modfacl default:group mygroup rx /tmp/house/kitchen
salt '*' acl.modfacl d:u myuser 7 /tmp/house/kitchen
salt '*' acl.modfacl g mygroup 0 /tmp/house/kitchen /tmp/house/livingroom
salt '*' acl.modfacl user myuser rwx /tmp/house/kitchen recursive=True
```

salt.modules.linux_acl.version()

Return facl version from getfacl --version

CLI Example:

```
salt '*' acl.version
```

salt.modules.linux_acl.wipefacls(*args, **kwargs)

Remove all FACLs from the specified file(s)

CLI Examples:

```
salt '*' acl.wipefacls /tmp/house/kitchen
salt '*' acl.wipefacls /tmp/house/kitchen /tmp/house/livingroom
salt '*' acl.wipefacls /tmp/house/kitchen /tmp/house/livingroom recursive=True
```

13.6.147 salt.modules.linux_ip module

The networking module for Non-RH/Deb Linux distros

salt.modules.linux_ip.down(iface, iface_type=None)

Shutdown a network interface

CLI Example:

```
salt '*' ip.down eth0
```
salt.modules.linux_ip.get_interface(iface)
   Return the contents of an interface script
   
   CLI Example:
   
   salt '*' ip.get_interface eth0

salt.modules.linux_ip.get_routes(iface=None)
   Return the current routing table
   
   CLI Examples:
   
   salt '*' ip.get_routes
   salt '*' ip.get_routes eth0

salt.modules.linux_ip.up(iface, iface_type=None)
   Start up a network interface
   
   CLI Example:
   
   salt '*' ip.up eth0

13.6.148 salt.modules.linux_lvm

Support for Linux LVM2

salt.modules.linux_lvm.fullversion()
   Return all version info from lvm version
   
   CLI Example:
   
   salt '*' lvm.fullversion

salt.modules.linux_lvm.lvcreate(lvname, vgname, size=None, extents=None, snapshot=None, pv=None, **kwargs)
   Create a new logical volume, with option for which physical volume to be used
   
   CLI Examples:
   
   salt '*' lvm.lvcreate new_volume_name vg_name size=10G
   salt '*' lvm.lvcreate new_volume_name vg_name extents=100 pv=/dev/sdb
   salt '*' lvm.lvcreate new_snapshot vg_name snapshot=volume_name size=3G

salt.modules.linux_lvm.lvdisplay(lvname=``)
   Return information about the logical volume(s)
   
   CLI Examples:
   
   salt '*' lvm.lvdisplay
   salt '*' lvm.lvdisplay /dev/vg_myserver/root

salt.modules.linux_lvm.lvremove(lvname, vgname)
   Remove a given existing logical volume from a named existing volume group
   
   CLI Example:
   
   salt '*' lvm.lvremove lvname vgname force=True
salt.modules.linux_lvm.lvresize(size, lvpath)

Return information about the logical volume(s)

CLI Examples:
salt '*' lvm.lvresize +12M /devmapper/vg1-test

salt.modules.linux_lvm.pvcreate(devices, override=True, **kwargs)

Set a physical device to be used as an LVM physical volume

override   Skip devices, if they are already an LVM physical volumes

CLI Examples:
salt mymachine lvm.pvcreate /dev/sdb1,/dev/sdb2
salt mymachine lvm.pvcreate /dev/sdb1 dataalignmentoffset=7s

salt.modules.linux_lvm.pvdisplay(pvname='', real=False)

Return information about the physical volume(s)

pvname   physical device name
real     dereference any symlinks and report the real device

New in version 2015.8.7.

CLI Examples:
salt '*' lvm.pvdisplay
salt '*' lvm.pvdisplay /dev/md0

salt.modules.linux_lvm.pvremove(devices, override=True)

Remove a physical device being used as an LVM physical volume

override   Skip devices, if they are already not used as an LVM physical volumes

CLI Examples:
salt mymachine lvm.pvremove /dev/sdb1,/dev/sdb2

salt.modules.linux_lvm.version()

Return LVM version from lvm version

CLI Example:
salt '*' lvm.version

salt.modules.linux_lvm.vgcreate(vgname, devices, **kwargs)

Create an LVM volume group

CLI Examples:
salt mymachine lvm.vgcreate my_vg /dev/sdb1,/dev/sdb2
salt mymachine lvm.vgcreate my_vg /dev/sdb1 clustered=y

salt.modules.linux_lvm.vgdisplay(vgname='')

Return information about the volume group(s)

CLI Examples:
salt '*' lvm.vgdisplay
salt '*' lvm.vgdisplay nova-volumes

salt.modules.linux_lvm.vgextend(vgname, devices)

Add physical volumes to an LVM volume group
CLI Examples:
```
salt mymachine lvm.vgextend my_vg /dev/sdb1,/dev/sdb2
salt mymachine lvm.vgextend my_vg /dev/sdb1
```

```
salt.modules.linux_lvm.vgremove(vgname)
Remove an LVM volume group
```

CLI Examples:
```
salt mymachine lvm.vgremove vgname
salt mymachine lvm.vgremove vgname force=True
```

### 13.6.149 salt.modules.linux_sysctl

Module for viewing and modifying sysctl parameters

```
salt.modules.linux_sysctl.assign(name, value)
Assign a single sysctl parameter for this minion
```

CLI Example:
```
salt '*' sysctl.assign net.ipv4.ip_forward 1
```

```
salt.modules.linux_sysctl.default_config()
Linux hosts using systemd 207 or later ignore /etc/sysctl.conf and only load from
/etc/sysctl.d/*.conf. This function will do the proper checks and return a default config file which
will be valid for the Minion. Hosts running systemd >= 207 will use /etc/sysctl.d/99-salt.conf.
```

CLI Example:
```
salt -G 'kernel:Linux' sysctl.default_config
```

```
salt.modules.linux_sysctl.get(name)
Return a single sysctl parameter for this minion
```

CLI Example:
```
salt '*' sysctl.get net.ipv4.ip_forward
```

```
salt.modules.linux_sysctl.persist(name, value, config=None)
Assign and persist a simple sysctl parameter for this minion. If config is not specified, a sensible default
will be chosen using sysctl.default_config.
```

CLI Example:
```
salt '*' sysctl.persist net.ipv4.ip_forward 1
```

```
salt.modules.linux_sysctl.show(config_file=False)
Return a list of sysctl parameters for this minion
```

CLI Example:
```
salt '*' sysctl.show
```
13.6.150  salt.modules.localemod

Module for managing locales on POSIX-like systems.
salt.modules.localemod.avail(locale)
Check if a locale is available.
   New in version 2014.7.0.
   CLI Example:
   salt '*' locale.avail 'en_US.UTF-8'
salt.modules.localemod.gen_locale(locale, **kwargs)
Generate a locale. Options:
   New in version 2014.7.0.
   Parameters locale -- Any locale listed in /usr/share/i18n/locales or
   /usr/share/i18n/SUPPORTED for Debian and Gentoo based distributions, which require the
   charmap to be specified as part of the locale when generating it.
   verbose Show extra warnings about errors that are normally ignored.
   CLI Example:
   salt '*' locale.gen_locale en_US.UTF-8
   salt '*' locale.gen_locale 'en_IE.UTF-8 UTF-8'   # Debian/Gentoo only
salt.modules.localemod.get_locale()
Get the current system locale
   CLI Example:
   salt '*' locale.get_locale
salt.modules.localemod.list_avail()
Lists available (compiled) locales
   CLI Example:
   salt '*' locale.list_avail
salt.modules.localemod.set_locale(locale)
Sets the current system locale
   CLI Example:
   salt '*' locale.set_locale 'en_US.UTF-8'

13.6.151  salt.modules.locate

Module for using the locate utilities
salt.modules.locate.locate(pattern, database='*', limit=0, **kwargs)
Performs a file lookup. Valid options (and their defaults) are:
basename=False
count=False
eexisting=False
Salt Documentation, Release 2016.3.6

follow=True
ignore=False
nofollow=False
wholename=True
regex=False
database=<locate's default database>
limit=<integer, not set by default>

See the manpage for locate(1) for further explanation of these options.

CLI Example:

salt '*' locate.locate

salt.modules.locate.stats()
Returns statistics about the locate database

CLI Example:

salt '*' locate.stats

salt.modules.locate.updatedb()
Updates the locate database

CLI Example:

salt '*' locate.updatedb

salt.modules.locate.version()
Returns the version of locate

CLI Example:

salt '*' locate.version

13.6.152 salt.modules.logadm

Module for managing Solaris logadm based log rotations.

salt.modules.logadm.remove(name, conf_file='/etc/logadm.conf')
Remove log pattern from logadm

CLI Example:

salt '*' logadm.remove myapplog

salt.modules.logadm.rotate(name, pattern=False, count=False, age=False, size=False, copy=True, conf_file='/etc/logadm.conf')
Set up pattern for logging.

CLI Example:

salt '*' logadm.rotate myapplog pattern='/var/log/myapp/*.log' count=7

salt.modules.logadm.show_conf(conf_file='/etc/logadm.conf')
Show parsed configuration

CLI Example:

13.6. execution modules 1177
13.6.153 `salt.modules.logrotate`

Module for managing logrotate.

`salt.modules.logrotate.set(key, value, setting=None, conf_file='/etc/logrotate.conf')`  
Set a new value for a specific configuration line  

CLI Example:

```py
salt '*' logrotate.set rotate 2
```

Can also be used to set a single value inside a multiline configuration block. For instance, to change rotate in the following block:

```sh
/var/log/wtmp {
  monthly
  create 0664 root root
  rotate 1
}
```

Use the following command:

```py
salt '*' logrotate.set /var/log/wtmp rotate 2
```

This module also has the ability to scan files inside an include directory, and make changes in the appropriate file.

`salt.modules.logrotate.show_conf(conf_file='/etc/logrotate.conf')`  
Show parsed configuration  

CLI Example:

```py
salt '*' logrotate.show_conf
```

13.6.154 `salt.modules.lvs`

Support for LVS (Linux Virtual Server)

`salt.modules.lvs.add_server(protocol=None, service_address=None, server_address=None, packet_forward_method='dr', weight=1, **kwargs)`  
Add a real server to a virtual service.  
protocol The service protocol(only support tcp, udp and fwmark service).  
service_address The LVS service address.  
server_address The real server address.  
packet_forward_method The LVS packet forwarding method(dr for direct routing, tunnel for tunneling, nat for network access translation).  
weight The capacity of a server relative to the others in the pool.  

CLI Example:

```py
salt '*' lvs.add_server tcp 1.1.1.1:80 192.168.0.11:8080 nat 1
```

`salt.modules.lvs.add_service(protocol=None, service_address=None, scheduler='wlc')`  
Add a virtual service.
protocol The service protocol (only support tcp, udp and fwmark service).

service_address The LVS service address.

the scheduler Algorithm for allocating TCP connections and UDP datagrams to real servers.

CLI Example:

```
salt '*' lvs.add_service tcp 1.1.1.1:80 rr
```

salt.modules.lvs.check_server( protocol=None, service_address=None, server_address=None, **kwargs)

Check the real server exists in the specified service.

CLI Example:

```
salt '*' lvs.check_server tcp 1.1.1.1:80 192.168.0.11:8080
```

salt.modules.lvs.check_service( protocol=None, service_address=None, **kwargs)

Check the virtual service exists.

CLI Example:

```
salt '*' lvs.check_service tcp 1.1.1.1:80
```

salt.modules.lvs.clear()

Clear the virtual server table

CLI Example:

```
salt '*' lvs.clear
```

salt.modules.lvs.delete_server( protocol=None, service_address=None, server_address=None)

Delete the realserver from the virtual service.

CLI Example:

```
salt '*' lvs.delete_server tcp 1.1.1.1:80 192.168.0.11:8080
```

salt.modules.lvs.delete_service( protocol=None, service_address=None)

Delete the virtual service.

CLI Example:

```
salt '*' lvs.delete_service tcp 1.1.1.1:80
```

salt.modules.lvs.edit_server( protocol=None, service_address=None, server_address=None, packet_forward_method=None, weight=None, **kwargs)

Edit a real server to a virtual service.

CLI Example:
salt 'minion' lvs.edit_server tcp 1.1.1.80 192.168.0.11:8080 nat 1

salt.modules.lvs.edit_service(protocol=None, service_address=None, scheduler=None)
Edit the virtual service.

protocol The service protocol (only support tcp, udp and fwmark service).
service_address The LVS service address.
scheduler Algorithm for allocating TCP connections and UDP datagrams to real servers.

CLI Example:
salt 'minion' lvs.edit_service tcp 1.1.1.80 rr

salt.modules.lvs.get_rules()
Get the virtual server rules

CLI Example:
salt 'minion' lvs.get_rules

salt.modules.lvs.list(protocol=None, service_address=None)
List the virtual server table if service_address is not specified. If a service_address is selected, list this service only.

CLI Example:
salt 'minion' lvs.list

salt.modules.lvs.zero(protocol=None, service_address=None)
Zero the packet, byte and rate counters in a service or all services.

CLI Example:
salt 'minion' lvs.zero

13.6.155 salt.modules.lxc

Control Linux Containers via Salt

depends lxc package for distribution
lxc >= 1.0 (even beta alpha) is required

salt.modules.lxc.apply_network_profile(name, network_profile, nic_opts=None, path=None)
New in version 2015.5.0.

Apply a network profile to a container
network_profile profile name or default values (dict)
nic_opts values to override in defaults (dict) indexed by nic card names
path path to the container parent

New in version 2015.8.0.

CLI Examples:
salt 'minion' lxc.apply_network_profile web1 centos
salt 'minion' lxc.apply_network_profile web1 centos
  nic_opts="{"eth0": {'mac': 'xx:xx:xx:xx:xx:xx'}}"
salt 'minion' lxc.apply_network_profile web1
  "{"eth0": {'mac': 'xx:xx:xx:xx:xx:yy'}}"
  nic_opts="{"eth0": {'mac': 'xx:xx:xx:xx:xx:xx'}}"
The special case to disable use of ethernet nics:

```
salt 'minion' lxc.apply_network_profile web1 centos \n  "{"eth0: {disable: true}}"
```

```
salt.modules.lxc.attachable(name, path=None)
```

Return True if the named container can be attached to via the lxc-attach command. `path` path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

CLI Example:

```
salt 'minion' lxc.attachable ubuntu
```

```
salt.modules.lxc.bootstrap(name, config=None, approve_key=True, install=True, pub_key=None, priv_key=None, bootstrap_url=None, force_install=False, unconditional_install=False, path=None, bootstrap_delay=None, bootstrap_args=None, bootstrap_shell=None)
```

Install and configure salt in a container.

- `config` Minion configuration options. By default, the master option is set to the target host's master.
- `approve_key` Request a pre-approval of the generated minion key. Requires that the salt-master be configured to either auto-accept all keys or expect a signing request from the target host. Default: True
- `path` path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

- `pub_key` Explicit public key to pressed the minion with (optional). This can be either a filepath or a string representing the key
- `priv_key` Explicit private key to pressed the minion with (optional). This can be either a filepath or a string representing the key
- `bootstrap_delay` Delay in seconds between end of container creation and bootstrapping. Useful when waiting for container to obtain a DHCP lease.

New in version 2015.5.0.

- `bootstrap_url` Url, content or filepath to the salt bootstrap script
- `bootstrap_args` salt bootstrap script arguments
- `bootstrap_shell` shell to execute the script into
- `install` Whether to attempt a full installation of salt-minion if needed.
- `force_install` Force installation even if salt-minion is detected, this is the way to run vendor bootstrap scripts even if a salt minion is already present in the container
- `unconditional_install` Run the script even if the container seems seeded

CLI Examples:

```
salt 'minion' lxc.bootstrap container_name [config=config_data] \n  [approve_key=(True|False)] [install=(True|False)]
```

```
salt.modules.lxc.clone(name, orig, profile=None, network_profile=None, nic_opts=None, **kwargs)
```

Create a new container as a clone of another container

- `name` Name of the container
- `orig` Name of the original container to be cloned
- `profile` Profile to use in container cloning (see `lxc.get_container_profile`). Values in a profile will be overridden by the Container Cloning Arguments listed below.
- `path` path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.

**Container Cloning Arguments**

- `snapshot` Use Copy On Write snapshots (LVM)
- `size` [1G] Size of the volume to create. Only applicable if `backing=lvm`.
backing The type of storage to use. Set to lvm to use an LVM group. Defaults to filesystem within /var/lib/lxc.

network_profile Network profile to use for container

    New in version 2015.8.0.

nic_opts give extra opts overriding network profile values

    New in version 2015.8.0.

CLI Examples:

    salt '*' lxc.clone myclone orig=orig_container
    salt '*' lxc.clone myclone orig=orig_container snapshot=True

salt.modules.lxc.cloud_init(name, vm_=None, **kwargs)
Thin wrapper to lxc.init to be used from the saltcloud lxc driver

name Name of the container may be None and then guessed from saltcloud mapping

vm_ saltcloud mapping defaults for the vm

CLI Example:

    salt '*' lxc.cloud_init foo

salt.modules.lxc.cloud_init_interface(name, vm_=None, **kwargs)
Interface between salt.cloud.lxc driver and lxc.init vm_ is a mapping of vm opts in the salt.cloud format as documented for the lxc driver.

This can be used either:

    • from the salt cloud driver
    • because you find the argument to give easier here than using directly lxc.init

    Warning: BE REALLY CAREFUL CHANGING DEFAULTS !!! IT'S A RETRO COMPATIBLE INTERFACE WITH THE SALT CLOUD DRIVER (ask kiorky).

name name of the lxc container to create

pub_key public key to preseed the minion with. Can be the keycontent or a filepath

priv_key private key to preseed the minion with. Can be the keycontent or a filepath

path path to the container parent directory (default: /var/lib/lxc)

    New in version 2015.8.0.

profile profile selection

network_profile network profile selection

nic_opts per interface settings compatibles with network profile (ipv4/ipv6/link/gateway/mac/netmask)

    eg:

    - {'eth0': {'mac': '00:16:3e:01:29:40',
              'gateway': None, (default)
              'link': 'br0', (default)
              'gateway': None, (default)
              'netmask': '', (default)
              'ip': '22.1.4.25'}}

unconditional_install given to lxc.bootstrap (see relative doc)
force_install given to lxc.bootstrap (see relative doc)
config any extra argument for the salt minion config
dnservers dns servers to set inside the container
autostart autostart the container at boot time
password administrative password for the container
bootstrap_delay delay before launching bootstrap script at Container init
Warning: Legacy but still supported options:

- **from_container** which container we use as a template when running lxc.clone
- **image** which template do we use when we are using lxc.create. This is the default mode unless you specify something in from_container
- **backing** which backing store to use. Values can be: overlayfs, dir(default), lvm, zfs, brtfs
- **fstype** When using a blockdevice level backing store, which filesystem to use on
- **size** When using a blockdevice level backing store, which size for the filesystem to use on
- **snapshot** Use snapshot when cloning the container source
- **vgname** if using LVM: vgname
- **lvname** if using LVM: lvname
- **ip** ip for the primary nic
- **mac** mac address for the primary nic
- **netmask** netmask for the primary nic (24) = vm_.get('netmask', '24')
- **bridge** bridge for the primary nic (lxcbr0)
- **gateway** network gateway for the container
- **additional_ips** additional ips which will be wired on the main bridge (br0) which is connected to internet.

  Be aware that you may use manual virtual mac addresses provided by your provider (online, ovh, etc). This is a list of mappings [ip: '', mac: '', netmask: ''] Set gateway to None and an interface with a gateway to escape from another interface that eth0. eg:

  ```
  {'mac': '00:16:3e:01:29:40',
  'gateway': 'None',
  'link': 'br0',
  'netmask': '',
  'ip': '22.1.4.25'}
  ```

- **users** administrative users for the container default: [root] and [root, ubuntu] on ubuntu
- **default_nic** name of the first interface, you should really not override this

CLI Example:

```
salt '*' lxc.cloud_init_interface foo
```

**salt.modules.lxc.copy_to**(name, source, dest, overwrite=False, makedirs=False, path=None)

Changed in version 2015.8.0: Function renamed from lxc.cp to lxc.copy_to for consistency with other container types. lxc.cp will continue to work, however. For versions 2015.2.x and earlier, use lxc.cp.

Copy a file or directory from the host into a container

- **name** Container name
- **source** File to be copied to the container
- **path** path to the container parent default: /var/lib/lxc (system default)

  New in version 2015.8.0.

- **dest** Destination on the container. Must be an absolute path.

  Changed in version 2015.5.0: If the destination is a directory, the file will be copied into that directory.

- **overwrite** [False] Unless this option is set to True, then if a file exists at the location specified by the dest argument, an error will be raised.
New in version 2015.8.0.
makedirs: False
Create the parent directory on the container if it does not already exist.

New in version 2015.5.0.

CLI Example:
```
salt 'minion' lxc.copy_to /tmp/foo /root/foo
salt 'minion' lxc.cp /tmp/foo /root/foo
```

```
salt.modules.lxc.create(name, config=None, profile=None, network_profile=None, nic_opts=None,**kwargs)
```
Create a new container.

name Name of the container
config The config file to use for the container. Defaults to system-wide config (usually in /etc/lxc/lxc.conf).
profile Profile to use in container creation (see \texttt{lxc.get_container_profile}). Values in a profile will be overridden by the \textbf{Container Creation Arguments} listed below.

network_profile Network profile to use for container

New in version 2015.5.0.

\textbf{Container Creation Arguments}

\textbf{template} The template to use. For example, ubuntu or fedora. Conflicts with the \texttt{image} argument.

\textbf{Note:} The download template requires the following three parameters to be defined in options:
\begin{itemize}
\item dist - The name of the distribution
\item release - Release name/version
\item arch - Architecture of the container
\end{itemize}
The available images can be listed using the \texttt{lxc.images} function.

\textbf{options} Template-specific options to pass to the lxc-create command. These correspond to the long options (ones beginning with two dashes) that the template script accepts. For example:
```
options=\{'dist": "centos", "release": "6", "arch": "amd64"\}'
```

image A tar archive to use as the rootfs for the container. Conflicts with the \texttt{template} argument.
backing The type of storage to use. Set to \texttt{lvm} to use an LVM group. Defaults to filesystem within /var/lib/lxc.
fstype Filesystem type to use on LVM logical volume
size [1G] Size of the volume to create. Only applicable if \texttt{backing=lvm}.
vgname [lxc] Name of the LVM volume group in which to create the volume for this container. Only applicable if \texttt{backing=lvm}.
lvname Name of the LVM logical volume in which to create the volume for this container. Only applicable if \texttt{backing=lvm}.
nic_opts give extra opts overriding network profile values
path parent path for the container creation (default: /var/lib/lxc)

New in version 2015.8.0.

```
salt.modules.lxc.destroy(name, stop=False, path=None)
```
Destroy the named container.

\textbf{Warning:} Destroys all data associated with the container.

path path to the container parent directory (default: /var/lib/lxc)

New in version 2015.8.0.

stop [False] If True, the container will be destroyed even if it is running/frozen.
Changed in version 2015.5.0: Default value changed to False. This more closely matches the behavior of `lxc-destroy(1)`, and also makes it less likely that an accidental command will destroy a running container that was being used for important things.

CLI Examples:

```text
salt '*' lxc.destroy foo
salt '*' lxc.destroy foo stop=True
```

```
salt.modules.lxc.edit_conf(conf_file, out_format='simple', read_only=False, lxc_config=None, **kwargs)
```

Edit an LXC configuration file. If a setting is already present inside the file, its value will be replaced. If it does not exist, it will be appended to the end of the file. Comments and blank lines will be kept in-tact if they already exist in the file.

**out_format**: Set to simple if you need backward compatibility (multiple items for a simple key is not supported).

**read_only**: return only the edited configuration without applying it to the underlying lxc configuration file

**lxc_config**: List of dict containing lxc configuration items. For network configuration, you also need to add the device it belongs to, otherwise it will default to eth0. Also, any change to a network parameter will result in the whole network reconfiguration to avoid mismatches, be aware of that!

After the file is edited, its contents will be returned. By default, it will be returned in simple format, meaning an unordered dict (which may not represent the actual file order). Passing in an out_format of commented will return a data structure which accurately represents the order and content of the file.

CLI Example:

```
salt 'minion' lxc.edit_conf /etc/lxc/mycontainer.conf \
    out_format=commented lxc.network.type=veth
salt 'minion' lxc.edit_conf /etc/lxc/mycontainer.conf \
    out_format=commented \n    lxc_config="[\"lxc.network.name\': \"eth0\','\"lxc.network.ipv4\': \"1.2.3.4\",\n        \"lxc.network.name\': \"eth2\','\"lxc.network.ipv4\': \"1.2.3.5\",\n        \"lxc.network.gateway\': \"1.2.3.1\"]"
```

```
salt.modules.lxc.exists(name, path=None)
```

Returns whether the named container exists.

**path** path to the container parent directory (default: /var/lib/lxc)

New in version 2015.8.0.

CLI Example:

```
salt '*' lxc.exists name
```

```
salt.modules.lxc.freeze(name, **kwargs)
```

Freeze the named container

**path** path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.

**start** [False] If True and the container is stopped, the container will be started before attempting to freeze.

New in version 2015.5.0.

**use_vt** run the command through VT

New in version 2015.8.0.

CLI Example:
salt '*' lxc.freeze name

salt.modules.lxc.get_container_profile(name=None, **kwargs)

New in version 2015.5.0.

Gather a pre-configured set of container configuration parameters. If no arguments are passed, an empty profile is returned.

Profiles can be defined in the minion or master config files, or in pillar or grains, and are loaded using `config.get`. The key under which LXC profiles must be configured is `lxc.container_profile.profile_name`. An example container profile would be as follows:

```python
lxc.container_profile:
    ubuntu:
        template: ubuntu
        backing: lvm
        vgname: lxc
        size: 1G
```

Parameters set in a profile can be overridden by passing additional container creation arguments (such as the ones passed to `lxc.create`) to this function.

A profile can be defined either as the name of the profile, or a dictionary of variable names and values. See the LXC Tutorial for more information on how to use LXC profiles.

CLI Example:

```
salt-call lxc.get_container_profile centos
salt-call lxc.get_container_profile ubuntu template=ubuntu backing=overlayfs
```

salt.modules.lxc.get_network_profile(name=None, **kwargs)

New in version 2015.5.0.

Gather a pre-configured set of network configuration parameters. If no arguments are passed, the following default profile is returned:

```python
['eth0': {'link': 'br0', 'type': 'veth', 'flags': 'up'}]
```

Profiles can be defined in the minion or master config files, or in pillar or grains, and are loaded using `config.get`. The key under which LXC profiles must be configured is `lxc.network_profile`. An example network profile would be as follows:

```python
lxc.network_profile.centos:
    eth0:
        link: br0
        type: veth
        flags: up
```

To disable networking entirely:

```python
lxc.network_profile.centos:
    eth0:
        disable: true
```

Parameters set in a profile can be overridden by passing additional arguments to this function.

A profile can be passed either as the name of the profile, or a dictionary of variable names and values. See the LXC Tutorial for more information on how to use network profiles.
Warning: The ipv4, ipv6, gateway, and link (bridge) settings in network profiles will only work if the container doesn’t redefine the network configuration (for example in /etc/sysconfig/network-scripts/ifcfg-<interface_name> on RHEL/CentOS, or /etc/network/interfaces on Debian/Ubuntu/etc.)

CLI Example:
```
salt-call lxc.get_network_profile default
```

```
salt.modules.lxc.get_parameter(name, parameter, path=None)
```
Returns the value of a cgroup parameter for a container

**path** path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.

CLI Example:
```
salt '*' lxc.get_parameter container_name memory.limit_in_bytes
```

```
salt.modules.lxc.get_root_path(path)
```
Get the configured lxc root for containers

New in version 2015.8.0.

CLI Example:
```
salt '*' lxc.get_root_path
```

```
salt.modules.lxc.images(dist=None)
```
List the available images for LXC's download template.

**dist** [None] Filter results to a single Linux distribution

CLI Examples:
```
salt myminion lxc.images
salt myminion lxc.images dist=centos
```

```
salt.modules.lxc.info(name, path=None)
```
Returns information about a container

**path** path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.

CLI Example:
```
salt '*' lxc.info name
```

```
salt.modules.lxc.init(name, config=None, cpuset=None, cpushare=None, memory=None, profile=None, network_profile=None, nic=<object object>, nic_opts=None, cpu=None, autostart=True, password=None, password_encrypted=None, users=None, dnservers=None, searchdomains=None, bridge=None, gateway=None, pub_key=None, priv_key=None, force_install=False, unconditional_install=False, bootstrap_delay=None, bootstrap_args=None, bootstrap_shell=None, bootstrap_url=None, **kwargs)
```
Initialize a new container.

This is a partial idempotent function as if it is already provisioned, we will reset a bit the lxc configuration file but much of the hard work will be escaped as markers will prevent re-execution of harmful tasks.
name  Name of the container
image  A tar archive to use as the rootfs for the container. Conflicts with the template argument.
cpus  Select a random number of cpu cores and assign it to the cpuset, if the cpuset option is set then this option will be ignored
cpuset  Explicitly define the cpus this container will be bound to
cpushare  cgroups cpu shares
autostart  autostart container on reboot
memory  cgroups memory limit, in MB

   Changed in version 2015.5.0: If no value is passed, no limit is set. In earlier Salt versions, not passing this value causes a 1024MB memory limit to be set, and it was necessary to pass memory=0 to set no limit.
gateway  the ipv4 gateway to use the default does nothing more than lxcutils does
bridge  the bridge to use the default does nothing more than lxcutils does
network_profile  Network profile to use for the container

   New in version 2015.5.0.
nic  Deprecated since version 2015.5.0: Use network_profile instead
nic_opts  Extra options for network interfaces, will override

   {}

either

users  Users for which the password defined in the password param should be set. Can be passed as a comma separated list or a python list. Defaults to just the root user.
password  Set the initial password for the users defined in the users parameter
password_encrypted  [False] Set to True to denote a password hash instead of a plaintext password

   New in version 2015.5.0.
profile  A LXC profile (defined in config or pillar). This can be either a real profile mapping or a string to retrieve it in configuration
start  Start the newly-created container
dnsservers  list of dns servers to set in the container, default [] (no setting)
seed  Seed the container with the minion config. Default: True
install  If salt-minion is not already installed, install it. Default: True
config  Optional config parameters. By default, the id is set to the name of the container.
master  salt master (default to minion's master)
master_port  salt master port (default to minion's master port)
pub_key  Explicit public key to preseed the minion with (optional). This can be either a filepath or a string representing the key
priv_key  Explicit private key to preseed the minion with (optional). This can be either a filepath or a string representing the key
approve_key  If explicit preseeding is not used; Attempt to request key approval from the master. Default: True
path  path to the container parent directory default: /var/lib/lxc (system)

   New in version 2015.8.0.
clone  Deprecated since version 2015.5.0: Use clone_from instead
clone_from  Original from which to use a clone operation to create the container. Default: None
bootstrap_delay  Delay in seconds between end of container creation and bootstrapping. Useful when waiting for container to obtain a DHCP lease.

   New in version 2015.5.0.
bootstrap_url  See lxc.bootstrap
bootstrap_shell  See lxc.bootstrap
bootstrap_args  See lxc.bootstrap
force_install  Force installation even if salt-minion is detected, this is the way to run vendor bootstrap scripts even if a salt minion is already present in the container
unconditional_install  Run the script even if the container seems seeded

**CLI Example:**
```bash
salt 'minion' lxc.init name [cpuset=cgroups_cpuset] \ 
    [cpushare=cgroups_cpushare] [memory=cgroups_memory] \ 
    [nic=nic_profile] [profile=lxc_profile] \ 
    [nic_opts=nic_opts] [start=(True|False)] \ 
    [seed=(True|False)] [install=(True|False)] \ 
    [config=minion_config] [approve_key=(True|False)] \ 
    [clone_from=original] [autostart=True] \ 
    [priv_key=/path_or_content] [pub_key=/path_or_content] \ 
    [bridge=lxcbr0] [gateway=10.0.3.1] \ 
    [dnsservers=dns1,dns2] \ 
    [users=[foo]] [password='secret'] \ 
    [password_encrypted=(True|False)]
```

**salt.modules.lxc.list**

List containers classified by state
- **extra**  Also get per-container specific info. This will change the return data. Instead of returning a list of containers, a dictionary of containers and each container's output from `lxc.info`
- **path**  path to the container parent directory default: `/var/lib/lxc` (system)

New in version 2015.8.0.

- **limit**  Return output matching a specific state (`frozen`, `running`, or `stopped`).

New in version 2015.5.0.

**CLI Examples:**
```bash
salt '*' lxc.list
salt '*' lxc.list extra=True
salt '*' lxc.list limit=running
```

**salt.modules.lxc.ls**

Return a list of the containers available on the minion
- **path**  path to the container parent directory default: `/var/lib/lxc` (system)

New in version 2015.8.0.

- **active**  If `True`, return only active (i.e. running) containers

New in version 2015.5.0.

**CLI Example:**
```bash
salt '*' lxc.ls
salt '*' lxc.ls active=True
```

**salt.modules.lxc.read_conf**

Read in an LXC configuration file. By default returns a simple, unsorted dict, but can also return a more detailed structure including blank lines and comments.
- **out_format**  set to `simple` if you need the old and unsupported behavior. This won't support the multiple lxc values (eg: multiple network nics)

**CLI Examples:**
```bash
salt 'minion' lxc.read_conf /etc/lxc/mycontainer.conf
salt 'minion' lxc.read_conf /etc/lxc/mycontainer.conf out_format=commented
```
salt.modules.lxc.reboot(name, path=None)

Reboot a container.

path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

CLI Examples:

```
salt 'minion' lxc.reboot myvm
```

salt.modules.lxc.reconfigure(name, cpu=None, cpuset=None, cpushare=None, memory=None, profile=None, network_profile=None, nic_opts=None, bridge=None, gateway=None, autostart=None, utsname=None, rootfs=None, path=None, **kwargs)

Reconfigure a container.

This only applies to a few property

name Name of the container.

utsname utsname of the container.

New in version 2016.3.0.

rootfs rootfs of the container.

New in version 2016.3.0.

cpu Select a random number of cpu cores and assign it to the cpuset, if the cpuset option is set then this option will be ignored

cpuset Explicitly define the cpus this container will be bound to

cpushare cgroups cpu shares.

autostart autostart container on reboot

memory cgroups memory limit, in MB. (0 for nolimit, None for old default 1024MB)

gateway the ipv4 gateway to use the default does nothing more than lxcutils does

bridge the bridge to use the default does nothing more than lxcutils does

nic Network interfaces profile (defined in config or pillar).

nic_opts Extra options for network interfaces, will override

```
{"eth0": {"mac": "aa:bb:cc:dd:ee:ff","ipv4": "10.1.1.1","ipv6": "2001:db8::ff00:42:8329"}}
```

or

```
{"eth0": {"mac": "aa:bb:cc:dd:ee:ff","ipv4": "10.1.1.1/24","ipv6": "2001:db8::ff00:42:8329"}}
```

path path to the container parent

New in version 2015.8.0.

CLI Example:

```
salt-call -l all mc_lxc_fork.reconfigure foobar nic_opts="{"eth1": {"mac": "00:16:3e:dd:ee:44"}}" memory=4
```

salt.modules.lxc.restart(name, path=None, lxc_config=None, force=False)

New in version 2015.5.0.

Restart the named container. If the container was not running, the container will merely be started.

name The name of the container

path path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.

lxc_config path to a lxc config file config file will be guessed from container name otherwise

New in version 2015.8.0.
force  [False] If True, the container will be force-stopped instead of gracefully shut down

CLI Example:

```
salt myminion lxc.restart name
```

`salt.modules.lxc.retcode(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, path=None, ignore_retcode=False, chroot_fallback=False, keep_env='http_proxy, https_proxy, no_proxy')`

New in version 2015.5.0.

Run `cmd.retcode` within a container

**Warning:** Many shell builtins do not work, failing with stderr similar to the following:

```
lxc_container: No such file or directory - failed to exec 'command'
```

The same error will be displayed in stderr if the command being run does not exist. If the retcode is nonzero and not what was expected, try using `lxc.run_stderr` or `lxc.run_all`.

- **name**  Name of the container in which to run the command
- **cmd**  Command to run
- **no_start**  [False] If the container is not running, don't start it
- **preserve_state**  [True] After running the command, return the container to its previous state
- **path**  path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

- **stdin**  [None] Standard input to be used for the command
- **output_loglevel**  [debug] Level at which to log the output from the command. Set to quiet to suppress logging.
- **use_vt**  [False] Use SaltStack's utils.vt to stream output to console output=all.
- **keep_env**  [http_proxy,https_proxy,no_proxy] A list of env vars to preserve. May be passed as comma-delimited list.
- **chroot_fallback**  if the container is not running, try to run the command using chroot default: false

CLI Example:

```
salt myminion lxc.retcode mycontainer 'ip addr show'
```

`salt.modules.lxc.run(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, path=None, ignore_retcode=False, chroot_fallback=False, keep_env='http_proxy, https_proxy, no_proxy')`

New in version 2015.8.0.

Run `cmd.run` within a container

**Warning:** Many shell builtins do not work, failing with stderr similar to the following:

```
lxc_container: No such file or directory - failed to exec 'command'
```

The same error will be displayed in stderr if the command being run does not exist. If no output is returned using this function, try using `lxc.run_stderr` or `lxc.run_all`.

- **name**  Name of the container in which to run the command
- **cmd**  Command to run
- **path**  path to the container parent default: /var/lib/lxc (system default)
New in version 2015.5.0.

**no_start** [False] If the container is not running, don't start it

**preserve_state** [True] After running the command, return the container to its previous state

**stdin** [None] Standard input to be used for the command

**output_loglevel** [debug] Level at which to log the output from the command. Set to quiet to suppress logging.

**use_vt** [False] Use SaltStack's utils.vt to stream output to console. Assumes output=all.

**chroot_fallback** if the container is not running, try to run the command using chroot default: false

**keep_env** [http_proxy,https_proxy,no_proxy] A list of env vars to preserve. May be passed as comma-delimited list.

CLI Example:

```bash
salt myminion lxc.run mycontainer 'ifconfig -a'
```

```python
salt.modules.lxc.run_all(name, cmd, no_start=False, preserve_state=True, stdin=None,
                         python_shell=True, output_loglevel='debug', use_vt=False, path=None,
                         ignore_retcode=False, chroot_fallback=False, keep_env='http_proxy,
                         https_proxy, no_proxy')
```

New in version 2015.8.0.

Run `cmd.run_all` within a container

**Note:** While the command is run within the container, it is initiated from the host. Therefore, the PID in the return dict is from the host, not from the container.

**Warning:** Many shell builtins do not work, failing with stderr similar to the following:

```bash
lxc_container: No such file or directory - failed to exec 'command'
```

The same error will be displayed in stderr if the command being run does not exist.

**name** Name of the container in which to run the command

**path** path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

**cmd** Command to run

**no_start** [False] If the container is not running, don't start it

**preserve_state** [True] After running the command, return the container to its previous state

**stdin** [None] Standard input to be used for the command

**output_loglevel** [debug] Level at which to log the output from the command. Set to quiet to suppress logging.

**use_vt** [False] Use SaltStack's utils.vt to stream output to console output=all.

**keep_env** [http_proxy,https_proxy,no_proxy] A list of env vars to preserve. May be passed as comma-delimited list.

**chroot_fallback** if the container is not running, try to run the command using chroot default: false

CLI Example:

```bash
salt myminion lxc.run_all mycontainer 'ip addr show'
```

```python
salt.modules.lxc.run_cmd(name, cmd, no_start=False, preserve_state=True, stdin=None,
                         stdout=True, stderr=False, python_shell=True, path=None,
                         output_loglevel='debug', use_vt=False, ignore_retcode=False, chroot_fallback=False, keep_env='http_proxy, https_proxy, no_proxy')
```
**path** path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

Deprecated since version 2015.5.0: Use `lxc.run` instead

```python
salt.modules.lxc.run_stderr(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, path=None, ignore_retcode=False, chroot_fallback=False, keep_env='http_proxy,https_proxy,no_proxy')
```

New in version 2015.5.0.

Run `cmd.run_stderr` within a container.

**Warning:** Many shell builtins do not work, failing with stderr similar to the following:

```bash
lxc_container: No such file or directory - failed to exec 'command'
```

The same error will be displayed if the command being run does not exist.

**name** Name of the container in which to run the command

**cmd** Command to run

**path** path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

**no_start** [False] If the container is not running, don't start it

**preserve_state** [True] After running the command, return the container to its previous state

**stdin** [None] Standard input to be used for the command

**output_loglevel** [debug] Level at which to log the output from the command. Set to `quiet` to suppress logging.

**use_vt** [False] Use SaltStack's `utils.vt` to stream output to console `output=all`.

**keep_env** [http_proxy,https_proxy,no_proxy] A list of env vars to preserve. May be passed as comma-delimited list.

**chroot_fallback** if the container is not running, try to run the command using chroot default: false

CLI Example:

```bash
salt myminion lxc.run_stderr mycontainer 'ip addr show'
```

```python
salt.modules.lxc.run_stdout(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, path=None, ignore_retcode=False, chroot_fallback=False, keep_env='http_proxy,https_proxy,no_proxy')
```

New in version 2015.5.0.

Run `cmd.run_stdout` within a container.

**Warning:** Many shell builtins do not work, failing with stdout similar to the following:

```bash
lxc_container: No such file or directory - failed to exec 'command'
```

The same error will be displayed in stdout if the command being run does not exist. If no output is returned using this function, try using `lxc.run_stderr` or `lxc.run_all`.

**name** Name of the container in which to run the command

**cmd** Command to run

**path** path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.
no_start [False] If the container is not running, don’t start it
preserve_state [True] After running the command, return the container to its previous state
stdin [None] Standard input to be used for the command
output_loglevel [debug] Level at which to log the output from the command. Set to quiet to suppress logging.
use_vt [False] Use SaltStack’s utils.vt to stream output to console output=all.
keep_env [http_proxy,https_proxy,no_proxy] A list of env vars to preserve. May be passed as comma-delimited list.
chroot_fallback if the container is not running, try to run the command using chroot default: false

CLI Example:
```
salt myminion lxc.run_stdout mycontainer 'ifconfig -a'
```

salt.modules.lxc.running_systemd(name, cache=True, path=None)
Determine if systemd is running
path path to the container parent

New in version 2015.8.0.

CLI Example:
```
salt '*' lxc.running_systemd ubuntu
```

salt.modules.lxc.search_lxc_bridge()
Search the first bridge which is potentially available as LXC bridge

CLI Example:
```
salt '*' lxc.search_lxc_bridge
```

salt.modules.lxc.search_lxc_bridges()
Search which bridges are potentially available as LXC bridges

CLI Example:
```
salt '*' lxc.search_lxc_bridges
```

salt.modules.lxc.set_dns(name, dnsservers=None, searchdomains=None, path=None)
Changed in version 2015.5.0: The dnsservers and searchdomains parameters can now be passed as a comma-separated list.
Update /etc/resolv.conf

path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

CLI Example:
```
salt myminion lxc.set_dns ubuntu "['8.8.8.8', '4.4.4.4']"
```

salt.modules.lxc.set_parameter(name, parameter, value, path=None)
Set the value of a cgroup parameter for a container.

path path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.

CLI Example:
Salt Documentation, Release 2016.3.6

salt ' '*' lxc.set_parameter name parameter value

salt.modules.lxc.set_password(name, users, password, encrypted=True, path= None)
  Changed in version 2015.5.0: Function renamed from set_pass to set_password. Additionally, this function now supports (and defaults to using) a password hash instead of a plaintext password.

  Set the password of one or more system users inside containers
  users  Comma-separated list (or python list) of users to change password
  password  Password to set for the specified user(s)
  encrypted  [True] If true, password must be a password hash. Set to False to set a plaintext password (not recommended).

  New in version 2015.5.0.

  path  path to the container parent directory default: /var/lib/lxc (system)

  New in version 2015.8.0.

  CLI Example:

  salt ' '*' lxc.set_pass container-name root ' $6$uJ2uAyLU$KoI67t8As/
  $0fXtJOPcHKGXmUpcoYUcVR2K6x93w2nShTCQvjRwq25yIkICBOgbfKQSFnAo28/ek6716vE'v1'
  salt ' '*' lxc.set_pass container-name root foo encrypted=False

salt.modules.lxc.start(name, **kwargs)
  Start the named container
  restart  [False] Deprecated since version 2015.5.0: Use lxc.restart

  Restart the container if it is already running
  path  path to the container parent directory default: /var/lib/lxc (system)

  New in version 2015.8.0.

  lxc_config  path to a lxc config file config file will be guessed from container name otherwise

  New in version 2015.8.0.

  use_vt  run the command through VT

  New in version 2015.8.0.

  CLI Example:

  salt myminion lxc.start name

salt.modules.lxc.state(name, path=None)
  Returns the state of a container.
  path  path to the container parent directory (default: /var/lib/lxc)

  New in version 2015.8.0.

  CLI Example:

  salt ' '*' lxc.state name

salt.modules.lxc.stop(name, kill=False, path=None, use_vt=None)
  Stop the named container
  path  path to the container parent directory default: /var/lib/lxc (system)

  New in version 2015.8.0.

  kill  False  Do not wait for the container to stop, kill all tasks in the container. Older LXC versions will stop containers like this irrespective of this argument.

  Changed in version 2015.5.0: Default value changed to False
use_vt  run the command through VT

    New in version 2015.8.0.
    CLI Example:
    
    salt myminion lxc.stop name

salt.modules.lxc.systemd_running_state(name, path=\None)
    Get the operational state of a systemd based container
    path  path to the container parent default: /var/lib/lxc (system default)

    New in version 2015.8.0.
    CLI Example:
    
    salt myminion lxc.systemd_running_state ubuntu

salt.modules.lxc.templates()
    New in version 2015.5.0.
    List the available LXC template scripts installed on the minion
    CLI Examples:
    
    salt myminion lxc.templates

salt.modules.lxc.test_bare_started_state(name, path=\None)
    Test if a non systemd container is fully started For now, it consists only to test if the container is attachable
    path  path to the container parent default: /var/lib/lxc (system default)

    New in version 2015.8.0.
    CLI Example:
    
    salt myminion lxc.test_bare_started_state ubuntu

salt.modules.lxc.test_sd_started_state(name, path=\None)
    Test if a systemd container is fully started
    path  path to the container parent default: /var/lib/lxc (system default)

    New in version 2015.8.0.
    CLI Example:
    
    salt myminion lxc.test_sd_started_state ubuntu

salt.modules.lxc.unfreeze(name, path=\None, use_vt=\None)
    Unfreeze the named container.
    path  path to the container parent directory default: /var/lib/lxc (system)

    New in version 2015.8.0.
    use_vt  run the command through VT

    New in version 2015.8.0.
    CLI Example:
    
    salt '*' lxc.unfreeze name

salt.modules.lxc.update_lxc_conf(name, lxc_conf, lxc_conf_unset, path=\None)
    Edit LXC configuration options
    path  path to the container parent default: /var/lib/lxc (system default)

    New in version 2015.8.0.
Salt Documentation, Release 2016.3.6

CLI Example:

```bash
salt myminion lxc.update_lxc_conf ubuntu \
   lxc_conf="[{'network.ipv4.ip':'10.0.3.5'}]" \
   lxc_conf_unset=['lxc.utsname']"
```

salt.modules.lxc.version()
Return the actual lxc client version

New in version 2015.8.0.

CLI Example:

```bash
salt '*' lxc.version
```

salt.modules.lxc.wait_started(name, path=None, timeout=300)
Check that the system has fully init

This is actually very important for systemD based containers

see https://github.com/saltstack/salt/issues/23847

```
path  path to the container parent default: /var/lib/lxc (system default)
```

New in version 2015.8.0.

CLI Example:

```bash
salt myminion lxc.wait_started ubuntu
```

salt.modules.lxc.write_conf(conf_file, conf)
Write out an LXC configuration file

This is normally only used internally. The format of the data structure must match that which is returned from lxc.read_conf(), with out_format set to commented.

An example might look like:

```json
[
    {'lxc.utsname': '$CONTAINER_NAME'},
    '# This is a commented line
    '\n',
    {'lxc.mount': '$CONTAINER_FSTAB'},
    {'lxc.rootfs': {'comment': 'This is another test',
                    'value': 'This is another test'}},
    '\n',
    {'lxc.network.type': 'veth'},
    {'lxc.network.flags': 'up'},
    {'lxc.network.link': 'br0'},
    {'lxc.network.mac': '$CONTAINER_MACADD'},
    {'lxc.network.ipv4': '$CONTAINER_IPADD'},
    {'lxc.network.name': '$CONTAINER_DEVICENAME'},
]
```

CLI Example:

```bash
salt 'minion' lxc.write_conf /etc/lxc/mycontainer.conf \
   out_format=commented
```
13.6.156 salt.modules.mac_assistive module

This module allows you to manage assistive access on OS X minions with 10.9+
New in version 2016.3.0.

```
salt '*' assistive.install /usr/bin/osascript
```

```
salt.modules.mac_assistive.enable(app_id, enabled=True)
   Enable or disable an existing assistive access application.
   app_id The bundle ID or command to set assistive access status.
   enabled Sets enabled or disabled status. Default is True.
   CLI Example:
   ```
salt '*' assistive.enable /usr/bin/osascript
   salt '*' assistive.enable com.smileonmymac.textexpander enabled=False
   ```

```
salt.modules.mac_assistive.enabled(app_id)
   Check if a bundle ID or command is listed in assistive access and enabled.
   app_id The bundle ID or command to retrieve assistive access status.
   CLI Example:
   ```
salt '*' assistive.enabled /usr/bin/osascript
   salt '*' assistive.enabled com.smileonmymac.textexpander
   ```

```
salt.modules.mac_assistive.install(app_id, enable=True)
   Install a bundle ID or command as being allowed to use assistive access.
   app_id The bundle ID or command to install for assistive access.
   enabled Sets enabled or disabled status. Default is True.
   CLI Example:
   ```
salt '*' assistive.install /usr/bin/osascript
   salt '*' assistive.install com.smileonmymac.textexpander
   ```

```
salt.modules.mac_assistive.installed(app_id)
   Check if a bundle ID or command is listed in assistive access. This will not check to see if it's enabled.
   app_id The bundle ID or command to check installed status.
   CLI Example:
   ```
salt '*' assistive.installed /usr/bin/osascript
   salt '*' assistive.installed com.smileonmymac.textexpander
   ```

```
salt.modules.mac_assistive.remove(app_id)
   Remove a bundle ID or command as being allowed to use assistive access.
   app_id The bundle ID or command to remove from assistive access list.
   CLI Example:
   ```
salt '*' assistive.remove /usr/bin/osascript
   salt '*' assistive.remove com.smileonmymac.textexpander
   ```

13.6.157 salt.modules.mac_brew module

Homebrew for Mac OS X
Important: If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to 'pkg.install' is not available), see here.

salt.modules.mac_brew.available_version(*names, **kwargs)
This function is an alias of latest_version.
Return the latest version of the named package available for upgrade or installation

CLI Example:
```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3>
```

salt.modules.mac_brew.info_installed(*names)
Return the information of the named package(s) installed on the system.

New in version 2016.3.1.

names The names of the packages for which to return information.

CLI example:
```
salt '*' pkg.info_installed <package1>
salt '*' pkg.info_installed <package1> <package2> <package3> ...
```

salt.modules.mac_brew.install(name=None, pkgs=None, taps=None, options=None, **kwargs)
Install the passed package(s) with brew install

name The name of the formula to be installed. Note that this parameter is ignored if "pkgs" is passed.

CLI Example:
```
salt '*' pkg.install <package name>
```

taps Unofficial GitHub repos to use when updating and installing formulas.

CLI Example:
```
salt '*' pkg.install <package name> tap='tap'
salt '*' pkg.install zlib taps='homebrew/dupes'
salt '*' pkg.install php54 taps='["josegonzalez/php", "homebrew/dupes"]'
```

options Options to pass to brew. Only applies to initial install. Due to how brew works, modifying chosen options requires a full uninstall followed by a fresh install. Note that if "pkgs" is used, all options will be passed to all packages. Unrecognized options for a package will be silently ignored by brew.

CLI Example:
```
salt '*' pkg.install <package name> tap='tap'
salt '*' pkg.install php54 taps='["josegonzalez/php", "homebrew/dupes"]' --options='["--with-fpm"]'
```

Multiple Package Installation Options:

pkgs A list of formulas to install. Must be passed as a python list.

CLI Example:
```
salt '*' pkg.install pkgs=['foo','bar']
```

Returns a dict containing the new package names and versions:
```
{"<package>": {'old': '<old-version>',
                'new': '<new-version>'}}
```
CLI Example:

```bash
salt '*' pkg.install 'package package package'
```

`salt.modules.mac_brew.latest_version(names, **kwargs)`

Return the latest version of the named package available for upgrade or installation

CLI Example:

```bash
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3>
```

`salt.modules.mac_brew.list_pkgs(versions_as_list=False, **kwargs)`

List the packages currently installed in a dict:

```bash
{'<package_name>': '<version>'}
```

CLI Example:

```bash
salt '*' pkg.list_pkgs
```

`salt.modules.mac_brew.list_upgrades(refresh=True, **kwargs)`

Check whether or not an upgrade is available for all packages

CLI Example:

```bash
salt '*' pkg.list_upgrades
```

`salt.modules.mac_brew.refresh_db()`

Update the homebrew package repository.

CLI Example:

```bash
salt '*' pkg.refresh_db
```

`salt.modules.mac_brew.remove(name=None, pkgs=None, **kwargs)`

Removes packages with `brew uninstall`.

**name** The name of the package to be deleted.

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The **name** parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```bash
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

`salt.modules.mac_brew.upgrade(refresh=True)`

Upgrade outdated, unpinned brews.

**refresh** Fetch the newest version of Homebrew and all formulae from GitHub before installing.

Return a dict containing the new package names and versions:

```bash
{'<package>': {'old': '<old-version>',
              'new': '<new-version>'}}
```
CLI Example:

```
salt '*' pkg.upgrade
```

```
salt.modules.mac_brew.upgrade_available(pkg)
Check whether or not an upgrade is available for a given package
```

CLI Example:

```
salt '*' pkg.upgrade_available <package name>
```

```
salt.modules.mac_brew.version('names', **kwargs)
Returns a string representing the package version or an empty string if not installed. If more than one package
name is specified, a dict of name/version pairs is returned.
```

CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3>
```

### 13.6.158 salt.modules.mac_defaults module

Set defaults on Mac OS

```
salt.modules.mac_defaults.read(domain, key, user=None)
Write a default to the system
```

CLI Example:

```
salt '*' macdefaults.read com.apple.CrashReporter DialogType
salt '*' macdefaults.read NSGlobalDomain ApplePersistence
```

- **domain** The name of the domain to read from
- **key** The key of the given domain to read from
- **user** The user to write the defaults to

```
salt.modules.mac_defaults.write(domain, key, value, type='string', user=None)
Write a default to the system
```

CLI Example:

```
salt '*' macdefaults.write com.apple.CrashReporter DialogType Server
salt '*' macdefaults.write NSGlobalDomain ApplePersistence True type=bool
```

- **domain** The name of the domain to write to
- **key** The key of the given domain to write to
- **value** The value to write to the given key
- **type** The type of value to be written, valid types are string, data, int[eger], float, bool[ean], date, array, array-
  add, dict, dict-add
- **user** The user to write the defaults to

### 13.6.159 salt.modules.mac_desktop module

Mac OS X implementations of various commands in the `''desktop`` interface
salt.modules.mac_desktop.get_output_volume()
Get the output volume (range 0 to 100)

CLI Example:
```
salt '*' desktop.get_output_volume
```

salt.modules.mac_desktop.lock()
Lock the desktop session

CLI Example:
```
salt '*' desktop.lock
```

salt.modules.mac_desktop.say(*words)
Say some words.
words The words to execute the say command with.

CLI Example:
```
salt '*' desktop.say <word0> <word1> ... <wordN>
```

salt.modules.mac_desktop.screensaver()
Launch the screensaver.

CLI Example:
```
salt '*' desktop.screensaver
```

salt.modules.mac_desktop.set_output_volume(volume)
Set the volume of sound.
volume The level of volume. Can range from 0 to 100.

CLI Example:
```
salt '*' desktop.set_output_volume <volume>
```

13.6.160 salt.modules.mac_group

Manage groups on Mac OS 10.7+

salt.modules.mac_group.add(name, gid=None, **kwargs)
Add the specified group

CLI Example:
```
salt '*' group.add foo 3456
```

salt.modules.mac_group.adduser(group, name)
Add a user in the group.

CLI Example:
```
salt '*' group.adduser foo bar
```

Verifies if a valid username `bar' as a member of an existing group `foo', if not then adds it.

salt.modules.mac_group.chgid(name, gid)
Change the gid for a named group

CLI Example:
salt.modules.mac_group.delete(name)
Remove the named group
CLI Example:
salt '*' group.delete foo

salt.modules.mac_group.deluser(group, name)
Remove a user from the group
New in version 2016.3.0.
CLI Example:
salt '*' group.deluser foo bar

Removes a member user 'bar' from a group 'foo'. If group is not present then returns True.

salt.modules.mac_group.getent(refresh=False)
Return info on all groups
CLI Example:
salt '*' group.getent

salt.modules.mac_group.info(name)
Return information about a group
CLI Example:
salt '*' group.info foo

salt.modules.mac_group.members(name, members_list)
Replaces members of the group with a provided list.
New in version 2016.3.0.
CLI Example:
salt '*' group.members foo 'user1,user2,user3,...'
Replaces a membership list for a local group 'foo'.

13.6.161 salt.modules.mac_keychain module
Install certificates into the keychain on Mac OS
New in version 2016.3.0.

salt.modules.mac_keychain.get_default_keychain(user=None, domain='user')
Get the default keychain
user The user to check the default keychain of
domain The domain to use valid values are user|system|common|dynamic, the default is user
CLI Example:
salt '*' keychain.get_default_keychain

salt.modules.mac_keychain.get_friendly_name(cert, password)
Get the friendly name of the given certificate
cert The certificate to install
password The password for the certificate being installed formatted in the way described for openssl command in the PASS PHRASE ARGUMENTS section

Note: The password given here will show up as plaintext in the returned job info.

CLI Example:
```
salt '*' keychain.get_friendly_name /tmp/test.p12 test123
```

**salt.modules.mac_keychain.get_hash**(*name*, **password**=*None*)

Returns the hash of a certificate in the keychain.

*name* The name of the certificate (which you can get from keychain.get_friendly_name) or the location of a p12 file.

*password* The password that is used in the certificate. Only required if your passing a p12 file. Note: This will be outputted to logs

CLI Example:
```
salt '*' keychain.get_hash /tmp/test.p12 test123
```

**salt.modules.mac_keychain.install**(*cert*, *password*, **keychain**=*'/Library/Keychains/System.keychain'*,

*allow_any*=*False*, **keychain_password**=*None*)

Install a certificate

cert The certificate to install
password The password for the certificate being installed formatted in the way described for openssl command in the PASS PHRASE ARGUMENTS section.

Note: The password given here will show up as plaintext in the job returned info.

*keychain* The keychain to install the certificate to, this defaults to /Library/Keychains/System.keychain

*allow_any* Allow any application to access the imported certificate without warning

*keychain_password* If your keychain is likely to be locked pass the password and it will be unlocked before running the import

Note: The password given here will show up as plaintext in the returned job info.

CLI Example:
```
salt '*' keychain.install test.p12 test123
```

**salt.modules.mac_keychain.list_certs**(*keychain*=/Library/Keychains/System.keychain')

List all of the installed certificates

*keychain* The keychain to install the certificate to, this defaults to /Library/Keychains/System.keychain

CLI Example:
```
salt '*' keychain.list_certs
```

**salt.modules.mac_keychain.set_default_keychain**(*keychain*, **domain**='user', **user**=*None*)

Set the default keychain

*keychain* The location of the keychain to set as default

*domain* The domain to use valid values are user|system|common|dynamic, the default is user

*user* The user to set the default keychain as

CLI Example:
```
salt '*' keychain.set_keychain /Users/fred/Library/Keychains/login.keychain
```

**salt.modules.mac_keychain.uninstall**(*cert_name*, **keychain**=*'/Library/Keychains/System.keychain'*,

**keychain_password**=*None*)

Uninstall a certificate from a keychain

cert_name The name of the certificate to remove
keychain  The keychain to install the certificate to, this defaults to /Library/Keychains/System.keychain
keychain_password  If your keychain is likely to be locked pass the password and it will be unlocked before running the import

Note: The password given here will show up as plaintext in the returned job info.

CLI Example:

```
salt '*' keychain.install test.p12 test123
```

salt.modules.mac_keychain.unlock_keychain(keychain, password)
Unlock the given keychain with the password
keychain  The keychain to unlock
password  The password to use to unlock the keychain.

Note: The password given here will show up as plaintext in the returned job info.

CLI Example:

```
salt '*' keychain.unlock_keychain /tmp/test.p12 test123
```

### 13.6.162 salt.modules.mac_pkgutil module

Installer support for OS X.

Installer is the native .pkg/.mpkg package manager for OS X.

salt.modules.mac_pkgutil.forget(package_id)
New in version 2016.3.0.
Remove the receipt data about the specified package. Does not remove files.

**Warning:** DO NOT use this command to fix broken package design

Parameters  package_id (str) -- The name of the package to forget
Returns  True if successful, otherwise False
Return type  bool

CLI Example:

```
salt '*' pkgutil.forget com.apple.pkg.gcc4.2Leo
```

salt.modules.mac_pkgutil.install(source, package_id)
Install a pkg from an URI or an absolute path.

Parameters

- source (str) -- The path to a package.
- package_id (str) -- The package ID

Returns  True if successful, otherwise False
Return type  bool

CLI Example:

```
salt '*' pkgutil.install source=/vagrant/build_essentials.pkg package_id=com.
→apple.pkg.gcc4.2Leo
```

salt.modules.mac_pkgutil.is_installed(package_id)
Returns whether a given package id is installed.

Returns  True if installed, otherwise False
Return type: **bool**

CLI Example:

```
salt '*' pkgutil.is_installed com.apple.pkg.gcc4.2Leo
```

salt.modules.mac_pkgutil.list()

List the installed packages.

**Returns** A list of installed packages

**Return type: list**

CLI Example:

```
salt '*' pkgutil.list
```

### 13.6.163 salt.modules.mac_ports module

Support for MacPorts under Mac OSX.

This module has some caveats.

1. Updating the database of available ports is quite resource-intensive. However, `refresh=True` is the default for all operations that need an up-to-date copy of available ports. Consider `refresh=False` when you are sure no db update is needed.

2. In some cases MacPorts doesn't always realize when another copy of itself is running and will gleefully tromp all over the available ports database. This makes MacPorts behave in undefined ways until a fresh complete copy is retrieved.

Because of 1 and 2 it is possible to get the salt-minion into a state where `salt mac-machine pkg./something/` won't want to return. Use `salt-run jobs.active` on the master to check for potentially long-running calls to `port`.

Finally, ports database updates are always handled with `port selfupdate` as opposed to `port sync`. This makes sense in the MacPorts user community but may confuse experienced Linux admins as Linux package managers don't upgrade the packaging software when doing a package database update. In other words `salt mac-machine pkg.refresh_db` is more like `apt-get update; apt-get upgrade dpkg apt-get` than simply `apt-get update`.

**salt.modules.mac_ports.available_version(names, **kwargs)**

This function is an alias of `latest_version`.

Return the latest version of the named package available for upgrade or installation

**Options:**

`refresh` Update ports with `port selfupdate`

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3>
```

**salt.modules.mac_ports.install(name=None, refresh=False, pkgs=None, **kwargs)**

Install the passed package(s) with `port install`

**name** The name of the formula to be installed. Note that this parameter is ignored if `''pkgs''` is passed.

CLI Example:

```
salt '*' pkg.install <package name>
```
**version** Specify a version to pkg to install. Ignored if pkgs is specified.

**CLI Example:**
```
salt '*' pkg.install <package name>
salt '*' pkg.install git-core version='1.8.5.5'
```

**variant** Specify a variant to pkg to install. Ignored if pkgs is specified.

**CLI Example:**
```
salt '*' pkg.install <package name>
salt '*' pkg.install git-core version='1.8.5.5' variant='+credential_
-osxkeychain+doc+pcre'
```

**Multiple Package Installation Options:**

**pkgs** A list of formulas to install. Must be passed as a python list.

**CLI Example:**
```
salt '*' pkg.install pkgs='["foo","bar"]'
salt '*' pkg.install pkgs='["foo@1.2","bar"]'
salt '*' pkg.install pkgs='["foo@1.2+ssl","bar@2.3"]'
```

Returns a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
              'new': '<new-version>'}}
```

**CLI Example:**
```
salt '*' pkg.install 'package package package'
```

**salt.modules.mac_ports.latest_version(names, **kwargs)**

Return the latest version of the named package available for upgrade or installation

Options:

**refresh** Update ports with port selfupdate

**CLI Example:**
```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3>
```

**salt.modules.mac_ports.list_pkgs(versions_as_list=False, **kwargs)**

List the packages currently installed in a dict:

```
{'<package_name>': '<version>'}
```

**CLI Example:**
```
salt '*' pkg.list_pkgs
```

**salt.modules.mac_ports.list_upgrades(refresh=True, **kwargs)**

Check whether or not an upgrade is available for all packages

Options:

**refresh** Update ports with port selfupdate

**CLI Example:**
```
salt '*' pkg.list_upgrades
```
salt.modules.mac_ports.refresh_db()
Update ports with port selfupdate

salt.modules.mac_ports.remove(name=None, pkgs=None, **kwargs)
Removes packages with port uninstall.
    name The name of the package to be deleted.
    Multiple Package Options:
    pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this
        option is passed.
    New in version 0.16.0.
    Returns a dict containing the changes.
    CLI Example:
        salt '*' pkg.remove <package name>
        salt '*' pkg.remove <package1>,<package2>,<package3>
        salt '*' pkg.remove pkgs='["foo", "bar"]'

salt.modules.mac_ports.upgrade(refresh=True)
Run a full upgrade using MacPorts `port upgrade outdated`

    Options:
        refresh Update ports with port selfupdate
    Return a dict containing the new package names and versions:
        {'<package>': {'old': '<old-version>',
                      'new': '<new-version>'}}
    CLI Example:
        salt '*' pkg.upgrade

salt.modules.mac_ports.upgrade_available(pkg, refresh=True)
Check whether or not an upgrade is available for a given package

    CLI Example:
        salt '*' pkg.upgrade_available <package name>

salt.modules.mac_ports.version(*names, **kwargs)
Returns a string representing the package version or an empty string if not installed. If more than one package
    name is specified, a dict of name/version pairs is returned.

    CLI Example:
        salt '*' pkg.version <package name>
        salt '*' pkg.version <package1> <package2> <package3>

13.6.164 salt.modules.mac_power module

Module for editing power settings on Mac OS X

    New in version 2016.3.0.

    salt.modules.mac_power.get_computer_sleep()
Display the amount of idle time until the computer sleeps.
    Returns A string representing the sleep settings for the computer
Return type: str
CLI Example:
```bash
salt '*' power.get_computer_sleep
```

salt.modules.mac_power.get_display_sleep()
Display the amount of idle time until the display sleeps.
Returns A string representing the sleep settings for the display
Return type: str
CLI Example:
```bash
salt '*' power.get_display_sleep
```

salt.modules.mac_power.get_harddisk_sleep()
Display the amount of idle time until the hard disk sleeps.
Returns A string representing the sleep settings for the hard disk
Return type: str
CLI Example:
```bash
salt '*' power.get_harddisk_sleep
```

salt.modules.mac_power.get_restart_freeze()
Displays whether `restart on freeze` is on or off if supported
Returns A string value representing the ```restart on freeze``` settings
Return type: string
CLI Example:
```
salt '*' power.get_restart_freeze
```

salt.modules.mac_power.get_restart_power_failure()
Displays whether `restart on power failure` is on or off if supported
Returns A string value representing the ```restart on power failure``` settings
Return type: string
CLI Example:
```
salt '*' power.get_restart_power_failure
```

salt.modules.mac_power.get_sleep()
Displays the amount of idle time until the machine sleeps. Settings for Computer, Display, and Hard Disk are displayed.
Returns A dictionary containing the sleep status for Computer, Display, and Hard Disk :rtype: dict
CLI Example:
```
salt '*' power.get_sleep
```

salt.modules.mac_power.get_sleep_on_power_button()
Displays whether `allow power button to sleep computer` is on or off if supported
Returns A string value representing the ```allow power button to sleep computer``` settings :rtype: string
CLI Example:
```
salt '*' power.get_sleep_on_power_button
```
salt.modules.mac_power.get_wake_on_modem()
Displays whether `wake on modem’ is on or off if supported
   Returns A string value representing the ``wake on modem’ settings
   Return type str
CLI Example:
salt '*' power.get_wake_on_modem

salt.modules.mac_power.get_wake_on_network()
Displays whether `wake on network’ is on or off if supported
   Returns A string value representing the ``wake on network’ settings
   Return type string
CLI Example:
salt '*' power.get_wake_on_network

salt.modules.mac_power.set_computer_sleep(minutes)
Set the amount of idle time until the computer sleeps. Pass ``Never’ of ``Off’ to never sleep.
   Parameters minutes -- Can be an integer between 1 and 180 or ``Never’ or ``Off’
   Ptype int, str
   Returns True if successful, False if not
   Return type bool
CLI Example:
salt '*' power.set_computer_sleep 120
salt '*' power.set_computer_sleep off

salt.modules.mac_power.set_display_sleep(minutes)
Set the amount of idle time until the display sleeps. Pass ``Never’ of ``Off’ to never sleep.
   Parameters minutes -- Can be an integer between 1 and 180 or ``Never’ or ``Off’
   Ptype int, str
   Returns True if successful, False if not
   Return type bool
CLI Example:
salt '*' power.set_display_sleep 120
salt '*' power.set_display_sleep off

salt.modules.mac_power.set_harddisk_sleep(minutes)
Set the amount of idle time until the harddisk sleeps. Pass ``Never’ of ``Off’ to never sleep.
   Parameters minutes -- Can be an integer between 1 and 180 or ``Never’ or ``Off’
   Ptype int, str
   Returns True if successful, False if not
   Return type bool
CLI Example:
salt '*' power.set_harddisk_sleep 120
salt '*' power.set_harddisk_sleep off

salt.modules.mac_power.set_restart_freeze(enabled)
Specifies whether the server restarts automatically after a system freeze. This setting doesn’t seem to be editable. The command completes successfully but the setting isn’t actually updated. This is probably an OS X bug. The functions remains in case they ever fix the bug.
   Parameters enabled (bool) -- True to enable, False to disable, ``On’ and ``Off’ are also acceptable values. Additionally you can pass 1 and 0 to represent True and False respectively
   Returns True if successful, False if not
Return type: bool

CLI Example:
```
salt '*' power.set_restart_freeze True
```

```python
salt.modules.mac_power.set_restart_power_failure(enabled)
```
Set whether or not the computer will automatically restart after a power failure.

Parameters:
- `enabled`: bool -- True to enable, False to disable. `"On"` and `"Off"` are also acceptable values. Additionally you can pass 1 and 0 to represent True and False respectively.

Returns:
- True if successful, False if not

Return type: bool

CLI Example:
```
salt '*' power.set_restart_power_failure True
```

```python
salt.modules.mac_power.set_sleep(minutes)
```
Sets the amount of idle time until the machine sleeps. Sets the same value for Computer, Display, and Hard Disk. Pass `"Never"` or `"Off"` for computers that should never sleep.

Parameters:
- `minutes`: Can be an integer between 1 and 180 or `"Never"` or `"Off"

Returns:
- True if successful, False if not

Return type: bool

CLI Example:
```
salt '*' power.set_sleep 120
salt '*' power.set_sleep never
```

```python
salt.modules.mac_power.set_sleep_on_power_button(enabled)
```
Set whether or not the power button can sleep the computer.

Parameters:
- `enabled`: bool -- True to enable, False to disable. `"On"` and `"Off"` are also acceptable values. Additionally you can pass 1 and 0 to represent True and False respectively.

Returns:
- True if successful, False if not

Return type: bool

CLI Example:
```
salt '*' power.set_sleep_on_power_button True
```

```python
salt.modules.mac_power.set_wake_on_modem(enabled)
```
Set whether or not the computer will wake from sleep when modem activity is detected.

Parameters:
- `enabled`: bool -- True to enable, False to disable. `"On"` and `"Off"` are also acceptable values. Additionally you can pass 1 and 0 to represent True and False respectively.

Returns:
- True if successful, False if not

Return type: bool

CLI Example:
```
salt '*' power.set_wake_on_modem True
```

```python
salt.modules.mac_power.set_wake_on_network(enabled)
```
Set whether or not the computer will wake from sleep when network activity is detected.

Parameters:
- `enabled`: bool -- True to enable, False to disable. `"On"` and `"Off"` are also acceptable values. Additionally you can pass 1 and 0 to represent True and False respectively.

Returns:
- True if successful, False if not

Return type: bool

CLI Example:
salt '*' power.set_wake_on_network True

### 13.6.165 salt.modules.mac_service module

The service module for Mac OS X. `versionadded:: 2016.3.0`

#### salt.modules.mac_service.available(name)
Check that the given service is available.

**Parameters**
- **name** *(str)* -- The name of the service

**Returns**
- True if the service is available, otherwise False

**Return type**
- bool

**CLI Example:**
```
salt '*' service.available com.openssh.sshd
```

#### salt.modules.mac_service.disable(name, runas=None)
Disable a launchd service. Raises an error if the service fails to be disabled

**Parameters**
- **name** *(str)* -- Service label, file name, or full path
- **runas** *(str)* -- User to run launchctl commands

**Returns**
- True if successful or if the service is already disabled

**Return type**
- bool

**CLI Example:**
```
salt '*' service.disable org.cups.cupsd
```

#### salt.modules.mac_service.disabled(name, runas=None)
Check if the specified service is not enabled. This is the opposite of `service.enabled`

**Parameters**
- **name** *(str)* -- The name to look up
- **runas** *(str)* -- User to run launchctl commands

**Returns**
- True if the specified service is NOT enabled, otherwise False

**Return type**
- bool

**CLI Example:**
```
salt '*' service.disabled org.cups.cupsd
```

#### salt.modules.mac_service.enable(name, runas=None)
Enable a launchd service. Raises an error if the service fails to be enabled

**Parameters**
- **name** *(str)* -- Service label, file name, or full path
- **runas** *(str)* -- User to run launchctl commands

**Returns**
- True if successful or if the service is already enabled

**Return type**
- bool

**CLI Example:**
```
salt '*' service.enable org.cups.cupsd
```

#### salt.modules.mac_service.enabled(name, runas=None)
Check if the specified service is enabled

**Parameters**
salt.modules.mac_service.get_all(runas=None)
    Return a list of services that are enabled or available. Can be used to find the name of a service.
    Parameters runas (str) -- User to run launchctl commands
    Returns A list of all the services available or enabled
    Return type list
    CLI Example:
    ```
salt '*' service.get_all
    ```

salt.modules.mac_service.get_enabled(runas=None)
    Return a list of all services that are enabled. Can be used to find the name of a service.
    Parameters runas (str) -- User to run launchctl commands
    Returns A list of all the services enabled on the system
    Return type list
    CLI Example:
    ```
salt '*' service.get_enabled
salt '*' service.get_enabled running=True
    ```

salt.modules.mac_service.launchctl(sub_cmd, *args, **kwargs)
    Run a launchctl command and raise an error if it fails
    Parameters
    • sub_cmd (str) -- Sub command supplied to launchctl
    • args (tuple) -- Tuple containing additional arguments to pass to launchctl
    • kwargs (dict) -- Dictionary containing arguments to pass to cmd.run_all
    • return_stdout (bool) -- A keyword argument. If true return the stdout of the launchctl command
    Returns True if successful, raise CommandExecutionError if not, or the stdout of the launchctl command if requested
    Return type bool, str
    CLI Example:
    ```
salt '*' service.launchctl debug org.cups.cupsd
    ```

salt.modules.mac_service.list(name=None, runas=None)
    Run launchctl list and return the output
    Parameters
    • name (str) -- The name of the service to list
    • runas (str) -- User to run launchctl commands
    Returns If a name is passed returns information about the named service, otherwise returns a list of all services and pids
    Return type str
    CLI Example:
salt.modules.mac_service.missing(name)

The inverse of service.available Check that the given service is not available.

Parameters
- **name** (str) -- The name of the service

Returns
- True if the service is not available, otherwise False

Return type
- bool

CLI Example:

```bash
salt '*' service.missing com.openssh.sshd
```

salt.modules.mac_service.restart(name, runas=None)

Unloads and reloads a launchd service. Raises an error if the service fails to reload

Parameters
- **name** (str) -- Service label, file name, or full path
- **runas** (str) -- User to run launchctl commands

Returns
- True if successful

Return type
- bool

CLI Example:

```bash
salt '*' service.restart org.cups.cupsd
```

salt.modules.mac_service.show(name)

Show properties of a launchctl service

Parameters
- **name** (str) -- Service label, file name, or full path

Returns
- The service information if the service is found

Return type
- dict

CLI Example:

```bash
salt '*' service.show org.cups.cupsd  # service label
salt '*' service.show org.cups.cupsd.plist  # file name
salt '*' service.show /System/Library/LaunchDaemons/org.cups.cupsd.plist  # full path
```

salt.modules.mac_service.start(name, runas=None)

Start a launchd service. Raises an error if the service fails to start

**Note:** To start a service in Mac OS X the service must be enabled first. Use service.enable to enable the service.

Parameters
- **name** (str) -- Service label, file name, or full path
- **runas** (str) -- User to run launchctl commands

Returns
- True if successful or if the service is already running

Return type
- bool

CLI Example:

```bash
salt '*' service.start org.cups.cupsd
```

salt.modules.mac_service.status(name, sig=None, runas=None)

Return the status for a service.
Parameters

- **name** *(str)* -- Used to find the service from launchctl. Can be any part of the service name or a regex expression.

- **sig** *(str)* -- Find the service with status.pid instead. Note that name must still be provided.

- **runas** *(str)* -- User to run launchctl commands

**Returns** The PID for the service if it is running, otherwise an empty string

**Return type** *str*

CLI Example:

```python
salt '*' service.status cups
```

**salt.modules.mac_service.stop** *(name, runas=None)*

Stop a launchd service. Raises an error if the service fails to stop

**Note:** Though **service.stop** will unload a service in Mac OS X, the service will start on next boot unless it is disabled. Use **service.disable** to disable the service

Parameters

- **name** *(str)* -- Service label, file name, or full path

- **runas** *(str)* -- User to run launchctl commands

**Returns** True if successful or if the service is already stopped

**Return type** *bool*

CLI Example:

```python
salt '*' service.stop org.cups.cupsd
```

**13.6.166 salt.modules.mac_shadow module**

New in version 2016.3.0.

Manage Mac OSX local directory passwords and policies.

Note that it is usually better to apply password policies through the creation of a configuration profile.

**salt.modules.mac_shadow.del_password** *(name)*

Deletes the account password

**Parameters** *name** *(str)* -- The user name of the account

**Returns** True if successful, otherwise False

**Return type** *bool*

**Raises** CommandExecutionError on user not found or any other unknown error

CLI Example:

```python
salt '*' shadow.del_password username
```

**salt.modules.mac_shadow.get_account_created** *(name)*

Get the date/time the account was created

**Parameters** *name** *(str)* -- The username of the account

**Returns** the date/time the account was created (yyyy-mm-dd hh:mm:ss)

**Return type** *str*

** Raises** CommandExecutionError on user not found or any other unknown error

13.6. execution modules
CLI Example:

```bash
salt '*' shadow.get_account_created admin
```

salt.modules.mac_shadow.get_change(name)

Gets the date on which the password expires

**Parameters**

- **name** *(str)* -- the name of the user account

**Returns**

The date the password will expire

**Return type**

str

**Raises**

CommandExecutionError on user not found or any other unknown error

CLI Example:

```bash
salt '*' shadow.get_change username
```

salt.modules.mac_shadow.get_expire(name)

Gets the date on which the account expires

**Parameters**

- **name** *(str)* -- the name of the user account

**Returns**

the date the account expires

**Return type**

str

**Raises**

CommandExecutionError on user not found or any other unknown error

CLI Example:

```bash
salt '*' shadow.get_expire username
```

salt.modules.mac_shadow.get_last_change(name)

Get the date/time the account was changed

**Parameters**

- **name** *(str)* -- the username of the account

**Returns**

the date/time the account was modified (yyyy-mm-dd hh:mm:ss)

**Return type**

str

**Raises**

CommandExecutionError on user not found or any other unknown error

CLI Example:

```bash
salt '*' shadow.get_last_change admin
```

salt.modules.mac_shadow.get_login_failed_count(name)

Get the number of failed login attempts

**Parameters**

- **name** *(str)* -- the username of the account

**Returns**

The number of failed login attempts

**Return type**

int

**Raises**

CommandExecutionError on user not found or any other unknown error

CLI Example:

```bash
salt '*' shadow.get_login_failed_count admin
```

salt.modules.mac_shadow.get_login_failed_last(name)

Get the date/time of the last failed login attempt

**Parameters**

- **name** *(str)* -- the username of the account

**Returns**

the date/time of the last failed login attempt on this account

**(yyyy-mm-dd hh:mm:ss)**

**Type:** str

**Raises**

CommandExecutionError on user not found or any other unknown error

CLI Example:

```bash
salt '*' shadow.get_login_failed_last admin
```

salt.modules.mac_shadow.get_maxdays(name)

Get the maximum age of the password

**Parameters**

- **name** *(str)* -- the name of the user account

**Returns**

the maximum age of the password

**Return type**

int

**Raises**

CommandExecutionError on user not found or any other unknown error

CLI Example:

```bash
salt '*' shadow.get_maxdays admin
```
Parameters `name (str)` -- the username of the account
Returns the maximum age of the password in days
Return type `int`
Raises `CommandExecutionError` on user not found or any other unknown error

CLI Example:
```
salt '*' shadow.get_maxdays admin 90
```

```
salt.modules.mac_shadow.info(name)
```
Return information for the specified user
Parameters `name (str)` -- the username
Returns A dictionary containing the user's shadow information
Return type `dict`

CLI Example:
```
salt '*' shadow.info admin
```

```
salt.modules.mac_shadow.set_change(name, date)
```
Sets the date on which the password expires. The user will be required to change their password. Format is mm/dd/yyyy
Parameters
  - `name (str)` -- the name of the user account
  - `date (date)` -- the date the password will expire. Must be in mm/dd/yyyy format.
Returns True if successful, otherwise False
Return type `bool`
Raises `CommandExecutionError` on user not found or any other unknown error

CLI Example:
```
salt '*' shadow.set_change username 09/21/2016
```

```
salt.modules.mac_shadow.set_expire(name, date)
```
Sets the date on which the account expires. The user will not be able to login after this date. Date format is mm/dd/yyyy
Parameters
  - `name (str)` -- the name of the user account
  - `date (datetime)` -- the date the account will expire. Format must be mm/dd/yyyy
Returns True if successful, False if not
Return type `bool`
 Raises `CommandExecutionError` on user not found or any other unknown error

CLI Example:
```
salt '*' shadow.set_expire username 07/23/2015
```

```
salt.modules.mac_shadow.set_inactdays(name, days)
```
Set the number if inactive days before the account is locked. Not available in OS X
Parameters
  - `name (str)` -- The user name
  - `days (int)` -- The number of days
Returns Will always return False until OSX supports this feature.
Return type `bool`
CLI Example:

```
salt '*' shadow.set_inactdays admin 90
```

`salt.modules.mac_shadow.set_maxdays(name, days)`
Set the maximum age of the password in days

Parameters
- `name (str)` -- the username of the account
- `days (int)` -- the maximum age of the account in days

Returns True if successful, False if not
Return type `bool`

Raises `CommandExecutionError` on user not found or any other unknown error

CLI Example:

```
salt '*' shadow.set_maxdays admin 90
```

`salt.modules.mac_shadow.set_mindays(name, days)`
Set the minimum password age in days. Not available in OS X.

Parameters
- `name (str)` -- The user name
- `days (int)` -- The number of days

Returns Will always return False until OSX supports this feature.
Return type `bool`

CLI Example:

```
salt '*' shadow.set_mindays admin 90
```

`salt.modules.mac_shadow.set_password(name, password)`
Set the password for a named user (insecure, the password will be in the process list while the command is running)

Parameters
- `name (str)` -- The name of the local user, which is assumed to be in the local directory service
- `password (str)` -- The plaintext password to set

Returns True if successful, otherwise False
Return type `bool`

Raises `CommandExecutionError` on user not found or any other unknown error

CLI Example:

```
salt '*' mac_shadow.set_password macuser macpassword
```

`salt.modules.mac_shadow.set_warndays(name, days)`
Set the number of days before the password expires that the user will start to see a warning. Not available in OS X

Parameters
- `name (str)` -- The user name
- `days (int)` -- The number of days

Returns Will always return False until OSX supports this feature.
Return type `bool`

CLI Example:

```
salt '*' shadow.set_warndays admin 90
```
13.6.167 salt.modules.mac_softwareupdate module

Support for the softwareupdate command on MacOS.

salt.modules.mac_softwareupdate.download(name)

Download a named update so that it can be installed later with the update or update_all functions

Parameters name (str) -- The update to download.
Returns True if successful, otherwise False
Return type bool

CLI Example:

salt '*' softwareupdate.download <update name>

salt.modules.mac_softwareupdate.download_all(recommended=False, restart=True)

Download all available updates so that they can be installed later with the update or update_all functions. It returns a list of updates that are now downloaded.

Parameters recommended (bool) -- If set to True, only install the recommended updates. If set to False (default) all updates are installed.
Parameters restart (bool) -- Set this to False if you do not want to install updates that require a restart. Default is True
Returns A list containing all downloaded updates on the system.
Return type list

CLI Example:

salt '*' softwareupdate.download_all

salt.modules.mac_softwareupdate.get_catalog()

New in version 2016.3.0.

Get the current catalog being used for update lookups. Will return a url if a custom catalog has been specified. Otherwise the word `Default' will be returned

Returns The catalog being used for update lookups
Return type str

CLI Example:

salt '*' softwareupdates.get_catalog

salt.modules.mac_softwareupdate.ignore(name)

Ignore a specific program update. When an update is ignored the `-` and version number at the end will be omitted, so `SecUpd2014-001-1.0` becomes `SecUpd2014-001`. It will be removed automatically if present. An update is successfully ignored when it no longer shows up after list_updates.

Parameters name -- The name of the update to add to the ignore list.
Ptype str
Returns True if successful, False if not
Return type bool

CLI Example:

salt '*' softwareupdate.ignore <update-name>

salt.modules.mac_softwareupdate.list_available(recommended=False, restart=False)

List all available updates.

Parameters

  - recommended (bool) -- Show only recommended updates.
  - restart (bool) -- Show only updates that require a restart.

Returns Returns a dictionary containing the updates
Return type  dict

CLI Example:

```bash
salt '*' softwareupdate.list_available
```

salt.modules.mac_softwareupdate.list_downloads()

Return a list of all updates that have been downloaded locally.

Returns  A list of updates that have been downloaded

Return type  list

CLI Example:

```bash
salt '*' softwareupdate.list_downloads
```

salt.modules.mac_softwareupdate.list_ignored()

List all updates that have been ignored. Ignored updates are shown without the `-` and version number at the end, this is how the softwareupdate command works.

Returns  The list of ignored updates

Return type  list

CLI Example:

```bash
salt '*' softwareupdate.list_ignored
```

salt.modules.mac_softwareupdate.reset_catalog()

New in version 2016.3.0.

Reset the Software Update Catalog to the default.

Returns  True if successful, False if not

Return type  bool

CLI Example:

```bash
salt '*' softwareupdates.reset_catalog
```

salt.modules.mac_softwareupdate.reset_ignored()

Make sure the ignored updates are not ignored anymore, returns a list of the updates that are no longer ignored.

Returns  True if the list was reset, Otherwise False

Return type  bool

CLI Example:

```bash
salt '*' softwareupdate.reset_ignored
```

salt.modules.mac_softwareupdate.schedule_enable(enable)

Enable/disable automatic update scheduling.

Parameters:

- **enable** -- True/On/Yes/1 to turn on automatic updates. False/No/Off/0 to turn off automatic updates. If this value is empty, the current status will be returned. :type: bool str

Returns  True if scheduling is enabled, False if disabled

Return type  bool

CLI Example:

```bash
salt '*' softwareupdate.schedule_enable on|off
```

salt.modules.mac_softwareupdate.schedule_enabled()

Check the status of automatic update scheduling.

Returns  True if scheduling is enabled, False if disabled - True: Automatic checking is on, - False: Automatic checking is off,

Return type  bool

CLI Example:
salt '*' softwareupdate.schedule_enabled

salt.modules.mac_softwareupdate.set_catalog(url)

New in version 2016.3.0.

Set the Software Update Catalog to the URL specified

Parameters
- url (str) -- The url to the update catalog
- Returns True if successful, False if not
- Return type bool

CLI Example:
salt '*' softwareupdates.set_catalog http://swupd.local:8888/index.sucatalog

salt.modules.mac_softwareupdate.update(name)

Install a named update.

Parameters
- name (str) -- The name of the update to install.
- Returns True if successfully updated, otherwise False
- Return type bool

CLI Example:
salt '*' softwareupdate.update <update-name>

salt.modules.mac_softwareupdate.update_all(recommended=False, restart=True)

Install all available updates. Returns a dictionary containing the name of the update and the status of its installation.

Parameters
- recommended (bool) -- If set to True, only install the recommended updates. If set to False (default) all updates are installed.
- restart (bool) -- Set this to False if you do not want to install updates that require a restart. Default is True
- Returns A dictionary containing the updates that were installed and the status of its installation. If no updates were installed an empty dictionary is returned.

CLI Example:
salt '*' softwareupdate.update_all

salt.modules.mac_softwareupdate.update_available(name)

Check whether or not an update is available with a given name.

Parameters
- name (str) -- The name of the update to look for
- Returns True if available, False if not
- Return type bool

CLI Example:
salt '*' softwareupdate.update_available <update-name>
salt '*' softwareupdate.update_available "<update with whitespace>"

13.6.168 salt.modules.mac_user

Manage users on Mac OS 10.7+

Important: If you feel that Salt should be using this module to manage users on a minion, and it is using a different module (or gives an error similar to 'user.info is not available'), see here.
salt.modules.mac_user.add(name, uid=None, gid=None, groups=None, home=None, shell=None, fullname=None, createhome=True, **kwargs)

Add a user to the minion

CLI Example:

```bash
salt '*' user.add name <uid> <gid> <groups> <home> <shell>
```

salt.modules.mac_user.chfullname(name, fullname)

Change the user's Full Name

CLI Example:

```bash
salt '*' user.chfullname foo 'Foo Bar'
```

salt.modules.mac_user.chgid(name, gid)

Change the default group of the user

CLI Example:

```bash
salt '*' user.chgid foo 4376
```

salt.modules.mac_user.chgroups(name, groups, append=False)

Change the groups to which the user belongs. Note that the user's primary group does not have to be one of the groups passed, membership in the user's primary group is automatically assumed.

groups Groups to which the user should belong, can be passed either as a python list or a comma-separated string

append Instead of removing user from groups not included in the groups parameter, just add user to any groups for which they are not members

CLI Example:

```bash
salt '*' user.chgroups foo wheel,root
```

salt.modules.mac_user.chhome(name, home, **kwargs)

Change the home directory of the user

CLI Example:

```bash
salt '*' user.chhome foo /Users/foo
```

salt.modules.mac_user.chshell(name, shell)

Change the default shell of the user

CLI Example:

```bash
salt '*' user.chshell foo /bin/zsh
```

salt.modules.mac_user.chuid(name, uid)

Change the uid for a named user

CLI Example:

```bash
salt '*' user.chuid foo 4376
```

salt.modules.mac_user.delete(name, remove=False, force=False)

Remove a user from the minion

CLI Example:
salt 'user.delete name remove=True force=True

salt.modules.mac_user.disable_auto_login()
    New in version 2016.3.0.
    Disables auto login on the machine
    Returns  True if successful, False if not
    Return type  bool
    CLI Example:
    salt '*' user.disable_auto_login

salt.modules.mac_user.enable_auto_login(name)
    New in version 2016.3.0.
    Configures the machine to auto login with the specified user
    Parameters  name (str) -- The user account used for auto login
    Returns  True if successful, False if not
    Return type  bool
    CLI Example:
    salt '*' user.enable_auto_login stevej

salt.modules.mac_user.get_auto_login()
    New in version 2016.3.0.
    Gets the current setting for Auto Login
    Returns  If enabled, returns the user name, otherwise returns False
    Return type  str, bool
    CLI Example:
    salt '*' user.get_auto_login

salt.modules.mac_user.getent(refresh=False)
    Return the list of all info for all users
    CLI Example:
    salt '*' user.getent

salt.modules.mac_user.info(name)
    Return user information
    CLI Example:
    salt '*' user.info root

salt.modules.mac_user.list_groups(name)
    Return a list of groups the named user belongs to
    CLI Example:
    salt '*' user.list_groups foo

salt.modules.mac_user.list_users()
    Return a list of all users
    CLI Example:
salt '*' user.list_users

```
salt.modules.mac_user.primary_group(name)
   Return the primary group of the named user

   New in version 2016.3.0.
   CLI Example:
   salt '*' user.primary_group saltadmin
```

```
salt.modules.mac_user.rename(name, new_name)
   Change the username for a named user

   CLI Example:
   salt '*' user.rename name new_name
```

### 13.6.169  salt.modules.mac_sysctl module

Module for viewing and modifying sysctl parameters

```
salt.modules.mac_sysctl.assign(name, value)
   Assign a single sysctl parameter for this minion
   name  The name of the sysctl value to edit.
   value The sysctl value to apply.

   CLI Example:
   salt '*' sysctl.assign net.inet.icmp.icmplim 50
```

```
salt.modules.mac_sysctl.get(name)
   Return a single sysctl parameter for this minion
   name  The name of the sysctl value to display.

   CLI Example:
   salt '*' sysctl.get hw.physmem
```

```
salt.modules.mac_sysctl.persist(name, value, config='/etc/sysctl.conf', apply_change=False)
   Assign and persist a simple sysctl parameter for this minion
   name  The name of the sysctl value to edit.
   value The sysctl value to apply.
   config The location of the sysctl configuration file.
   apply_change Default is False; Default behavior only creates or edits the sysctl.conf file. If apply is set to True, the changes are applied to the system.

   CLI Example:
   salt '*' sysctl.persist net.inet.icmp.icmplim 50
   salt '*' sysctl.persist coretemp_load NO config=/etc/sysctl.conf
```

```
salt.modules.mac_sysctl.show(config_file=False)
   Return a list of sysctl parameters for this minion

   CLI Example:
   salt '*' sysctl.show
```
13.6.170  salt.modules.mac_system module

New in version 2016.3.0.
System module for sleeping, restarting, and shutting down the system on Mac OS X.

Warning: Using this module will enable `atrun` on the system if it is disabled.

salt.modules.mac_system.get_boot_arch()
Get the kernel architecture setting from `com.apple.Boot.plist`
  Returns  A string value representing the boot architecture setting
  Return type  str
  CLI Example:
  ```
salt '*' system.get_boot_arch
  ```

salt.modules.mac_system.get_computer_name()
Gets the computer name
  Returns  The computer name
  Return type  str
  CLI Example:
  ```
salt '*' system.get_computer_name
  ```

salt.modules.mac_system.get_disable_keyboard_on_lock()
Get whether or not the keyboard should be disabled when the X Serve enclosure lock is engaged.
  Returns  True if disable keyboard on lock is on, False if off
  Return type  bool
  CLI Example:
  ```
  ..code-block:: bash
     salt '*' system.get_disable_keyboard_on_lock
  ```

salt.modules.mac_system.get_remote_events()
Displays whether remote apple events are on or off.
  Returns  True if remote apple events are on, False if off
  Return type  bool
  CLI Example:
  ```
salt '*' system.get_remote_events
  ```

salt.modules.mac_system.get_remote_login()
Displays whether remote login (SSH) is on or off.
  Returns  True if remote login is on, False if off
  Return type  bool
  CLI Example:
  ```
salt '*' system.get_remote_login
  ```

salt.modules.mac_system.get_restart_delay()
Get the number of seconds after which the computer will start up after a power failure.
  Returns  A string value representing the number of seconds the system will
delay restart after power loss :rtype: str
  CLI Example:
salt '*' system.get_restart_delay

**salt.modules.mac_system.get_startup_disk()**
Displays the current startup disk

**Returns** The current startup disk

**Return type** str

**CLI Example:**
salt '*' system.get_startup_disk

**salt.modules.mac_system.get_subnet_name()**
Gets the local subnet name

**Returns** The local subnet name

**Return type** str

**CLI Example:**
salt '*' system.get_subnet_name

**salt.modules.mac_system.halt(at_time=None)**
Halt a running system

**Parameters** `at_time` *(str)* -- Any valid at expression. For example, some valid at expressions could be: - noon - midnight - fri - 9:00 AM - 2:30 PM tomorrow - now + 10 minutes

**Note:** If you pass a time only, with no `AM/PM` designation, you have to double quote the parameter on the command line. For example: ```14:00```

**CLI Example:**
salt '*' system.halt
salt '*' system.halt 'now + 10 minutes'

**salt.modules.mac_system.list_startup_disks()**
List all valid startup disks on the system.

**Returns** A list of valid startup disks

**Return type** list

**CLI Example:**
salt '*' system.list_startup_disks

**salt.modules.mac_system.restart(at_time=None)**
Restart the system

**Parameters** `at_time` *(str)* -- Any valid at expression. For example, some valid at expressions could be: - noon - midnight - fri - 9:00 AM - 2:30 PM tomorrow - now + 10 minutes

**Note:** If you pass a time only, with no `AM/PM` designation, you have to double quote the parameter on the command line. For example: ```14:00```

**CLI Example:**
salt '*' system.restart
salt '*' system.restart '12:00 PM fri'

**salt.modules.mac_system.set_boot_arch(arch='default')**
Set the kernel to boot in 32 or 64 bit mode on next boot.

**Note:** This command fails with the following error:
changes to kernel architecture failed to save!
The setting is not updated. This is either an apple bug, not available on the test system, or a result of system files now being locked down in OS X (SIP Protection).

Parameters arch (str) -- A string representing the desired architecture. If no value is passed, default is assumed. Valid values include: - i386 - x86_64 - default

Returns True if successful, False if not

Return type bool

CLI Example:

```bash
salt '*' system.set_boot_arch i386
```

salt.modules.mac_system.set_computer_name(name)
Set the computer name

Parameters name (str) -- The new computer name

Returns True if successful, False if not

Return type bool

CLI Example:

```bash
salt '*' system.set_computer_name "Mike's Mac"
```

salt.modules.mac_system.set_disable_keyboard_on_lock(enable)
Get whether or not the keyboard should be disabled when the X Serve enclosure lock is engaged.

Parameters enable (bool) -- True to enable, False to disable. ”On” and ”Off” are also acceptable values. Additionally you can pass 1 and 0 to represent True and False respectively

Returns True if successful, False if not

Return type bool

CLI Example:

```bash
salt '*' system.set_disable_keyboard_on_lock False
```

salt.modules.mac_system.set_remote_events(enable)
Set whether the server responds to events sent by other computers (such as AppleScripts)

Parameters enable (bool) -- True to enable, False to disable. ”On” and ”Off” are also acceptable values. Additionally you can pass 1 and 0 to represent True and False respectively

Returns True if successful, False if not

Return type bool

CLI Example:

```bash
salt '*' system.set_remote_events On
```

salt.modules.mac_system.set_remote_login(enable)
Set the remote login (SSH) to either on or off.

Parameters enable (bool) -- True to enable, False to disable. ”On” and ”Off” are also acceptable values. Additionally you can pass 1 and 0 to represent True and False respectively

Returns True if successful, False if not

Return type bool

CLI Example:

```bash
salt '*' system.set_remote_login True
```

salt.modules.mac_system.set_restart_delay(seconds)
Set the number of seconds after which the computer will start up after a power failure.
Warning: This command fails with the following error:

`Error,IOServiceOpen returned 0x10000003`

The setting is not updated. This is an apple bug. It seems like it may only work on certain versions of Mac Server X. This article explains the issue in more detail, though it is quite old.

Parameters `seconds (int)` -- The number of seconds. Must be a multiple of 30

Returns True if successful, False if not

Return type `bool`

CLI Example:

```
salt '*' system.set_restart_delay 180
```

```
salt.modules.mac_system.set_startup_disk(path)
```

Set the current startup disk to the indicated path. Use `system.list_startup_disks` to find valid startup disks on the system.

Parameters `path (str)` -- The valid startup disk path

Returns True if successful, False if not

Return type `bool`

CLI Example:

```
salt '*' system.set_startup_disk /System/Library/CoreServices
```

```
salt.modules.mac_system.set_subnet_name(name)
```

Set the local subnet name

Parameters `name (str)` -- The new local subnet name

Note: Spaces are changed to dashes. Other special characters are removed.

Returns True if successful, False if not

Return type `bool`

CLI Example:

```
The following will be set as 'Mikes-Mac'
salt '*' system.set_subnet_name "Mike's Mac"
```

```
salt.modules.mac_system.shutdown(at_time=None)
```

Shutdown the system

Parameters `at_time (str)` -- Any valid `at` expression. For example, some valid `at` expressions could be: - noon - midnight - fri - 9:00 AM - 2:30 PM tomorrow - now + 10 minutes

Note: If you pass a time only, with no `AM/PM` designation, you have to double quote the parameter on the command line. For example: `”14:00”`

CLI Example:

```
salt '*' system.shutdown
salt '*' system.shutdown 'now + 1 hour'
```

```
salt.modules.mac_system.sleep(at_time=None)
```

Sleep the system. If a user is active on the system it will likely fail to sleep.

Parameters `at_time (str)` -- Any valid `at` expression. For example, some valid `at` expressions could be: - noon - midnight - fri - 9:00 AM - 2:30 PM tomorrow - now + 10 minutes

Note: If you pass a time only, with no `AM/PM` designation, you have to double quote the parameter on the command line. For example: `”14:00”`

CLI Example:
expressions could be: - noon - midnight - fri - 9:00 AM - 2:30 PM tomorrow - now + 10 minutes

Note: If you pass a time only, with no `AM/PM` designation, you have to double quote the parameter on the command line. For example: ```"14:00"```

CLI Example:

```bash
salt '*' system.sleep
salt '*' system.sleep '10:00 PM'
```

### 13.6.171 salt.modules.mac_timezone module

Module for editing date/time settings on Mac OS X

New in version 2016.3.0.

salt.modules.mac_timezone.get_date()
Displays the current date
- **Returns**: the system date
- **Return type**: str

CLI Example:

```bash
salt '*' timezone.get_date
```

salt.modules.mac_timezone.get_hwclock()
Get current hardware clock setting (UTC or localtime)

CLI Example:

```bash
salt '*' timezone.get_hwclock
```

salt.modules.mac_timezone.get_offset()
Displays the current time zone offset
- **Returns**: The current time zone offset
- **Return type**: str

CLI Example:

```bash
salt '*' timezone.get_offset
```

salt.modules.mac_timezone.get_time()
Get the current system time.
- **Returns**: The current time in 24 hour format
- **Return type**: str

CLI Example:

```bash
salt '*' timezone.get_time
```

salt.modules.mac_timezone.get_time_server()
Display the currently set network time server.
- **Returns**: the network time server
- **Return type**: str

CLI Example:

```bash
salt '*' timezone.get_time_server
```

salt.modules.mac_timezone.get_using_network_time()
Display whether network time is on or off
Returns: True if network time is on, False if off
Return type: bool

CLI Example:
salt '*' timezone.get_using_network_time

salt.modules.mac_timezone.get_zone()
Displays the current time zone
Returns: The current time zone
Return type: str

CLI Example:
salt '*' timezone.get_zone

salt.modules.mac_timezone.get_zonecode()
Displays the current time zone abbreviated code
Returns: The current time zone code
Return type: str

CLI Example:
salt '*' timezone.get_zonecode

salt.modules.mac_timezone.list_zones()
Displays a list of available time zones. Use this list when setting a time zone using timezone.set_zone
Returns: a list of time zones
Return type: list

CLI Example:
salt '*' timezone.list_zones

salt.modules.mac_timezone.set_date(date)
Set the current month, day, and year
Parameters:
- date (str): The date to set. Valid date formats are:
  - %m:%d:%y
  - %m:%d:%Y
  - %m/%d/%y
  - %m/%d/%Y

Returns: True if successful, False if not
Return type: bool
Raises: SaltInvocationError on Invalid Date format
Raises: CommandExecutionError on failure

CLI Example:
salt '*' timezone.set_date 1/13/2016

salt.modules.mac_timezone.set_hwclock(clock)
Sets the hardware clock to be either UTC or localtime

CLI Example:
salt '*' timezone.set_hwclock UTC

salt.modules.mac_timezone.set_time(time)
Sets the current time. Must be in 24 hour format.
Parameters:
- time (str): The time to set in 24 hour format.
The value must be double quoted. ie: `''17:46''`

Returns  True if successful, False if not
Return type  bool
Raises  SaltInvocationError on Invalid Time format
Raises  CommandExecutionError on failure

CLI Example:
```
salt '*' timezone.set_time ''17:34''
```

salt.modules.mac_timezone.set_time_server(time_server='time.apple.com')
Designates a network time server. Enter the IP address or DNS name for the network time server.

Parameters  time_server -- IP or DNS name of the network time server. If nothing is passed the time server will be set to the OS X default of `time.apple.com`.
Type  str

Returns  True if successful, False if not
Return type  bool
Raises  CommandExecutionError on failure

CLI Example:
```
salt '*' timezone.set_time_server time.acme.com
```

salt.modules.mac_timezone.set_using_network_time(enable)
Set whether network time is on or off.

Parameters  enable -- True to enable, False to disable. Can also use `on` or `off`.
Type  str bool

Returns  True if successful, False if not
Return type  bool
Raises  CommandExecutionError on failure

CLI Example:
```
salt '*' timezone.set_using_network_time True
```

salt.modules.mac_timezone.set_zone(time_zone)
Set the local time zone. Use timezone.list_zones to list valid time_zone arguments

Parameters  time_zone (str) -- The time zone to apply

Returns  True if successful, False if not
Return type  bool
Raises  SaltInvocationError on Invalid Timezone
Raises  CommandExecutionError on failure

CLI Example:
```
salt '*' timezone.set_zone America/Denver
```

salt.modules.mac_timezone.zone_compare(time_zone)
Compares the given timezone name with the system timezone name.

Returns  True if they are the same, False if not
Return type  bool

CLI Example:
```
salt '*' timezone.zone_compare America/Boise
```

13.6.172  salt.modules.mac_xattr module

This module allows you to manage extended attributes on files or directories
salt '*' xattr.list /path/to/file

salt.modules.mac_xattr.clear(path)
Causes the all attributes on the file/directory to be removed
  Parameters path (str) -- The file(s) to get attributes from
  Returns True if successful, otherwise False
  Raises CommandExecutionError on file not found or any other unknown error
  CLI Example:
salt '*' xattr.delete /path/to/file "com.test.attr"

salt.modules.mac_xattr.delete(path, attribute)
Removes the given attribute from the file
  Parameters
    • path (str) -- The file(s) to get attributes from
    • attribute (str) -- The attribute name to be deleted from the
      file/directory
  Returns False
  Return type bool
  Raises CommandExecutionError on file not found, attribute not found, and
  any other unknown error
  CLI Example:
salt '*' xattr.delete /path/to/file "com.test.attr"

salt.modules.mac_xattr.list(path, **kwargs)
List all of the extended attributes on the given file/directory
  Parameters
    • path (str) -- The file(s) to get attributes from
    • hex (bool) -- Return the values with forced hexadecimal values
  Returns A dictionary containing extended attributes and values for the
    given file
  Return type dict
  Raises CommandExecutionError on file not found or any other unknown error
  CLI Example:
salt '*' xattr.list /path/to/file
salt '*' xattr.list /path/to/file hex=True

salt.modules.mac_xattr.read(path, attribute, **kwargs)
Read the given attributes on the given file/directory
  Parameters
    • path (str) -- The file to get attributes from
    • attribute (str) -- The attribute to read
    • hex (bool) -- Return the values with forced hexadecimal values
  Returns A string containing the value of the named attribute
  Return type str
  Raises CommandExecutionError on file not found, attribute not found, and
  any other unknown error
  CLI Example:
salt 'x' xattr.read /path/to/file com.test.attr
salt 'x' xattr.read /path/to/file com.test.attr hex=True

salt.modules.mac_xattr.write(path, attribute, value, **kwargs)
Causes the given attribute name to be assigned the given value

Parameters
- **path** (str) -- The file(s) to get attributes from
- **attribute** (str) -- The attribute name to be written to the file/directory
- **value** (str) -- The value to assign to the given attribute
- **hex** (bool) -- Set the values with forced hexadecimal values

Returns True if successful, otherwise False
Return type bool
Raises CommandExecutionError on file not found or any other unknown error

CLI Example:
salt 'x' xattr.write /path/to/file "com.test.attr" "value"

13.6.173 salt.modules.makeconf

Support for modifying make.conf under Gentoo
	salt.modules.makeconf.append_cflags(value)
Add to or create a new CFLAGS in the make.conf

Return a dict containing the new value for variable:

```python
{'<variable>': {'old': '<old-value>',
               'new': '<new-value>'}}
```

CLI Example:
salt 'x' makeconf.append_cflags '-pipe'
	salt.modules.makeconf.append_cxxflags(value)
Add to or create a new CXXFLAGS in the make.conf

Return a dict containing the new value for variable:

```python
{'<variable>': {'old': '<old-value>',
               'new': '<new-value>'}}
```

CLI Example:
salt 'x' makeconf.append_cxxflags '-pipe'
	salt.modules.makeconf.append_emerge_default_opts(value)
Add to or create a new EMERGE_DEFAULT_OPTS in the make.conf

Return a dict containing the new value for variable:

```python
{'<variable>': {'old': '<old-value>',
               'new': '<new-value>'}}
```

CLI Example:
salt '*' makeconf.append_emerge_default_opts '--jobs'

```
salt.modules.makeconf.append_features(value)
Add to or create a new FEATURES in the make.conf

Return a dict containing the new value for variable:

```json```
{ 'variable': { 'old': '<old-value>', 'new': '<new-value>' }}
```

CLI Example:
```
salt '*' makeconf.append_features 'webrsync-gpg'
```

```
salt.modules.makeconf.append_gentoo_mirrors(value)
Add to or create a new GENTOO_MIRRORS in the make.conf

Return a dict containing the new value for variable:

```json```
{ 'variable': { 'old': '<old-value>', 'new': '<new-value>' }}
```

CLI Example:
```
salt '*' makeconf.append_gentoo_mirrors 'http://distfiles.gentoo.org'
```

```
salt.modules.makeconf.append_makeopts(value)
Add to or create a new MAKEOPTS in the make.conf

Return a dict containing the new value for variable:

```json```
{ 'variable': { 'old': '<old-value>', 'new': '<new-value>' }}
```

CLI Example:
```
salt '*' makeconf.append_makeopts '-j3'
```

```
salt.modules.makeconf.append_var(var, value)
Add to or create a new variable in the make.conf

Return a dict containing the new value for variable:

```json```
{ 'variable': { 'old': '<old-value>', 'new': '<new-value>' }}
```

CLI Example:
```
salt '*' makeconf.append_var 'LINGUAS' 'en'
```

```
salt.modules.makeconf.cflags_contains(value)
Verify if CFLAGS variable contains a value in make.conf

Return True if value is set for var
```

CLI Example:
```
salt '*' makeconf.cflags_contains '-pipe'
```
salt.modules.makeconf.chost_contains(value)
Verify if CHOST variable contains a value in make.conf
Return True if value is set for var
CLI Example:
```
salt '*' makeconf.chost_contains 'x86_64-pc-linux-gnu'
```

class.modules.makeconf.cxxflags_contains(value)
Verify if CXXFLAGS variable contains a value in make.conf
Return True if value is set for var
CLI Example:
```
salt '*' makeconf.cxxflags_contains '-pipe'
```

class.modules.makeconf.emerge_default_opts_contains(value)
Verify if EMERGE_DEFAULT_OPTS variable contains a value in make.conf
Return True if value is set for var
CLI Example:
```
salt '*' makeconf.emerge_default_opts_contains '--jobs'
```

class.modules.makeconf.features_contains(value)
Verify if FEATURES variable contains a value in make.conf
Return True if value is set for var
CLI Example:
```
salt '*' makeconf.features_contains 'webrsync-gpg'
```

class.modules.makeconf.gentoo_mirrors_contains(value)
Verify if GENTOO_MIRRORS variable contains a value in make.conf
Return True if value is set for var
CLI Example:
```
salt '*' makeconf.gentoo_mirrors_contains 'http://distfiles.gentoo.org'
```

class.modules.makeconf.get_cflags()
Get the value of CFLAGS variable in the make.conf
Return the value of the variable or None if the variable is not in the make.conf
CLI Example:
```
salt '*' makeconf.get_cflags
```

class.modules.makeconf.get_chost()
Get the value of CHOST variable in the make.conf
Return the value of the variable or None if the variable is not in the make.conf
CLI Example:
```
salt '*' makeconf.get_chost
```
salt.modules.makeconf.get_cxxflags()

Get the value of CXXFLAGS variable in the make.conf

Return the value of the variable or None if the variable is not in the make.conf

CLI Example:

```
salt '*' makeconf.get_cxxflags
```

salt.modules.makeconf.get_emerge_default_opts()

Get the value of EMERGE_DEFAULT_OPTS variable in the make.conf

Return the value of the variable or None if the variable is not in the make.conf

CLI Example:

```
salt '*' makeconf.get_emerge_default_opts
```

salt.modules.makeconf.get_features()

Get the value of FEATURES variable in the make.conf

Return the value of the variable or None if the variable is not in the make.conf

CLI Example:

```
salt '*' makeconf.get_features
```

salt.modules.makeconf.get_gentoo_mirrors()

Get the value of GENTOO_MIRRORS variable in the make.conf

Return the value of the variable or None if the variable is not in the make.conf

CLI Example:

```
salt '*' makeconf.get_gentoo_mirrors
```

salt.modules.makeconf.get_makeopts()

Get the value of MAKEOPTS variable in the make.conf

Return the value of the variable or None if the variable is not in the make.conf

CLI Example:

```
salt '*' makeconf.get_makeopts
```

salt.modules.makeconf.get_sync()

Get the value of SYNC variable in the make.conf

Return the value of the variable or None if the variable is not in the make.conf

CLI Example:

```
salt '*' makeconf.get_sync
```

salt.modules.makeconf.get_var(var)

Get the value of a variable in make.conf

Return the value of the variable or None if the variable is not in make.conf

CLI Example:

```
salt '*' makeconf.get_var 'LINGUAS'
```
salt.modules.makeconf.makeopts_contains(value)
Verify if MAKEOPTS variable contains a value in make.conf

Return True if value is set for var

CLI Example:
```
salt '*' makeconf.makeopts_contains '-j3'
```
	salt.modules.makeconf.remove_var(var)
Remove a variable from the make.conf

Return a dict containing the new value for the variable:

```
{'<variable>': {'old': '<old-value>',
               'new': '<new-value>'}}
```

CLI Example:
```
salt '*' makeconf.remove_var 'LINGUAS'
```
	salt.modules.makeconf.set_cflags(value)
Set the CFLAGS variable

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
               'new': '<new-value>'}}
```

CLI Example:
```
salt '*' makeconf.set_cflags '-march=native -O2 -pipe'
```
	salt.modules.makeconf.set_chost(value)
Set the CHOST variable

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
               'new': '<new-value>'}}
```

CLI Example:
```
salt '*' makeconf.set_chost 'x86_64-pc-linux-gnu'
```
	salt.modules.makeconf.set_cxxflags(value)
Set the CXXFLAGS variable

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
               'new': '<new-value>'}}
```

CLI Example:
```
salt '*' makeconf.set_cxxflags '-march=native -O2 -pipe'
```
	salt.modules.makeconf.set_emerge_default_opts(value)
Set the EMERGE_DEFAULT_OPTS variable
Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
               'new': '<new-value>'}}
```

CLI Example:
```
salt '*' makeconf.set_emerge_default_opts '--jobs'
```

**salt.modules.makeconf.set_gentoo_mirrors(value)**
Set the GENTOO_MIRRORS variable

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
               'new': '<new-value>'}}
```

CLI Example:
```
salt '*' makeconf.set_gentoo_mirrors 'http://distfiles.gentoo.org'
```

**salt.modules.makeconf.set_makeopts(value)**
Set the MAKEOPTS variable

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
               'new': '<new-value>'}}
```

CLI Example:
```
salt '*' makeconf.set_makeopts '-j3'
```

**salt.modules.makeconf.set_sync(value)**
Set the SYNC variable

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
               'new': '<new-value>'}}
```

CLI Example:
```
salt '*' makeconf.set_sync 'rsync://rsync.namerica.gentoo.org/gentoo-portage'
```

**salt.modules.makeconf.set_var(var, value)**
Set a variable in the make.conf

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
               'new': '<new-value>'}}
```

CLI Example:
```
salt '*' makeconf.set_var 'LINGUAS' 'en'
```

**salt.modules.makeconf.sync_contains(value)**
Verify if SYNC variable contains a value in make.conf
Return True if value is set for var

CLI Example:
```bash
salt '*' makeconf.sync_contains 'rsync://rsync.namerica.gentoo.org/gentoo-portage'
```

salt.modules.makeconf.trim_cflags(value)
Remove a value from CFLAGS variable in the make.conf

Return a dict containing the new value for variable:

```json
{
'<variable>': {
'old': '<old-value>',
'new': '<new-value>'
}
}
```

CLI Example:
```bash
salt '*' makeconf.trim_cflags '-pipe'
```

salt.modules.makeconf.trim_cxxflags(value)
Remove a value from CXXFLAGS variable in the make.conf

Return a dict containing the new value for variable:

```json
{
'<variable>': {
'old': '<old-value>',
'new': '<new-value>'
}
}
```

CLI Example:
```bash
salt '*' makeconf.trim_cxxflags '-pipe'
```

salt.modules.makeconf.trim_emerge_default_opts(value)
Remove a value from EMERGE_DEFAULT_OPTS variable in the make.conf

Return a dict containing the new value for variable:

```json
{
'<variable>': {
'old': '<old-value>',
'new': '<new-value>'
}
}
```

CLI Example:
```bash
salt '*' makeconf.trim_emerge_default_opts '--jobs'
```

salt.modules.makeconf.trim_features(value)
Remove a value from FEATURES variable in the make.conf

Return a dict containing the new value for variable:

```json
{
'<variable>': {
'old': '<old-value>',
'new': '<new-value>'
}
}
```

CLI Example:
```bash
salt '*' makeconf.trim_features 'webrsync-gpg'
```

salt.modules.makeconf.trim_gentoo_mirrors(value)
Remove a value from GENTOO_MIRRORS variable in the make.conf

Return a dict containing the new value for variable:
CLI Example:
```
salt '*' makeconf.trim_gentoo_mirrors 'http://distfiles.gentoo.org'
```

```
salt.modules.makeconf.trim_makeopts(value)
```
Remove a value from MAKEOPTS variable in the make.conf

```
Return a dict containing the new value for variable:
```
```
{'<variable>': {'old': '<old-value>',
               'new': '<new-value>'}}
```

CLI Example:
```
salt '*' makeconf.trim_makeopts '-j3'
```

```
salt.modules.makeconf.trim_var(var, value)
```
Remove a value from a variable in the make.conf

```
Return a dict containing the new value for variable:
```
```
{'<variable>': {'old': '<old-value>',
               'new': '<new-value>'}}
```

CLI Example:
```
salt '*' makeconf.trim_var 'LINGUAS' 'en'
```

```
salt.modules.makeconf.var_contains(var, value)
```
Verify if variable contains a value in make.conf

```
Return True if value is set for var
```

CLI Example:
```
salt '*' makeconf.var_contains 'LINGUAS' 'en'
```

### 13.6.174 salt.modules.marathon module

Module providing a simple management interface to a marathon cluster.

Currently this only works when run through a proxy minion.

New in version 2015.8.2.

```
salt.modules.marathon.app(id)
```
Return the current server configuration for the specified app.

CLI Example:
```
.. code-block:: bash
    salt marathon-minion-id marathon.app my-app
```

```
salt.modules.marathon.apps()
```
Return a list of the currently installed app ids.

CLI Example:
```
.. code-block:: bash
    salt marathon-minion-id marathon.apps
```
**salt.modules.marathon.has_app(id)**

Return whether the given app id is currently configured.

CLI Example:
```bash
salt marathon-minion-id marathon.has_app my-app
```

**salt.modules.marathon.info()**

Return configuration and status information about the marathon instance.

CLI Example:
```bash
salt marathon-minion-id marathon.info
```

**salt.modules.marathon.rm_app(id)**

Remove the specified app from the server.

CLI Example:
```bash
salt marathon-minion-id marathon.rm_app my-app
```

**salt.modules.marathon.update_app(id, config)**

Update the specified app with the given configuration.

CLI Example:
```bash
salt marathon-minion-id marathon.update_app my-app `<config yaml>'
```

### 13.6.175 salt.modules.match

The match module allows for match routines to be run and determine target specs

**salt.modules.match.compound(tgt, minion_id=None)**

Return True if the minion ID matches the given compound target

- **minion_id** Specify the minion ID to match against the target expression

  New in version 2014.7.0.

  CLI Example:

  ```bash
  salt '*' match.compound '{foo*: Foo!, bar*: Bar!}'
  ```

**salt.modules.match.data(tgt)**

Return True if the minion matches the given data target

CLI Example:
```bash
salt '*' match.data 'spam:eggs'
```

**salt.modules.match.filter_by(lookup, expr_form='compound', minion_id=None)**

Return the first match in a dictionary of target patterns

New in version 2014.7.0.

CLI Example:
```bash
salt '*' match.filter_by '{foo*: Foo!, bar*: Bar!}' minion_id=bar03
```

Pillar Example:
```yaml
{% set roles = salt['match.filter_by']({
    'web*': ['app', 'caching'],
    'db*': ['db'],
}) %}
```
salt.modules.match.glob(tgt, minion_id=None)
Return True if the minion ID matches the given glob target

```
minion_id Specify the minion ID to match against the target expression
```

New in version 2014.7.0.

CLI Example:

```
salt '*' match.glob '*'
```

salt.modules.match.grain(tgt, delimiter=': ')
Return True if the minion matches the given grain target. The delimiter argument can be used to specify a different delimiter.

```
\n\n```

delimiter Specify an alternate delimiter to use when traversing a nested dict

New in version 2014.7.0.

```
delim Specify an alternate delimiter to use when traversing a nested dict

New in version 0.16.4.

Deprecated since version 2015.8.0.
```

salt.modules.match.grain_pcre(tgt, delimiter=': ')
Return True if the minion matches the given grain_pcre target. The delimiter argument can be used to specify a different delimiter.

```
\n\n```

delimiter Specify an alternate delimiter to use when traversing a nested dict

New in version 2014.7.0.

delim Specify an alternate delimiter to use when traversing a nested dict

New in version 0.16.4.

Deprecated since version 2015.8.0.
```

salt.modules.match.ipcidr(tgt)
Return True if the minion matches the given ipcidr target

```
\n```

delimiter Pillar Example:

```
'172.16.0.0/12':
  - match: ipcidr
  - nodeclass: internal
```

salt.modules.match.list(tgt, minion_id=None)
Return True if the minion ID matches the given list target
minion_id  Specify the minion ID to match against the target expression

New in version 2014.7.0.
CLI Example:

```
salt '*' match.list 'server1,server2'
```

salt.modules.match.pcre(tgt, minion_id=None)
Return True if the minion ID matches the given pcre target

- **minion_id**: Specify the minion ID to match against the target expression

New in version 2014.7.0.
CLI Example:

```
salt '*' match.pcre ',.*'
```

salt.modules.match.pillar(tgt, delimiter=': ')
Return True if the minion matches the given pillar target. The `delimiter` argument can be used to specify a different delimiter.

CLI Example:

```
salt '*' match.pillar 'cheese:foo'
salt '*' match.pillar 'clone_url|https://github.com/saltstack/salt.git' delimiter= '|
```

delimiter  Specify an alternate delimiter to use when traversing a nested dict

New in version 2014.7.0.

delim  Specify an alternate delimiter to use when traversing a nested dict

New in version 0.16.4.
Deprecated since version 2015.8.0.

salt.modules.match.pillar_pcre(tgt, delimiter=': ')
Return True if the minion matches the given pillar_pcre target. The `delimiter` argument can be used to specify a different delimiter.

CLI Example:

```
salt '*' match.pillar_pcre 'cheese:(swiss|american)'
salt '*' match.pillar_pcre 'clone_url|https://github\.com/.*\.git' delimiter='|'
```

delimiter  Specify an alternate delimiter to use when traversing a nested dict

New in version 2014.7.0.

delim  Specify an alternate delimiter to use when traversing a nested dict

New in version 0.16.4.
Deprecated since version 2015.8.0.

### 13.6.176 salt.modules.mdadm

Salt module to manage RAID arrays with mdadm

salt.modules.mdadm.assemble(name, devices, test_mode=False, **kwargs)
Assemble a RAID device.

CLI Examples:
salt '*' raid.assemble /dev/md0 [''/dev/xvdd', '/dev/xvde']

Note: Adding test_mode=True as an argument will print out the mdadm command that would have been run.

name The name of the array to assemble.
devices The list of devices comprising the array to assemble.
kwarg Optional arguments to be passed to mdadm.
returns
  test_mode=True: Prints out the full command.
  test_mode=False (Default): Executes command on the host(s) and prints out the mdadm output.

For more info, read the mdadm manpage.
salt.modules.mdadm.create(name, level, devices, metadata='default', test_mode=False, **kwargs)
Create a RAID device.
Changed in version 2014.7.0.

Warning: Use with CAUTION, as this function can be very destructive if not used properly!

CLI Examples:
salt '*' raid.create /dev/md0 level=1 chunk=256 devices=[''/dev/xvdd', '/dev/xvde'] test_mode=True

Note: Adding test_mode=True as an argument will print out the mdadm command that would have been run.

name The name of the array to create.
level The RAID level to use when creating the raid.
devices A list of devices used to build the array.
metadata Version of metadata to use when creating the array.
kwarg Optional arguments to be passed to mdadm.
returns
  test_mode=True: Prints out the full command.
  test_mode=False (Default): Executes command on remote the host(s) and Prints out the mdadm output.

Note: It takes time to create a RAID array. You can check the progress in `resync_status:` field of the results from the following command:
salt '*' raid.detail /dev/md0

For more info, read the mdadm(8) manpage

salt.modules.mdadm.destroy(device)
Destroy a RAID device.

WARNING This will zero the superblock of all members of the RAID array.

CLI Example:
salt '*' raid.destroy /dev/md0

salt.modules.mdadm.detail(device="/dev/md0")
    Show detail for a specified RAID device
    CLI Example:
    salt '*' raid.detail '/dev/md0'

salt.modules.mdadm.list()
    List the RAID devices.
    CLI Example:
    salt '*' raid.list

salt.modules.mdadm.save_config()
    Save RAID configuration to config file.
    Same as: mdadm --detail --scan >> /etc/mdadm/mdadm.conf
    Fixes this issue with Ubuntu REF: http://askubuntu.com/questions/209702/why-is-my-raid-dev-md1-showing-up-as-dev-md126-is-mdadm-conf-being-ignored
    CLI Example:
    salt '*' raid.save_config

salt.modules.mdadm.stop()
    Shut down all arrays that can be shut down (i.e. are not currently in use).
    CLI Example:
    salt '*' raid.stop

13.6.177 salt.modules.mdata

Module for managing metadata in SmartOS Zones
New in version 2016.3.0.

    maintainer Jorge Schrauwen <sjorge@blackdot.be>
    maturity new
    platform smartos

salt.modules.mdata.delete(*keyname)
    Delete metadata
    prop [string] name of property
    CLI Example:
    salt '*' mdata.get salt:role
    salt '*' mdata.get user-script salt:role

salt.modules.mdata.get(*keyname)
    Get metadata
    keyname [string] name of key
Note: If no keynames are specified, we get all (public) properties

CLI Example:
```
salt '*' mdata.get salt:role
salt '*' mdata.get user-script salt:role
```

salt.modules.mdata.list()
List available metadata

CLI Example:
```
salt '*' mdata.list
```

salt.modules.mdata.put(keyname, val)
Put metadata
prop [string] name of property
val [string] value to set

CLI Example:
```
salt '*' mdata.list
```

**13.6.178 salt.modules.memcached**

Module for Management of Memcached Keys

New in version 2014.1.0.

salt.modules.memcached.add(key, value, host='127.0.0.1'; port=11211, time=0, min_compress_len=0)
Add a key to the memcached server, but only if it does not exist. Returns False if the key already exists.

CLI Example:
```
salt '*' memcached.add <key> <value>
```

salt.modules.memcached.decrement(key, delta=1, host='127.0.0.1'; port=11211)
Decrement the value of a key

CLI Example:
```
salt '*' memcached.decrement <key>
salt '*' memcached.decrement <key> 2
```

salt.modules.memcached.delete(key, host='127.0.0.1'; port=11211, time=0)
Delete a key from memcache server

CLI Example:
```
salt '*' memcached.delete <key>
```

salt.modules.memcached.get(key, host='127.0.0.1'; port=11211)
Retrieve value for a key

CLI Example:
```
salt '*' memcached.get <key>
```
salt.modules.memcached.increment

Increment the value of a key

CLI Example:
```
salt '*' memcached.increment <key>
salt '*' memcached.increment <key> 2
```

salt.modules.memcached.replace

Replace a key on the memcached server. This only succeeds if the key already exists. This is the opposite of `memcached.add`

CLI Example:
```
salt '*' memcached.replace <key> <value>
```

salt.modules.memcached.set

Set a key on the memcached server, overwriting the value if it exists.

CLI Example:
```
salt '*' memcached.set <key> <value>
```

salt.modules.memcached.status

Get memcached status

CLI Example:
```
salt '*' memcached.status
```

---

13.6.179 salt.modules.mine

The function cache system allows for data to be stored on the master so it can be easily read by other minions

salt.modules.mine.delete

Remove specific function contents of minion. Returns True on success.

CLI Example:
```
salt '*' mine.delete 'network.interfaces'
```

salt.modules.mine.flush

Remove all mine contents of minion. Returns True on success.

CLI Example:
```
salt '*' mine.flush
```

salt.modules.mine.get

Get data from the mine based on the target, function and expr_form

Targets can be matched based on any standard matching system that can be matched on the master via these keywords:

- **glob**
- **pcre**
- **grain**
- **grain_pcre**
compound
pillar
pillar_pcre

Note that all pillar matches, whether using the compound matching system or the pillar matching system, will be exact matches, with globbing disabled.

exclude_minion Excludes the current minion from the result set

CLI Example:

```
salt '*' mine.get '*' network.interfaces
salt '*' mine.get 'os:Fedora' network.interfaces
salt '*' mine.get 'os:Fedora and S@192.168.5.0/24' network.ip_addrs
```

See also:

Retrieving Mine data from Pillar and Orchestrate

This execution module is intended to be executed on minions. Master-side operations such as Pillar or Orchestrate that require Mine data should use the Mine Runner module instead; it can be invoked from an SLS file using the `saltutil.runner` module. For example:

```
{% set minion_ips = salt.saltutil.runner('mine.get',
   tgt='*',
   fun='network.ip_addrs',
   tgt_type='glob') %}
```

**salt.modules.mine.get_docker** *(interfaces=*, cidrs=*, with_container_id=False)*

Get all mine data for `docker.get_containers` and run an aggregation routine. The `"interfaces"` parameter allows for specifying which network interfaces to select ip addresses from. The `"cidrs"` parameter allows for specifying a list of cidrs which the ip address must match.

**with_container_id** Boolean, to expose container_id in the list of results

New in version 2015.8.2.

CLI Example:

```
salt '*' mine.get_docker
salt '*' mine.get_docker interfaces='eth0'
salt '*' mine.get_docker interfaces='["eth0", "eth1"]'
salt '*' mine.get_docker cidrs='107.170.147.0/24'
salt '*' mine.get_docker cidrs='["107.170.147.0/24", "172.17.42.0/24"]'
salt '*' mine.get_docker interfaces='["eth0", "eth1"]' cidrs='["107.170.147.0/24", "172.17.42.0/24"]'
```

**salt.modules.mine.send** *(func, *args, **kwargs)*

Send a specific function to the mine.

CLI Example:

```
salt '*' mine.send network.ip_addrs eth0
salt '*' mine.send eth0_ip_addrs mine_function=network.ip_addrs eth0
```

**salt.modules.mine.update** *(clear=False)*

Execute the configured functions and send the data back up to the master. The functions to be executed are merged from the master config, pillar and minion config under the option `mine_functions`:

```
mine_functions:
   network.ip_addrs:
```

1248 Chapter 13. Salt Module Reference
- eth0
  disk.usage: []

The function cache will be populated with information from executing these functions

CLI Example:
```
salt '*' mine.update
```

### 13.6.180 salt.modules.minion module

Module to provide information about minions

```
salt.modules.minion.list()
```

Return a list of accepted, denied, unaccepted and rejected keys. This is the same output as `salt-key -L`.

CLI Example:
```
salt 'master' minion.list
```

### 13.6.181 salt.modules.mod_random

**Provides access to randomness generators.**

New in version 2014.7.0.

```
salt.modules.mod_random.get_str(length=20)
```

New in version 2014.7.0.

Returns a random string of the specified length.

- **length** [20] Any valid number of bytes.

CLI Example:
```
salt '*' random.get_str 128
```

```
salt.modules.mod_random.hash(value, algorithm='sha512')
```

New in version 2014.7.0.

Encodes a value with the specified encoder.

- **value** The value to be hashed.
- **algorithm** [sha512] The algorithm to use. May be any valid algorithm supported by hashlib.

CLI Example:
```
salt '*' random.hash 'I am a string' md5
```

```
salt.modules.mod_random.rand_int(start=1, end=10)
```

Returns a random integer number between the start and end number.

- **start** [1] Any valid integer number
- **end** [10] Any valid integer number

CLI Example:
```
salt '*' random.rand_int 1 10
```
salt.modules.mod_random.seed \(\text{range}=10, \text{hash}={\text{None}}\)

Returns a random number within a range. Optional hash argument can be any hashable object. If hash is omitted or None, the id of the minion is used.

- **hash**: Any hashable object.
- **range**: Any valid integer number

CLI Example:

```
salt '*' random.seed 10 hash=\{None\}
```

salt.modules.mod_random.shadow_hash \(\text{crypt_salt}={\text{None}}, \text{password}={\text{None}}, \text{algorithm}={\text{sha512}}\)

Generates a salted hash suitable for /etc/shadow.

- **crypt_salt**: [None] Salt to be used in the generation of the hash. If one is not provided, a random salt will be generated.
- **password**: [None] Value to be salted and hashed. If one is not provided, a random password will be generated.
- **algorithm**: [sha512] Hash algorithm to use.

CLI Example:

```
salt '*' random.shadow_hash 'MySalT' 'MyP@sswd' md5
```

salt.modules.mod_random.str_encode \(\text{value}, \text{encoder}={\text{base64}}\)

New in version 2014.7.0.

- **value**: The value to be encoded.
- **encoder**: [base64] The encoder to use on the subsequent string.

CLI Example:

```
salt '*' random.str_encode 'I am a new string' base64
```

13.6.182 salt.modules.modjk

Below is an example of the configuration needed for this module. This configuration data can be placed either in grains or pillar.

If using grains, this can be accomplished statically or via a grain module.

If using pillar, the yaml configuration can be placed directly into a pillar SLS file, making this both the easier and more dynamic method of configuring this module.

```
modjk:
  default:
    url: http://localhost/jkstatus
    user: modjk
    pass: secret
    realm: authentication realm for digest passwords
    timeout: 5
  otherVhost:
    url: http://otherVhost/jkstatus
    user: modjk
    pass: secret2
    realm: authentication realm2 for digest passwords
    timeout: 600
```

salt.modules.modjk.bulk_activate \(\text{workers}, \text{lbn}, \text{profile}={\text{default}}\)

Activate all the given workers in the specific load balancer
**CLI Examples:**

```bash
salt '*' modjk.bulk_activate node1,node2,node3 loadbalancer1
salt '*' modjk.bulk_activate node1,node2,node3 loadbalancer1 other-profile
salt '*' modjk.bulk_activate ['node1','node2','node3'] loadbalancer1
salt '*' modjk.bulk_activate ['node1','node2','node3'] loadbalancer1 other-profile
```

**salt.modules.modjk.bulk_disable** *(workers, lbn, profile='default')*

Disable all the given workers in the specific load balancer

**CLI Examples:**

```bash
salt '*' modjk.bulk_disable node1,node2,node3 loadbalancer1
salt '*' modjk.bulk_disable node1,node2,node3 loadbalancer1 other-profile
salt '*' modjk.bulk_disable ['node1','node2','node3'] loadbalancer1
salt '*' modjk.bulk_disable ['node1','node2','node3'] loadbalancer1 other-profile
```

**salt.modules.modjk.bulk_recover** *(workers, lbn, profile='default')*

Recover all the given workers in the specific load balancer

**CLI Examples:**

```bash
salt '*' modjk.bulk_recover node1,node2,node3 loadbalancer1
salt '*' modjk.bulk_recover node1,node2,node3 loadbalancer1 other-profile
salt '*' modjk.bulk_recover ['node1','node2','node3'] loadbalancer1
salt '*' modjk.bulk_recover ['node1','node2','node3'] loadbalancer1 other-profile
```

**salt.modules.modjk.bulk_stop** *(workers, lbn, profile='default')*

Stop all the given workers in the specific load balancer

**CLI Examples:**

```bash
salt '*' modjk.bulk_stop node1,node2,node3 loadbalancer1
salt '*' modjk.bulk_stop node1,node2,node3 loadbalancer1 other-profile
salt '*' modjk.bulk_stop ['node1','node2','node3'] loadbalancer1
salt '*' modjk.bulk_stop ['node1','node2','node3'] loadbalancer1 other-profile
```

**salt.modules.modjk.dump_config** *(profile='default')*

Dump the original configuration that was loaded from disk

**CLI Examples:**

```bash
salt '*' modjk.dump_config
salt '*' modjk.dump_config other-profile
```

**salt.modules.modjk.get_running** *(profile='default')*

Get the current running config (not from disk)

**CLI Examples:**

```bash
salt '*' modjk.get_running
salt '*' modjk.get_running other-profile
```

**salt.modules.modjk.lb_edit** *(lbn, settings, profile='default')*

Edit the loadbalancer settings
Note: http://tomcat.apache.org/connectors-doc/reference/status.html Data Parameters for the standard Update Action

CLI Examples:

```
salt '*' modjk.lb_edit loadbalancer1 "{'vlr': 1, 'vlt': 60}"
salt '*' modjk.lb_edit loadbalancer1 "{'vlr': 1, 'vlt': 60}" other-profile
```

salt.modules.modjk.list_configured_members(lbn, profile='default')
Return a list of member workers from the configuration files

CLI Examples:

```
salt '*' modjk.list_configured_members loadbalancer1
salt '*' modjk.list_configured_members loadbalancer1 other-profile
```

salt.modules.modjk.recover_all(lbn, profile='default')
Set the all the workers in lbn to recover and activate them if they are not

CLI Examples:

```
salt '*' modjk.recover_all loadbalancer1
salt '*' modjk.recover_all loadbalancer1 other-profile
```

salt.modules.modjk.reset_stats(lbn, profile='default')
Reset all runtime statistics for the load balancer

CLI Examples:

```
salt '*' modjk.reset_stats loadbalancer1
salt '*' modjk.reset_stats loadbalancer1 other-profile
```

salt.modules.modjk.version(profile='default')
Return the modjk version

CLI Examples:

```
salt '*' modjk.version
salt '*' modjk.version other-profile
```

salt.modules.modjk.worker_activate(worker, lbn, profile='default')
Set the worker to activate state in the lbn load balancer

CLI Examples:

```
salt '*' modjk.worker_activate node1 loadbalancer1
salt '*' modjk.worker_activate node1 loadbalancer1 other-profile
```

salt.modules.modjk.worker_disable(worker, lbn, profile='default')
Set the worker to disable state in the lbn load balancer

CLI Examples:

```
salt '*' modjk.worker_disable node1 loadbalancer1
salt '*' modjk.worker_disable node1 loadbalancer1 other-profile
```

salt.modules.modjk.worker_edit(worker, lbn, settings, profile='default')
Edit the worker settings

Note: http://tomcat.apache.org/connectors-doc/reference/status.html Data Parameters for the standard Update Action
CLI Examples:

```
salt '*' modjk.worker_edit node1 loadbalancer1 "\{'vwf': 500, 'vwd': 60\}"
salt '*' modjk.worker_edit node1 loadbalancer1 "\{'vwf': 500, 'vwd': 60\}" other-profile
```

salt.modules.modjk.worker_recover(worker, lbn, profile='default')
Set the worker to recover this module will fail if it is in OK state

CLI Examples:

```
salt '*' modjk.worker_recover node1 loadbalancer1
salt modjk.worker_recover node1 loadbalancer1 other-profile
```

salt.modules.modjk.worker_status(worker, profile='default')
Return the state of the worker

CLI Examples:

```
salt '*' modjk.worker_status node1
salt '*' modjk.worker_status node1 other-profile
```

salt.modules.modjk.worker_stop(worker, lbn, profile='default')
Set the worker to stopped state in the lbn load balancer

CLI Examples:

```
salt '*' modjk.worker_activate node1 loadbalancer1
salt '*' modjk.worker_activate node1 loadbalancer1 other-profile
```

salt.modules.modjk.workers(profile='default')
Return a list of member workers and their status

CLI Examples:

```
salt '*' modjk.workers
salt '*' modjk.workers other-profile
```

13.6.183 salt.modules.mongodb

Module to provide MongoDB functionality to Salt

**configuration** This module uses PyMongo, and accepts configuration details as parameters as well as configuration settings:

```
mongodb.host: 'localhost'
mongodb.port: 27017
mongodb.user: '
mongodb.password: ''
```

This data can also be passed into pillar. Options passed into opts will overwrite options passed into pillar.

salt.modules.mongodb.db_exists(name, user=None, password=None, host=None, port=None)
Checks if a database exists in Mongoddb

CLI Example:
**Salt Documentation, Release 2016.3.6**

```bash
salt '*' mongodb.db_exists <name> <user> <password> <host> <port>
```

**salt.modules.mongodb.db_list**(user=None, password=None, host=None, port=None)

List all Mongodb databases

CLI Example:

```bash
salt '*' mongodb.db_list <user> <password> <host> <port>
```

**salt.modules.mongodb.db_remove**(name, user=None, password=None, host=None, port=None)

Remove a Mongodb database

CLI Example:

```bash
salt '*' mongodb.db_remove <name> <user> <password> <host> <port>
```

**salt.modules.mongodb.find**(collection, query=None, user=None, password=None, host=None, port=None, database='admin')

Find an object or list of objects in a collection

CLI Example:

```bash
salt '*' mongodb.find mycollection '[["foo": "FOO", "bar": "BAR"]]' <user> <password> <host> <port> <database>
```

**salt.modules.mongodb.insert**(objects, collection, user=None, password=None, host=None, port=None, database='admin')

Insert an object or list of objects into a collection

CLI Example:

```bash
salt '*' mongodb.insert '[["foo": "FOO", "bar": "BAR"], "foo": "BAZ", "bar": "BAM"]]' mycollection <user> <password> <host> <port> <database>
```

**salt.modules.mongodb.remove**(collection, query=None, user=None, password=None, host=None, port=None, database='admin', w=1)

Remove an object or list of objects into a collection

CLI Example:

```bash
salt '*' mongodb.remove mycollection '[["foo": "FOO", "bar": "BAR"], "foo": "BAZ", "bar": "BAM"]]' <user> <password> <host> <port> <database>
```

**salt.modules.mongodb.user_create**(name, passwd, user=None, password=None, host=None, port=None, database='admin')

Create a Mongodb user

CLI Example:

```bash
salt '*' mongodb.user_create <name> <user> <password> <host> <port> <database>
```

**salt.modules.mongodb.user_exists**(name, user=None, password=None, host=None, port=None, database='admin')

Checks if a user exists in Mongodb

CLI Example:

```bash
salt '*' mongodb.user_exists <name> <user> <password> <host> <port> <database>
```
The `salt.modules.mongodb.user_grant_roles` function is used to grant one or many roles to a MongoDB user:

```python
salt.modules.mongodb.user_grant_roles(name, roles, database, user=None, password=None, host=None, port=None)
```

**CLI Examples:**

- `salt '*' mongodb.user_grant_roles johndoe ['"readWrite"'] dbname admin adminpwd localhost 27017`
- `salt '*' mongodb.user_grant_roles janedoe [{'"role": "readWrite", "db": "dbname"} ←, {'"role": "read", "db": "otherdb"}]' dbname admin adminpwd localhost 27017`

The `salt.modules.mongodb.user_list` function lists users of a MongoDB database:

```python
salt.modules.mongodb.user_list(user=None, password=None, host=None, port=None, database='admin')
```

**CLI Example:**

- `salt '*' mongodb.user_list <user> <password> <host> <port> <database>`

The `salt.modules.mongodb.user_remove` function removes a MongoDB user:

```python
salt.modules.mongodb.user_remove(name, user=None, password=None, host=None, port=None, database='admin')
```

**CLI Example:**

- `salt '*' mongodb.user_remove <name> <user> <password> <host> <port> <database>`

The `salt.modules.mongodb.user_revoke_roles` function revokes one or many roles to a MongoDB user:

```python
salt.modules.mongodb.user_revoke_roles(name, roles, database, user=None, password=None, host=None, port=None)
```

**CLI Examples:**

- `salt '*' mongodb.user_revoke_roles johndoe ['"readWrite"'] dbname admin adminpwd localhost 27017`
- `salt '*' mongodb.user_revoke_roles janedoe [{'"role": "readWrite", "db": "dbname"} ←, {'"role": "read", "db": "otherdb"}]' dbname admin adminpwd localhost 27017`

The `salt.modules.mongodb.user_roles_exists` function checks if a user of a MongoDB database has specified roles:

```python
salt.modules.mongodb.user_roles_exists(name, roles, database, user=None, password=None, host=None, port=None)
```

**CLI Examples:**

- `salt '*' mongodb.user_roles_exists johndoe ['"readWrite"'] dbname admin adminpwd localhost 27017`
- `salt '*' mongodb.user_roles_exists johndoe [{'"role": "readWrite", "db": "dbname"} ←, {'"role": "read", "db": "otherdb"}]' dbname admin adminpwd localhost 27017`

### 13.6.184 salt.modules.monit

Monit service module. This module will create a monit type service watcher.

```python
salt.modules.monit.configtest()
```

New in version 2016.3.0.
Test monit configuration syntax

CLI Example:

```
salt '*' monit.configtest
```

salt.modules.monit.id(reset=False)

New in version 2016.3.0.

Return monit unique id.
reset [False] Reset current id and generate a new id when it's True.

CLI Example:

```
salt '*' monit.id [reset=True]
```

salt.modules.monit.monitor(name)

monitor service via monit

CLI Example:

```
salt '*' monit.monitor <service name>
```

salt.modules.monit.reload()

New in version 2016.3.0.

Reload monit configuration

CLI Example:

```
salt '*' monit.reload
```

salt.modules.monit.restart(name)

Restart service via monit

CLI Example:

```
salt '*' monit.restart <service name>
```

salt.modules.monit.start(name)

CLI Example:

```
salt '*' monit.start <service name>
```

salt.modules.monit.status(svc_name='')

Display a process status from monit

CLI Example:

```
salt '*' monit.status
salt '*' monit.status <service name>
```

salt.modules.monit.stop(name)

Stops service via monit

CLI Example:

```
salt '*' monit.stop <service name>
```

salt.modules.monit.summary(svc_name='')

Display a summary from monit
CLI Example:
```
salt '*' monit.summary
salt '*' monit.summary <service name>
```

```
salt.modules.monit.unmonitor(name)
Unmonitor service via monit
```

CLI Example:
```
salt '*' monit.unmonitor <service name>
```

```
salt.modules.monit.validate()
New in version 2016.3.0.
Check all services
```

CLI Example:
```
salt '*' monit.validate
```

```
salt.modules.monit.version()
New in version 2016.3.0.
Return version from monit -V
```

CLI Example:
```
salt '*' monit.version
```

### 13.6.185 `salt.modules.moosefs`

Module for gathering and managing information about MooseFS

```
salt.modules.moosefs.dirinfo(path, opts=None)
Return information on a directory located on the Moose
```

CLI Example:
```
salt '*' moosefs.dirinfo /path/to/dir/ [-n][h|H]]
```

```
salt.modules.moosefs.fileinfo(path)
Return information on a file located on the Moose
```

CLI Example:
```
salt '*' moosefs.fileinfo /path/to/dir/
```

```
salt.modules.moosefs.getgoal(path, opts=None)
Return goal(s) for a file or directory
```

CLI Example:
```
salt '*' moosefs.getgoal /path/to/file [-n][h|H]]
salt '*' moosefs.getgoal /path/to/dir/ [-n][h|H][r]
```

```
salt.modules.moosefs.mounts()
Return a list of current MooseFS mounts
```

CLI Example:
13.6.186 salt.modules.mount

Salt module to manage Unix mounts and the fstab file

salt.modules.mount.active(extended=False)
List the active mounts.

CLI Example:

```
salt '*' mount.active
```

salt.modules.mount.automaster(config='/etc/auto_salt')
List the contents of the auto master

CLI Example:

```
salt '*' mount.automaster
```

salt.modules.mount.fstab(config='/etc/fstab')
Changed in version 2016.3.2.
List the contents of the fstab

CLI Example:

```
salt '*' mount.fstab
```

salt.modules.mount.is_fuse_exec(cmd)
Returns true if the command passed is a fuse mountable application.

CLI Example:

```
salt '*' mount.is_fuse_exec sshfs
```

salt.modules.mount.is_mounted(name)
New in version 2014.7.0.
Provide information if the path is mounted

CLI Example:

```
salt '*' mount.is_mounted /mnt/share
```

salt.modules.mount.mount(name, device, mkmnt=False, fstype='', opts='defaults', user=None, util='mount')
Mount a device

CLI Example:

```
salt '*' mount.mount /mnt/foo /dev/sdz1 True
```

salt.modules.mount.remount(name, device, mkmnt=False, fstype='', opts='defaults', user=None)
Attempt to remount a device, if the device is not already mounted, mount is called

CLI Example:
**salt**

```python
salt '*' mount.remount /mnt/foo /dev/sdz1 True
```

**salt.modules.mount.rm_automaster**(name, device, config='''/etc/auto_salt')

Remove the mount point from the auto_master

CLI Example:

```python
salt '*' mount.rm_automaster /mnt/foo /dev/sdg
```

**salt.modules.mount.rm_fstab**(name, device, config='''/etc/fstab')

Changed in version 2016.3.2.

Remove the mount point from the fstab

CLI Example:

```python
salt '*' mount.rm_fstab /mnt/foo /dev/sdg
```

**salt.modules.mount.rm_vfstab**(name, device, config='''/etc/vfstab')

New in version 2016.3.2.

Remove the mount point from the vfstab

CLI Example:

```python
salt '*' mount.rm_vfstab /mnt/foo /device/c0t0d0p0
```

**salt.modules.mount.set_automaster**(name, device, fstype, opts='''', config='''/etc/auto_salt', test=False, **kwargs)

Verify that this mount is represented in the auto_salt, change the mount to match the data passed, or add the mount if it is not present.

CLI Example:

```python
salt '*' mount.set_automaster /mnt/foo /dev/sdz1 ext4
```

**salt.modules.mount.set_fstab**(name, device, fstype, opts=''' defaults'', dump=0, pass_num=0, config='''/etc/fstab', test=False, match_on='''auto'', **kwargs)

Verify that this mount is represented in the fstab, change the mount to match the data passed, or add the mount if it is not present.

CLI Example:

```python
salt '*' mount.set_fstab /mnt/foo /dev/sdz1 ext4
```

**salt.modules.mount.set_vfstab**(name, device, fstype, opts=''' -'', device_fsck=''' -'', pass_fsck=''' -'', mount_at_boot='''yes'', config='''/etc/vfstab', test=False, match_on='''auto'', **kwargs)

.. versionadded:: 2016.3.2 Verify that this mount is represented in the vfstab, change the mount to match the data passed, or add the mount if it is not present.

CLI Example:

```python
salt '*' mount.set_vfstab /mnt/foo /device/c0t0d0p0 ufs
```

**salt.modules.mount.swapoff**(name)

Deactivate a named swap mount

Changed in version 2016.3.2.

CLI Example:
Salt Documentation, Release 2016.3.6

```shell
salt '*' mount.swapoff /root/swapfile
```

**salt.modules.mount.swapon**(name, priority=None)
Activate a swap disk

Changed in version 2016.3.2.

CLI Example:
```
salt '*' mount.swapon /root/swapfile
```

**salt.modules.mount.swaps()**
Return a dict containing information on active swap

Changed in version 2016.3.2.

CLI Example:
```
salt '*' mount.swaps
```

**salt.modules.mount.umount**(name, device=None, user=None, util='mount')
Attempt to unmount a device by specifying the directory it is mounted on

CLI Example:
```
salt '*' mount.umount /mnt/foo
```

New in version 2015.5.0.
```
salt '*' mount.umount /mnt/foo /dev/xvdc1
```

**salt.modules.mount.vfstab**(config='/etc/vfstab')
List the contents of the vfstab

New in version 2016.3.2.
```
salt '*' mount.vfstab
```

13.6.187  **salt.modules.mssql**

Module to provide MS SQL Server compatibility to salt.

**depends**
- FreeTDS
- pymssql Python module

**configuration** In order to connect to MS SQL Server, certain configuration is required in minion configs/pillars on the relevant minions. Some sample pillars might look like:

```yaml
mssql.server: 'localhost'
mssql.port: 1433
mssql.user: 'sysdba'
mssql.password: 'Some preferable complex password'
mssql.database: '
```
The default for the port is `1433' and for the database is `'(empty string); in most cases they can be left at the default setting. Options that are directly passed into functions will overwrite options from configs or pillars.

```python
salt.modules.mssql.db_exists(database_name, **kwargs)
Find if a specific database exists on the MS SQL server.

CLI Example:
```
salt minion mssql.db_exists database_name='DBNAME'
```

```python
salt.modules.mssql.db_list(**kwargs)
Return the database list created on a MS SQL server.

CLI Example:
```
salt minion mssql.db_list
```

```python
salt.modules.mssql.db_remove(database_name, **kwargs)
Drops a specific database from the MS SQL server. It will not drop any of `master', `model', `msdb' or `tempdb'.

CLI Example:
```
salt minion mssql.db_remove database_name='DBNAME'
```

```python
salt.modules.mssql.login_exists(login, **kwargs)
Find if a login exists in the MS SQL server.

CLI Example:
```
salt minion mssql.login_exists 'LOGIN'
```

```python
salt.modules.mssql.role_create(role, owner=None, **kwargs)
Creates a new database role. If no owner is specified, the role will be owned by the user that executes CREATE ROLE, which is the user argument or mssql.user option.

CLI Example:
```
salt minion mssql.role_create role=product01 owner=sysdba
```

```python
salt.modules.mssql.role_exists(role, **kwargs)
Checks if a role exists.

CLI Example:
```
salt minion mssql.role_exists db_owner
```

```python
salt.modules.mssql.role_list(**kwargs)
Lists database roles.

CLI Example:
```
salt minion mssql.role_list
```

```python
salt.modules.mssql.role_remove(role, **kwargs)
Remove a database role.

CLI Example:
```
**salt minion mssql.role_create** role=test_role01

```python
salt.modules.mssql.tsql_query(query, **kwargs)
```

Run a SQL query and return query result as list of tuples, or a list of dictionaries if as_dict was passed, or an empty list if no data is available.

CLI Example:
```
salt minion mssql.tsql_query 'SELECT @@version as version' as_dict=True
```

**salt.modules.mssql.user_create**(username, new_login_password=None, **kwargs)

Creates a new user. If new_login_password is not specified, the user will be created without a login.

CLI Example:
```
salt minion mssql.user_create USERNAME database=DBNAME [new_login_password=PASSWORD]
```

**salt.modules.mssql.user_exists**(username, **kwargs)

Find if an user exists in a specific database on the MS SQL server.

**Note:** database argument is mandatory

CLI Example:
```
salt minion mssql.user_exists 'USERNAME' [database='DBNAME']
```

**salt.modules.mssql.user_list**(**kwargs)

Get the user list for a specific database on the MS SQL server.

CLI Example:
```
salt minion mssql.user_list [database='DBNAME']
```

**salt.modules.mssql.user_remove**(username, **kwargs)

Removes an user.

CLI Example:
```
salt minion mssql.user_remove USERNAME database=DBNAME
```

**salt.modules.mssql.version**(**kwargs)**

Return the version of a MS SQL server.

CLI Example:
```
salt minion mssql.version
```

### 13.6.188 salt.modules.munin

Run munin plugins/checks from salt and format the output as data.

**salt.modules.munin.list_plugins()**

List all the munin plugins

CLI Example:
```
salt '*' munin.list_plugins
```
salt.modules.munin.run(plugins)
Run one or more named munin plugins

CLI Example:
```
salt '*' munin.run uptime
salt '*' munin.run uptime,cpu,load,memory
```

salt.modules.munin.run_all()
Run all the munin plugins

CLI Example:
```
salt '*' munin.run_all
```

13.6.189 salt.modules.mysql

Module to provide MySQL compatibility to salt.

depends

• MySQLdb Python module

Note: On CentOS 5 (and possibly RHEL 5) both MySQL-python and python26-mysqldb need to be installed.

configuration In order to connect to MySQL, certain configuration is required in /etc/salt/minion on the relevant minions. Some sample configs might look like:

```
mysql.host: 'localhost'
mysql.port: 3306
mysql.user: 'root'
mysql.pass: ''
mysql.db: 'mysql'
mysql.unix_socket: '/tmp/mysql.sock'
mysql.charset: 'utf8'
```

You can also use a defaults file:
```
mysql.default_file: '/etc/mysql/debian.cnf'
```

Changed in version 2014.1.0: `charset` connection argument added. This is a MySQL charset, not a python one.

Changed in version 0.16.2: Connection arguments from the minion config file can be overridden on the CLI by using the arguments defined here. Additionally, it is now possible to setup a user with no password.

salt.modules.mysql.alter_db(name, character_set=None, collate=None, **connection_args)
Modify database using `ALTER DATABASE %(dbname)s CHARACTER SET %(charset)s COLLATE %(collation)s;` query.

CLI Example:
```
salt '*' mysql.alter_db testdb charset='latin1'
```

salt.modules.mysql.db_check(name, table=None, **connection_args)
Repairs the full database or just a given table

CLI Example:
salt ' '*' mysql.db_check dbname
salt ' '*' mysql.db_check dbname dbtable

salt.modules.mysql.db_create(name, character_set=None, collate=None, **connection_args)
Add a databases to the MySQL server.

name The name of the database to manage
character_set The character set, if left empty the MySQL default will be used
collate The collation, if left empty the MySQL default will be used

CLI Example:
salt ' '*' mysql.db_create 'dbname'
salt ' '*' mysql.db_create 'dbname' 'utf8' 'utf8_general_ci'

salt.modules.mysql.db_exists(name, **connection_args)
Checks if a database exists on the MySQL server.

CLI Example:
salt ' '*' mysql.db_exists 'dbname'

salt.modules.mysql.db_get(name, **connection_args)
Return a list of databases of a MySQL server using the output from the SELECT DEFAULT_CHARACTER_SET_NAME,DEFAULT_COLLATION_NAME FROM INFORMATION_SCHEMA.SCHEMATA WHERE SCHEMA_NAME='dbname'; query.

CLI Example:
salt ' '*' mysql.db_get test

salt.modules.mysql.db_list(**connection_args)
Return a list of databases of a MySQL server using the output from the SHOW DATABASES query.

CLI Example:
salt ' '*' mysql.db_list

salt.modules.mysql.db_optimize(name, table=None, **connection_args)
Optimizes the full database or just a given table

CLI Example:
salt ' '*' mysql.db_optimize dbname

salt.modules.mysql.db_remove(name, **connection_args)
Removes a databases from the MySQL server.

CLI Example:
salt ' '*' mysql.db_remove 'dbname'

salt.modules.mysql.db_repair(name, table=None, **connection_args)
Repairs the full database or just a given table

CLI Example:
salt ' '*' mysql.db_repair dbname

salt.modules.mysql.db_tables(name, **connection_args)
Shows the tables in the given MySQL database (if exists)
CLI Example:

```
salt '*' mysql.db_tables 'database'
```

```
salt.modules.mysql.free_slave(**connection_args)

Frees a slave from its master. This is a WIP, do not use.
```

CLI Example:

```
salt '*' mysql.free_slave
```

```
salt.modules.mysql.get_master_status(**connection_args)

Retrieves the master status from the minion.

Returns:

```
{
'host.domain.com': {
'Binlog_Do_DB': '',
'Binlog_Ignore_DB': '',
'File': 'mysql-bin.000021',
'Position': 107}
}
```

CLI Example:

```
salt '*' mysql.get_master_status
```

```
salt.modules.mysql.get_slave_status(**connection_args)

Retrieves the slave status from the minion.

Returns:

```
{
'host.domain.com': {
'Connect_Retry': 60,
'Exec_Master_Log_Pos': 107,
'Last_Errno': 0,
'Last_Error': '',
'Last_IO_Errno': 0,
'Last_IO_Error': '',
'Last_SQL_Errno': 0,
'Last_SQL_Error': '',
'Master_Host': 'comet.scion-eng.com',
'Master_Log_File': 'mysql-bin.000021',
'Master_Port': 3306,
'Master_SSL_Allowed': 'No',
'Master_SSL_CA_File': '',
'Master_SSL_CA_Path': '',
'Master_SSL_Cert': '',
'Master_SSL_Cipher': '',
'Master_SSL_Cert': '',
'Master_SSL_Cipher': '',
'Master_SSL_Cert': '',

```

13.6. execution modules
CLI Example:
```
salt '*' mysql.get_slave_status
```

salt.modules.mysql.grant_add(grant, database, user, host=’localhost’, grant_option=False, escape=True, ssl_option=False, **connection_args)

Adds a grant to the MySQL server.

For database, make sure you specify database.table or database.*

CLI Example:
```
salt '*' mysql.grant_add 'SELECT,INSERT,UPDATE,...' 'database.*' 'frank' 'localhost'
```

salt.modules.mysql.grant_exists(grant, database, user, host=’localhost’, grant_option=False, escape=True, **connection_args)

Checks to see if a grant exists in the database

CLI Example:
```
salt '*' mysql.grant_exists 'SELECT,INSERT,UPDATE,...' 'database.*' 'frank' 'localhost'
```

salt.modules.mysql.grant_revoke(grant, database, user, host=’localhost’, grant_option=False, escape=True, **connection_args)

Removes a grant from the MySQL server.

CLI Example:
```
salt '*' mysql.grant_revoke 'SELECT,INSERT,UPDATE' 'database.*' 'frank' 'localhost'
```

salt.modules.mysql.processlist(**connection_args)

Retrieves the processlist from the MySQL server via `"SHOW FULL PROCESSLIST"`.

Returns: a list of dicts, with each dict representing a process:
```
```

CLI Example:
```
salt '*' mysql.processlist
```

salt.modules.mysql.query(database, query, **connection_args)

Run an arbitrary SQL query and return the results or the number of affected rows.

CLI Example:
salt '*' mysql.query mydb "UPDATE mytable set myfield=1 limit 1"

Return data:

```json
{'query time': {'human': '39.0ms', 'raw': '0.03899'}, 'rows affected': 1L}
```

CLI Example:
salt '*' mysql.query mydb "SELECT id,name,cash from users limit 3"

Return data:

```json
{'columns': ('id', 'name', 'cash'),
 'query time': {'human': '1.0ms', 'raw': '0.001'},
 'results': ([1L, 'User 1', Decimal('110.000000')],
             [2L, 'User 2', Decimal('215.636756')],
             [3L, 'User 3', Decimal('0.040000')]},
 'rows returned': 3L}
```

CLI Example:
salt '*' mysql.query mydb 'INSERT into users values (null,"user 4", 5)'

Return data:

```json
{'query time': {'human': '25.6ms', 'raw': '0.02563'}, 'rows affected': 1L}
```

CLI Example:
salt '*' mysql.query mydb 'DELETE from users where id = 4 limit 1'

Return data:

```json
{'query time': {'human': '39.0ms', 'raw': '0.03899'}, 'rows affected': 1L}
```

Jinja Example: Run a query on `mydb` and use row 0, column 0's data.

```python
{{ salt['mysql.query']('mydb', 'SELECT info from mytable limit 1')['results']
                          [0][0] }}
```

salt.modules.mysql.quote_identifier( identifier, for_grants=True)

Return an identifier name (column, table, database, etc) escaped for MySQL.

This means means surrounded by ```''``` character and escaping this character inside. It also means doubling the `%` character for MySQLdb internal usage.

**Parameters**

- **identifier** -- the table, column or database identifier
- **for_grants** -- is `True` by default, when using database names on grant queries you should set it to `True` to also escape ```'``` and ```%``` characters as requested by MySQL. Note that these characters should only be escaped when requesting grants on the database level (```my_%db:``) but not for table level grants (```my_%db:`foo```) 

CLI Example:
salt '*' mysql.quote_identifier 'foo%bar'
**salt.modules.mysql.showglobal(“connection_args”)**
Retrieves the show global variables from the minion.

**Returns:** show global variables full dict

CLI Example:
```
salt '*' mysql.showglobal
```

**salt.modules.mysql.showvariables(“connection_args”)**
Retrieves the show variables from the minion.

**Returns:** show variables full dict

CLI Example:
```
salt '*' mysql.showvariables
```

**salt.modules.mysql.slave_lag(“connection_args”)**
Return the number of seconds that a slave SQL server is lagging behind the master, if the host is not a slave it will return -1. If the server is configured to be a slave for replication but slave IO is not running then -2 will be returned. If there was an error connecting to the database or checking the slave status, -3 will be returned.

CLI Example:
```
salt '*' mysql.slave_lag
```

**salt.modules.mysql.status(“connection_args”)**
Return the status of a MySQL server using the output from the SHOW STATUS query.

CLI Example:
```
salt '*' mysql.status
```

**salt.modules.mysql.tokenize_grant(grant)**
External wrapper function

:param grant: :return: dict

CLI Example:
```
salt '*' mysql.tokenize_grant

   "GRANT SELECT, INSERT ON testdb.* TO
   
   ->'testuser'@'localhost'"
```

**salt.modules.mysql.user_chpass(user, host=’localhost’, password=None, password_hash=None, allow_passwordless=False, unix_socket=None, password_column=None, “connection_args”)**
Change password for a MySQL user

:param host: Host for which this user/password combo applies
:param password: The password to set for the new user. Will take precedence over the password_hash option if both are specified.
:param password_hash: The password in hashed form. Be sure to quote the password because YAML doesn’t like the *.

A password hash can be obtained from the mysql command-line client like so:
```
mysql> SELECT PASSWORD(‘mypass’);
+----------------------------------+|
| PASSWORD(‘mypass’)               |
+----------------------------------+|
| 6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4 |
+----------------------------------+|
1 row in set (0.00 sec)
```

allow_passwordless: If True, then password and password_hash can be omitted (or set to None) to permit a passwordless login.
New in version 0.16.2: The allow_passwordless option was added.

CLI Examples:

```
salt '*' mysql.user_chpass frank localhost newpassword
salt '*' mysql.user_chpass frank localhost password_hash='hash'
salt '*' mysql.user_chpass frank localhost allow_passwordless=True
```

```
salt.modules.mysql.user_create(user, host='localhost', password=None, password_hash=None, allow_passwordless=False, unix_socket=False, password_column=None, **connection_args)
```

Creates a MySQL user

- **host** Host for which this user/password combo applies
- **password** The password to use for the new user. Will take precedence over the password_hash option if both are specified.
- **password_hash** The password in hashed form. Be sure to quote the password because YAML doesn't like the *

A password hash can be obtained from the mysql command-line client like so:

```
mysql> SELECT PASSWORD('mypass');
+------------------------------------------+
| PASSWORD('mypass')                      |
| +6C989366EAF75BB670AD8EA7A7FC1176A95CEF4 |
+------------------------------------------+
1 row in set (0.00 sec)
```

- **allow_passwordless** If True, then password and password_hash can be omitted (or set to None) to permit a passwordless login.
- **unix_socket** If True and allow_passwordless is True then will be used unix_socket auth plugin.

New in version 0.16.2: The allow_passwordless option was added.

CLI Examples:

```
salt '*' mysql.user_create 'username' 'hostname' 'password'
salt '*' mysql.user_create 'username' 'hostname' password_hash='hash'
salt '*' mysql.user_create 'username' 'hostname' allow_passwordless=True
```

```
salt.modules.mysql.user_exists(user, host='localhost', password=None, password_hash=None, passwordless=False, unix_socket=False, password_column=None, **connection_args)
```

Checks if a user exists on the MySQL server. A login can be checked to see if passwordless login is permitted by omitting password and password_hash, and using passwordless=True.

New in version 0.16.2: The passwordless option was added.

CLI Example:

```
salt '*' mysql.user_exists 'username' 'hostname' 'password'
salt '*' mysql.user_exists 'username' 'hostname' password_hash='hash'
salt '*' mysql.user_exists 'username' passwordless=True
salt '*' mysql.user_exists 'username' password_column='authentication_string'
```

```
salt.modules.mysql.user_grants(user, host='localhost', **connection_args)
```

Shows the grants for the given MySQL user (if it exists)

CLI Example:

```
salt '*' mysql.user_grants 'frank' 'localhost'
```
salt.modules.mysql.

**user_info** *(user, host='localhost', **connection_args)***

Get full info on a MySQL user

CLI Example:

```
salt ' '*' mysql.user_info root localhost
```

**user_list** *(**connection_args)***

Return a list of users on a MySQL server

CLI Example:

```
salt ' '* mysql.user_list
```

**user_remove** *(user, host='localhost', **connection_args)***

Delete MySQL user

CLI Example:

```
salt ' '* mysql.user_remove frank localhost
```

**version** *(**connection_args)***

Return the version of a MySQL server using the output from the `SELECT VERSION()` query.

CLI Example:

```
salt ' '* mysql.version
```

### 13.6.190 salt.modules.nacl

This module helps include encrypted passwords in pillars, grains and salt state files.

**depends** libnacl, https://github.com/saltstack/libnacl

This is often useful if you wish to store your pillars in source control or share your pillar data with others that you trust. I don't advise making your pillars public regardless if they are encrypted or not.

When generating keys and encrypting passwords use `--local` when using salt-call for extra security. Also consider using just the salt runner `nacl` when encrypting pillar passwords.

The nacl lib uses 32byte keys, these keys are base64 encoded to make your life more simple. To generate your `key` or `keyfile` you can use:

```
salt-call --local nacl.keygen keyfile=/root/.nacl
```

Now with your key, you can encrypt some data:

```
salt-call --local nacl.enc mypass keyfile=/root/.nacl
```

To decrypt the data:

```
salt-call --local nacl.dec data='DRB7Q6/X5gGSRCTpZyxS6hX05LnJI4ivbmUlbWojllUA+uaVvou3vJ4=' keyfile=/root/.nacl
```

The following optional configurations can be defined in the minion or master config. Avoid storing the config in pillars!
When the key is defined in the master config you can use it from the nacl runner:

```
salt-run nacl.enc 'myotherpass'
```

Now you can create a pillar with protected data like:

```
pillarexample:
  user: root
  password: {{ salt.nacl.dec('DRB7Q6/X5gGSRCTpZyxS6hX05LnlJIJ4ivbmUlWj8llU4+uAvVvou3vJ4=') }}
```

Or do something interesting with grains like:

```
salt-call nacl.enc minionname:dbrole
AL24Z2C50lkReer3DuQTFdrNLchLuz3NGIhGjZkLtKRYry/b/CksWM809yskLwH2AVGVoEXI5jAa
salt minionname grains.setval role 'AL24Z2C50lkReer3DuQTFdrNLchLuz3NGIhGjZkLtKRYry/b/ CksWM809yskLwH2AVGVoEXI5jAa'

{% set r = grains.get('role') %}
{% set role = None %}
{% if r and 'nacl.dec' in salt %}
  {% set r = salt.nacl.dec(r,keyfile='/root/.nacl').split(':' %}
  {% if opts['id'] == r[0] %}
    {% set role = r[1] %}
  {% endif %}
  {% endif %}
base:
  '{%- if role %}'
  '{{ opts['id'] }}':
    - {{ role }}
  '{%- endif %}
```

Multi-line text items like certificates require a bit of extra work. You have to strip the new lines and replace them with ‘\n’ characters. Certificates specifically require some leading white space when calling nacl.enc so that the ‘---’ in the first line (commonly -----BEGIN CERTIFICATE-----) doesn’t get interpreted as an argument to nacl.enc. For instance if you have a certificate file that lives in cert.crt:

```
cert=$(cat cert.crt |awk '{printf "%s\n",$0} END {print "\"}'); salt-run nacl.enc "$cert"
```

Pillar data should look the same, even though the secret will be quite long. However, when calling multiline encrypted secrets from pillar in a state, use the following format to avoid issues with /n creating extra whitespace at the beginning of each line in the cert file:

```
secret.txt:
  file.managed:
    - template: jinja
      user: user
      group: group
      mode: 700
      contents: "{{- salt['pillar.get']('secret') }}"
```

13.6. execution modules
The `{{-` will tell jinja to strip the whitespace from the beginning of each of the new lines.

```python
salt.modules.nacl.dec(data, **kwargs)
```

Takes a key generated from `nacl.keygen` and decrypt some data.

CLI Examples:

```shell
salt-call --local nacl.dec pEXHQM6cuaF7A=
salt-call --local nacl.dec data='pEXHQM6cuaF7A=' keyfile=/root/.nacl
salt-call --local nacl.dec data='pEXHQM6cuaF7A=' key='cKEzd4kXsbeCE7/
 lTIqXwnUiD1ulg4NoeeYcCFpd9k='
```

```python
salt.modules.nacl.enc(data, **kwargs)
```

Takes a key generated from `nacl.keygen` and encrypt some data.

CLI Examples:

```shell
salt-call --local nacl.enc datatoenc
salt-call --local nacl.enc datatoenc keyfile=/root/.nacl
salt-call --local nacl.enc datatoenc key='cKEzd4kXsbeCE7/
 lTIqXwnUiD1ulg4NoeeYcCFpd9k='
```

```python
salt.modules.nacl.keygen(keyfile=None)
```

Use `libnacl` to generate a private key

CLI Examples:

```shell
salt-call --local nacl.keygen
salt-call --local nacl.keygen keyfile=/root/.nacl
salt-call --local --out=newline_values_only nacl.keygen > /root/.nacl
```

## 13.6.191 `salt.modules.nagios`

Run nagios plugins/checks from salt and get the return as data.

```python
salt.modules.nagios.list_plugins()
```

List all the nagios plugins

CLI Example:

```shell
salt '*' nagios.list_plugins
```

```python
salt.modules.nagios.retcde(plugin, args='`, key_name=None)
```

Run one nagios plugin and return retcode of the execution

```python
salt.modules.nagios.retcde_pillar(pillar_name)
```

Run one or more nagios plugins from pillar data and get the result of cmd.retcde. The pillar have to be in this format:

```yaml
webserver:
    - check_icmp: 8.8.8.8
    - check_icmp: google.com
Load:
    - check_load: -w 0.8 -c 1
APT:
    - check_apt
```
webserver is the role to check, the next keys are the group and the items the check with the arguments if needed

You must to group different checks (one or more) and always it will return the highest value of all the checks

CLI Example:

```
salt '*' nagios.retcode webserver
```

```
salt.modules.nagios.run(plugin, args='')
  Run nagios plugin and return all the data execution with cmd.run
```

CLI Example:

```
salt '*' nagios.run check_apt
salt '*' nagios.run check_icmp '8.8.8.8'
```

```
salt.modules.nagios.run_all(plugin, args='')
  Run nagios plugin and return all the data execution with cmd.run_all
```

```
salt.modules.nagios.run_all_pillar(pillar_name)
  Run one or more nagios plugins from pillar data and get the result of cmd.run_all The pillar have to be in this format:

```
------
webserver:
  Ping_google:
    - check_icmp: 8.8.8.8
    - check_icmp: google.com
  Load:
    - check_load: -w 0.8 -c 1
  APT:
    - check_apt
------
```

webserver is the role to check, the next keys are the group and the items the check with the arguments if needed

You have to group different checks in a group

CLI Example:

```
salt '*' nagios.run webserver
```

```
salt.modules.nagios.run_pillar(pillar_name)
  Run one or more nagios plugins from pillar data and get the result of cmd.run The pillar have to be in this format:

```
------
webserver:
  Ping_google:
    - check_icmp: 8.8.8.8
    - check_icmp: google.com
  Load:
    - check_load: -w 0.8 -c 1
  APT:
    - check_apt
------
```
webserver is the role to check, the next keys are the group and the items the check with the arguments if needed
You have to group different checks in a group

CLI Example:

```
salt '*' nagios.run webserver
```

### 13.6.192 salt.modules.nagios_rpc

Check Host & Service status from Nagios via JSON RPC.

New in version 2015.8.0.

salt.modules.nagios_rpc.host_status(hostname=None, **kwargs)

Check status of a particular host. By default statuses are returned in a numeric format.

- **hostname** The hostname to check the status of the service in Nagios.
- **numeric** Turn to false in order to return status in text format (‘OK’ instead of 0, ‘Warning’ instead of 1 etc)

**Returns** status: ‘OK’, ‘Warning’, ‘Critical’ or ‘Unknown’

CLI Example:

```
salt '*' nagios_rpc.host_status hostname=webserver.domain.com
salt '*' nagios_rpc.host_status hostname=webserver.domain.com numeric=False
```

salt.modules.nagios_rpc.service_status(hostname=None, service=None, **kwargs)

Check status of a particular service on a host on it in Nagios. By default statuses are returned in a numeric format.

- **hostname** The hostname to check the status of the service in Nagios.
- **service** The service to check the status of in Nagios.
- **numeric** Turn to false in order to return status in text format (‘OK’ instead of 0, ‘Warning’ instead of 1 etc)

**Returns** status: ‘OK’, ‘Warning’, ‘Critical’ or ‘Unknown’

CLI Example:

```
salt '*' nagios_rpc.service_status hostname=webserver.domain.com service='HTTP'
salt '*' nagios_rpc.service_status hostname=webserver.domain.com service='HTTP' numeric=False
```

### 13.6.193 salt.modules.netaddress

Module for getting information about network addresses.

New in version 2016.3.0.

- **depends** netaddr

salt.modules.netaddress.cidr_broadcast(cidr)

Get the broadcast address associated with a CIDR address.

CLI example:
salt modules.netaddress.cidr_netmask(cidr)
Get the netmask address associated with a CIDR address.

CLI example:
```
salt myminion netaddress.cidr_netmask 192.168.0.0/20
```

salt modules.netaddress.list_cidr_ips(cidr)
Get a list of IP addresses from a CIDR.

CLI example:
```
salt myminion netaddress.list_cidr_ips 192.168.0.0/20
```

salt modules.netaddress.list_cidr_ips_ipv6(cidr)
Get a list of IPv6 addresses from a CIDR.

CLI example:
```
salt myminion netaddress.list_cidr_ips_ipv6 192.168.0.0/20
```

13.6.194 salt.modules.netbsd_sysctl
Module for viewing and modifying sysctl parameters

salt.modules.netbsd_sysctl.assign(name, value)
Assign a single sysctl parameter for this minion

CLI Example:
```
salt '*' syslogd.assign net.inet.icmp.icmplim 50
```

salt.modules.netbsd_sysctl.get(name)
Return a single sysctl parameter for this minion

CLI Example:
```
salt '*' syslogd.get hw.physmem
```

salt.modules.netbsd_sysctl.persist(name, value, config='/etc/sysctl.conf')
Assign and persist a simple sysctl parameter for this minion

CLI Example:
```
salt '*' syslogd.persist net.inet.icmp.icmplim 50
```

salt.modules.netbsd_sysctl.show(config_file=False)
Return a list of sysctl parameters for this minion

CLI Example:
```
salt '*' syslogd.show
```
salt.modules.netbsdservice

The service module for NetBSD

**Important:** If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `service.start` is not available), see here.

salt.modules.netbsdservice.available(name)

Returns True if the specified service is available, otherwise returns False.

CLI Example:

```
salt '*' service.available sshd
```

salt.modules.netbsdservice.disable(name, **kwargs)

Disable the named service to start at boot

CLI Example:

```
salt '*' service.disable <service name>
```

salt.modules.netbsdservice.disabled(name)

Return True if the named service is enabled, false otherwise

CLI Example:

```
salt '*' service.disabled <service name>
```

salt.modules.netbsdservice.enable(name, **kwargs)

Enable the named service to start at boot

CLI Example:

```
salt '*' service.enable <service name>
```

salt.modules.netbsdservice.enabled(name, **kwargs)

Return True if the named service is enabled, false otherwise

CLI Example:

```
salt '*' service.enabled <service name>
```

salt.modules.netbsdservice.force_reload(name)

Force-reload the named service

CLI Example:

```
salt '*' service.force_reload <service name>
```

salt.modules.netbsdservice.get_all()

Return all available boot services

CLI Example:

```
salt '*' service.get_all
```

salt.modules.netbsdservice.get_disabled()

Return a set of services that are installed but disabled
CLI Example:
```
salt '*' service.get_disabled
```

salt.modules.netbsdservice.get_enabled()
Return a list of service that are enabled on boot

CLI Example:
```
salt '*' service.get_enabled
```

salt.modules.netbsdservice.missing(name)
The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:
```
salt '*' service.missing sshd
```

salt.modules.netbsdservice.reload(name)
Reload the named service

CLI Example:
```
salt '*' service.reload <service name>
```

salt.modules.netbsdservice.restart(name)
Restart the named service

CLI Example:
```
salt '*' service.restart <service name>
```

salt.modules.netbsdservice.start(name)
Start the specified service

CLI Example:
```
salt '*' service.start <service name>
```

salt.modules.netbsdservice.status(name, sig=None)
Return the status for a service, returns a bool whether the service is running.

CLI Example:
```
salt '*' service.status <service name>
```

salt.modules.netbsdservice.stop(name)
Stop the specified service

CLI Example:
```
salt '*' service.stop <service name>
```

13.6.196 salt.modules.netscaler

Module to provide Citrix Netscaler compatibility to Salt (compatible with netscaler 9.2+)

New in version 2015.2.0.

13.6. execution modules
depends

- nsnitro Python module

Note: You can install nsnitro using:

```bash
pip install nsnitro
```

configuration This module accepts connection configuration details either as parameters, or as configuration settings in `/etc/salt/minion` on the relevant minions

```yaml
netscaler.host: 1.2.3.4
netscaler.user: user
netscaler.pass: password
```

This data can also be passed into pillar. Options passed into opts will overwrite options passed into pillar.

CLI Examples Calls relying on configuration passed using `/etc/salt/minion`, grains, or pillars:

```bash
code-block:: bash
salt-call netscaler.server_exists server_name
```

Calls passing configuration as opts:

```bash
code-block:: bash
salt-call netscaler.server_exists server_name netscaler_host=1.2.3.4 netscaler_user=username netscaler_pass=password
```

```bash
code-block:: bash
salt-call netscaler.server_exists server_name netscaler_host=1.2.3.5 netscaler_user=username2 netscaler_pass=password2
```

```bash
code-block:: bash
salt-call netscaler.server_enable server_name2 netscaler_host=1.2.3.5
```

```python
salt.modules.netscaler.server_add(s_name, s_ip, s_state=None, **connection_args)
```

Add a server Note: The default server state is ENABLED

CLI Example:

```bash
salt '*' netscaler.server_add 'serverName' 'serverIpAddress'
```

```bash
salt '*' netscaler.server_add 'serverName' 'serverIpAddress' 'serverState'
```

```python
salt.modules.netscaler.server_delete(s_name, **connection_args)
```

Delete a server

CLI Example:

```bash
salt '*' netscaler.server_delete 'serverName'
```

```python
salt.modules.netscaler.server_disable(s_name, **connection_args)
```

Disable a server globally

CLI Example:

```bash
salt '*' netscaler.server_disable 'serverName'
```

```python
salt.modules.netscaler.server_enable(s_name, **connection_args)
```

Enables a server globally

CLI Example:
salt '*' netscaler.server_enable 'serverName'
salt.modules.netscaler.server_enabled(s_name, **connection_args)
    Check if a server is enabled globally
    CLI Example:
    salt '*' netscaler.server_enabled 'serverName'

salt.modules.netscaler.server_exists(s_name, ip=None, s_state=None, **connection_args)
    Checks if a server exists
    CLI Example:
    salt '*' netscaler.server_exists 'serverName'

salt.modules.netscaler.server_update(s_name, s_ip, **connection_args)
    Update a server's attributes
    CLI Example:
    salt '*' netscaler.server_update 'serverName' 'serverIP'

salt.modules.netscaler.service_disable(s_name, s_delay=None, **connection_args)
    Disable a service
    CLI Example:
    salt '*' netscaler.service_disable 'serviceName'
    salt '*' netscaler.service_disable 'serviceName' 'delayInSeconds'

salt.modules.netscaler.service_enable(s_name, **connection_args)
    Enable a service
    CLI Example:
    salt '*' netscaler.service_enable 'serviceName'

salt.modules.netscaler.service_exists(s_name, **connection_args)
    Checks if a service exists
    CLI Example:
    salt '*' netscaler.service_exists 'serviceName'

salt.modules.netscaler.service_up(s_name, **connection_args)
    Checks if a service is UP
    CLI Example:
    salt '*' netscaler.service_up 'serviceName'

salt.modules.netscaler.servicegroup_add(sg_name, sg_type='HTTP', **connection_args)
    Add a new service group If no service type is specified, HTTP will be used. Most common service types: HTTP, SSL, and SSL_BRIDGE
    CLI Example:
    salt '*' netscaler.servicegroup_add 'serviceGroupName'
    salt '*' netscaler.servicegroup_add 'serviceGroupName' 'serviceGroupType'
salt.modules.netscaler.servicegroup_delete

Delete a new service group

CLI Example:

```
salt '*' netscaler.servicegroup_delete 'serviceGroupName'
```

salt.modules.netscaler.servicegroup_exists

Checks if a service group exists

CLI Example:

```
salt '*' netscaler.servicegroup_exists 'serviceGroupName'
```

salt.modules.netscaler.servicegroup_server_add

Add a server:port member to a servicegroup

CLI Example:

```
salt '*' netscaler.servicegroup_server_add 'serviceGroupName' 'serverName'
    ! 'serverPort'
```

salt.modules.netscaler.servicegroup_server_delete

Remove a server:port member from a servicegroup

CLI Example:

```
salt '*' netscaler.servicegroup_server_delete 'serviceGroupName' 'serverName'
    ! 'serverPort'
```

salt.modules.netscaler.servicegroup_server_disable

Disable a server:port member of a servicegroup

CLI Example:

```
salt '*' netscaler.servicegroup_server_disable 'serviceGroupName' 'serverName'
    ! 'serverPort'
```

salt.modules.netscaler.servicegroup_server_enable

Enable a server:port member of a servicegroup

CLI Example:

```
salt '*' netscaler.servicegroup_server_enable 'serviceGroupName' 'serverName'
    ! 'serverPort'
```

salt.modules.netscaler.servicegroup_server_exists

Check if a server:port combination is a member of a servicegroup

CLI Example:

```
salt '*' netscaler.servicegroup_server_exists 'serviceGroupName' 'serverName'
    ! 'serverPort'
```
salt.modules.netscaler.servicegroup_server_up(sg_name, s_name, s_port, **connection_args)

Check if a server:port combination is in state UP in a servicegroup

CLI Example:

```python
salt '*' netscaler.servicegroup_server_up 'serviceGroupName' 'serverName' ~'serverPort'
```

salt.modules.netscaler.vserver_add(v_name, v_ip, v_port, v_type, **connection_args)

Add a new lb vserver

CLI Example:

```python
salt '*' netscaler.vserver_add 'vserverName' 'vserverIP' 'vserverPort' ~'vserverType'
salt '*' netscaler.vserver_add 'alex.patate.chaude.443' '1.2.3.4' '443' 'SSL'
```

salt.modules.netscaler.vserver_delete(v_name, **connection_args)

Delete a lb vserver

CLI Example:

```python
salt '*' netscaler.vserver_delete 'vserverName'
```

salt.modules.netscaler.vserver_exists(v_name, **connection_args)

Checks if a vserver exists

CLI Example:

```python
salt '*' netscaler.vserver_exists 'vserverName'
```

salt.modules.netscaler.vserver_servicegroup_add(v_name, sg_name, **connection_args)

Bind a servicegroup to a vserver

CLI Example:

```python
salt '*' netscaler.vserver_servicegroup_add 'vserverName' 'serviceGroupName'
```

salt.modules.netscaler.vserver_servicegroup_delete(v_name, sg_name, **connection_args)

Unbind a servicegroup from a vserver

CLI Example:

```python
salt '*' netscaler.vserver_servicegroup_delete 'vserverName' 'serviceGroupName'
```

salt.modules.netscaler.vserver_servicegroup_exists(v_name, sg_name, **connection_args)

Checks if a servicegroup is tied to a vserver

CLI Example:

```python
salt '*' netscaler.vserver_servicegroup_exists 'vserverName' 'serviceGroupName'
```

salt.modules.netscaler.vserver_sslcert_add(v_name, sc_name, **connection_args)

Binds a SSL certificate to a vserver

CLI Example:
salt '*' netscaler.vserver_sslcert_add 'vserverName' 'sslCertificateName'
salt.modules.netscaler.vserver_sslcert_delete(v_name, sc_name, **connection_args)
    Unbinds a SSL certificate from a vserver
    CLI Example:
    salt '*' netscaler.vserver_sslcert_delete 'vserverName' 'sslCertificateName'
salt.modules.netscaler.vserver_sslcert_exists(v_name, sc_name, **connection_args)
    Checks if a SSL certificate is tied to a vserver
    CLI Example:
    salt '*' netscaler.vserver_sslcert_exists 'vserverName' 'sslCertificateName'

13.6.197  salt.modules.network

Module for gathering and managing network information
salt.modules.network.active_tcp()
    Return a dict containing information on all of the running TCP connections (currently linux and solaris only)
    Changed in version 2015.8.4: Added support for SunOS
    CLI Example:
    salt '*' network.active_tcp
salt.modules.network.arp()
    Return the arp table from the minion
    Changed in version 2015.8.0: Added support for SunOS
    CLI Example:
    salt '*' network.arp
salt.modules.network.calc_net(ip_addr, netmask=None)
    Returns the CIDR of a subnet based on an IP address (CIDR notation supported) and optional netmask.
    CLI Example:
    salt '*' network.calc_net 172.17.0.5 255.255.255.240
    salt '*' network.calc_net 2a02:f6e:a000:80:84d8:8332:7866:4e07/64
    New in version 2015.8.0.
salt.modules.network.connect(host, port=None, **kwargs)
    Test connectivity to a host using a particular port from the minion.
    New in version 2014.7.0.
    CLI Example:
    salt '*' network.connect archlinux.org 80
    salt '*' network.connect archlinux.org 80 timeout=3
salt '*/' network.connect archlinux.org 80 timeout=3 family=ipv4
salt '*/' network.connect google-public-dns-a.google.com port=53 proto=udp timeout=3

salt.modules.network.convert_cidr(cidr)
returns the network and subnet mask of a cidr addr
New in version 2016.3.0.
CLI Example:
salt '*/' network.convert_cidr 172.31.0.0/16

salt.modules.network.default_route(family=None)
Return default route(s) from routing table
Changed in version 2015.8.0: Added support for SunOS (Solaris 10, Illumos, SmartOS)
CLI Example:
salt '*/' network.default_route

salt.modules.network.dig(host)
Performs a DNS lookup with dig
CLI Example:
salt '*/' network.dig archlinux.org

salt.modules.network.get_bufsize(iface)
Return network buffer sizes as a dict (currently linux only)
CLI Example:
salt '*/' network.get_bufsize eth0

salt.modules.network.get_hostname()
Get hostname
CLI Example:
salt '*/' network.get_hostname

salt.modules.network.get_route(ip)
Return routing information for given destination ip
New in version 2015.5.3.
Changed in version 2015.8.0: Added support for SunOS (Solaris 10, Illumos, SmartOS) Added support for OpenBSD
CLI Example:
salt '*/' network.get_route 10.10.10.10

salt.modules.network.hw_addr(iface)
Return the hardware address (a.k.a. MAC address) for a given interface
CLI Example:
salt '*' network.hw_addr eth0

salt.modules.network.hwaddr(iface)
This function is an alias of hw_addr.
Return the hardware address (a.k.a. MAC address) for a given interface

CLI Example:
salt '*' network.hw_addr eth0

salt.modules.network.in_subnet(cidr)
Returns True if host is within specified subnet, otherwise False.

CLI Example:
salt '*' network.in_subnet 10.0.0.0/16

salt.modules.network.interface(iface)
Return the inet address for a given interface

New in version 2014.7.0.

CLI Example:
salt '*' network.interface eth0

salt.modules.network.interface_ip(iface)
Return the inet address for a given interface

New in version 2014.7.0.

CLI Example:
salt '*' network.interface_ip eth0

salt.modules.network.interfaces()
Return a dictionary of information about all the interfaces on the minion

CLI Example:
salt '*' network.interfaces

salt.modules.network.ip_addrs(interface=None, include_loopback=False, cidr=None, type=None)
Returns a list of IPv4 addresses assigned to the host. 127.0.0.1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned. Providing a CIDR via `cidr='10.0.0.0/8'` will return only the addresses which are within that subnet. If `type` is `public`, then only public addresses will be returned. Ditto for `type='private'.

CLI Example:
salt '*' network.ip_addrs

salt.modules.network.ip_addrs6(interface=None, include_loopback=False, cidr=None)
Returns a list of IPv6 addresses assigned to the host. ::1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned. Providing a CIDR via `cidr='2000::/3'` will return only the addresses which are within that subnet.

CLI Example:
salt '.*' network.ip_addrs6

salt.modules.network.ip_in_subnet(ip_addr, cidr)
    Returns True if given IP is within specified subnet, otherwise False.

    CLI Example:
    ```
salt '.*' network.ip_in_subnet 172.17.0.4 172.16.0.0/12
    ```

salt.modules.network.ipaddr(interface=None, include_loopback=False, cidr=None, type=None)
    This function is an alias of ip_addrs.
    Returns a list of IPv4 addresses assigned to the host. 127.0.0.1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned. Providing a CIDR via `cidr='10.0.0.0/8'` will return only the addresses which are within that subnet. If `type` is `public`, then only public addresses will be returned. Ditto for `type='private'`.

    CLI Example:
    ```
salt '.*' network.ip_addr
    ```

salt.modules.network.ipaddr6(interface=None, include_loopback=False, cidr=None)
    This function is an alias of ip_addrs6.
    Returns a list of IPv6 addresses assigned to the host. ::1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned. Providing a CIDR via `cidr='2000::/3'` will return only the addresses which are within that subnet.

    CLI Example:
    ```
salt '.*' network.ip_addrs6
    ```

salt.modules.network.is_loopback(ip_addr)
    Check if the given IP address is a loopback address

    New in version 2014.7.0.
    Changed in version 2015.8.0: IPv6 support

    CLI Example:
    ```
salt '.*' network.is_loopback 127.0.0.1
    ```

salt.modules.network.is_private(ip_addr)
    Check if the given IP address is a private address

    New in version 2014.7.0.
    Changed in version 2015.8.0: IPv6 support

    CLI Example:
    ```
salt '.*' network.is_private 10.0.0.3
    ```

salt.modules.network.mod_bufsize(iface, *args, **kwargs)
    Modify network interface buffers (currently linux only)

    CLI Example:
    ```
salt '.*' network.mod_bufsize tx=<val> rx=<val> rx-mini=<val> rx-jumbo=<val>
    ```
salt.modules.network.mod_hostname(hostname)
Modify hostname

Changed in version 2015.8.0: Added support for SunOS (Solaris 10, Illumos, SmartOS)

CLI Example:
salt '*' network.mod_hostname master.saltstack.com

salt.modules.network.netstat()
Return information on open ports and states

**Note:** On BSD minions, the output contains PID info (where available) for each netstat entry, fetched from sockstat/fstat output.

Changed in version 2014.1.4: Added support for OpenBSD, FreeBSD, and NetBSD
Changed in version 2015.8.0: Added support for SunOS

CLI Example:
salt '*' network.netstat

salt.modules.network.ping(host, timeout=False, return_boolean=False)
Performs an ICMP ping to a host

Changed in version 2015.8.0: Added support for SunOS

CLI Example:
salt '*' network.ping archlinux.org

New in version 2015.5.0.
Return a True or False instead of ping output.

salt '*' network.ping archlinux.org return_boolean=True

Set the time to wait for a response in seconds.

salt '*' network.ping archlinux.org timeout=3

salt.modules.network.reverse_ip(ip_addr)
Returns the reversed IP address

Changed in version 2015.8.0: IPv6 support

CLI Example:
salt '*' network.reverse_ip 172.17.0.4

salt.modules.network.routes(family=None)
Return currently configured routes from routing table

Changed in version 2015.8.0: Added support for SunOS (Solaris 10, Illumos, SmartOS)

CLI Example:
salt '*' network.routes
salt.modules.network.subnets

Returns a list of IPv4 subnets to which the host belongs

CLI Example:

```
salt '*' network.subnets
salt '*' network.subnets interfaces=eth1
```

salt.modules.network.subnets6()

Returns a list of IPv6 subnets to which the host belongs

CLI Example:

```
salt '*' network.subnets6
```

salt.modules.network.traceroute(host)

Performs a traceroute to a 3rd party host

Changed in version 2015.8.0: Added support for SunOS

CLI Example:

```
salt '*' network.traceroute archlinux.org
```

salt.modules.network.wol(mac, bcast='255.255.255.255', destport=9)

Send Wake On Lan packet to a host

CLI Example:

```
salt '*' network.wol 08-00-27-13-69-77
salt '*' network.wol 080027136977 255.255.255.255 7
salt '*' network.wol 08:00:27:13:69:77 255.255.255.255 7
```

13.6.198 salt.modules.neutron

Module for handling OpenStack Neutron calls

depends

- neutronclient Python module

configuration

This module is not usable until the user, password, tenant, and auth URL are specified either in a pillar or in the minion’s config file. For example:

```
keystone.user: 'admin'
keystone.password: 'password'
keystone.tenant: 'admin'
keystone.auth_url: 'http://127.0.0.1:5000/v2.0/
keystone.region_name: 'RegionOne'
keystone.service_type: 'network'
```

If configuration for multiple OpenStack accounts is required, they can be set up as different configuration profiles: For example:

```
openstack1:
    keystone.user: 'admin'
    keystone.password: 'password'
    keystone.tenant: 'admin'
    keystone.auth_url: 'http://127.0.0.1:5000/v2.0/
```
With this configuration in place, any of the neutron functions can make use of a configuration profile by declaring it explicitly. For example:

```
salt '*' neutron.network_list profile=openstack1
```

```
salt.modules.neutron.add_gateway_router(router, ext_network, profile=None)
```
Adds an external network gateway to the specified router

CLI Example:

```
salt '*' neutron.add_gateway_router router-name ext-network-name
```

Parameters

- **router** -- ID or name of the router
- **ext_network** -- ID or name of the external network the gateway
- **profile** -- Profile to build on (Optional)

Returns Added Gateway router information

```
salt.modules.neutron.add_interface_router(router, subnet, profile=None)
```
Adds an internal network interface to the specified router

CLI Example:

```
salt '*' neutron.add_interface_router router-name subnet-name
```

Parameters

- **router** -- ID or name of the router
- **subnet** -- ID or name of the subnet
- **profile** -- Profile to build on (Optional)

Returns Added interface information

```
salt.modules.neutron.create_firewall_rule(protocol, action, profile=None, **kwargs)
```
Creates a new firewall rule

CLI Example:

```
salt '*' neutron.create_firewall_rule protocol action
```

Parameters

- **protocol** -- Protocol for the firewall rule, choose `'tcp'`, `'udp'`, `'icmp'` or `None`.
- **action** -- Action for the firewall rule, choose `allow` or `deny`.
- **tenant_id** -- The owner tenant ID. (Optional)
- **name** -- Name for the firewall rule. (Optional)
- **description** -- Description for the firewall rule. (Optional)
- **ip_version** -- IP protocol version, default: 4. (Optional)
- **source_ip_address** -- Source IP address or subnet. (Optional)
- **destination_ip_address** -- Destination IP address or subnet. (Optional)
- **source_port** -- Source port (integer in [1, 65535] or range in a:b). (Optional)
- **destination_port** -- Destination port (integer in [1, 65535] or range in a:b). (Optional)
- **shared** -- Set shared to True, default: False. (Optional)
- **enabled** -- To enable this rule, default: True. (Optional)

```python
salt.modules.neutron.create_floatingip(floating_network, port=None, profile=None)
```

Creates a new floatingIP

**CLI Example:**

```
salt '*' neutron.create_floatingip network-name port-name
```

**Parameters**

- **floating_network** -- Network name or ID to allocate floatingIP from
- **port** -- Of the port to be associated with the floatingIP (Optional)
- **profile** -- Profile to build on (Optional)

**Returns**

Created floatingIP information

```python
salt.modules.neutron.create_ikepolicy(name, profile=None, **kwargs)
```

Creates a new IKEPolicy

**CLI Example:**

```
salt '*' neutron.create_ikepolicy ikepolicy-name
    phase1_negotiation_mode=main auth_algorithm=sha1
    encryption_algorithm=aes-128 pfs=group5
```

**Parameters**

- **name** -- Name of the IKE policy
- **phase1_negotiation_mode** -- IKE Phase1 negotiation mode in lowercase, default: main (Optional)
- **auth_algorithm** -- Authentication algorithm in lowercase, default: sha1 (Optional)
- **encryption_algorithm** -- Encryption algorithm in lowercase, default: aes-128 (Optional)
- **pfs** -- Perfect Forward Security in lowercase, default: group5 (Optional)
- **units** -- IKE lifetime attribute. default: seconds (Optional)
- **value** -- IKE lifetime attribute. default: 3600 (Optional)
- **ike_version** -- IKE version in lowercase, default: v1 (Optional)
- **profile** -- Profile to build on (Optional)
- **kwargs**

Returns Created IKE policy information

```python
salt.modules.neutron.create_ipsec_site_connection(
    name, ipsecpolicy, ikepolicy, vpnservice, peer_cidrs, peer_address,
    peer_id, psk, admin_state_up=True,
    profile=None, **kwargs)
```

Creates a new IPsecSiteConnection

CLI Example:

```bash
salt '*' neutron.show_ipsec_site_connection connection-name
ipsec-policy-name ikepolicy-name vpnservice-name
192.168.XXX.XXX/24 192.168.XXX.XXX 192.168.XXX.XXX secret
```

Parameters

- **name** -- Set friendly name for the connection
- **ipsecpolicy** -- IPSec policy ID or name associated with this connection
- **ikepolicy** -- IKE policy ID or name associated with this connection
- **vpnservice** -- VPN service instance ID or name associated with this connection
- **peer_cidrs** -- Remote subnet(s) in CIDR format
- **peer_address** -- Peer gateway public IPv4/IPv6 address or FQDN
- **peer_id** -- Peer router identity for authentication Can be IPv4/IPv6 address, e-mail address, key id, or FQDN
- **psk** -- Pre-shared key string
- **initiator** -- Initiator state in lowercase, default: bi-directional
- **admin_state_up** -- Set admin state up to true or false, default: True (Optional)
- **mtu** -- size for the connection, default: 1500 (Optional)
- **dpd_action** -- Dead Peer Detection attribute: hold/clear/disabled/restart/restart-by-peer (Optional)
- **dpd_interval** -- Dead Peer Detection attribute (Optional)
- **dpd_timeout** -- Dead Peer Detection attribute (Optional)
- **profile** -- Profile to build on (Optional)

Returns Created IPSec site connection information

```python
salt.modules.neutron.create_ipsecpolicy(
    name, profile=None, **kwargs)
```

Creates a new IPsecPolicy

CLI Example:

```bash
salt '*' neutron.create_ipsecpolicy ipsecpolicy-name
transform_protocol=esp auth_algorithm=sha1
encapsulation_mode=tunnel encryption_algorithm=aes-128
```

Parameters

- **name** -- Name of the IPSec policy
- `transform_protocol` -- Transform protocol in lowercase, default: esp (Optional)
- `auth_algorithm` -- Authentication algorithm in lowercase, default: sha1 (Optional)
- `encapsulation_mode` -- Encapsulation mode in lowercase, default: tunnel (Optional)
- `encryption_algorithm` -- Encryption algorithm in lowercase, default: aes-128 (Optional)
- `pfs` -- Perfect Forward Security in lowercase, default: group5 (Optional)
- `units` -- IPSec lifetime attribute. default: seconds (Optional)
- `value` -- IPSec lifetime attribute. default: 3600 (Optional)
- `profile` -- Profile to build on (Optional)

**Returns** Created IPSec policy information

```
salt.modules.neutron.create_network(name, router_ext=None, admin_state_up=True, network_type=None, physical_network=None, segmentation_id=None, shared=None, profile=None)
```

Creates a new network

**CLI Example:**

```
salt '*' neutron.create_network network-name
salt '*' neutron.create_network network-name profile=openstack1
```

**Parameters**

- `name` -- Name of network to create
- `admin_state_up` -- Should the state of the network be up? default: True (Optional)
- `router_ext` -- True then if create the external network (Optional)
- `network_type` -- The Type of network that the provider is such as GRE, VXLAN, VLAN, FLAT, or LOCAL (Optional)
- `physical_network` -- The name of the physical network as neutron knows it (Optional)
- `segmentation_id` -- The vlan id or GRE id (Optional)
- `shared` -- Is the network shared or not (Optional)
- `profile` -- Profile to build on (Optional)

**Returns** Created network information

```
salt.modules.neutron.create_port(name, network, device_id=None, admin_state_up=True, profile=None)
```

Creates a new port

**CLI Example:**

```
salt '*' neutron.create_port network-name port-name
```

**Parameters**

- `name` -- Name of port to create
- `network` -- Network name or ID
- `device_id` -- ID of device (Optional)
salt.modules.neutron.create_router

Creates a new router

CLI Example:
```
salt '*' neutron.create_router new-router-name
```

Parameters

- **name** -- Name of router to create (must be first)
- **ext_network** -- ID or name of the external for the gateway (Optional)
- **admin_state_up** -- Set admin state up to true or false, default: true (Optional)
- **profile** -- Profile to build on (Optional)

Returns

Created router information

salt.modules.neutron.create_security_group

Creates a new security group

CLI Example:
```
salt '*' neutron.create_security_group security-group-name
   --description='Security group for servers'
```

Parameters

- **name** -- Name of security group (Optional)
- **description** -- Description of security group (Optional)
- **profile** -- Profile to build on (Optional)

Returns

Created security group information

salt.modules.neutron.create_security_group_rule

Creates a new security group rule

CLI Example:
```
salt '*' neutron.show_security_group_rule security-group-rule-id
```

Parameters

- **security_group** -- Security group name or ID to add rule
- **remote_group_id** -- Remote security group name or ID to apply rule (Optional)
- **direction** -- Direction of traffic: ingress/egress, default: ingress (Optional)
- **protocol** -- Protocol of packet: null/icmp/tcp/udp, default: null (Optional)
- **port_range_min** -- Starting port range (Optional)
- **port_range_max** -- Ending port range (Optional)
- **ether-type** -- Ethernet type: IPv4 (default), IPv6
- `port_range_max` -- Ending port range (Optional)
- `ethertype` -- IPv4/IPv6, default: IPv4 (Optional)
- `profile` -- Profile to build on (Optional)

Returns Created security group rule information

```python
salt.modules.neutron.create_subnet(network, cidr, name=None, ip_version=4, profile=None)
```

Creates a new subnet

CLI Example:

```bash
salt '*' neutron.create_subnet network-name 192.168.1.0/24
```

Parameters

- `network` -- Network ID or name this subnet belongs to
- `cidr` -- CIDR of subnet to create (Ex. `192.168.1.0/24`)
- `name` -- Name of the subnet to create (Optional)
- `ip_version` -- Version to use, default is 4(IPv4) (Optional)
- `profile` -- Profile to build on (Optional)

Returns Created subnet information

```python
salt.modules.neutron.create_vpnservice(subnet, router, name, admin_state_up=True, profile=None)
```

Creates a new VPN service

CLI Example:

```bash
salt '*' neutron.create_vpnservice router-name name
```

Parameters

- `subnet` -- Subnet unique identifier for the VPN service deployment
- `router` -- Router unique identifier for the VPN service
- `name` -- Set a name for the VPN service
- `admin_state_up` -- Set admin state up to true or false, default:True (Optional)
- `profile` -- Profile to build on (Optional)

Returns Created VPN service information

```python
salt.modules.neutron.delete_firewall_rule(firewall_rule, profile=None)
```

Deletes the specified firewall_rule

CLI Example:

```bash
salt '*' neutron.delete_firewall_rule firewall-rule
```

Parameters

- `firewall_rule` -- ID or name of firewall rule to delete
- `profile` -- Profile to build on (Optional)

Returns True(Succeed) or False

```python
salt.modules.neutron.delete_floatingip(floatingip_id, profile=None)
```

Deletes the specified floating IP

CLI Example: 13.6. execution modules 1293
salt '*' neutron.delete_floatingip floatingip-id

Parameters
  • floatingip_id -- ID of floatingIP to delete
  • profile -- Profile to build on (Optional)

Returns True(Succeed) or False

salt.modules.neutron.delete_ikepolicy(ikepolicy, profile=None)

Deletes the specified IKEPolicy

CLI Example:
salt '*' neutron.delete_ikepolicy ikepolicy-name

Parameters
  • ikepolicy -- ID or name of IKE policy to delete
  • profile -- Profile to build on (Optional)

Returns True(Succeed) or False

salt.modules.neutron.delete_ipsec_site_connection(ipsec_site_connection, profile=None)

Deletes the specified IPsecSiteConnection

CLI Example:
salt '*' neutron.delete_ipsec_site_connection connection-name

Parameters
  • ipsec_site_connection -- ID or name of ipsec site connection to delete
  • profile -- Profile to build on (Optional)

Returns True(Succeed) or False

salt.modules.neutron.delete_ipsecpolicy(ipsecpolicy, profile=None)

Deletes the specified IPsecPolicy

CLI Example:
salt '*' neutron.delete_ipsecpolicy ipsecpolicy-name

Parameters
  • ipsecpolicy -- ID or name of IPSec policy to delete
  • profile -- Profile to build on (Optional)

Returns True(Succeed) or False

salt.modules.neutron.delete_network(network, profile=None)

Deletes the specified network

CLI Example:
salt '*' neutron.delete_network network-name
salt '*' neutron.delete_network network-name profile=openstack1

Parameters
  • network -- ID or name of network to delete
- **profile** -- Profile to build on (Optional)
- **Returns** True(Succeed) or False

salt.modules.neutron.delete_port(*port, profile=None*)

Deletes the specified port

CLI Example:

```bash
salt '*' neutron.delete_network port-name
salt '*' neutron.delete_network port-name profile=openstack1
```

Parameters

- **port** -- port name or ID
- **profile** -- Profile to build on (Optional)
- **Returns** True(Succeed) or False

salt.modules.neutron.delete_quota(*tenant_id, profile=None*)

Delete the specified tenant's quota value

CLI Example:

```bash
salt '*' neutron.update_quota tenant-id
salt '*' neutron.update_quota tenant-id profile=openstack1
```

Parameters

- **tenant_id** -- ID of tenant to quota delete
- **profile** -- Profile to build on (Optional)
- **Returns** True(Delete succeed) or False(Delete failed)

salt.modules.neutron.delete_router(*router, profile=None*)

Delete the specified router

CLI Example:

```bash
salt '*' neutron.delete_router router-name
```

Parameters

- **router** -- ID or name of router to delete
- **profile** -- Profile to build on (Optional)
- **Returns** True(Succeed) or False

salt.modules.neutron.delete_security_group(*security_group, profile=None*)

Deletes the specified security group

CLI Example:

```bash
salt '*' neutron.delete_security_group security-group-name
```

Parameters

- **security_group** -- ID or name of security group to delete
- **profile** -- Profile to build on (Optional)
- **Returns** True(Succeed) or False

salt.modules.neutron.delete_security_group_rule(*security_group_rule_id, profile=None*)

Deletes the specified security group rule
CLI Example:

```
salt '*' neutron.delete_security_group_rule security-group-rule-id
```

**Parameters**

- `security_group_rule_id` -- ID of security group rule to delete
- `profile` -- Profile to build on (Optional)

**Returns**

True(Succeed) or False

`salt.modules.neutron.delete_subnet(subnet, profile=None)`

Deletes the specified subnet

CLI Example:

```
salt '*' neutron.delete_subnet subnet-name
salt '*' neutron.delete_subnet subnet-name profile=openstack1
```

**Parameters**

- `subnet` -- ID or name of subnet to delete
- `profile` -- Profile to build on (Optional)

**Returns**

True(Succeed) or False

`salt.modules.neutron.delete_vpnservice(vpnservice, profile=None)`

Deletes the specified VPN service

CLI Example:

```
salt '*' neutron.delete_vpnservice vpnservice-name
```

**Parameters**

- `vpnservice` -- ID or name of vpn service to delete
- `profile` -- Profile to build on (Optional)

**Returns**

True(Succeed) or False

`salt.modules.neutron.get_quotas_tenant(profile=None)`

Fetches tenant info in server's context for following quota operation

CLI Example:

```
salt '*' neutron.get_quotas_tenant
salt '*' neutron.get_quotas_tenant profile=openstack1
```

**Parameters**

- `profile` -- Profile to build on (Optional)

**Returns**

Quotas information

`salt.modules.neutron.list_agents(profile=None)`

List agents.

CLI Example:

```
salt '*' neutron.list_agents
```

**Parameters**

- `profile` -- Profile to build on (Optional)

**Returns**

agents message.
**salt.modules.neutron.list_extensions**(profile=None)

Fetches a list of all extensions on server side

CLI Example:

```
salt '*' neutron.list_extensions
salt '*' neutron.list_extensions profile=openstack1
```

**Parameters** profile-- Profile to build on (Optional)

**Returns** List of extensions

**salt.modules.neutron.list_firewall_rules**(profile=None)

Fetches a list of all firewall rules for a tenant CLI Example:

```
salt '*' neutron.list_firewall_rules
```

**Parameters** profile-- Profile to build on (Optional)

**Returns** List of firewall rules

**salt.modules.neutron.list_firewalls**(profile=None)

Fetches a list of all firewalls for a tenant CLI Example:

```
salt '*' neutron.list_firewalls
```

**Parameters** profile-- Profile to build on (Optional)

**Returns** List of firewalls

**salt.modules.neutron.list_floatingips**(profile=None)

Fetch a list of all floatingIPs for a tenant

CLI Example:

```
salt '*' neutron.list_floatingips
salt '*' neutron.list_floatingips profile=openstack1
```

**Parameters** profile-- Profile to build on (Optional)

**Returns** List of floatingIP

**salt.modules.neutron.list_ikepolicies**(profile=None)

Fetches a list of all configured IKEPolicies for a tenant

CLI Example:

```
salt '*' neutron.list_ikepolicies
salt '*' neutron.list_ikepolicies profile=openstack1
```

**Parameters** profile-- Profile to build on (Optional)

**Returns** List of IKE policy

**salt.modules.neutron.list_ipsec_site_connections**(profile=None)

Fetches all configured IPsec Site Connections for a tenant

CLI Example:

```
salt '*' neutron.list_ipsec_site_connections
salt '*' neutron.list_ipsec_site_connections profile=openstack1
```

**Parameters** profile-- Profile to build on (Optional)

**Returns** List of IPSec site connection
salt.modules.neutron.list_ipsecpolicies(profile=None)
Fetched a list of all configured IPSecPolicies for a tenant

CLI Example:
```
salt '*' neutron.list_ipsecpolicies ipsecpolicy-name
salt '*' neutron.list_ipsecpolicies ipsecpolicy-name profile=openstack1
```

Parameters profile -- Profile to build on (Optional)
Returns List of IPSec policy

salt.modules.neutron.list_l3_agent_hosting_routers(router, profile=None)
List L3 agents hosting a router.

CLI Example:
```
salt '*' neutron.list_l3_agent_hosting_routers router
```

:param router: router name or ID to query.
:param profile: Profile to build on (Optional)
:return: L3 agents message.

salt.modules.neutron.list_networks(profile=None)
Fetched a list of all networks for a tenant

CLI Example:
```
salt '*' neutron.list_networks
salt '*' neutron.list_networks profile=openstack1
```

Parameters profile -- Profile to build on (Optional)
Returns List of network

salt.modules.neutron.list_ports(profile=None)
Fetched a list of all networks for a tenant

CLI Example:
```
salt '*' neutron.list_ports
salt '*' neutron.list_ports profile=openstack1
```

Parameters profile -- Profile to build on (Optional)
Returns List of port

salt.modules.neutron.list_quotas(profile=None)
Fetched all tenants quotas

CLI Example:
```
salt '*' neutron.list_quotas
salt '*' neutron.list_quotas profile=openstack1
```

Parameters profile -- Profile to build on (Optional)
Returns List of quotas

salt.modules.neutron.list_routers(profile=None)
Fetched a list of all routers for a tenant

CLI Example:
```
salt '*' neutron.list_routers
salt '*' neutron.list_routers profile=openstack1
```
Parameters **profile** -- Profile to build on (Optional)

Returns List of router

```python
salt.modules.neutron.list_security_group_rules(profile=None)
```

Fetched a list of all security group rules for a tenant

CLI Example:

```
salt '*' neutron.list_security_group_rules
salt '*' neutron.list_security_group_rules profile=openstack1
```

Parameters **profile** -- Profile to build on (Optional)

Returns List of security group rule

```python
salt.modules.neutron.list_security_groups(profile=None)
```

Fetched a list of all security groups for a tenant

CLI Example:

```
salt '*' neutron.list_security_groups
salt '*' neutron.list_security_groups profile=openstack1
```

Parameters **profile** -- Profile to build on (Optional)

Returns List of security group

```python
salt.modules.neutron.list_subnets(profile=None)
```

Fetched a list of all networks for a tenant

CLI Example:

```
salt '*' neutron.list_subnets
salt '*' neutron.list_subnets profile=openstack1
```

Parameters **profile** -- Profile to build on (Optional)

Returns List of subnet

```python
salt.modules.neutron.list_vpnservices(retrieve_all=True, profile=None, **kwargs)
```

Fetched a list of all configured VPN services for a tenant

CLI Example:

```
salt '*' neutron.list_vpnservices
```

Parameters

- **retrieve_all** -- True or False, default: True (Optional)
- **profile** -- Profile to build on (Optional)

Returns List of VPN service

```python
salt.modules.neutron.remove_gateway_router(router, profile=None)
```

Removes an external network gateway from the specified router

CLI Example:

```
salt '*' neutron.remove_gateway_router router-name
```

Parameters

- **router** -- ID or name of router
- **profile** -- Profile to build on (Optional)

Returns True(Succeed) or False
salt.modules.neutron.remove_interface_router(router, subnet, profile=None)
Removes an internal network interface from the specified router

CLI Example:
```
salt '*' neutron.remove_interface_router router-name subnet-name
```

Parameters
- **router** -- ID or name of the router
- **subnet** -- ID or name of the subnet
- **profile** -- Profile to build on (Optional)

Returns True (Succeed) or False

salt.modules.neutron.show_firewall(firewall, profile=None)
Fetches information of a specific firewall rule

CLI Example:
```
salt '*' neutron.show_firewall firewall
```

Parameters
- **firewall** -- ID or name of firewall to look up
- **profile** -- Profile to build on (Optional)

Returns firewall information

salt.modules.neutron.show_firewall_rule(firewall_rule, profile=None)
Fetches information of a specific firewall rule

CLI Example:
```
salt '*' neutron.show_firewall_rule firewall-rule-name
```

Parameters
- **ipsecpolicy** -- ID or name of firewall rule to look up
- **profile** -- Profile to build on (Optional)

Returns firewall rule information

salt.modules.neutron.show_floatingip(floatingip_id, profile=None)
Fetches information of a certain floatingIP

CLI Example:
```
salt '*' neutron.show_floatingip floatingip-id
```

Parameters
- **floatingip_id** -- ID of floatingIP to look up
- **profile** -- Profile to build on (Optional)

Returns Floating IP information

salt.modules.neutron.show_ikepolicy(ikepolicy, profile=None)
Fetches information of a specific IKEPolicy

CLI Example:
salt '*' neutron.show_ikepolicy ikepolicy-name

Parameters

- **ikepolicy** -- ID or name of ikepolicy to look up
- **profile** -- Profile to build on (Optional)

Returns IKE policy information

salt.modules.neutron.show_ipsec_site_connection(ipsec_site_connection, profile=None)

Fetches information of a specific IPsecSiteConnection

CLI Example:

```
salt '*' neutron.show_ipsec_site_connection connection-name
```

Parameters

- **ipsec_site_connection** -- ID or name of ipsec site connection to look up
- **profile** -- Profile to build on (Optional)

Returns IPSec site connection information

salt.modules.neutron.show_ipsecpolicy(ipsecpolicy, profile=None)

Fetches information of a specific IPsecPolicy

CLI Example:

```
salt '*' neutron.show_ipsecpolicy ipsecpolicy-name
```

Parameters

- **ipsecpolicy** -- ID or name of IPSec policy to look up
- **profile** -- Profile to build on (Optional)

Returns IPSec policy information

salt.modules.neutron.show_network(network, profile=None)

Fetches information of a certain network

CLI Example:

```
salt '*' neutron.show_network network-name
salt '*' neutron.show_network network-name profile=openstack1
```

Parameters

- **network** -- ID or name of network to look up
- **profile** -- Profile to build on (Optional)

Returns Network information

salt.modules.neutron.show_port(port, profile=None)

Fetches information of a certain port

CLI Example:

```
salt '*' neutron.show_port port-id
salt '*' neutron.show_port port-id profile=openstack1
```

Parameters

- **port** -- ID or name of port to look up
• profile -- Profile to build on (Optional)

Returns Port information

salt.modules.neutron.show_quota(tenant_id, profile=None)
Fetched information of a certain tenant's quotas

CLI Example:

```
salt '*' neutron.show_quota tenant-id
salt '*' neutron.show_quota tenant-id profile=openstack1
```

Parameters

• tenant_id -- ID of tenant

• profile -- Profile to build on (Optional)

Returns Quota information

salt.modules.neutron.show_router(router, profile=None)
Fetched information of a certain router

CLI Example:

```
salt '*' neutron.show_router router-name
```

Parameters

• router -- ID or name of router to look up

• profile -- Profile to build on (Optional)

Returns Router information

salt.modules.neutron.show_security_group(security_group, profile=None)
Fetched information of a certain security group

CLI Example:

```
salt '*' neutron.show_security_group security-group-name
```

Parameters

• security_group -- ID or name of security group to look up

• profile -- Profile to build on (Optional)

Returns Security group information

salt.modules.neutron.show_security_group_rule(security_group_rule_id, profile=None)
Fetched information of a certain security group rule

CLI Example:

```
salt '*' neutron.show_security_group_rule security-group-rule-id
```

Parameters

• security_group_rule_id -- ID of security group rule to look up

• profile -- Profile to build on (Optional)

Returns Security group rule information

salt.modules.neutron.show_subnet(subnet, profile=None)
Fetched information of a certain subnet

CLI Example:
### Salt Documentation, Release 2016.3.6

#### 13.6. execution modules

**Salt**

### `neutron.show_subnet subnet-name`

**Parameters**

- `subnet` -- ID or name of subnet to look up
- `profile` -- Profile to build on (Optional)

**Returns**

Subnet information

### `salt.modules.neutron.show_vpnservice(vpnservice, profile=None, **kwargs)`

Fetches information of a specific VPN service

**Parameters**

- `vpnservice` -- ID or name of vpn service to look up
- `profile` -- Profile to build on (Optional)

**Returns**

VPN service information

### `salt.modules.neutron.update_firewall_rule(firewall_rule, protocol=None, action=None, name=None, description=None, ip_version=None, source_ip_address=None, destination_ip_address=None, source_port=None, destination_port=None, shared=None, enabled=None, profile=None)`

Update a firewall rule

**Parameters**

- `firewall_rule` -- ID or name of firewall rule to update.
- `protocol` -- Protocol for the firewall rule, choose `''tcp'',''udp'',''icmp'' or `''None''`. (Optional)
- `action` -- Action for the firewall rule, choose `''allow'' or `''deny''`. (Optional)
- `name` -- Name for the firewall rule. (Optional)
- `description` -- Description for the firewall rule. (Optional)
- `ip_version` -- IP protocol version, default: 4. (Optional)
- `source_ip_address` -- Source IP address or subnet. (Optional)
- `destination_ip_address` -- Destination IP address or subnet. (Optional)
- `source_port` -- Source port (integer in [1, 65535] or range in a:b). (Optional)
- `destination_port` -- Destination port (integer in [1, 65535] or range in a:b). (Optional)
- `shared` -- (Optional)
- `enabled` -- (Optional)
- **shared** -- Set shared to True, default: False. (Optional)
- **enabled** -- To enable this rule, default: True. (Optional)
- **profile** -- Profile to build on (Optional)

`salt.modules.neutron.update_floatingip(floatingip_id, port, profile=None)`

Updates a floatingIP

CLI Example:

```
salt '*' neutron.update_floatingip network-name port-name
```

Parameters

- **floatingip_id** -- ID of floatingIP
- **port** -- ID or name of port
- **profile** -- Profile to build on (Optional)

Returns Value of updated floating IP information

`salt.modules.neutron.update_network(network, name, profile=None)`

Updates a network

CLI Example:

```
salt '*' neutron.update_network network-name new-network-name
```

Parameters

- **network** -- ID or name of network to update
- **name** -- Name of this network
- **profile** -- Profile to build on (Optional)

Returns Value of updated network information

`salt.modules.neutron.update_port(port, name, admin_state_up=True, profile=None)`

Updates a port

CLI Example:

```
salt '*' neutron.update_port port-name network-name new-port-name
```

Parameters

- **port** -- Port name or ID
- **name** -- Name of this port
- **admin_state_up** -- Set admin state up to true or false, default: true (Optional)
- **profile** -- Profile to build on (Optional)

Returns Value of updated port information

`salt.modules.neutron.update_quota(tenant_id, subnet=None, router=None, network=None, floatingip=None, port=None, security_group=None, security_group_rule=None, profile=None)`

Update a tenant’s quota

CLI Example:

```
salt '*' neutron.update_quota tenant-id subnet=40 router=50
network=10 floatingip=30 port=30
```
Parameters

- **tenant_id** -- ID of tenant
- **subnet** -- Value of subnet quota (Optional)
- **router** -- Value of router quota (Optional)
- **network** -- Value of network quota (Optional)
- **floatingip** -- Value of floatingip quota (Optional)
- **port** -- Value of port quota (Optional)
- **security_group** -- Value of security group (Optional)
- **security_group_rule** -- Value of security group rule (Optional)
- **profile** -- Profile to build on (Optional)

Returns
Value of updated quota

```
salt.modules.neutron.update_router(router, name=None, admin_state_up=None, profile=None, **kwargs)
```

Updates a router

CLI Example:

```
salt '*' neutron.update_router router_id name=new-router-name admin_state_up=True
```

Parameters

- **router** -- ID or name of router to update
- **name** -- Name of this router
- **ext_network** -- ID or name of the external for the gateway (Optional)
- **admin_state_up** -- Set admin state up to true or false, default: true (Optional)
- **profile** -- Profile to build on (Optional)
- **kwargs** --

Returns
Value of updated router information

```
salt.modules.neutron.update_security_group(security_group, name=None, description=None, profile=None)
```

Updates a security group

CLI Example:

```
salt '*' neutron.update_security_group security-group-name new-security-group-name
```

Parameters

- **security_group** -- ID or name of security group to update
- **name** -- Name of this security group (Optional)
- **description** -- Description of security group (Optional)
- **profile** -- Profile to build on (Optional)

Returns
Value of updated security group information
salt.modules.neutron.update_subnet(subnet, name, profile=None)

Updates a subnet

CLI Example:

```
salt '*' neutron.update_subnet subnet-name new-subnet-name
```

Parameters

- **subnet** -- ID or name of subnet to update
- **name** -- Name of this subnet
- **profile** -- Profile to build on (Optional)

Returns

Value of updated subnet information

salt.modules.neutron.update_vpnservice(vpnservice, desc, profile=None)

Updates a VPN service

CLI Example:

```
salt '*' neutron.update_vpnservice vpnservice-name desc='VPN Service1'
```

Parameters

- **vpnservice** -- ID or name of vpn service to update
- **desc** -- Set a description for the VPN service
- **profile** -- Profile to build on (Optional)

Returns

Value of updated VPN service information

13.6.199 salt.modules.nfs3

Module for managing NFS version 3.

salt.modules.nfs3.del_export(exports='/etc/exports', path=None)

Remove an export

CLI Example:

```
salt '*' nfs.del_export /media/storage
```

salt.modules.nfs3.list_exports(exports='/etc/exports')

List configured exports

CLI Example:

```
salt '*' nfs.list_exports
```

13.6.200 salt.modules.nftables

Support for nftables

salt.modules.nftables.append(table='filter', chain=None, rule=None, family='ipv4')

Append a rule to the specified table & chain.

This function accepts a rule in a standard nftables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.
CLI Example:

```python
salt '*' nftables.append filter input
  rule='input tcp dport 22 log accept'
```

**IPv6:**

```python
salt '*' nftables.append filter input
  rule='input tcp dport 22 log accept'
  family=ipv6
```

**salt.modules.nftables.build_rule**

```python
salt.modules.nftables.build_rule(table=None, chain=None, command=None, position='`,
  full=None, family='ipv4', **kwargs)
```

Build a well-formatted nftables rule based on kwargs. A `table` and `chain` are not required, unless `full` is True.

- If `full` is True, then `table`, `chain` and `command` are required. `command` may be specified as either insert, append, or delete. This will return the nftables command, exactly as it would be used from the command line.
- If a position is required (as with insert or delete), it may be specified as `position`. This will only be useful if `full` is True.
- If `connstate` is passed in, it will automatically be changed to `state`.

CLI Examples:

```python
salt '*' nftables.build_rule match=state
  connstate=RELATED,ESTABLISHED
  jump=ACCEPT
```

**IPv6:**

```python
salt '*' nftables.build_rule match=state
  connstate=related,established
  jump=accept
  family=ipv6
```

**salt.modules.nftables.check**

```python
salt.modules.nftables.check(table='filter', chain=None, rule=None, family='ipv4')
```

Check for the existence of a rule in the table and chain

This function accepts a rule in a standard nftables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Example:

```python
salt '*' nftables.check filter input
  rule='input tcp dport 22 log accept'
```

**IPv6:**

```python
salt '*' nftables.check filter input
  rule='input tcp dport 22 log accept'
  family=ipv6
```

**salt.modules.nftables.check_chain**

```python
salt.modules.nftables.check_chain(table='filter', chain=None, family='ipv4')
```

New in version 2014.7.0.

Check for the existence of a chain in the table

CLI Example:

```python
salt '*' nftables.check_chain
```

**IPv6:**

```python
salt '*' nftables.check_chain
```
Salt Documentation, Release 2016.3.6

```python
salt '*' nftables.check_chain filter input

IPv6:
salt '*' nftables.check_chain filter input family=ipv6
```

```python
salt.modules.nftables.check_table(table=None, family='ipv4')
    Check for the existence of a table
    CLI Example:
    salt '*' nftables.check_table nat
```

```python
salt.modules.nftables.delete(table, chain=None, position=None, rule=None, family='ipv4')
    Delete a rule from the specified table & chain, specifying either the rule in its entirety, or the rule's position in the chain.
    This function accepts a rule in a standard nftables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.
    CLI Examples:
    salt '*' nftables.delete filter input position=3
    salt '*' nftables.delete filter input \rul...log accept'

IPv6:
salt '*' nftables.delete filter input position=3 family=ipv6
    salt '*' nftables.delete filter input \rul...log accept' \family=ipv6
```

```python
salt.modules.nftables.delete_chain(table='filter', chain=None, family='ipv4')
    New in version 2014.7.0.
    Delete the chain from the specified table.
    CLI Example:
    salt '*' nftables.delete_chain filter
```

```python
salt.modules.nftables.delete_table(table, family='ipv4')
    New in version 2014.7.0.
    Create new custom table.
    CLI Example:
    salt '*' nftables.delete_table filter
```

IPv6:
salt '*' nftables.delete_table filter family=ipv6
salt.modules.nftables.flush(table='filter', chain='`, family='ipv4')
Flush the chain in the specified table, flush all chains in the specified table if chain is not specified.

CLI Example:

```
salt '*' nftables.flush filter
salt '*' nftables.flush filter input
IPv6:
salt '*' nftables.flush filter input family=ipv6
```

salt.modules.nftables.get_rule_handle(table='filter', chain=None, rule=None, family='ipv4')
Get the handle for a particular rule

This function accepts a rule in a standard nftables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Example:

```
salt '*' nftables.get_rule_handle filter input "rule=\"input tcp dport 22 log accept\""
IPv6:
salt '*' nftables.get_rule_handle filter input "rule=\"input tcp dport 22 log accept\" \nfamily=ipv6"
```

salt.modules.nftables.get_rules(family='ipv4')
Return a data structure of the current, in-memory rules

CLI Example:

```
salt '*' nftables.get_rules
salt '*' nftables.get_rules family=ipv6
```

salt.modules.nftables.get_saved_rules(conf_file=None, family='ipv4')
Return a data structure of the rules in the conf file

CLI Example:

```
salt '*' nftables.get_saved_rules
```

salt.modules.nftables.insert(table='filter', chain=None, position=None, rule=None, family='ipv4')
Insert a rule into the specified table & chain, at the specified position.

If position is not specified, rule will be inserted in first position.

This function accepts a rule in a standard nftables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Examples:

```
salt '*' nftables.insert filter input "rule=\"input tcp dport 22 log accept\""
salt '*' nftables.insert filter input position=3 "rule=\"input tcp dport 22 log accept\""
IPv6:
```

13.6. execution modules 1309
salt 'nftables.insert filter input
    rules='input tcp dport 22 log accept'
    family=ipv6

salt 'nftables.insert filter input position=3
    rules='input tcp dport 22 log accept'
    family=ipv6

salt.modules.nftables.new_chain(table='filter', chain=None, table_type=None, hook=None, priority=None, family='ipv4')

New in version 2014.7.0.
Create new chain to the specified table.

CLI Example:
salt 'nftables.new_chain filter input
salt 'nftables.new_chain filter input
    table_type=filter hook=input priority=0
salt 'nftables.new_chain filter foo
IPv6:
salt 'nftables.new_chain filter input family=ipv6
salt 'nftables.new_chain filter input
    table_type=filter hook=input priority=0 family=ipv6
salt 'nftables.new_chain filter foo family=ipv6

salt.modules.nftables.new_table(table, family='ipv4')

New in version 2014.7.0.
Create new custom table.

CLI Example:
salt 'nftables.new_table filter
IPv6:
salt 'nftables.new_table filter family=ipv6

salt.modules.nftables.save(filename=None, family='ipv4')

Save the current in-memory rules to disk

CLI Example:
salt 'nftables.save /etc/nftables

salt.modules.nftables.version()

Return version from nftables --version

CLI Example:
salt 'nftables.version
13.6.201 salt.modules.nginx

Support for nginx

salt.modules.nginx.build_info()

Return server and build arguments

CLI Example:

```
salt '*' nginx.build_info
```

salt.modules.nginx.configtest()

Test configuration and exit

CLI Example:

```
salt '*' nginx.configtest
```

salt.modules.nginx.signal(signal=None)

Signals nginx to start, reload, reopen or stop.

CLI Example:

```
salt '*' nginx.signal reload
```

salt.modules.nginx.status(url='http://127.0.0.1/status')

Return the data from an Nginx status page as a dictionary. http://wiki.nginx.org/HttpStubStatusModule

url The URL of the status page. Defaults to 'http://127.0.0.1/status'

CLI Example:

```
salt '*' nginx.status
```

salt.modules.nginx.version()

Return server version from nginx -v

CLI Example:

```
salt '*' nginx.version
```

13.6.202 salt.modules.node

Module for full system inspection.

salt.modules.node.build(format='qcow2', path='/tmp/')

Build an image from a current system description. The image is a system image can be output in bootable ISO or QCOW2 formats.

Node uses the image building library Kiwi to perform the actual build.

Parameters:

- **format**: Specifies output format: `qcow2` or `iso`. Default: `qcow2`
- **path**: Specifies output path where to store built image. Default: `/tmp`

CLI Example:

```
salt myminion node.build
salt myminion node.build format=iso path=/opt/builds/
```
salt.modules.node.export(local=False, path='/tmp', format='qcow2')

Export an image description for Kiwi.

Parameters:

- `local`: Specifies True or False if the export has to be in the local file. Default: False.
- `path`: If `local=True`, then specifies the path where file with the Kiwi description is written. Default: `/tmp`.

CLI Example:

```
salt myminion node.export
salt myminion node.export format=iso path=/opt/builds/
```

salt.modules.node.inspect(mode='all', priority=19, **kwargs)

Start node inspection and save the data to the database for further query.

Parameters:

- `mode`: Clarify inspection mode: configuration, payload, all (default)

  - `payload`

    - `filter`: Comma-separated directories to track payload.

- `priority`: (advanced) Set priority of the inspection. Default is low priority.

CLI Example:

```
salt '*' node.inspect
salt '*' node.inspect configuration
salt '*' node.inspect payload filter=/opt,/ext/oracle
```

salt.modules.node.query(scope, **kwargs)

Query the node for specific information.

Parameters:

- `scope`: Specify scope of the query.
  - `System`: Return system data.
  - `Software`: Return software information.
  - `Services`: Return known services.
  - `Identity`: Return user accounts information for this system.

  - `accounts` Can be either `local`, `remote` or `all` (equal to `local,remote`). Remote accounts cannot be resolved on all systems, but only those, which supports `passwd -S -a`.

  - `disabled`: True (or False, default) to return only disabled accounts.

- `payload`: Payload scope parameters:

  - `filter`: Include only results which path starts from the filter string.

  - `time`: Display time in Unix ticks or format according to the configured TZ (default) Values: ticks, tz (default)

  - `size`: Format size. Values: B, KB, MB, GB

  - `type`: Include payload type. Values (comma-separated): directory (or dir), link, file (default)

    - `Example` (returns everything): type=directory, link, file

  - `owners`: Resolve UID/GID to an actual names or leave them numeric (default). Values: name (default), id

    - `brief`: Return just a list of payload elements, if True. Default: False.

- `all`: Return all information (default).

CLI Example:
13.6.203 salt.modules.nova

Module for handling OpenStack Nova calls

depends

- novaclient Python module

configuration This module is not usable until the user, password, tenant, and auth URL are specified either in a pillar or in the minion’s config file. For example:

```
keystone.user: admin
keystone.password: verybadpass
keystone.tenant: admin
keystone.auth_url: 'http://127.0.0.1:5000/v2.0/
# Optional
keystone.region_name: 'regionOne'
```

If configuration for multiple OpenStack accounts is required, they can be set up as different configuration profiles: For example:

```
openstack1:
  keystone.user: admin
  keystone.password: verybadpass
  keystone.tenant: admin
  keystone.auth_url: 'http://127.0.0.1:5000/v2.0/
openstack2:
  keystone.user: admin
  keystone.password: verybadpass
  keystone.tenant: admin
  keystone.auth_url: 'http://127.0.0.2:5000/v2.0/
```

With this configuration in place, any of the nova functions can make use of a configuration profile by declaring it explicitly. For example:

```
salt '*' nova.flavor_list profile=openstack1
```

salt.modules.nova.boot(name, flavor_id=0, image_id=0, profile=None, timeout=300)

Boot (create) a new instance

- **name** Name of the new instance (must be first)
- **flavor_id** Unique integer ID for the flavor
- **image_id** Unique integer ID for the image
- **timeout** How long to wait, after creating the instance, for the provider to return information about it (default 300 seconds).

New in version 2014.1.0.

CLI Example:

```
salt '*' nova.boot myinstance flavor_id=4596 image_id=2
```

The flavor_id and image_id are obtained from nova.flavor_list and nova.image_list
Salt Documentation, Release 2016.3.6

```python
salt '*' nova.flavor_list
salt '*' nova.image_list
```

**salt.modules.nova.delete** *(instance_id, profile= *)

Delete an instance

- `instance_id` ID of the instance to be deleted

CLI Example:

```bash
salt '*' nova.delete 1138
```

**salt.modules.nova.flavor_create** *(name, flavor_id=0, ram=0, disk=0, vcpus=1, profile= *)

Add a flavor to nova (nova flavor-create). The following parameters are required:

- `name` Name of the new flavor (must be first)
- `flavor_id` Unique integer ID for the new flavor
- `ram` Memory size in MB
- `disk` Disk size in GB
- `vcpus` Number of vcpus

CLI Example:

```bash
salt '*' nova.flavor_create myflavor flavor_id=6 ram=4096 disk=10 vcpus=1
```

**salt.modules.nova.flavor_delete** *(flavor_id, profile= *)

Delete a flavor from nova by id (nova flavor-delete)

CLI Example:

```bash
salt '*' nova.flavor_delete 7
```

**salt.modules.nova.flavor_list** *(profile= *)

Return a list of available flavors (nova flavor-list)

CLI Example:

```bash
salt '*' nova.flavor_list
```

**salt.modules.nova.image_list** *(name= None, profile= *)

Return a list of available images (nova images-list + nova image-show) If a name is provided, only that image will be displayed.

CLI Examples:

```bash
salt '*' nova.image_list
salt '*' nova.image_list myimage
```

**salt.modules.nova.image_meta_delete** *(image_id= None, name= None, keys= None, profile= *)

Delete a key=value pair from the metadata for an image (nova image-meta set)

CLI Examples:

```bash
salt '*' nova.image_meta_delete 6f52b2ff-0b31-4d84-8fd1-af45b84824f6 keys=cheese
salt '*' nova.image_meta_delete name=myimage keys=salad,beans
```

**salt.modules.nova.image_meta_set** *(image_id= None, name= None, profile= None, **kwargs *)

Sets a key=value pair in the metadata for an image (nova image-meta set)

CLI Examples:
salt.modules.nova.keypair_add(name, pubfile=None, pubkey=None, profile=None)
Add a keypair to nova (nova keypair-add)

CLI Examples:
salt '*' nova.keypair_add mykey pubfile='/home/myuser/.ssh/id_rsa.pub'
salt '*' nova.keypair_add mykey pubkey='ssh-rsa <key> myuser@mybox'

salt.modules.nova.keypair_delete(name, profile=None)
Add a keypair to nova (nova keypair-delete)

CLI Example:
salt '*' nova.keypair_delete mykey'

salt.modules.nova.keypair_list(profile=None)
Return a list of available keypairs (nova keypair-list)

CLI Example:
salt '*' nova.keypair_list

salt.modules.nova.list(profile=None)
To maintain the feel of the nova command line, this function simply calls the server_list function.

CLI Example:
salt '*' nova.list

salt.modules.nova.lock(instance_id, profile=None)
Lock an instance

instance_id ID of the instance to be locked

CLI Example:
salt '*' nova.lock 1138

salt.modules.nova.resume(instance_id, profile=None)
Resume an instance

instance_id ID of the instance to be resumed

CLI Example:
salt '*' nova.resume 1138

salt.modules.nova.secgroup_create(name, description, profile=None)
Add a secgroup to nova (nova secgroup-create)

CLI Example:
salt '*' nova.secgroup_create mygroup 'This is my security group'

salt.modules.nova.secgroup_delete(name, profile=None)
Delete a secgroup to nova (nova secgroup-delete)

CLI Example:
salt '***' nova.secgroup_delete mygroup

```python
salt.modules.nova.secgroup_list(profile=None)
Return a list of available security groups (nova items-list)

  CLI Example:
  salt '***' nova.secgroup_list
```

salt.modules.nova.server_by_name(name, profile=None)
Return information about a server
  name  Server Name

  CLI Example:
  salt '***' nova.server_by_name myserver profile=openstack

salt.modules.nova.server_list(profile=None)
Return list of active servers

  CLI Example:
  salt '***' nova.server_list

salt.modules.nova.server_list_detailed(profile=None)
Return detailed list of active servers

  CLI Example:
  salt '***' nova.server_list_detailed

salt.modules.nova.server_show(server_id, profile=None)
Return detailed information for an active server

  CLI Example:
  salt '***' nova.server_show <server_id>

salt.modules.nova.show(server_id, profile=None)
To maintain the feel of the nova command line, this function simply calls the server_show function.

  CLI Example:
  salt '***' nova.show

salt.modules.nova.suspend(instance_id, profile=None)
Suspend an instance
  instance_id  ID of the instance to be suspended

  CLI Example:
  salt '***' nova.suspend 1138

salt.modules.nova.volume_attach(name, server_name, device='/dev/xvdb', profile=None, timeout=300)
Attach a block storage volume
  name  Name of the new volume to attach
  server_name  Name of the server to attach to
  device  Name of the device on the server
  profile  Profile to build on
CLI Example:

```
salt '*' nova.volume_attach myblock slice.example.com profile=openstack
salt '*' nova.volume_attach myblock server.example.com device='/
   ^dev/xvdb' profile=openstack
```

```
salt.modules.nova.volume_create(name, size=100, snapshot=None, voltype=None, profile=None)
```
Create a block storage volume

- **name** Name of the new volume (must be first)
- **size** Volume size
- **snapshot** Block storage snapshot id
- **voltype** Type of storage
- **profile** Profile to build on

CLI Example:

```
salt '*' nova.volume_create myblock size=300 profile=openstack
```

```
salt.modules.nova.volume_delete(name, profile=None)
```
Destroy the volume

- **name** Name of the volume
- **profile** Profile to build on

CLI Example:

```
salt '*' nova.volume_delete myblock profile=openstack
```

```
salt.modules.nova.volume_detach(name, profile=None, timeout=300)
```
Attach a block storage volume

- **name** Name of the new volume to attach
- **server_name** Name of the server to detach from
- **profile** Profile to build on

CLI Example:

```
salt '*' nova.volume_detach myblock profile=openstack
```

```
salt.modules.nova.volume_list(search_opts=None, profile=None)
```
List storage volumes

- **search_opts** Dictionary of search options
- **profile** Profile to use

CLI Example:

```
salt '*' nova.volume_list search_opts='{"display_name": "myblock"}' profile=openstack
```

```
salt.modules.nova.volume_show(name, profile=None)
```
Create a block storage volume

- **name** Name of the volume
- **profile** Profile to use

CLI Example:

```
salt '*' nova.volume_show myblock profile=openstack
```

13.6.204 salt.modules.npm

Manage and query NPM packages.
salt.modules.npm.install(pkg=None, pkgs=None, dir=None, runas=None, registry=None, env=None, dry_run=False, silent=True)

Install an NPM package.
If no directory is specified, the package will be installed globally. If no package is specified, the dependencies (from package.json) of the package in the given directory will be installed.

pkg A package name in any format accepted by NPM, including a version identifier
pkgs A list of package names in the same format as the name parameter

dir The target directory in which to install the package, or None for global installation
runas The user to run NPM with
registry The NPM registry to install the package from.

env Environment variables to set when invoking npm. Uses the same env format as the cmd.run execution function.

silent Whether or not to run NPM install with --silent flag.

dry_run Whether or not to run NPM install with --dry-run flag.

CLI Example:

```
salt '*' npm.install coffee-script
salt '*' npm.install coffee-script@1.0.1
```

salt.modules.npm.list(pkg=None, dir=None, runas=None, env=None)

List installed NPM packages.
If no directory is specified, this will return the list of globally-installed packages.

pkg Limit package listing by name
dir The directory whose packages will be listed, or None for global installation
runas The user to run NPM with

env Environment variables to set when invoking npm. Uses the same env format as the cmd.run execution function.

CLI Example:

```
salt '*' npm.list
```

salt.modules.npm.uninstall(pkg, dir=None, runas=None, env=None)

Uninstall an NPM package.
If no directory is specified, the package will be uninstalled globally.

pkg A package name in any format accepted by NPM
dir The target directory from which to uninstall the package, or None for global installation
runas The user to run NPM with
env Environment variables to set when invoking npm. Uses the same env format as the cmd.run execution function.
CLI Example:
```
salt '*' npm.uninstall coffee-script
```

13.6.205 salt.modules.nspawn

Manage nspawn containers

New in version 2015.8.0.

`systemd-nspawn(1)` is a tool used to manage lightweight namespace containers. This execution module provides several functions to help manage these containers.

Minions running systemd >= 219 will place new containers in `/var/lib/machines`, while those running systemd < 219 will place them in `/var/lib/container`.

salt.modules.nspawn.bootstrap_container(name, dist=None, version=None)

Bootstrap a container from package servers, if dist is None the os the minion is running as will be created, otherwise the needed bootstrapping tools will need to be available on the host.

CLI Example:
```
salt myminion nspawn.bootstrap_container <name>
```

salt.modules.nspawn.bootstrap_salt(name, config=None, approve_key=True, install=True, pub_key=None, priv_key=None, bootstrap_url=None, force_install=False, unconditional_install=False, bootstrap_delay=None, bootstrap_args=None, bootstrap_shell=None)

Bootstrap a container from package servers, if dist is None the os the minion is running as will be created, otherwise the needed bootstrapping tools will need to be available on the host.

CLI Example:
```
salt '*' nspawn.bootstrap_salt arch1
```

salt.modules.nspawn.copy_to(name, args, **kwargs)

Copy a file from the host into a container

name Container name
source File to be copied to the container
dest Destination on the container. Must be an absolute path.
overwrite [False] Unless this option is set to True, then if a file exists at the location specified by the dest argument, an error will be raised.
makedirs : False
Create the parent directory on the container if it does not already exist.

CLI Example:
```
salt 'minion' nspawn.copy_to /tmp/foo /root/foo
```

salt.modules.nspawn.disable(name, args, **kwargs)

Set the named container to not be launched at boot

CLI Example:
```
salt myminion nspawn.enable <name>
```
salt.modules.nspawn.enable(name, *args, **kwargs)
   Set the named container to be launched at boot
   CLI Example:
   ```
salt myminion nspawn.enable <name>
   ```

salt.modules.nspawn.exists(name)
   Returns true if the named container exists
   CLI Example:
   ```
salt myminion nspawn.exists <name>
   ```

salt.modules.nspawn.info(name, **kwargs)
   Return info about a container
   Note: The container must be running for machinectl to gather information about it. If the container is stopped, then this function will start it.
   start [False] If True, then the container will be started to retrieve the info. A Started key will be in the return data if the container was started.
   CLI Example:
   ```
salt myminion nspawn.info arch1
salt myminion nspawn.info arch1 force_start=False
   ```

salt.modules.nspawn.list_all()
   Lists all nspawn containers
   CLI Example:
   ```
salt myminion nspawn.list_all
   ```

salt.modules.nspawn.list_running()
   Lists running nspawn containers
   Note: nspawn.list also works to list running containers
   CLI Example:
   ```
salt myminion nspawn.list_running
salt myminion nspawn.list
   ```

salt.modules.nspawn.list_stopped()
   Lists stopped nspawn containers
   CLI Example:
   ```
salt myminion nspawn.list_stopped
   ```

salt.modules.nspawn.pid(name, *args, **kwargs)
   Returns the PID of a container
   name  Container name
   CLI Example:
salt myminion nspawn.pid arch1

salt.modules.nspawn.poweroff(name)
Issue a clean shutdown to the container. Equivalent to running machinectl poweroff on the named container.

For convenience, running nspawn.stop`as shown in the CLI examples below) is equivalent to running `nspawn.poweroff.

Note: machinectl poweroff is only supported in systemd >= 219. On earlier systemd versions, running this function will simply issue a clean shutdown via systemctl.

CLI Examples:
salt myminion nspawn.poweroff arch1
salt myminion nspawn.stop arch1

salt.modules.nspawn.pull_dkr(url, name, index)
Execute a machinectl pull-dkr to download a docker image and add it to /var/lib/machines as a new container.

Note: Requires systemd >= 219

url URL from which to download the container
name Name for the new container
index URL of the Docker index server from which to pull (must be an http:// or https:// URL).

CLI Examples:
salt myminion nspawn.pull_dkr centos/centos6 cent6
salt myminion nspawn.pull_docker centos/centos6 cent6

salt.modules.nspawn.pull_raw(url, name, verify=False)
Execute a machinectl pull-raw to download a .qcow2 or raw disk image, and add it to /var/lib/machines as a new container.

Note: Requires systemd >= 219

url URL from which to download the container
name Name for the new container
verify [False] Perform signature or checksum verification on the container. See the machinectl(1) man page (section titled "Image Transfer Commands") for more information on requirements for image verification. To perform signature verification, use verify=signature. For checksum verification, use verify=checksum. By default, no verification will be performed.

CLI Examples:
salt myminion nspawn.pull_raw http://ftp.halifax.rwth-aachen.de/fedora/linux/
--releases/21/Cloud/Images/x86_64/Fedora-Cloud-Base-20141203-21.x86_64.raw.xz
--fedora21

salt.modules.nspawn.pull_tar(url, name, verify=False)
Execute a machinectl pull-tar to download a .tar container image, and add it to /var/lib/machines as
a new container.

### URL from which to download the container

- `url`
  - Name: `url`
  - Description: URL from which to download the container

### Name for the new container

- `name`
  - Name: `name`
  - Description: Name for the new container

### Perform signature or checksum verification on the container

- `verify`
  - Default: `False`
  - Options: `signature`, `checksum`
  - Description: Perform signature or checksum verification on the container. See the `machinectl(1)` man page (section titled "Image Transfer Commands") for more information on requirements for image verification. To perform signature verification, use `verify=signature`. For checksum verification, use `verify=checksum`. By default, no verification will be performed.

#### CLI Examples:

```
salt myminion nspawn.pull_tar http://foo.domain.tld/containers/archlinux-2015.02.01.tar.gz arch2
```

### Rebooting the container

- `reboot`
  - Description: Reboot the container by sending a SIGINT to its init process. Equivalent to running `machinectl reboot` on the named container.

#### CLI Examples:

```
salt myminion nspawn.reboot arch1
```

### Removing a container

- `remove`
  - Description: Remove the named container

#### Warning:

This function will remove all data associated with the container. It will not, however, remove the btrfs subvolumes created by pulling container images (`nspawn.pull_raw`, `nspawn.pull_tar`, `nspawn.pull_dkr`).

- `stop`
  - Default: `False`
  - Description: If `True`, the container will be destroyed even if it is running/frozen.

#### CLI Examples:

```
salt '*' nspawn.remove foo
salt '*' nspawn.remove foo stop=True
```

### Running a command within a container

- `retcode`
  - Description: Run `cmd.retcode` within a container

#### Parameters:

- `name`
  - Description: Name of the container in which to run the command

- `cmd`
  - Description: Command to run

- `no_start`
  - Default: `False`
  - Description: If the container is not running, don't start it

- `preserve_state`
  - Default: `True`
  - Description: After running the command, return the container to its previous state

- `stdin`
  - Default: `None`
  - Description: Standard input to be used for the command

#### CLI Examples:

```
salt.modules.nspawn.recode(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)
```

---

**Note:** Requires `systemd` >= 219

---

**Note:** `machinectl reboot` is only supported in `systemd` >= 219. On earlier `systemd` versions, running this function will instead restart the container via `systemctl`.

---

**Note:** Requires `systemd` >= 219

---

**Note:** Requires `systemd` >= 219
**output_loglevel** [debug] Level at which to log the output from the command. Set to quiet to suppress logging.

**use_vt** [False] Use SaltStack's utils.vt to stream output to console. Assumes output=all.

**keep_env** [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:

```
salt myminion nspawn.retcode mycontainer 'ip addr show'
```

salt.modules.nspawn.run(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)

Run cmd.run within a container

- **name** Name of the container in which to run the command
- **cmd** Command to run
- **no_start** [False] If the container is not running, don't start it
- **preserve_state** [True] After running the command, return the container to its previous state
- **stdin** [None] Standard input to be used for the command
- **output_loglevel** [debug] Level at which to log the output from the command. Set to quiet to suppress logging.
- **use_vt** [False] Use SaltStack's utils.vt to stream output to console.
- **keep_env** [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:

```
salt myminion nspawn.run mycontainer 'ifconfig -a'
```

salt.modules.nspawn.run_all(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)

Run cmd.run_all within a container

**Note:** While the command is run within the container, it is initiated from the host. Therefore, the PID in the return dict is from the host, not from the container.
salt myminion nspawn.run_all mycontainer 'ip addr show'

salt.modules.nspawn.run_stderr(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)

Run `cmd.run_stderr` within a container

- **name**: Name of the container in which to run the command
- **cmd**: Command to run
- **no_start** [False]: If the container is not running, don’t start it
- **preserve_state** [True]: After running the command, return the container to its previous state
- **stdin** [None]: Standard input to be used for the command
- **output_loglevel** [debug]: Level at which to log the output from the command. Set to `quiet` to suppress logging.
- **use_vt** [False]: Use SaltStack’s `utils.vt` to stream output to console. Assumes `output=all`.
- **keep_env** [None]: If not passed, only a sane default `PATH` environment variable will be set. If `True`, all environment variables from the container’s host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:

```
salt myminion nspawn.run_stderr mycontainer 'ip addr show'
```

salt.modules.nspawn.run_stdout(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)

Run `cmd.run_stdout` within a container

- **name**: Name of the container in which to run the command
- **cmd**: Command to run
- **no_start** [False]: If the container is not running, don’t start it
- **preserve_state** [True]: After running the command, return the container to its previous state
- **stdin** [None]: Standard input to be used for the command
- **output_loglevel** [debug]: Level at which to log the output from the command. Set to `quiet` to suppress logging.
- **use_vt** [False]: Use SaltStack’s `utils.vt` to stream output to console. Assumes `output=all`.
- **keep_env** [None]: If not passed, only a sane default `PATH` environment variable will be set. If `True`, all environment variables from the container’s host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:

```
salt myminion nspawn.run_stdout mycontainer 'ifconfig -a'
```

salt.modules.nspawn.start(name, *args, **kwargs)

Start the named container

CLI Example:

```
salt myminion nspawn.start <name>
```

salt.modules.nspawn.state(name, *args, **kwargs)

Return state of container (running or stopped)

CLI Example:

```
salt myminion nspawn.state <name>
```
salt.modules.nspawn.**terminate**(name)

Kill all processes in the container without issuing a clean shutdown. Equivalent to running `machinectl terminate` on the named container.

For convenience, running `nspawn.stop` and passing `kill=True` (as shown in the CLI examples below) is equivalent to running `nspawn.terminate`.

**Note:** `machinectl terminate` is only supported in systemd >= 219. On earlier systemd versions, running this function will simply issue a clean shutdown via `systemctl`.

CLI Examples:

```
salt myminion nspawn.terminate arch1
salt myminion nspawn.stop arch1 kill=True
```

### 13.6.206 salt.modules.omapi

This module interacts with an ISC DHCP Server via OMAPI. `server_ip` and `server_port` params may be set in the minion config or pillar:

```
omapi.server_ip: 127.0.0.1
omapi.server_port: 7991
```

**depends** pypureomapi Python module

salt.modules.omapi.**add_host**(mac, name=None, ip=None, ddns=False, group=None, supersede_host=False)

Add a host object for the given mac.

CLI Example:

```
salt dhcp-server omapi.add_host ab:ab:ab:ab:ab:ab name=host1
```

Add ddns-hostname and a fixed-ip statements:

```
salt dhcp-server omapi.add_host ab:ab:ab:ab:ab:ab name=host1 ip=10.1.1.1 ddns=true
```

salt.modules.omapi.**delete_host**(mac=None, name=None)

Delete the host with the given mac or name.

CLI Examples:

```
salt dhcp-server omapi.delete_host name=host1
salt dhcp-server omapi.delete_host mac=ab:ab:ab:ab:ab:ab
```

### 13.6.207 salt.modules.openbsd_sysctl

Module for viewing and modifying OpenBSD sysctl parameters

salt.modules.openbsd_sysctl.**assign**(name, value)

Assign a single sysctl parameter for this minion

CLI Example:
salt '*' sysctl.assign net.inet.ip.forwarding 1

salt.modules.openbsd_sysctl.get(name)
  Return a single sysctl parameter for this minion
  
  CLI Example:
  
salt '*' sysctl.get hw.physmem

salt.modules.openbsd_sysctl.persist(name, value, config='/etc/sysctl.conf')
  Assign and persist a simple sysctl parameter for this minion
  
  CLI Example:
  
salt '*' sysctl.persist net.inet.ip.forwarding 1

salt.modules.openbsd_sysctl.show(config_file=False)
  Return a list of sysctl parameters for this minion
  
  CLI Example:
  
salt '*' sysctl.show

13.6.208 salt.modules.openbsdpkg

Package support for OpenBSD

Important: If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install' is not available), see here.

salt.modules.openbsdpkg.install(name=None, pkgs=None, sources=None, **kwargs)
  Install the passed package
  Return a dict containing the new package names and versions:

  ```
  {'<package>': {'old': '<old-version>', 'new': '<new-version>'}}
  ```
  
  CLI Example, Install one package:

  ```
  salt '*' pkg.install <package name>
  ```

  CLI Example, Install more than one package:

  ```
  salt '*' pkg.install pkgs='["<package name>", 
"<package name>"]'
  ```

  CLI Example, Install more than one package from a alternate source (e.g. salt file-server, HTTP, FTP, local filesystem):

  ```
  salt '*' pkg.install sources='[{"<pkg name>": "salt://pkgs/<pkg filename>"}]'
  ```

salt.modules.openbsdpkg.latest_version(*names, **kwargs)
  The available version of the package in the repository
  
  CLI Example:
salt '*$' pkg.latest_version <package name>

salt.modules.openbsdpkg.list_pkgs(versions_as_list=False, **kwargs)
List the packages currently installed as a dict:

```
{'<package_name>': '<version>'}
```

CLI Example:

```
salt '*$' pkg.list_pkgs
```

salt.modules.openbsdpkg.purge(name=None, pkgs=None, **kwargs)
Package purges are not supported, this function is identical to remove().

- **name**: The name of the package to be deleted.

Multiple Package Options:

- **pkgs**: A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*$' pkg.purge <package name>
salt '*$' pkg.purge <package1>,<package2>,<package3>
salt '*$' pkg.purge pkgs=['"foo", "bar"]'
```

salt.modules.openbsdpkg.remove(name=None, pkgs=None, **kwargs)
Remove a single package with pkg_delete

Multiple Package Options:

- **pkgs**: A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*$' pkg.remove <package name>
salt '*$' pkg.remove <package1>,<package2>,<package3>
salt '*$' pkg.remove pkgs=['"foo", "bar"]'
```

salt.modules.openbsdpkg.version(*names, **kwargs)
Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```
salt '*$' pkg.version <package name>
salt '*$' pkg.version <package1> <package2> <package3> ...
```

13.6.209 salt.modules.openbsdrcctl

The rcctl service module for OpenBSD
salt.modules.openbsdrcctl.available(name)
  Return True if the named service is available.
  CLI Example:
  ```
  salt '*' service.available sshd
  ```

salt.modules.openbsdrcctl.disable(name, **kwargs)
  Disable the named service to not start at boot.
  CLI Example:
  ```
  salt '*' service.disable <service name>
  ```

salt.modules.openbsdrcctl.disabled(name)
  Return True if the named service is disabled at boot, False otherwise.
  CLI Example:
  ```
  salt '*' service.disabled <service name>
  ```

salt.modules.openbsdrcctl.enable(name, **kwargs)
  Enable the named service to start at boot.
  flags [None] Set optional flags to run the service with.
  service.flags can be used to change the default flags.
  CLI Example:
  ```
  salt '*' service.enable <service name>
  salt '*' service.enable <service name> flags=<flags>
  ```

salt.modules.openbsdrcctl.enabled(name, **kwargs)
  Return True if the named service is enabled at boot and the provided flags match the configured ones (if any).
  Return False otherwise.
  name Service name
  CLI Example:
  ```
  salt '*' service.enabled <service name>
  salt '*' service.enabled <service name> flags=<flags>
  ```

salt.modules.openbsdrcctl.get_all()
  Return all installed services.
  CLI Example:
  ```
  salt '*' service.get_all
  ```

salt.modules.openbsdrcctl.get_disabled()
  Return what services are available but not enabled to start at boot.
  CLI Example:
  ```
  salt '*' service.get_disabled
  ```

salt.modules.openbsdrcctl.get_enabled()
  Return what services are set to run on boot.
  CLI Example:
salt '!' service.get_enabled

salt.modules.openbsdrctl.missing(name)
The inverse of service.available. Return True if the named service is not available.

CLI Example:
salt '!' service.missing sshd

salt.modules.openbsdrctl.reload(name)
Reload the named service.

CLI Example:
salt '!' service.reload <service name>

salt.modules.openbsdrctl.restart(name)
Restart the named service.

CLI Example:
salt '!' service.restart <service name>

salt.modules.openbsdrctl.start(name)
Start the named service.

CLI Example:
salt '!' service.start <service name>

salt.modules.openbsdrctl.status(name, sig=None)
Return the status for a service, returns a bool whether the service is running.

CLI Example:
salt '!' service.status <service name>

salt.modules.openbsdrctl.stop(name)
Stop the named service.

CLI Example:
salt '!' service.stop <service name>

13.6.210 salt.modules.openbsdservice

The service module for OpenBSD

Important: If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `service.start` is not available), see here.

salt.modules.openbsdservice.available(name)

New in version 2014.7.0.

Returns True if the specified service is available, otherwise returns False.

CLI Example:
salt 'salt '*' service.available sshd

`salt.modules.openbsdservice.disabled(name)`
New in version 2014.7.0.
Return True if the named service is disabled, false otherwise
CLI Example:
```
salt 'salt '*' service.disabled <service name>
```

`salt.modules.openbsdservice.enabled(name, **kwargs)`
New in version 2014.7.0.
Return True if the named service is enabled, false otherwise
CLI Example:
```
salt 'salt '*' service.enabled <service name>
```

`salt.modules.openbsdservice.get_all()`
New in version 2014.7.0.
Return all available boot services
CLI Example:
```
salt 'salt '*' service.get_all
```

`salt.modules.openbsdservice.get_disabled()`
New in version 2014.7.0.
Return a set of services that are installed but disabled
CLI Example:
```
salt 'salt '*' service.get_disabled
```

`salt.modules.openbsdservice.get_enabled()`
New in version 2014.7.0.
Return a list of service that are enabled on boot
CLI Example:
```
salt 'salt '*' service.get_enabled
```

`salt.modules.openbsdservice.missing(name)`
New in version 2014.7.0.
The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.
CLI Example:
```
salt 'salt '*' service.missing sshd
```

`salt.modules.openbsdservice.reload(name)`
New in version 2014.7.0.
Reload the named service
13.6.211 salt.modules.openstack_config

Modify, retrieve, or delete values from OpenStack configuration files.

salt.modules.openstack_config.delete(filename, section, parameter)
Delete a value from an OpenStack configuration file.
filename The full path to the configuration file
section The section from which to delete the parameter
parameter The parameter to delete

CLI Example:
salt-call openstack_config.delete /etc/keystone/keystone.conf sql_connection

salt.modules.openstack_config.get(filename, section, parameter)
Get a value from an OpenStack configuration file.
filename The full path to the configuration file
section The section from which to search for the parameter
parameter The parameter to return
CLI Example:

```
salt-call openstack_config.get /etc/keystone/keystone.conf sql connection
```

```
salt.modules.openstack_config.set(filename, section, parameter, value)
```

Set a value in an OpenStack configuration file.

- **filename** The full path to the configuration file
- **section** The section in which the parameter will be set
- **parameter** The parameter to change
- **value** The value to set

CLI Example:

```
salt-call openstack_config.set /etc/keystone/keystone.conf sql connection foo
```

## 13.6.212 salt.modules.openvswitch module

Support for Open vSwitch - module with basic Open vSwitch commands.

Suitable for setting up Openstack Neutron.

**codeauthor** Jiri Kotlin &lt;jiri.kotlin@ultimum.io&gt;

```
salt.modules.openvswitch.bridge_create(br, may_exist=True)
```

Creates a new bridge.

**Args:**
- **br:** A string - bridge name
- **may_exist:** Bool, if False - attempting to create a bridge that exists returns False.

**Returns:** True on success, else False.

New in version 2016.3.0.

CLI Example: .. code-block:: bash

```
salt '*' openvswitch.bridge_create br0
```

```
salt.modules.openvswitch.bridge_delete(br, if_exists=True)
```

Deletes bridge and all of its ports.

**Args:**
- **br:** A string - bridge name
- **if_exists:** Bool, if False - attempting to delete a bridge that does not exist returns False.

**Returns:** True on success, else False.

New in version 2016.3.0.

CLI Example: .. code-block:: bash

```
salt '*' openvswitch.bridge_delete br0
```

```
salt.modules.openvswitch.bridge_exists(br)
```

Tests whether bridge exists as a real or fake bridge.

**Returns:** True if Bridge exists, else False.

New in version 2016.3.0.

CLI Example: .. code-block:: bash

```
salt '*' openvswitch.bridge_exists br0
```

```
salt.modules.openvswitch.bridge_list()
```

Lists all existing real and fake bridges.

**Returns:** List of bridges (or empty list), False on failure.

New in version 2016.3.0.

CLI Example: .. code-block:: bash

```
salt '*' openvswitch.bridge_list
```
salt.modules.openvswitch.\texttt{interface\_get\_options}(port)

Port's interface's optional parameters.

\textbf{Args:}\ port: A string - port name.
\textbf{Returns:}\ String containing optional parameters of port's interface, False on failure.

New in version 2016.3.0.

CLI Example: .. code-block:: bash
   salt `*` openvswitch.interface_get_options tap0

salt.modules.openvswitch.\texttt{interface\_get\_type}(port)

Type of port's interface.

\textbf{Args:}\ port: A string - port name.
\textbf{Returns:}\ String - type of interface or empty string, False on failure.

New in version 2016.3.0.

CLI Example: .. code-block:: bash
   salt `*` openvswitch.interface_get_type tap0

salt.modules.openvswitch.\texttt{port\_add}(br, port, may_exist=False)

Creates on bridge a new port named port.

\textbf{Returns:}\ True on success, else False.

\textbf{Args:}\ br: A string - bridge name port: A string - port name may_exist: Bool, if False - attempting to create a port that exists returns False.

New in version 2016.3.0.

CLI Example: .. code-block:: bash
   salt `*` openvswitch.port_add br0 8080

salt.modules.openvswitch.\texttt{port\_create\_gre}(br, port, id, remote)

Generic Routing Encapsulation - creates GRE tunnel between endpoints.

\textbf{Args:}\ br: A string - bridge name port: A string - port name id: An integer - unsigned 32-bit number, tunnel's key. remote: A string - remote endpoint's IP address.
\textbf{Returns:}\ True on success, else False.

New in version 2016.3.0.

CLI Example: .. code-block:: bash
   salt `*` openvswitch.port_create_gre br0 gre1 5001 192.168.1.10

salt.modules.openvswitch.\texttt{port\_create\_vlan}(br, port, id)

Isolate VM traffic using VLANs.

\textbf{Args:}\ br: A string - bridge name. port: A string - port name. id: An integer in the valid range 0 to 4095 (inclusive), name of VLAN.
\textbf{Returns:}\ True on success, else False.

New in version 2016.3.0.

CLI Example: .. code-block:: bash
   salt `*` openvswitch.port_create_vlan br0 tap0 100

salt.modules.openvswitch.\texttt{port\_create\_vxlan}(br, port, id, remote, dst_port=None)

Virtual eXtensible Local Area Network - creates VXLAN tunnel between endpoints.

\textbf{Args:}\ br: A string - bridge name. port: A string - port name. id: An integer - unsigned 64-bit number, tunnel's key. remote: A string - remote endpoint's IP address. dst_port: An integer - port to use when creating tunnelport in the switch.
\textbf{Returns:}\ True on success, else False.

New in version 2016.3.0.

CLI Example: .. code-block:: bash
   salt `*` openvswitch.port_create_vxlan br0 vx1 5001 192.168.1.10 8472
salt.modules.openvswitch.port_get_tag(port)
    Lists tags of the port.
    Args: port: A string - port name.
    Returns: List of tags (or empty list), False on failure.
    New in version 2016.3.0.
    CLI Example: .. code-block:: bash
        salt '*' openvswitch.port_get_tag tap0

salt.modules.openvswitch.port_list(br)
    Lists all of the ports within bridge.
    Args: br: A string - bridge name.
    Returns: List of bridges (or empty list), False on failure.
    New in version 2016.3.0.
    CLI Example: .. code-block:: bash
        salt '*' openvswitch.port_list br0

salt.modules.openvswitch.port_remove(br, port, if_exists=True)
    Deletes port.
    Args: br: A string - bridge name (If bridge is None, port is removed from whatever bridge contains it) port: A string - port name. if_exists: Bool, if False - attempting to delete a port that does not exist returns False. (Default True)
    Returns: True on success, else False.
    New in version 2016.3.0.
    CLI Example: .. code-block:: bash
        salt '*' openvswitch.port_remove br0 8080

13.6.213 salt.modules.opkg module

Support for Opkg

Important: If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install' is not available), see here.

Note: For version comparison support, the opkg-utils package must be installed.

salt.modules.opkg.available_version(*names, **kwargs)
    Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.
    If the latest version of a given package is already installed, an empty string will be returned for that package.
    CLI Example:
        salt '*' pkg.latest_version <package name>
salt '*' pkg,latest_version <package name>
salt '*' pkg,latest_version <package1> <package2> <package3> ...

salt.modules.opkg.del_repo(alias)
    Delete a repo from /etc/opkg/* .conf
    If the file does not contain any other repo configuration, the file itself will be deleted.
Let's go through each function and its description:

- **salt.modules.opkg.file_dict('packages')**
  - List the files that belong to a package, grouped by package. Not specifying any packages will return a list of _every_ file on the system's package database (not generally recommended).
  - CLI Examples:
    ```
salt '* pkg.del_repo alias
    ```

- **salt.modules.opkg.file_list('packages')**
  - List the files that belong to a package. Not specifying any packages will return a list of _every_ file on the system's package database (not generally recommended).
  - CLI Examples:
    ```
salt '* pkg.file_list httpd
salt '* pkg.file_list httpd postfix
salt '* pkg.file_list
    ```

- **salt.modules.opkg.get_repo(alias)**
  - Display a repo from the /etc/opkg/* .conf
  - CLI Examples:
    ```
salt '* pkg.get_repo alias
    ```

- **salt.modules.opkg.hold(name=None, pkgs=None, sources=None, **kwargs)**
  - Set package in `hold` state, meaning it will not be upgraded.
  - **name** The name of the package, e.g., `tmux`
    - CLI Example:
      ```
salt '* pkg.hold <package name>
    ```
  - **pkgs** A list of packages to hold. Must be passed as a python list.
    - CLI Example:
      ```
salt '* pkg.hold pkgs=['"foo", "bar"]'
    ```

- **salt.modules.opkg.install(name=None, refresh=False, pkgs=None, sources=None, **kwargs)**
  - Install the passed package, add refresh=True to update the opkg database.
  - **name** The name of the package to be installed. Note that this parameter is ignored if either ``pkgs`` or ``sources`` is passed. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the ``sources`` option.
    - CLI Example:
      ```
salt '*' pkg.install <package name>
    ```
  - **refresh** Whether or not to refresh the package database before installing.
  - **pkgs** A list of packages to install from a software repository. Must be passed as a python list.
    - CLI Example:
salt 'salt '*' pkg.install pkgs='["foo", "bar"]'  
sources A list of IPK packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package. Dependencies are automatically resolved and marked as auto-installed.

CLI Example:

```bash
salt 'salt '*' pkg.install sources='["foo": "salt://foo.deb"],{"bar": "salt://bar.deb"}]'
```

install_recommends Whether to install the packages marked as recommended. Default is True.

Returns a dict containing the new package names and versions:

```python
{
    '<package>': {
        'old': '<old-version>',
        'new': '<new-version>'
    }
}
```

salt.modules.opkg.latest_version(names, **kwargs)

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:

```bash
salt 'salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

salt.modules.opkg.list_pkgs(versions_as_list=False, **kwargs)

List the packages currently installed in a dict:

```python
{
    '<package_name>': '<version>'
}
```

CLI Example:

```bash
salt 'salt '*' pkg.list_pkgs
salt '*' pkg.list_pkgs versions_as_list=True
```

salt.modules.opkg.list_repos()

Lists all repos on /etc/opkg/*/*.conf

CLI Example:

```bash
salt 'salt '*' pkg.list_repos
```

salt.modules.opkg.list_upgrades(refresh=True)

List all available package upgrades.

CLI Example:

```bash
salt 'salt '*' pkg.list_upgrades
```

salt.modules.opkg.mod_repo(alias, **kwargs)

Modify one or more values for a repo. If the repo does not exist, it will be created, so long as uri is defined.

The following options are available to modify a repo definition:

- **alias** alias by which opkg refers to the repo.
- **uri** the URI to the repo.
- **compressed** defines (True or False) if the index file is compressed
enabled enable or disable (True or False) repository but do not remove if disabled.
refresh enable or disable (True or False) auto-refresh of the repositories

CLI Examples:

```
salt '*' pkg.mod_repo alias uri=http://new/uri
salt '*' pkg.mod_repo alias enabled=False
```

salt.modules.opkg.owner("paths")
Return the name of the package that owns the file. Multiple file paths can be passed. Like pkg.version
salt.modules.opkg.version, if a single path is passed, a string will be returned, and if multiple paths
are passed, a dictionary of file/package name pairs will be returned.

If the file is not owned by a package, or is not present on the minion, then an empty string will be returned
for that path.

CLI Example:
```
salt '*' pkg.owner /usr/bin/apachectl salt '*' pkg.owner /usr/bin/apachectl /usr/bin/basename
```

salt.modules.opkg.purge(name=None, pkgs=None, **kwargs)
Package purges are not supported by opkg, this function is identical to pkg.remove.
name The name of the package to be deleted.

Multiple Package Options:
pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this
option is passed.

Returns a dict containing the changes.

CLI Example:
```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'
```

salt.modules.opkg.refresh_db()
Updates the opkg database to latest packages based upon repositories

Returns a dict, with the keys being package databases and the values being the result of the update attempt.

Values can be one of the following:
- True: Database updated successfully
- False: Problem updating database

CLI Example:
```
salt '*' pkg.refresh_db
```

salt.modules.opkg.remove(name=None, pkgs=None, **kwargs)
Remove packages using opkg remove.
name The name of the package to be deleted.

Multiple Package Options:

pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this
option is passed.

Returns a dict containing the changes.

CLI Example:
```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

salt.modules.opkg.unhold(name=None, pkgs=None, sources=None, **kwargs)
Set package current in 'hold' state to install state, meaning it will be upgraded.
name  The name of the package, e.g., 'tmux'

CLI Example:

```
salt '*' pkg.unhold <package name>
```

pkgs  A list of packages to hold. Must be passed as a python list.

CLI Example:

```
salt '*' pkg.unhold pkgs=\['"foo", "bar"\']
```

salt.modules.opkg.upgrade( `refresh=True` )

Upgrades all packages via `opkg upgrade`

Returns a dict containing the changes.

{`<package>`: `{`old`: `<old-version>`, `new`: `<new-version>`}`}

CLI Example:

```
salt '*' pkg.upgrade
```

salt.modules.opkg.upgrade_available( `name` )

Check whether or not an upgrade is available for a given package

CLI Example:

```
salt '*' pkg.upgrade_available <package name>
```

salt.modules.opkg.version( `names`, **kwargs `)`

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

salt.modules.opkg.version_cmp( `pkg1`, `pkg2`, ignore_epoch=False `)`

Do a cmp-style comparison on two packages. Return -1 if pkg1 < pkg2, 0 if pkg1 == pkg2, and 1 if pkg1 > pkg2. Return None if there was a problem making the comparison.

`ignore_epoch` [False] Set to True to ignore the epoch when comparing versions

New in version 2016.3.4.

CLI Example:

```
salt '*' pkg.version_cmp '0.2.4-0' '0.2.4.1-0'
```

13.6.214 salt.modules.oracle

Oracle Database connection module

maintainer  Vladimir Bormotov <bormotov@gmail.com>
maturity  new
depends  cx_Oracle
platform  all
configuration module provide connections for multiple Oracle DB instances.

OS Environment

<table>
<thead>
<tr>
<th>configuration</th>
<th>ORACLE_HOME: path to oracle product</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>PATH: path to Oracle Client libs need to be in PATH</td>
</tr>
</tbody>
</table>

pillar

<table>
<thead>
<tr>
<th>configuration</th>
<th>oracle.dbs: list of known based</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>oracle.dbs.&lt;db&gt;.uri: connection credentials in format:</td>
</tr>
<tr>
<td></td>
<td>user/password@host[:port]/sid[ as {sysdba</td>
</tr>
</tbody>
</table>

salt.modules.oracle.client_version()  
Oracle Client Version  
CLI Example:

```
salt '*' oracle.client_version
```

salt.modules.oracle.run_query(db, query)  
Run SQL query and return result  
CLI Example:

```
salt '*' oracle.run_query my_db "select * from my_table"
```

salt.modules.oracle.show_dbs('dbs)  
Show databases configuration from pillar. Filter by 'args  
CLI Example:

```
salt '*' oracle.show_dbs  
salt '*' oracle.show_dbs my_db
```

salt.modules.oracle.show_env()  
Show Environment used by Oracle Client  
CLI Example:

```
salt '*' oracle.show_env
```

Note: at first _connect() NLS_LANG will forced to `.AL32UTF8`

salt.modules.oracle.show_pillar(item=None)  
Show Pillar segment oracle:* and subitem with notation `"item:subitem"`  
CLI Example:

```
salt '*' oracle.show_pillar  
salt '*' oracle.show_pillar dbs:my_db
```

salt.modules.oracle.version('dbs)  
Server Version (select banner from v$version)  
CLI Example:
13.6.215 salt.modules.osquery

New in version 2015.8.0.
salt.modules.osquery.acpi_tables(*, where=None)
    Return acpi_tables information from osquery
    CLI Example:
    `salt '*' osquery.acpi_tables`

salt.modules.osquery.alf(*, where=None)
    Return alf information from osquery
    CLI Example:
    `salt '*' osquery.alf`

salt.modules.osquery.alf_exceptions(*, where=None)
    Return alf_exceptions information from osquery
    CLI Example:
    `salt '*' osquery.alf_exceptions`

salt.modules.osquery.alf_explicit_auths(*, where=None)
    Return alf_explicit_auths information from osquery
    CLI Example:
    `salt '*' osquery.alf_explicit_auths`

salt.modules.osquery.alf_services(*, where=None)
    Return alf_services information from osquery
    CLI Example:
    `salt '*' osquery.alf_services`

salt.modules.osquery.apps(*, where=None)
    Return apps information from osquery
    CLI Example:
    `salt '*' osquery.apps`

salt.modules.osquery.apt_sources(*, where=None)
    Return apt_sources information from osquery
    CLI Example:
    `salt '*' osquery.apt_sources`
salt.modules.osquery.arp_cache(*args=None, where=None)
    Return arp_cache information from osquery
    CLI Example:
    
    salt '*' osquery.arp_cache

salt.modules.osquery.block_devices(*args=None, where=None)
    Return block_devices information from osquery
    CLI Example:
    
    salt '*' osquery.block_devices

salt.modules.osquery.certificates(*args=None, where=None)
    Return certificates information from osquery
    CLI Example:
    
    salt '*' osquery.certificates

salt.modules.osquery.chrome_extensions(*args=None, where=None)
    Return chrome_extensions information from osquery
    CLI Example:
    
    salt '*' osquery.chrome_extensions

salt.modules.osquery.cpuid(*args=None, where=None)
    Return cpuid information from osquery
    CLI Example:
    
    salt '*' osquery.cpuid

salt.modules.osquery.crontab(*args=None, where=None)
    Return crontab information from osquery
    CLI Example:
    
    salt '*' osquery.crontab

salt.modules.osquery.deb_packages(*args=None, where=None)
    Return deb_packages information from osquery
    CLI Example:
    
    salt '*' osquery.deb_packages

salt.modules.osquery.etc_hosts(*args=None, where=None)
    Return etc_hosts information from osquery
    CLI Example:
    
    salt '*' osquery.etc_hosts

salt.modules.osquery.etc_services(*args=None, where=None)
    Return etc_services information from osquery
    CLI Example:
salt '*' osquery.etc_services

```
salt.modules.osquery.file(attrs=None, where=None)
    Return file information from osquery
    CLI Example:
    salt '*' osquery.file
```

```
salt.modules.osquery.file_changes(attrs=None, where=None)
    Return file_changes information from osquery
    CLI Example:
    salt '*' osquery.file_changes
```

```
salt.modules.osquery.firefox_addons(attrs=None, where=None)
    Return firefox_addons information from osquery
    CLI Example:
    salt '*' osquery.firefox_addons
```

```
salt.modules.osquery.groups(attrs=None, where=None)
    Return groups information from osquery
    CLI Example:
    salt '*' osquery.groups
```

```
salt.modules.osquery.hardware_events(attrs=None, where=None)
    Return hardware_events information from osquery
    CLI Example:
    salt '*' osquery.hardware_events
```

```
salt.modules.osquery.hash(attrs=None, where=None)
    Return hash information from osquery
    CLI Example:
    salt '*' osquery.hash
```

```
salt.modules.osquery.homebrew_packages(attrs=None, where=None)
    Return homebrew_packages information from osquery
    CLI Example:
    salt '*' osquery.homebrew_packages
```

```
salt.modules.osquery.interface_addresses(attrs=None, where=None)
    Return interface_addresses information from osquery
    CLI Example:
    salt '*' osquery.interface_addresses
```
salt.modules.osquery.**interface_details**(atts=None, where=None)
Return interface_details information from osquery

CLI Example:
```
salt '*' osquery.interface_details
```

salt.modules.osquery.**iokit_devicetree**(atts=None, where=None)
Return iokit_devicetree information from osquery

CLI Example:
```
salt '*' osquery.iokit_devicetree
```

salt.modules.osquery.**iokit_registry**(atts=None, where=None)
Return iokit_registry information from osquery

CLI Example:
```
salt '*' osquery.iokit_registry
```

salt.modules.osquery.**kernel_extensions**(atts=None, where=None)
Return kernel_extensions information from osquery

CLI Example:
```
salt '*' osquery.kernel_extensions
```

salt.modules.osquery.**kernel_info**(atts=None, where=None)
Return kernel_info information from osquery

CLI Example:
```
salt '*' osquery.kernel_info
```

salt.modules.osquery.**kernel_integrity**(atts=None, where=None)
Return kernel_integrity information from osquery

CLI Example:
```
salt '*' osquery.kernel_integrity
```

salt.modules.osquery.**kernel_modules**(atts=None, where=None)
Return kernel_modules information from osquery

CLI Example:
```
salt '*' osquery.kernel_modules
```

salt.modules.osquery.**keychain_items**(atts=None, where=None)
Return keychain_items information from osquery

CLI Example:
```
salt '*' osquery.keychain_items
```

salt.modules.osquery.**last**(atts=None, where=None)
Return last information from osquery

CLI Example:
```
salt '*' osquery.last
```

```
salt.modules.osquery.launchd(attrs=None, where=None)
Return launchd information from osquery

CLI Example:

```
salt '*' osquery.launchd
```
```
salt.modules.osquery.listening_ports(attrs=None, where=None)
Return listening_ports information from osquery

CLI Example:

```
salt '*' osquery.listening_ports
```
```
salt.modules.osquery.logged_in_users(attrs=None, where=None)
Return logged_in_users information from osquery

CLI Example:

```
salt '*' osquery.logged_in_users
```
```
salt.modules.osquery.memory_map(attrs=None, where=None)
Return memory_map information from osquery

CLI Example:

```
salt '*' osquery.memory_map
```
```
salt.modules.osquery.mounts(attrs=None, where=None)
Return mounts information from osquery

CLI Example:

```
salt '*' osquery.mounts
```
```
salt.modules.osquery.nfs_shares(attrs=None, where=None)
Return nfs_shares information from osquery

CLI Example:

```
salt '*' osquery.nfs_shares
```
```
salt.modules.osquery.nvram(attrs=None, where=None)
Return nvram information from osquery

CLI Example:

```
salt '*' osquery.nvram
```
```
salt.modules.osquery.os_version(attrs=None, where=None)
Return os_version information from osquery

CLI Example:

```
salt '*' osquery.os_version
```

salt.modules.osquery.osquery_extensions(attrs=None, where=None)
Return osquery_extensions information from osquery

CLI Example:
```
salt '*' osquery.osquery_extensions
```

salt.modules.osquery.osquery_flags(attrs=None, where=None)
Return osquery_flags information from osquery

CLI Example:
```
salt '*' osquery.osquery_flags
```

salt.modules.osquery.osquery_info(attrs=None, where=None)
Return osquery_info information from osquery

CLI Example:
```
salt '*' osquery.osquery_info
```

salt.modules.osquery.osquery_registry(attrs=None, where=None)
Return osquery_registry information from osquery

CLI Example:
```
salt '*' osquery.osquery_registry
```

salt.modules.osquery.passwd_changes(attrs=None, where=None)
Return passwd_changes information from osquery

CLI Example:
```
salt '*' osquery.passwd_changes
```

salt.modules.osquery.pci_devices(attrs=None, where=None)
Return pci_devices information from osquery

CLI Example:
```
salt '*' osquery.pci_devices
```

salt.modules.osquery.preferences(attrs=None, where=None)
Return preferences information from osquery

CLI Example:
```
salt '*' osquery.preferences
```

salt.modules.osquery.process_envs(attrs=None, where=None)
Return process_envs information from osquery

CLI Example:
```
salt '*' osquery.process_envs
```

salt.modules.osquery.process_memory_map(attrs=None, where=None)
Return process_memory_map information from osquery

CLI Example:
salt '*' osquery.process_memory_map

salt.modules.osquery.process_open_files(attrs=None, where=None)
Return process_open_files information from osquery
CLI Example:
salt '*' osquery.process_open_files

salt.modules.osquery.process_open_sockets(attrs=None, where=None)
Return process_open_sockets information from osquery
CLI Example:
salt '*' osquery.process_open_sockets

salt.modules.osquery.processes(attrs=None, where=None)
Return processes information from osquery
CLI Example:
salt '*' osquery.processes

salt.modules.osquery.quarantine(attrs=None, where=None)
Return quarantine information from osquery
CLI Example:
salt '*' osquery.quarantine

salt.modules.osquery.query(sql=None)
Return time information from osquery
CLI Example:
salt '*' osquery.query "select * from users;"

salt.modules.osquery.routes(attrs=None, where=None)
Return routes information from osquery
CLI Example:
salt '*' osquery.routes

salt.modules.osquery.rpm_packages(attrs=None, where=None)
Return cpuid information from osquery
CLI Example:
salt '*' osquery.rpm_packages

salt.modules.osquery.safari_extensions(attrs=None, where=None)
Return safari_extensions information from osquery
CLI Example:
salt '*' osquery.safari_extensions
- **salt.modules.osquery.shared_memory**(attrs=None, where=None)
  Return shared_memory information from osquery

  CLI Example:
  ```
salt '*' osquery.shared_memory
  ```

- **salt.modules.osquery.shell_history**(attrs=None, where=None)
  Return shell_history information from osquery

  CLI Example:
  ```
salt '*' osquery.shell_history
  ```

- **salt.modules.osquery.smbios_tables**(attrs=None, where=None)
  Return smbios_tables information from osquery

  CLI Example:
  ```
salt '*' osquery.smbios_tables
  ```

- **salt.modules.osquery.startup_items**(attrs=None, where=None)
  Return startup_items information from osquery

  CLI Example:
  ```
salt '*' osquery.startup_items
  ```

- **salt.modules.osquery.suid_bin**(attrs=None, where=None)
  Return suid_bin information from osquery

  CLI Example:
  ```
salt '*' osquery.suid_bin
  ```

- **salt.modules.osquery.system_controls**(attrs=None, where=None)
  Return system_controls information from osquery

  CLI Example:
  ```
salt '*' osquery.system_controls
  ```

- **salt.modules.osquery.time**(attrs=None)
  Return time information from osquery

  CLI Example:
  ```
salt '*' osquery.time
  ```

- **salt.modules.osquery.usb_devices**(attrs=None, where=None)
  Return usb_devices information from osquery

  CLI Example:
  ```
salt '*' osquery.usb_devices
  ```

- **salt.modules.osquery.users**(attrs=None, where=None)
  Return users information from osquery

  CLI Example:
salt '*' osquery.users

salt.modules.osquery.version()
    Return version of osquery
    CLI Example:
    
salt '*' osquery.version

salt.modules.osquery.xattr_where_from(attrs=None, where=None)
    Return xattr_where_from information from osquery
    CLI Example:
    
salt '*' osquery.xattr_where_from

salt.modules.osquery.xprotect_entries(attrs=None, where=None)
    Return xprotect_entries information from osquery
    CLI Example:
    
salt '*' osquery.xprotect_entries

salt.modules.osquery.xprotect_reports(attrs=None, where=None)
    Return xprotect_reports information from osquery
    CLI Example:
    
salt '*' osquery.xprotect_reports

13.6.216 salt.modules.pacman

A module to wrap pacman calls, since Arch is the best (https://wiki.archlinux.org/index.php/Arch_is_the_best)

Important: If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install' is not available), see here.

salt.modules.pacman.file_dict('packages)
    List the files that belong to a package, grouped by package. Not specifying any packages will return a list of _every_ file on the system's package database (not generally recommended).
    CLI Examples:
    
    salt '*' pkg.file_list httpd
    salt '*' pkg.file_list httpd postfix
    salt '*' pkg.file_list

salt.modules.pacman.file_list('packages)
    List the files that belong to a package. Not specifying any packages will return a list of _every_ file on the system's package database (not generally recommended).
    CLI Examples:
    
    salt '*' pkg.file_list httpd
    salt '*' pkg.file_list httpd postfix
    salt '*' pkg.file_list
salt.modules.pacman.install(name=None, refresh=False, sysupgrade=False, pkgs=None, sources=None, **kwargs)

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, systemd-run(1) is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any pacman commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Install (pacman -S) the specified packag(s). Add refresh=True to install with -y, add sysupgrade=True to install with -u.

name The name of the package to be installed. Note that this parameter is ignored if either pkgs or sources is passed. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the sources option.

CLI Example:

```
salt '*' pkg.install <package name>
```

refresh Whether or not to refresh the package database before installing.

sysupgrade Whether or not to upgrade the system packages before installing.

Multiple Package Installation Options:

pkgs A list of packages to install from a software repository. Must be passed as a python list. A specific version number can be specified by using a single-element dict representing the package and its version. As with the version parameter above, comparison operators can be used to target a specific version of a package.

CLI Examples:

```
salt '*' pkg.install pkgs='["foo", "bar"]'
salt '*' pkg.install pkgs='["foo", {"bar": "1.2.3-4"}]'
salt '*' pkg.install pkgs='["foo", {"bar": "<1.2.3-4"}]'
```

sources A list of packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

CLI Example:

```
salt '*' pkg.install sources='[{"foo": "salt://foo.pkg.tar.xz"},
                           {"bar": "salt://bar.pkg.tar.xz"}]'
```

Returns a dict containing the new package names and versions:

```
{
    '<package>': 
        {'old': '<old-version>',
         'new': '<new-version>'}
}
```

salt.modules.pacman.latest_version(*names, **kwargs)

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

salt.modules.pacman.list_pkgs(versions_as_list=False, **kwargs)

List the packages currently installed as a dict:
{'<package_name>': '<version>'}

CLI Example:
```
salt '*' pkg.list_pkgs
```

`salt.modules.pacman.list_upgrades(refresh=False, root=None, **kwargs)`
List all available package upgrades on this system

CLI Example:
```
salt '*' pkg.list_upgrades
```

`salt.modules.pacman.owner(*paths)`
New in version 2014.7.0.
Return the name of the package that owns the file. Multiple file paths can be passed. Like `pkg.version`
`<salt.modules.yumpkg.version`, if a single path is passed, a string will be returned, and if multiple
paths are passed, a dictionary of file/package name pairs will be returned.
If the file is not owned by a package, or is not present on the minion, then an empty string will be returned
for that path.

CLI Example:
```
salt '*' pkg.owner /usr/bin/apachectl salt '*' pkg.owner /usr/bin/apachectl /usr/bin/zsh
```

`salt.modules.pacman.purge(name=None, pkgs=None, **kwargs)`
Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, `systemd-run(1)`
is now used to isolate commands which modify installed packages from the `salt-minion` daemon's control group.
This is done to keep systemd from killing any pacman commands spawned by Salt when the `salt-minion`
service is restarted. (see `KillMode` in the `systemd.kill(5)` manpage for more information). If desired, usage
of `systemd-run(1)` can be suppressed by setting a config option called `systemd.scope`, with a value
of `False` (no quotes).
Recursively remove a package and all dependencies which were installed with it, this will call a `pacman -Rsc`
name The name of the package to be deleted.
Multiple Package Options:

pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this
option is passed.
New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:
```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'
```

`salt.modules.pacman.refresh_db(root=None)`

Just run a `pacman -Sy`, return a dict:
```
{'<database name>': Bool}
```

CLI Example:
```
salt '*' pkg.refresh_db
```
**salt.modules.pacman.remove** *(name=None, pkgs=None, **kwargs)*

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any pacman commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of `systemd-run(1)` can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Remove packages with `pacman -R`.

**name** The name of the package to be deleted.

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```bash
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

**salt.modules.pacman.upgrade** *(refresh=False, root=None, **kwargs)*

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any pacman commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of `systemd-run(1)` can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Run a full system upgrade, a pacman -Syu.

**refresh** Whether or not to refresh the package database before installing.

Return a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
               'new': '<new-version>'}}
```

CLI Example:

```bash
salt '*' pkg.upgrade
```

**salt.modules.pacman.upgrade_available** *(name)*

Check whether or not an upgrade is available for a given package

CLI Example:

```bash
salt '*' pkg.upgrade_available <package name>
```

**salt.modules.pacman.version** *(names, **kwargs)*

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```bash
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```
13.6.217 salt.modules.pagerduty

Module for Firing Events via PagerDuty

New in version 2014.1.0.

configuration This module can be used by specifying the name of a configuration profile in the minion config, minion pillar, or master config.

For example:

```yaml
my-pagerduty-account:
pagerduty.api_key: F3Rbyjbve43rfFw2214
pagerduty.subdomain: mysubdomain
```

salt.modules.pagerduty.create_event(service_key=None, description=None, details=None, incident_key=None, profile=None)

Create an event in PagerDuty. Designed for use in states.

CLI Example:

```
salt myminion pagerduty.create_event <service_key> <description> <details> ⬤
−profile=my-pagerduty-account
```

The following parameters are required:

- **service_key** This key can be found by using pagerduty.list_services.
- **description** This is a short description of the event.
- **details** This can be a more detailed description of the event.
- **profile** This refers to the configuration profile to use to connect to the PagerDuty service.

salt.modules.pagerduty.list_escalation_policies(profile=None, api_key=None)

This function is an alias of list_policies.

List escalation policies belonging to this account

CLI Example:

```
salt myminion pagerduty.list_policies my-pagerduty-account salt myminion pagerduty.list_escalation_policies my-pagerduty-account
```

salt.modules.pagerduty.list_incidents(profile=None, api_key=None)

List incidents belonging to this account

CLI Example:

```
salt myminion pagerduty.list_incidents my-pagerduty-account
```

salt.modules.pagerduty.list_maintenance_windows(profile=None, api_key=None)

This function is an alias of list_windows.

List maintenance windows belonging to this account

CLI Example:

```
salt myminion pagerduty.list_windows my-pagerduty-account salt myminion pagerduty.list_maintenance_windows my-pagerduty-account
```

salt.modules.pagerduty.list_policies(profile=None, api_key=None)

List escalation policies belonging to this account

CLI Example:

```
salt myminion pagerduty.list_policies my-pagerduty-account salt myminion pagerduty.list_escalation_policies my-pagerduty-account
```

salt.modules.pagerduty.list_schedules(profile=None, api_key=None)

List schedules belonging to this account

CLI Example:

```
salt myminion pagerduty.list_schedules my-pagerduty-account
```
CLI Example:
salt myminion pagerduty.list_schedules my-pagerduty-account

```
salt.modules.pagerduty.list_services(profile=None, api_key=None)
```
List services belonging to this account

CLI Example:
salt myminion pagerduty.list_services my-pagerduty-account

```
salt.modules.pagerduty.list_users(profile=None, api_key=None)
```
List users belonging to this account

CLI Example:
salt myminion pagerduty.list_users my-pagerduty-account

```
salt.modules.pagerduty.list_windows(profile=None, api_key=None)
```
List maintenance windows belonging to this account

CLI Example:
salt myminion pagerduty.list_windows my-pagerduty-account salt myminion pagerduty.list_maintenance_windows my-pagerduty-account

### 13.6.218 salt.modules.pagerduty_util

Module for managing PagerDuty resource

**configuration**  
This module can be used by specifying the name of a configuration profile in the minion config, minion pillar, or master config. The default configuration profile name is `pagerduty`.

For example:

```
pagerduty:
    pagerduty.api_key: F3Rbyjbve43rfWFw2214
    pagerduty.subdomain: mysubdomain
```

For PagerDuty API details, see [https://developer.pagerduty.com/documentation/rest](https://developer.pagerduty.com/documentation/rest)

```
salt.modules.pagerduty_util.create_or_update_resource(resource_name, identifier_fields, data, diff=None, profile='pagerduty', subdomain=None, api_key=None)
```
create or update any pagerduty resource  
Helper method for present().

Determining if two resources are the same is different for different PD resource, so this method accepts a diff function. The diff function will be invoked as `diff(state_information, object_returned_from_pagerduty)`, and should return a dict of data to pass to the PagerDuty update API method, or None if no update is to be performed. If no diff method is provided, the default behavior is to scan the keys in the state_information, comparing the matching values in the object_returned_from_pagerduty, and update any values that differ.

**examples:**

```
create_or_update_resource(``user'', [''id'',''name'',''email''])
create_or_update_resource(``escalation_policies'', [''id'',''name''], diff=my_diff_function)
```

```
salt.modules.pagerduty_util.delete_resource(resource_name, key, identifier_fields, profile='pagerduty', subdomain=None, api_key=None)
```
delete any pagerduty resource

Helper method for absent()

**example:**

```
delete_resource(``users'', key, [''id'',''name'',''email'']) # delete by id or name or email
```
```python
salt.modules.pagerduty_util.get_escalation_policies(profile='pagerduty', subdomain=None, api_key=None)
```

List escalation_policies belonging to this account

CLI Example:
```
salt myminion pagerduty.get_escalation_policies
```

```python
salt.modules.pagerduty_util.get_resource(resource_name, key, identifier_fields, profile='pagerduty', subdomain=None, api_key=None)
```

Get any single pagerduty resource by key.

We allow flexible lookup by any of a list of identifier_fields. So, for example, you can look up users by email address or name by calling:
```
get_resource('users', key, ['name', 'email'], ...)
```

This method is mainly used to translate state sls into pagerduty id’s for dependent objects. For example, a pagerduty escalation policy contains one or more schedules, which must be passed by their pagerduty id. We look up the schedules by name (using this method), and then translate the names into id’s.

This method is implemented by getting all objects of the resource type (cached into __context__), then brute force searching through the list and trying to match any of the identifier_fields. The __context__ cache is purged after any create, update or delete to the resource.

```python
salt.modules.pagerduty_util.get_schedules(profile='pagerduty', subdomain=None, api_key=None)
```

List schedules belonging to this account

CLI Example:
```
salt myminion pagerduty.get_schedules
```

```python
salt.modules.pagerduty_util.get_services(profile='pagerduty', subdomain=None, api_key=None)
```

List services belonging to this account

CLI Example:
```
salt myminion pagerduty.get_services
```

```python
salt.modules.pagerduty_util.get_users(profile='pagerduty', subdomain=None, api_key=None)
```

List users belonging to this account

CLI Example:
```
salt myminion pagerduty.get_users
```

```python
salt.modules.pagerduty_util.resource_absent(resource, identifier_fields, profile='pagerduty', subdomain=None, api_key=None, **kwargs)
```

Generic resource.absent state method. Pagerduty state modules should be a thin wrapper over this method, with a custom diff function.

This method calls delete_resource() and formats the result as a salt state return value.

example: `resource_absent(``users'', [``id'',''name'',''email''])`

```python
salt.modules.pagerduty_util.resource_present(resource, identifier_fields, diff=None, profile='pagerduty', subdomain=None, api_key=None, **kwargs)
```

Generic resource.present state method. Pagerduty state modules should be a thin wrapper over this method, with a custom diff function.

This method calls create_or_update_resource() and formats the result as a salt state return value.

example: `resource_present(``users'', [``id'',''name'',''email''])`
13.6.219 salt.modules.pam

Support for pam

salt.modules.pam.read_file(file_name)
This is just a test function, to make sure parsing works

CLI Example:
```
salt '*' pam.read_file /etc/pam.d/login
```

13.6.220 salt.modules.parted

Module for managing partitions on POSIX-like systems.

depends

- parted, partprobe, lsblk (usually parted and util-linux packages)

Some functions may not be available, depending on your version of parted.

Check the manpage for parted(8) for more information, or the online docs at:

In light of parted not directly supporting partition IDs, some of this module has been written to utilize sfdisk instead.
For further information, please reference the man page for sfdisk(8).

salt.modules.parted.align_check(device, part_type, partition)
Check if partition satisfies the alignment constraint of part_type. Type must be "minimal" or "optimal".

CLI Example:
```
salt '*' partition.align_check /dev/sda minimal 1
```

salt.modules.parted.check(device, minor)
Checks if the file system on partition <minor> has any errors.

CLI Example:
```
salt '*' partition.check 1
```

salt.modules.parted.cp(device, from_minor, to_minor)
Copies the file system on the partition <from-minor> to partition <to-minor>, deleting the original contents
of the destination partition.

CLI Example:
```
salt '*' partition.cp /dev/sda 2 3
```

salt.modules.parted.exists(device='')
Check to see if the partition exists

CLI Example:
```
salt '*' partition.exists /dev/sdb1
```

salt.modules.parted.get_block_device()
Retrieve a list of disk devices

New in version 2014.7.0.
CLI Example:
```
salt '*' partition.get_block_device
```

```
salt.modules.parted.get_id(device, minor)
Prints the system ID for the partition. Some typical values are:
```
b: FAT32 (vfat)
7: HPFS/NTFS
82: Linux Swap
83: Linux
8e: Linux LVM
fd: Linux RAID Auto
```

CLI Example:
```
salt '*' partition.get_id /dev/sda 1
```

```
salt.modules.parted.list(device, unit=None)
Prints partition information of given <device>
```

CLI Examples:
```
salt '*' partition.list /dev/sda
salt '*' partition.list /dev/sda unit=s
salt '*' partition.list /dev/sda unit=kB
```

```
salt.modules.parted.mkfs(device, fs_type)
Makes a file system <fs_type> on partition <device>, destroying all data that resides on that partition.
<fs_type> must be one of "ext2", "fat32", "fat16", "linux-swap" or "reiserfs" (if libreiserfs is installed)
```

CLI Example:
```
salt '*' partition.mkfs /dev/sda2 fat32
```

```
salt.modules.parted.mklabel(device, label_type)
Create a new disklabel (partition table) of label_type.
Type should be one of "aix", "amiga", "bsd", "dvh", "gpt", "loop", "mac", "msdos", "pc98", or "sun".
```

CLI Example:
```
salt '*' partition.mklabel /dev/sda msdos
```

```
salt.modules.parted.mkpart(device, part_type=None, fs_type=None, start=None, end=None)
Make a part_type partition for filesystem fs_type, beginning at start and ending at end (by default in megabytes). part_type should be one of "primary", "logical", or "extended".
```

CLI Examples:
```
salt '*' partition.mkpart /dev/sda primary fs_type=fat32 start=0 end=639
salt '*' partition.mkpart /dev/sda primary start=0 end=639
```

```
salt.modules.parted.mkpartfs(device, part_type, fs_type, start, end)
Make a <part_type> partition with a new filesystem of <fs_type>, beginning at <start> and ending at <end> (by default in megabytes).
<part_type> should be one of "primary", "logical", or "extended". <fs_type> must be one of "ext2", "fat32", "fat16", "linux-swap" or "reiserfs" (if libreiserfs is installed)
```
CLI Example:

```bash
salt '*' partition.mkpartfs /dev/sda logical ext2 440 670
```

**salt.modules.parted.name**(device, partition, name)
Set the name of partition to name. This option works only on Mac, PC98, and GPT disklabels. The name can be placed in quotes, if necessary.

CLI Example:

```bash
salt '*' partition.name /dev/sda 1 'My Documents'
```

**salt.modules.partedprobe**(devices)
Ask the kernel to update its local partition data. When no args are specified all block devices are tried.

Caution: Generally only works on devices with no mounted partitions and may take a long time to return if specified devices are in use.

CLI Examples:

```bash
salt '*' partition.probe
salt '*' partition.probe /dev/sda
salt '*' partition.probe /dev/sda /dev/sdb
```

**salt.modules.parted.rescue**(device, start, end)
Rescue a lost partition that was located somewhere between start and end. If a partition is found, parted will ask if you want to create an entry for it in the partition table.

CLI Example:

```bash
salt '*' partition.rescue /dev/sda 0 8056
```

**salt.modules.parted.resize**(device, minor, start, end)
Resizes the partition with number <minor>.

The partition will start <start> from the beginning of the disk, and end <end> from the beginning of the disk.

resize never changes the minor number. Extended partitions can be resized, so long as the new extended partition completely contains all logical partitions.

CLI Example:

```bash
salt '*' partition.resize /dev/sda 3 200 850
```

**salt.modules.parted.rm**(device, minor)
Removes the partition with number <minor>.

CLI Example:

```bash
salt '*' partition.rm /dev/sda 5
```

**salt.modules.parted.set**(device, minor, flag, state)
Changes a flag on the partition with number <minor>.

A flag can be either `"on"` or `"off"` (make sure to use proper quoting, see YAML Idiosyncrasies). Some or all of these flags will be available, depending on what disk label you are using.

Valid flags are: bios_grub, legacy_boot, boot, lba, root, swap, hidden, raid, LVM, PALO, PREP, DIAG

CLI Example:

```bash
salt '*' partition.set /dev/sda 1 boot "on"
```
**salt.modules.parted.set_id**(device, minor, system_id)

Sets the system ID for the partition. Some typical values are:

- **b**: FAT32 (vfat)
- **7**: HPFS/NTFS
- **82**: Linux Swap
- **83**: Linux
- **8e**: Linux LVM
- **fd**: Linux RAID Auto

CLI Example:

```
salt '*' partition.set_id /dev/sda 1 83
```

**salt.modules.parted.system_types()**

List the system types that are supported by the installed version of sfdisk

CLI Example:

```
salt '*' partition.system_types
```

**salt.modules.parted.toggle**(device, partition, flag)

Toggle the state of `<flag>` on `<partition>`. Valid flags are the same as the set command.

CLI Example:

```
salt '*' partition.toggle /dev/sda 1 boot
```

---

**13.6.221 salt.modules.pecl**

Manage PHP pecl extensions.

**salt.modules.pecl.install**(pecls, defaults=False, force=False, preferred_state='stable')

New in version 0.17.0.

Installs one or several pecl extensions.

- **pecls**: The pecl extensions to install.
- **defaults**: Use default answers for extensions such as `pecl_http` which ask questions before installation. Without this option, the `pecl.installed` state will hang indefinitely when trying to install these extensions.
- **force**: Whether to force the installed version or not

CLI Example:

```
salt '*' pecl.install fuse
```

**salt.modules.pecl.list**(channel=None)

List installed pecl extensions.

CLI Example:

```
salt '*' pecl.list
```

**salt.modules.pecl.uninstall**(pecls)

Uninstall one or several pecl extensions.

- **pecls**: The pecl extensions to uninstall.

CLI Example:

```
salt '*' pecl.uninstall fuse
```
salt.modules.pecl.update(pecls)
Update one or several pecl extensions.
pecls  The pecl extensions to update.
CLI Example:

salt '*' pecl.update fuse

13.6.222 salt.modules.philips_hue module
Philips HUE lamps module for proxy.
New in version 2015.8.3.

13.6.223 salt.modules.pillar
Extract the pillar data for this minion
salt.modules.pillar.ext(external, pillar=None)
Changed in version 2016.3.6,2016.11.3,Nitrogen: The supported ext_pillar types are now tunable using the on_demand_ext_pillar config option. Earlier releases used a hard-coded default.

Generate the pillar and apply an explicit external pillar
external A single ext_pillar to add to the ext_pillar configuration. This must be passed as a single section from the ext_pillar configuration (see CLI examples below). For more complicated ext_pillar configurations, it can be helpful to use the Python shell to load YAML configuration into a dictionary, and figure out

```python
>>> import yaml
>>> ext_pillar = yaml.safe_load(""
... ext_pillar:
...   - git:
...     - issue38440 https://github.com/terminalmage/git_pillar:
...       - env: base
...     - ""
...   - ""
... ext_pillar['ext_pillar'][0]
{'git': [{'mybranch https://github.com/myuser/myrepo': [{'env': 'base'}]}]}
```

In the above example, the value to pass would be `{git: [{'mybranch https://github.com/myuser/myrepo': [{'env': 'base'}]}]}`. Note that this would need to be quoted when passing on the CLI (as in the CLI examples below).
pillar [None] If specified, allows for a dictionary of pillar data to be made available to pillar and ext_pillar rendering. These pillar variables will also override any variables of the same name in pillar or ext_pillar.

New in version 2015.5.0.
CLI Examples:

salt '*' pillar.ext '{libvirt: _}'
salt '*' pillar.ext '{git: [master https://github.com/myuser/myrepo]}'
salt '*' pillar.ext '{git: [mybranch https://github.com/myuser/myrepo': [{'env': 'base'}]}]}

13.6. execution modules 1359
salt.modules.pillar.fetch

salt.modules.pillar.fetch(key, default=<type `exceptions.KeyError'>, merge=False, delimiter=':', saltenv=None)

New in version 0.14.

Attempt to retrieve the named value from pillar, if the named value is not available return the passed default. The default return is an empty string except __opts__['pillar_raise_on_missing'] is set to True, in which case a KeyError will be raised.

If the merge parameter is set to True, the default will be recursively merged into the returned pillar data.

The value can also represent a value in a nested dict using a "::" delimiter for the dict. This means that if a dict in pillar looks like this:

```
{ 'pkg': { 'apache': 'httpd' } }
```

To retrieve the value associated with the apache key in the pkg dict this key can be passed:

```
pkg:apache
```

merge [False] If True, the retrieved values will be merged into the passed default. When the default and the retrieved value are both dictionaries, the dictionaries will be recursively merged.

New in version 2014.7.0.

Changed in version 2016.3.7, 2016.11.4, Nitrogen: If the default and the retrieved value are not of the same type, then merging will be skipped and the retrieved value will be returned. Earlier releases raised an error in these cases.

delimiter Specify an alternate delimiter to use when traversing a nested dict. This is useful for when the desired key contains a colon. See CLI example below for usage.

New in version 2014.7.0.

saltenv If specified, this function will query the master to generate fresh pillar data on the fly, specifically from the requested pillar environment. Note that this can produce different pillar data than executing this function without an environment, as its normal behavior is just to return a value from minion’s pillar data in memory (which can be sourced from more than one pillar environment).

Using this argument will not affect the pillar data in memory. It will however be slightly slower and use more resources on the master due to the need for the master to generate and send the minion fresh pillar data. This tradeoff in performance however allows for the use case where pillar data is desired only from a single environment.

New in version Nitrogen.

CLI Example:

```
salt '*' pillar.get pkg:apache
salt '*' pillar.get abc::def|ghi delimiter='|'
```

salt.modules.pillar.file_exists

salt.modules.pillar.file_exists(path, saltenv=None)

New in version 2016.3.0.

This is a master-only function. Calling from the minion is not supported.

Use the given path and search relative to the pillar environments to see if a file exists at that path.

If the saltenv argument is given, restrict search to that environment only.

Will only work with pillar_roots, not external pillars.

Returns True if the file is found, and False otherwise.

path The path to the file in question. Will be treated as a relative path
saltenv Optional argument to restrict the search to a specific saltenv
CLI Example:

```
salt '*' pillar.file_exists foo/bar.sls
```

```python
salt.modules.pillar.get(key, default=exceptions.KeyError, merge=False, delimiter=':',
                              saltenv=None)
```

New in version 0.14.

Attempt to retrieve the named value from pillar, if the named value is not available return the passed default. The default return is an empty string except __opts__['pillar_raise_on_missing'] is set to True, in which case a KeyError will be raised.

If the merge parameter is set to True, the default will be recursively merged into the returned pillar data.

The value can also represent a value in a nested dict using a "::" delimiter for the dict. This means that if a dict in pillar looks like this:

```
{'pkg': {'apache': 'httpd'}}
```

To retrieve the value associated with the apache key in the pkg dict this key can be passed:

```
pkg:apache
```

**merge** [False] If True, the retrieved values will be merged into the passed default. When the default and the retrieved value are both dictionaries, the dictionaries will be recursively merged.

New in version 2014.7.0.

Changed in version 2016.3.7, 2016.11.4, Nitrogen: If the default and the retrieved value are not of the same type, then merging will be skipped and the retrieved value will be returned. Earlier releases raised an error in these cases.

**delimiter** Specify an alternate delimiter to use when traversing a nested dict. This is useful for when the desired key contains a colon. See CLI example below for usage.

New in version 2014.7.0.

**saltenv** If specified, this function will query the master to generate fresh pillar data on the fly, specifically from the requested pillar environment. Note that this can produce different pillar data than executing this function without an environment, as its normal behavior is just to return a value from minion's pillar data in memory (which can be sourced from more than one pillar environment).

Using this argument will not affect the pillar data in memory. It will however be slightly slower and use more resources on the master due to the need for the master to generate and send the minion fresh pillar data. This tradeoff in performance however allows for the use case where pillar data is desired only from a single environment.

New in version Nitrogen.

CLI Example:

```
salt '*' pillar.get pkg:apache
salt '*' pillar.get abc::def|ghi delimiter='|'
```

```python
salt.modules.pillar.item(*args, **kwargs)
```

New in version 0.16.2.

Return one or more pillar entries from the in-memory pillar data.

**delimiter** Delimiter used to traverse nested dictionaries.

---

**Note:** This is different from `pillar.get` in that no default value can be specified. `pillar.get` should probably still be used in most cases to retrieve nested pillar values, as it is a bit more flexible.
One reason to use this function instead of `pillar.get` however is when it is desirable to retrieve the values of more than one key, since `pillar.get` can only retrieve one key at a time.

New in version 2015.8.0.

CLI Examples:

```bash
salt '*' pillar.item foo
salt '*' pillar.item foo:bar
salt '*' pillar.item foo bar baz
```

`salt.modules.pillar.items`(*args, **kwargs)

Calls the master for a fresh pillar and generates the pillar data on the fly

Contrast with `raw()` which returns the pillar data that is currently loaded into the minion.

`pillar` if specified, allows for a dictionary of pillar data to be made available to pillar and ext_pillar rendering. these pillar variables will also override any variables of the same name in pillar or ext_pillar.

New in version 2015.5.0.

`saltenv` Pass a specific pillar environment from which to compile pillar data. If unspecified, the minion's `environment` option is used, and if that also is not specified then all configured pillar environments will be merged into a single pillar dictionary and returned.

New in version Nitrogen.

CLI Example:

```bash
salt '*' pillar.items
```

`salt.modules.pillar.keys`(*key, delimiter=':')

New in version 2015.8.0.

Attempt to retrieve a list of keys from the named value from the pillar.

The value can also represent a value in a nested dict using a "\:" delimiter for the dict, similar to how `pillar.get` works.

`delimiter` Specify an alternate delimiter to use when traversing a nested dict

CLI Example:

```bash
salt '*' pillar.keys web:sites
```

`salt.modules.pillar.ls`(*args)

New in version 2015.8.0.

Calls the master for a fresh pillar, generates the pillar data on the fly (same as `items()`), but only shows the available main keys.

CLI Examples:

```bash
salt '*' pillar.ls
```

`salt.modules.pillar.obfuscate`(*args)

New in version 2015.8.0.

Same as `items()`, but replace pillar values with a simple type indication.

This is useful to avoid displaying sensitive information on console or flooding the console with long output, such as certificates. For many debug or control purposes, the stakes lie more in dispatching than in actual values.

In case the value is itself a collection type, obfuscation occurs within the value. For mapping types, keys are not obfuscated. Here are some examples:
• 'secret password' becomes '<str>'
• ['secret',1] becomes ['<str>', '<int>']
• {'login': 'somelogin', 'pwd': 'secret'} becomes {'login': '<str>', 'pwd': '<str>'}

CLI Examples:

```bash
salt '*' pillar.obfuscate
```

```
salt.modules.pillar.raw(key=None)
Return the raw pillar data that is currently loaded into the minion.
Contrast with `items()` which calls the master to fetch the most up-to-date Pillar.
CLI Example:

```bash
salt '*' pillar.raw
```

With the optional key argument, you can select a subtree of the pillar raw data:

```bash
salt '*' pillar.raw key='roles'
```

### 13.6.224 salt.modules.pip

Install Python packages with pip to either the system or a virtualenv

#### Windows Support

New in version 2014.7.4.

Salt now uses a portable python. As a result the entire pip module is now functional on the salt installation itself. You can pip install dependencies for your custom modules. You can even upgrade salt itself using pip. For this to work properly, you must specify the Current Working Directory (cwd) and the Pip Binary (bin_env) salt should use. The variable pip_bin can be either a virtualenv path or the path to the pip binary itself.

For example, the following command will list all software installed using pip to your current salt environment:

```bash
salt <minion> pip.list cwd='C:\salt\bin\Scripts' bin_env='C:\salt\bin\Scripts\pip.exe'
```

Specifying the cwd and bin_env options ensures you're modifying the salt environment. If these are omitted, it will default to the local installation of python. If python is not installed locally it will fail saying it couldn't find pip.

#### State File Support

This functionality works in states as well. If you need to pip install colorama with a state, for example, the following will work:

```python
install_colorama:
  pip.installed:
    - name: colorama
    - cwd: 'C:\salt\bin\scripts'
    - bin_env: 'C:\salt\bin\scripts\pip.exe'
    - upgrade: True
```
Upgrading Salt using Pip

You can now update salt using pip to any version from the 2014.7 branch forward. Previous version require recompiling some of the dependencies which is painful in windows.

To do this you just use pip with git to update to the version you want and then restart the service. Here is a sample state file that upgrades salt to the head of the 2015.5 branch:

```python
install_salt:
  pip.installed:
    - cwd: 'C:\salt\bin\scripts'
    - bin_env: 'C:\salt\bin\scripts\pip.exe'
    - editable: git+https://github.com/saltstack/salt@2015.5#egg=salt
    - upgrade: True
restart_service:
  service.running:
    - name: salt-minion
    - enable: True
    - watch:
      - pip: install_salt

Note: If you're having problems, you might try doubling the back slashes. For example, cwd: `C:\salt\bin\scripts'. Sometimes python thinks the single back slash is an escape character.

salt.modules.pip.freeze(bin_env=None, user=None, cwd=None, use_vt=False)
Return a list of installed packages either globally or in the specified virtualenv
bin_env path to pip bin or path to virtualenv. If doing an uninstall from the system python and want to use a specific pip bin (pip-2.7, pip-2.6, etc..) just specify the pip bin you want. If uninstalling from a virtualenv, just use the path to the virtualenv (/home/code/path/to/virtualenv/)
user The user under which to run pip
cwd Current working directory to run pip from

CLI Example:

```bash
salt '*' pip.freeze /home/code/path/to/virtualenv/
```

salt.modules.pip.install(pkgs=None, requirements=None, env=None, bin_env=None, use_wheel=False, no_use_wheel=False, log=None, proxy=None, timeout=None, editable=None, find_links=None, index_url=None, extra_index_url=None, no_index=False, mirrors=None, build=None, target=None, download=None, download_cache=None, source=None, upgrade=False, force_reinstall=False, ignore_installed=False, exists_action=None, no_deps=False, no_install=False, no_download=False, global_options=None, install_options=None, user=None, no_chown=False, cwd=None, activate=False, pre_releases=False, cert=None, allow_all_external=False, allow_external=None, allow_unverified=None, process_dependency_links=False, __env__=None, saltenv='base', env_vars=None, use_vt=False, trusted_host=None)

Install packages with pip

Install packages individually or from a pip requirements file. Install packages globally or to a virtualenv.

pkgs Comma separated list of packages to install

requirements Path to requirements

bin_env Path to pip bin or path to virtualenv. If doing a system install, and want to use a specific pip bin (pip-2.7, pip-2.6, etc..) just specify the pip bin you want.
Note: If installing into a virtualenv, just use the path to the virtualenv (e.g. /home/code/path/to/virtualenv/)

env Deprecated, use bin_env now
use_wheel Prefer wheel archives (requires pip>=1.4)
no_use_wheel Force to not use wheel archives (requires pip>=1.4)
log Log file where a complete (maximum verbosity) record will be kept
proxy Specify a proxy in the form user:passwd@proxy.server:port. Note that the user:password@ is optional and required only if you are behind an authenticated proxy. If you provide user@proxy.server:port then you will be prompted for a password.
timeout Set the socket timeout (default 15 seconds)
editable install something editable (e.g. git+https://github.com/worldcompany/djangoembed.git#egg=djangoembed)
find_links URL to search for packages
index_url Base URL of Python Package Index
extra_index_url Extra URLs of package indexes to use in addition to index_url
no_index Ignore package index
mirrors Specific mirror URL(s) to query (automatically adds --use-mirrors)

Warning: This option has been deprecated and removed in pip version 7.0.0. Please use index_url and/or extra_index_url instead.

build Unpack packages into build dir
target Install packages into target dir
download Download packages into download instead of installing them
download_cache Cache downloaded packages in download_cache dir
source Check out editable packages into source dir
upgrade Upgrade all packages to the newest available version
force_reinstall When upgrading, reinstall all packages even if they are already up-to-date.
ignore_installed Ignore the installed packages (reinstalling instead)
exists_action Default action when a path already exists: (s)witch, (i)gnore, (w)ipe, (b)ackup
no_deps Ignore package dependencies
no_install Download and unpack all packages, but don’t actually install them
no_download Don’t download any packages, just install the ones already downloaded (completes an install run with --no-install)
install_options Extra arguments to be supplied to the setup.py install command (e.g. like --install-option='--install-scripts=/usr/local/bin'). Use multiple --install-option options to pass multiple options to setup.py install. If you are using an option with a directory path, be sure to use absolute path.
global_options Extra global options to be supplied to the setup.py call before the install command.
user The user under which to run pip
no_chown When user is given, do not attempt to copy and chown a requirements file
cwd Current working directory to run pip from
activate Activates the virtual environment, if given via bin_env, before running install.

Deprecated since version 2014.7.2: If bin_env is given, pip will already be sourced from that virtualenv, making activate effectively a noop.
pre_releases Include pre-releases in the available versions
cert Provide a path to an alternate CA bundle
allow_all_external Allow the installation of all externally hosted files
allow_external Allow the installation of externally hosted files (comma separated list)
allow_unverified Allow the installation of insecure and unverifiable files (comma separated list)
process_dependency_links Enable the processing of dependency links
env_vars Set environment variables that some builds will depend on. For example, a Python C-module may
have a Makefile that needs INCLUDE_PATH set to pick up a header file while compiling. This must be
in the form of a dictionary or a mapping.

Example:

```bash
salt '*' pip.install django_app env_vars="{'CUSTOM_PATH': '/opt/django_app'}"
```

**trusted_host** Mark this host as trusted, even though it does not have valid or any HTTPS.

**use_vt** Use VT terminal emulation (see output while installing)

CLI Example:

```bash
salt '*' pip.install <package name>,<package2 name>
salt '*' pip.install requirements=/path/to/requirements.txt
salt '*' pip.install <package name> bin_env=/path/to/virtualenv
salt '*' pip.install <package name> bin_env=/path/to/pip_bin
```

Complicated CLI example:

```bash
salt '*' pip.install markdown,django editable=git+https://github.com/worldcompany/djangoembed.git#egg=djangoembed upgrade=True no_deps=True
```

**salt.modules.pip.list**

Filter list of installed apps from freeze and check to see if prefix exists in the list of packages installed.

CLI Example:

```bash
salt '*' pip.list salt
```

**salt.modules.pip.list_upgrades**

Check whether or not an upgrade is available for all packages

CLI Example:

```bash
salt '*' pip.list_upgrades
```

**salt.modules.pip.uninstall**

Uninstall packages with pip

Uninstall packages individually or from a pip requirements file. Uninstall packages globally or from a vir-
tualenv.

**pkgs** comma separated list of packages to install

**requirements** path to requirements

**bin_env** path to pip bin or path to virtualenv. If doing an uninstall from the system python and want to use a
specific pip bin (pip-2.7, pip-2.6, etc.) just specify the pip bin you want. If uninstalling from a virtualenv,
just use the path to the virtualenv (/home/code/path/to/virtualenv/)

**log** Log file where a complete (maximum verbosity) record will be kept

**proxy** Specify a proxy in the form user:passwd@proxy.server:port. Note that the user:password@ is optional
and required only if you are behind an authenticated proxy. If you provide user@proxy.server:port then
you will be prompted for a password.

**timeout** Set the socket timeout (default 15 seconds)

**user** The user under which to run pip

**no_chown** When user is given, do not attempt to copy and chown a requirements file (needed if the require-
ments file refers to other files via relative paths, as the copy-and-chown procedure does not account for
such files)

**cwd** Current working directory to run pip from

**use_vt** Use VT terminal emulation (see output while installing)
CLI Example:
```
salt '*' pip.uninstall <package name>,<package2 name>
salt '*' pip.uninstall requirements=/path/to/requirements.txt
salt '*' pip.uninstall <package name> bin_env=/path/to/virtualenv
salt '*' pip.uninstall <package name> bin_env=/path/to/pip_bin
```

```python
salt.modules.pip.upgrade(bin_env=None, user=None, cwd=None, use_vt=False)
```
New in version 2015.5.0.
Upgrades outdated pip packages

Returns a dict containing the changes.
```
{`<package>`: {`old`: `<old-version>'}, `new`: `<new-version>'}}
```

CLI Example:
```
salt '*' pip.upgrade
```

```python
salt.modules.pip.upgrade_available(pkg, bin_env=None, user=None, cwd=None)
```
New in version 2015.5.0.
Check whether or not an upgrade is available for a given package

CLI Example:
```
salt '*' pip.upgrade_available <package name>
```

```python
salt.modules.pip.version(bin_env=None)
```
New in version 0.17.0.
Returns the version of pip. Use bin_env to specify the path to a virtualenv and get the version of pip in that virtualenv.

If unable to detect the pip version, returns None.

CLI Example:
```
salt '*' pip.version
```

### 13.6.225 salt.modules.pkg_resource

Resources needed by pkg providers

```python
salt.modules.pkg_resource.add_pkg(pkgs, name, pkgver)
```
Add a package to a dict of installed packages.

CLI Example:
```
salt '*' pkg_resource.add_pkg '{}' bind 9
```

```python
salt.modules.pkg_resource.check_extra_requirements(pkgname, pkgver)
```
Check if the installed package already has the given requirements. This function will return the result of pkg.check_extra_requirements if this function exists for the minion, otherwise it will return True.

CLI Example:
```
salt '*' pkg_resource.check_extra_requirements <pkgname> <extra_requirements>
```
salt.modules.pkg_resource.pack_sources(sources, normalize=True)

Accepts list of dicts (or a string representing a list of dicts) and packs the key/value pairs into a single dict.

'{{"foo": "salt://foo.rpm"},{"bar": "salt://bar.rpm"}}' would become {{"foo": "salt://foo.rpm"},{"bar": "salt://bar.rpm"}}

normalize [True] Normalize the package name by removing the architecture, if the architecture of the package is different from the architecture of the operating system. The ability to disable this behavior is useful for poorly-created packages which include the architecture as an actual part of the name, such as kernel modules which match a specific kernel version.

New in version 2015.8.0.

CLI Example:

```
salt '*' pkg_resource.pack_sources '[["foo": "salt://foo.rpm"],{"bar": "salt://bar.rpm"}]'
```

salt.modules.pkg_resource.parse_targets(name=None, pkgs=None, sources=None, saltenv='base', normalize=True, **kwargs)

Parses the input to pkg.install and returns back the package(s) to be installed. Returns a list of packages, as well as a string noting whether the packages are to come from a repository or a binary package.

CLI Example:

```
salt '*' pkg_resource.parse_targets
```

salt.modules.pkg_resource.sort_pkglist(pkgs)

Accepts a dict obtained from pkg.list_pkgs() and sorts in place the list of versions for any packages that have multiple versions installed, so that two package lists can be compared to one another.

CLI Example:

```
salt '*' pkg_resource.sort_pkglist ['["3.45", "2.13"]]
```

salt.modules.pkg_resource.stringify(pkgs)

Takes a dict of package name/version information and joins each list of installed versions into a string.

CLI Example:

```
salt '*' pkg_resource.stringify 'vim: 7.127'
```

salt.modules.pkg_resource.version(names, **kwargs)

Common interface for obtaining the version of installed packages.

CLI Example:

```
salt '*' pkg_resource.version vim
salt '*' pkg_resource.version foo bar baz
salt '*' pkg_resource.version 'python*'
```

salt.modules.pkg_resource.version_clean(versstr)

Clean the version string removing extra data. This function will simply try to call pkg.version_clean.

CLI Example:

```
salt '*' pkg_resource.version_clean <version_string>
```

**13.6.226 salt.modules.pkgin**

Package support for pkgin based systems, inspired from freebsdpkg module
Important: If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to 'pkg.install' is not available), see here.

salt.modules.pkgin.available_version(*names, **kwargs)
This function is an alias of latest_version.
Return the latest version of the named package available for upgrade or installation.
If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:
```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> ...
```

salt.modules.pkgin.file_dict(*packages)
List the files that belong to a package.

CLI Examples:
```
salt '*' pkg.file_dict nginx
salt '*' pkg.file_dict nginx varnish
```

salt.modules.pkgin.file_list(package)
List the files that belong to a package.

CLI Examples:
```
salt '*' pkg.file_list nginx
```

salt.modules.pkgin.install(name=None, refresh=False, fromrepo=None, pkgs=None, sources=None, **kwargs)
Install the passed package

name The name of the package to be installed.
refresh Whether or not to refresh the package database before installing.
fromrepo Specify a package repository to install from.

Multiple Package Installation Options:

pkgs A list of packages to install from a software repository. Must be passed as a python list.

CLI Example:
```
salt '*' pkg.install pkgs='["foo","bar"]'
```

sources A list of packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

CLI Example:
```
salt '*' pkg.install sources='[{"foo": "salt://foo.deb"},{"bar": "salt://bar.
...deb"}]'
```

Return a dict containing the new package names and versions:
```
{'<package>': {'old': '<old-version>', 'new': '<new-version>'}}
```

CLI Example:
salt '*' pkg.install <package name>

salt.modules.pkgin.latest_version(names, **kwargs)
Return the latest version of the named package available for upgrade or installation.
If the latest version of a given package is already installed, an empty string will be returned for that package.
CLI Example:
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> ...

salt.modules.pkgin.list_pkgs(versions_as_list=False, **kwargs)
List the packages currently installed as a dict:
{'<package_name>': '<version>'}
CLI Example:
salt '*' pkg.list_pkgs

salt.modules.pkgin.purge(name=None, pkgs=None, **kwargs)
Package purges are not supported, this function is identical to remove().
note The name of the package to be deleted.
Multiple Package Options:
pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this
option is passed.
New in version 0.16.0.
Returns a dict containing the changes.
CLI Example:
salt '*' pkg.purge <package, name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'

salt.modules.pkgin.refresh_db()
Use pkg update to get latest pkg_summary
CLI Example:
salt '*' pkg.refresh_db

salt.modules.pkgin.remove(name=None, pkgs=None, **kwargs)
name The name of the package to be deleted.
Multiple Package Options:
pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this
option is passed.
New in version 0.16.0.
Returns a list containing the removed packages.
CLI Example:
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
salt.modules.pkgin.search(pkg_name)
Searches for an exact match using pkgin `package$`

CLI Example:
salt '*' pkg.search 'mysql-server'

salt.modules.pkgin.upgrade()
Run pkg upgrade, if pkgin used. Otherwise do nothing

Return a dict containing the new package names and versions:

```json
{ '<package>': {'old': '<old-version>', 'new': '<new-version>'} }
```

CLI Example:
salt '*' pkg.upgrade

salt.modules.pkgin.version(*names, **kwargs)
Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...

## 13.6.227 salt.modules.pkgng

Support for pkgng, the new package manager for FreeBSD

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install' is not available), see [here](#).

**Warning:** This module has been completely rewritten. Up to and including version 0.17.x, it was available as the pkgng module, (pkgng.install, pkgng.delete, etc.), but moving forward this module will no longer be available as pkgng, as it will behave like a normal Salt pkg provider. The documentation below should not be considered to apply to this module in versions <= 0.17.x. If your minion is running a 0.17.x release or older, then the documentation for this module can be viewed using the sys.doc function:
salt bsdminion sys.doc pkgng

This module provides an interface to pkg(8). It acts as the default package provider for FreeBSD 10 and newer. For FreeBSD hosts which have been upgraded to use pkgng, you will need to override the pkg provider by setting the `providers` parameter in your Minion config file, in order to use this module to manage packages, like so:

```yaml
providers:
  pkg: pkgng
```

salt.modules.pkgng.audit(jail=None, chroot=None)
Audits installed packages against known vulnerabilities

CLI Example:
salt '*' pkg.audit

**jail**  Audit packages within the specified jail

CLI Example:

```
salt '*' pkg.audit jail=<jail name or id>
```

**chroot**  Audit packages within the specified chroot (ignored if jail is specified)

CLI Example:

```
salt '*' pkg.audit chroot=/path/to/chroot
```

**salt.modules.pkgng.autoremove**(jail=None, chroot=None, dryrun=False)

Delete packages which were automatically installed as dependencies and are not required anymore.

**dryrun**  Dry-run mode. The list of changes to packages is always printed, but no changes are actually made.

CLI Example:

```
salt '*' pkg.autoremove
salt '*' pkg.autoremove jail=<jail name or id>
salt '*' pkg.autoremove dryrun=True
salt '*' pkg.autoremove jail=<jail name or id> dryrun=True
```

**salt.modules.pkgng.backup**(file_name, jail=None, chroot=None)

Export installed packages into yaml+mtree file

CLI Example:

```
salt '*' pkg.backup /tmp/pkg
```

**jail**  Backup packages from the specified jail. Note that this will run the command within the jail, and so the path to the backup file will be relative to the root of the jail

CLI Example:

```
salt '*' pkg.backup /tmp/pkg jail=<jail name or id>
```

**chroot**  Backup packages from the specified chroot (ignored if jail is specified). Note that this will run the command within the chroot, and so the path to the backup file will be relative to the root of the chroot.

CLI Example:

```
salt '*' pkg.backup /tmp/pkg chroot=/path/to/chroot
```

**salt.modules.pkgng.check**(jail=None, chroot=None, depends=False, recompute=False, checksum=False)

Sanity checks installed packages

**jail**  Perform the sanity check in the specified jail

CLI Example:

```
salt '*' pkg.check jail=<jail name or id>
```

**chroot**  Perform the sanity check in the specified chroot (ignored if jail is specified)

CLI Example:

```
salt '*' pkg.check chroot=/path/to/chroot
```

Of the below, at least one must be set to True.
depends  Check for and install missing dependencies.

CLI Example:

```
salt '*' pkg.check recompute=True
```

recompute  Recompute sizes and checksums of installed packages.

CLI Example:

```
salt '*' pkg.check depends=True
```

checksum  Find invalid checksums for installed packages.

CLI Example:

```
salt '*' pkg.check checksum=True
```

```
salt.modules.pkgng.clean(jail=None, chroot=None)
```
Cleans the local cache of fetched remote packages

CLI Example:

```
salt '*' pkg.clean
salt '*' pkg.clean jail=<jail name or id>
salt '*' pkg.clean chroot=/path/to/chroot
```

```
salt.modules.pkgng.fetch(name, jail=None, chroot=None, fetch_all=False, quiet=False, fromrepo=None, glob=True, regex=False, pcre=False, local=False, depends=False)
```
Fetches remote packages

CLI Example:

```
salt '*' pkg.fetch <package name>
```

```
jail  Fetch package in the specified jail
```

CLI Example:

```
salt '*' pkg.fetch <package name> jail=<jail name or id>
```

```
chroot  Fetch package in the specified chroot (ignored if jail is specified)
```

CLI Example:

```
salt '*' pkg.fetch <package name> chroot=/path/to/chroot
```

```
fet_all  Fetch all packages.
```

CLI Example:

```
salt '*' pkg.fetch <package name> fetch_all=True
```

```
quiet  Quiet mode. Show less output.
```

CLI Example:

```
salt '*' pkg.fetch <package name> quiet=True
```

```
fromrepo  Fetches packages from the given repo if multiple repo support is enabled. See pkg.conf(5).
```

CLI Example:
`salt '*' pkg.fetch <package name> fromrepo=repo`

**glob**  Treat pkg_name as a shell glob pattern.

CLI Example:

```bash
salt '*' pkg.fetch <package name> glob=True
```

**regex**  Treat pkg_name as a regular expression.

CLI Example:

```bash
salt '*' pkg.fetch <regular expression> regex=True
```

**pcre**  Treat pkg_name as an extended regular expression.

CLI Example:

```bash
salt '*' pkg.fetch <extended regular expression> pcre=True
```

**local**  Skip updating the repository catalogs with pkg-update(8). Use the local cache only.

CLI Example:

```bash
salt '*' pkg.fetch <package name> local=True
```

**depends**  Fetch the package and its dependencies as well.

CLI Example:

```bash
salt '*' pkg.fetch <package name> depends=True
```

```
salt.modules.pkgng.install(name=None, fromrepo=None, pkgs=None, sources=None, jail=None, chroot=None, orphan=False, force=False, glob=False, local=False, dryrun=False, quiet=False, reinstall_requires=False, regex=False, pcre=False, **kwargs)
```

Install package(s) from a repository

**name**  The name of the package to install

CLI Example:

```bash
salt '*' pkg.install <package name>
```

**jail**  Install the package into the specified jail

**chroot**  Install the package into the specified chroot (ignored if jail is specified)

**orphan**  Mark the installed package as orphan. Will be automatically removed if no other packages depend on them. For more information please refer to pkg-autoremove(8).

CLI Example:

```bash
salt '*' pkg.install <package name> orphan=True
```

**force**  Force the reinstallation of the package if already installed.

CLI Example:

```bash
salt '*' pkg.install <package name> force=True
```

**glob**  Treat the package names as shell glob patterns.

CLI Example:

```bash
salt '*' pkg.install <package name> glob=True
```
local Do not update the repository catalogs with pkg-update(8). A value of True here is equivalent to using the -U flag with pkg install.

CLI Example:
```
salt '*' pkg.install <package name> local=True
```

dryrun Dru-run mode. The list of changes to packages is always printed, but no changes are actually made.

CLI Example:
```
salt '*' pkg.install <package name> dryrun=True
```

quiet Force quiet output, except when dryrun is used, where pkg install will always show packages to be installed, upgraded or deleted.

CLI Example:
```
salt '*' pkg.install <package name> quiet=True
```

reinstall_requires When used with force, reinstalls any packages that require the given package.

CLI Example:
```
salt '*' pkg.install <package name> reinstall_requires=True force=True
```

Changed in version 2014.7.0: require kwarg renamed to reinstall_requires

fromrepo In multi-repo mode, override the pkg.conf ordering and only attempt to download packages from the named repository.

CLI Example:
```
salt '*' pkg.install <package name> fromrepo=repo
```

regex Treat the package names as a regular expression

CLI Example:
```
salt '*' pkg.install <regular expression> regex=True
```

pcre Treat the package names as extended regular expressions.

CLI Example:
```
salt '*' pkg.install <extended regular expression> pcre=True
```

salt.modules.pkgng.latest_version("names", **kwargs)
 Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:
```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package name> jail=<jail name or id>
salt '*' pkg.latest_version <package name> chroot=/path/to/chroot
```

salt.modules.pkgng.list_pkgs(versions_as_list=False, jail=None, chroot=None, with_origin=False, **kwargs)
 List the packages currently installed as a dict:
```
{"<package_name>": '<version>'}
```
**jail** List the packages in the specified jail
**chroot** List the packages in the specified chroot (ignored if jail is specified)
**with_origin** [False] Return a nested dictionary containing both the origin name and version for each installed package.

New in version 2014.1.0.

**CLI Example:**
```
salt '*' pkg.list_pkgs
salt '*' pkg.list_pkgs jail=<jail name or id>
salt '*' pkg.list_pkgs chroot=/path/to/chroot
```

**salt.modules.pkgng.parse_config(file_name='/usr/local/etc/pkg.conf')**
Return dict of uncommented global variables.

**CLI Example:**
```
salt '*' pkg.parse_config
```

**NOTE:** not working properly right now

**salt.modules.pkgng.refresh_db(jail=None, chroot=None, force=False)**
Refresh PACKAGESITE contents

**Note:** This function can accessed using pkg.update in addition to pkg.refresh_db, to more closely match the CLI usage of pkg(8).

**CLI Example:**
```
salt '*' pkg.refresh_db
```

**jail** Refresh the pkg database within the specified jail
**chroot** Refresh the pkg database within the specified chroot (ignored if jail is specified)
**force** Force a full download of the repository catalog without regard to the respective ages of the local and remote copies of the catalog.

**CLI Example:**
```
salt '*' pkg.refresh_db force=True
```

**salt.modules.pkgng.remove(name=None, pkgs=None, jail=None, chroot=None, all_installed=False, force=False, glob=False, dryrun=False, recurse=False, regex=False, pcre=False, **kwargs)**
Remove a package from the database and system

**Note:** This function can accessed using pkg.delete in addition to pkg.remove, to more closely match the CLI usage of pkg(8).

**name** The package to remove

**CLI Example:**
```
salt '*' pkg.remove <package name>
```

**jail** Delete the package from the specified jail
**chroot** Delete the package from the specified chroot (ignored if jail is specified)
**all_installed**  Deletes all installed packages from the system and empties the database. USE WITH CAUTION!

CLI Example:
```
salt '*' pkg.remove all all_installed=True force=True
```

**force**  Forces packages to be removed despite leaving unresolved dependencies.

CLI Example:
```
salt '*' pkg.remove <package name> force=True
```

**glob**  Treat the package names as shell glob patterns.

CLI Example:
```
salt '*' pkg.remove <package name> glob=True
```

**dryrun**  Dry run mode. The list of packages to delete is always printed, but no packages are actually deleted.

CLI Example:
```
salt '*' pkg.remove <package name> dryrun=True
```

**recurse**  Delete all packages that require the listed package as well.

CLI Example:
```
salt '*' pkg.remove <package name> recurse=True
```

**regex**  Treat the package names as regular expressions.

CLI Example:
```
salt '*' pkg.remove <regular expression> regex=True
```

**pcre**  Treat the package names as extended regular expressions.

CLI Example:
```
salt '*' pkg.remove <extended regular expression> pcre=True
```

**salt.modules.pkgng.restore**  
```
(file_name, jail=None, chroot=None)
```

Reads archive created by pkg backup -d and recreates the database.

CLI Example:
```
salt '*' pkg.restore /tmp/pkg
```

**jail**  Restore database to the specified jail. Note that this will run the command within the jail, and so the path to the file from which the pkg database will be restored is relative to the root of the jail.

CLI Example:
```
salt '*' pkg.restore /tmp/pkg jail=<jail name or id>
```

**chroot**  Restore database to the specified chroot (ignored if jail is specified). Note that this will run the command within the chroot, and so the path to the file from which the pkg database will be restored is relative to the root of the chroot.

CLI Example:
```
salt '*' pkg.restore /tmp/pkg chroot=/path/to/chroot
salt.modules.pkgng.search(name, jail=None, chroot=None, exact=False, glob=False, regex=False, pcre=False, comment=False, desc=False, full=False, depends=False, size=False, quiet=False, origin=False, prefix=False)

Searches in remote package repositories

CLI Example:
```
salt '*' pkg.search pattern
```

**jail** Perform the search using the `pkg.conf(5)` from the specified jail

CLI Example:
```
salt '*' pkg.search pattern jail=<jail name or id>
```

**chroot** Perform the search using the `pkg.conf(5)` from the specified chroot (ignored if `jail` is specified)

CLI Example:
```
salt '*' pkg.search pattern chroot=/path/to/chroot
```

**exact** Treat pattern as exact pattern.

CLI Example:
```
salt '*' pkg.search pattern exact=True
```

**glob** Treat pattern as a shell glob pattern.

CLI Example:
```
salt '*' pkg.search pattern glob=True
```

**regex** Treat pattern as a regular expression.

CLI Example:
```
salt '*' pkg.search pattern regex=True
```

**pcre** Treat pattern as an extended regular expression.

CLI Example:
```
salt '*' pkg.search pattern pcre=True
```

**comment** Search for pattern in the package comment one-line description.

CLI Example:
```
salt '*' pkg.search pattern comment=True
```

**desc** Search for pattern in the package description.

CLI Example:
```
salt '*' pkg.search pattern desc=True
```

**full** Displays full information about the matching packages.

CLI Example:
```
salt '*' pkg.search pattern full=True
```

**depends** Displays the dependencies of pattern.

CLI Example:
size  Displays the size of the package
    CLI Example:
    ```
salt '*' pkg.search pattern size=True
    ```

quiet  Be quiet. Prints only the requested information without displaying many hints.
    CLI Example:
    ```
salt '*' pkg.search pattern quiet=True
    ```

origin  Displays pattern origin.
    CLI Example:
    ```
salt '*' pkg.search pattern origin=True
    ```

prefix  Displays the installation prefix for each package matching pattern.
    CLI Example:
    ```
salt '*' pkg.search pattern prefix=True
    ```

salt.modules.pkgng.stats(local=False, remote=False, jail=None, chroot=None)
    Return pkgng stats.
    CLI Example:
    ```
salt '*' pkg.stats
    ```

local  Display stats only for the local package database.
    CLI Example:
    ```
salt '*' pkg.stats local=True
    ```

remote  Display stats only for the remote package database(s).
    CLI Example:
    ```
salt '*' pkg.stats remote=True
    ```

jail  Retrieve stats from the specified jail.
    CLI Example:
    ```
salt '*' pkg.stats jail=<jail name or id>
salt '*' pkg.stats jail=<jail name or id> local=True
salt '*' pkg.stats jail=<jail name or id> remote=True
    ```

chroot  Retrieve stats from the specified chroot (ignored if jail is specified).
    CLI Example:
    ```
salt '*' pkg.stats chroot=/path/to/chroot
salt '*' pkg.stats chroot=/path/to/chroot local=True
salt '*' pkg.stats chroot=/path/to/chroot remote=True
    ```

salt.modules.pkgng.update_package_site(new_url)
    Updates remote package repo URL, PACKAGESITE var to be exact.
    Must use http://, ftp://, or https:// protocol
CLI Example:

```bash
salt '*' pkg.update_package_site http://127.0.0.1/
```

salt.modules.pkgng.updating(name=None, jail=None, filedate=None, filename=None)

- Displays UPDATING entries of software packages

CLI Example:

```bash
salt '*' pkg.updating foo
```

**jail** Perform the action in the specified jail

CLI Example:

```bash
salt '*' pkg.updating foo jail=<jail name or id>
```

**chroot** Perform the action in the specified chroot (ignored if jail is specified)

CLI Example:

```bash
salt '*' pkg.updating foo chroot=/path/to/chroot
```

**filedate** Only entries newer than date are shown. Use a YYYYMMDD date format.

CLI Example:

```bash
salt '*' pkg.updating foo filedate=20130101
```

**filename** Defines an alternative location of the UPDATING file.

CLI Example:

```bash
salt '*' pkg.updating foo filename=/tmp/UPDATING
```

salt.modules.pkgng.upgrade(*names, **kwargs)

- Upgrade named or all packages (run a pkg upgrade). If <package name> is omitted, the operation is executed on all packages.

CLI Example:

```bash
salt '*' pkg.upgrade <package name>
```

**jail** Audit packages within the specified jail

CLI Example:

```bash
salt '*' pkg.upgrade <package name> jail=<jail name or id>
```

**chroot** Audit packages within the specified chroot (ignored if jail is specified)

CLI Example:

```bash
salt '*' pkg.upgrade <package name> chroot=/path/to/chroot
```

Any of the below options can also be used with jail or chroot.

**force** Force reinstalling/upgrading the whole set of packages.

CLI Example:

```bash
salt '*' pkg.upgrade <package name> force=True
```
local  Do not update the repository catalogs with `pkg-update(8)`. A value of `True` here is equivalent to using the `~U` flag with `pkg upgrade`.

CLI Example:

```
salt '*' pkg.upgrade <package name> local=True
```

dryrun  Dry-run mode: show what packages have updates available, but do not perform any upgrades. Repository catalogs will be updated as usual unless the local option is also given.

CLI Example:

```
salt '*' pkg.upgrade <package name> dryrun=True
```

`salt.modules.pkgng.version`(*names*, **kwargs)

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

**Note:** This function can accessed using `pkg.info` in addition to `pkg.version`, to more closely match the CLI usage of `pkg(8)`.

jail  Get package version information for the specified jail

chroot  Get package version information for the specified chroot (ignored if `jail` is specified)

with_origin  [False] Return an nested dictionary containing both the origin name and version for each specified package.

New in version 2014.1.0.

CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package name> jail=<jail name or id>
salt '*' pkg.version <package name> package1 <package2> <package3> ...
```

`salt.modules.pkgng.version_cmp`(*pkg1*, *pkg2*, *ignore_epoch=False*)

Do a cmp-style comparison on two packages. Return `-1` if `pkg1 < pkg2`, `0` if `pkg1 == pkg2`, and `1` if `pkg1 > pkg2`. Return `None` if there was a problem making the comparison.

CLI Example:

```
salt '*' pkg.version_cmp '2.1.11' '2.1.12'
```

`salt.modules.pkgng.which`(*path*, *jail=None*, *chroot=None*, *origin=False*, *quiet=False*)

Displays which package installed a specific file

CLI Example:

```
salt '*' pkg.which <file name>
```

jail  Perform the check in the specified jail

CLI Example:

```
salt '*' pkg.which <file name> jail=<jail name or id>
```

chroot  Perform the check in the specified chroot (ignored if `jail` is specified)

CLI Example:
**salt '('* pkg.which <file name> chroot=/path/to/chroot**

- **origin** Shows the origin of the package instead of name-version.
  - CLI Example:
    ```
salt '('* pkg.which <file name> origin=True
    ```
- **quiet** Quiet output.
  - CLI Example:
    ```
salt '('* pkg.which <file name> quiet=True
    ```

### 13.6.228 salt.modules.pkgutil

Pkgutil support for Solaris

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install' is not available), see [here](#).

**salt.modules.pkgutil.install**(name=None, refresh=False, version=None, pkgs=None, **kwargs)

Install packages using the pkgutil tool.

- CLI Example:
  ```
salt '*' pkg.install <package_name>
salt '*' pkg.install SMClgcc346
  ```

  Multiple Package Installation Options:
  ```
  salt '*' pkg.install pkgs=['"foo", "bar"]'
  salt '*' pkg.install pkgs=['"foo", {"bar": "1.2.3"}']
  ```

  Returns a dict containing the new package names and versions:
  ```
  {'<package>': {'old': '<old-version>',
                'new': '<new-version>'}}
  ```

**salt.modules.pkgutil.latest_version**(names, **kwargs)

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

- If the latest version of a given package is already installed, an empty string will be returned for that package.

  CLI Example:
  ```
salt '*' pkgutil.latest_version CSWpython
salt '*' pkgutil.latest_version <package1> <package2> <package3> ...
  ```

**salt.modules.pkgutil.list_pkgs**(versions_as_list=False, **kwargs)

List the packages currently installed as a dict:

- CLI Example:
  ```
  [{'<package_name>': '<version>'}
  ```
CLI Example:

```shell
salt '*' pkg.list_pkgs
salt '*' pkg.list_pkgs versions_as_list=True
```

`salt.modules.pkgutil.list_upgrades(refresh=True, **kwargs)`
List all available package upgrades on this system

CLI Example:

```shell
salt '*' pkgutil.list_upgrades
```

`salt.modules.pkgutil.purge(name=None, pkgs=None, **kwargs)`
Package purges are not supported, this function is identical to `remove()`.

- **name** The name of the package to be deleted.
- Multiple Package Options:
  - **pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.
  - New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```shell
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'
```

`salt.modules.pkgutil.refresh_db()`
Updates the pkgutil repo database (pkgutil -U)

CLI Example:

```shell
salt '*' pkgutil.refresh_db
```

`salt.modules.pkgutil.remove(name=None, pkgs=None, **kwargs)`
Remove a package and all its dependencies which are not in use by other packages.

- **name** The name of the package to be deleted.
- Multiple Package Options:
  - **pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.
  - New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```shell
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

`salt.modules.pkgutil.upgrade(refresh=True)`
Upgrade all of the packages to the latest available version.

Returns a dict containing the changes:

```json
{"<package>": {"old": '<old-version>',
     "new": '<new-version>'}}
```
CLI Example:

```
salt '*' pkgutil.upgrade
```

```python
salt.modules.pkgutil.upgrade_available(name)
```

Check if there is an upgrade available for a certain package

CLI Example:

```
salt '*' pkgutil.upgrade_available CSWpython
```

```python
salt.modules.pkgutil.version(*names, **kwargs)
```

Returns a version if the package is installed, else returns an empty string

CLI Example:

```
salt '*' pkgutil.version CSWpython
```

### 13.6.229 salt.modules.portage_config

Configure `portage(5)`

```python
salt.modules.portage_config.append_to_package_conf(conf, atom='', flags=None, string='', overwrite=False)
```

Append a string or a list of flags for a given package or DEPEND atom to a given configuration file.

CLI Example:

```
salt '*' portage_config.append_to_package_conf use string="app-admin/salt ldap -\n\nlibvirt"
salt '*' portage_config.append_to_package_conf use atom="> = app-admin/salt-0.14.1\n\n" flags="[['ldap', '-\n\nlibvirt']"
```

```python
salt.modules.portage_config.append_use_flags(atom, uses=None, overwrite=False)
```

Append a list of use flags for a given package or DEPEND atom

CLI Example:

```
salt '*' portage_config.append_use_flags "app-admin/salt[ldap, \n\n-libvirt]"
salt '*' portage_config.append_use_flags ">=app-admin/salt-0.14.1" [['ldap', '\n\n-libvirt']"
```

```python
salt.modules.portage_config.enforce_nice_config()
```

Enforce a nice tree structure for `/etc/portage/package.*` configuration files.

See also:

```python
salt.modules.ebuild.ex_mod_init() for information on automatically running this when pkg is
```

used.

CLI Example:

```
salt '*' portage_config.enforce_nice_config
```

```python
salt.modules.portage_config.filter_flags(use, use_expand_hidden, usemasked, useforced)
```

New in version 2015.8.0.

Filter function to remove hidden or otherwise not normally visible USE flags from a list.
@type use: list @param use: the USE flag list to be filtered. @type use_expand_hidden: list @param use_expand_hidden: list of flags hidden. @type usemasked: list @param usemasked: list of masked USE flags. @type useforced: list @param useforced: the forced USE flags. @rtype: list @return the filtered USE flags.

```
salt.modules.portage_config.get_all_cpv_use(cp)
```

New in version 2015.8.0.

Uses portage to determine final USE flags and settings for an emerge.

@type cp: string @param cp: eg cat/pkg @rtype: list @return use, use_expand_hidden, use_mask, use_force

```
salt.modules.portage_config.get_cleared_flags(cp)
```

New in version 2015.8.0.

Uses portage for compare use flags which is used for installing package and use flags which now exist in /etc/portage/package.use/.

@type cp: string @param cp: eg cat/pkg @rtype: tuple @rparam: tuple with two lists - list of used flags and list of flags which will be used

```
salt.modules.portage_config.get_flags_from_package_conf(conf, atom)
```

Get flags for a given package or DEPEND atom. Warning: This only works if the configuration files tree is in the correct format (the one enforced by enforce_nice_config)

CLI Example:
```
salt '*' portage_config.get_flags_from_package_conf license salt
```

```
salt.modules.portage_config.get_installed_use(cp, use='USE')
```

New in version 2015.8.0.

Gets the installed USE flags from the VARDB.

@type: cp: string @param cp: cat/pkg @type use: string @param use: 1 of ['USE', 'PKGUSE'] @rtype list @returns [] or the list of IUSE flags

```
salt.modules.portage_config.get_iuse(cp)
```

New in version 2015.8.0.

Gets the current IUSE flags from the tree.

@type: cpv: string @param cpv: cat/pkg @rtype list @returns [] or the list of IUSE flags

```
salt.modules.portage_config.get_missing_flags(conf, atom, flags)
```

Find out which of the given flags are currently not set. CLI Example:
```
salt '*' portage_config.get_missing_flags use salt "["ldap", "-libvirt", "openssl"
```
salt 'salt' portage_config.has_use salt libvirt

salt.modules.portage_config.is_changed_uses(cp)
New in version 2015.8.0.
Uses portage for determine if the use flags of installed package is compatible with use flags in portage configs.
@type cp: string @param cp: eg cat/pkg

salt.modules.portage_config.is_present(conf, atom)
Tell if a given package or DEPEND atom is present in the configuration files tree. Warning: This only works if the configuration files tree is in the correct format (the one enforced by enforce_nice_config)

CLI Example:
salt '*' portage_config.is_present unmask salt

13.6.230 salt.modules.postfix

Support for Postfix
This module is currently little more than a config file viewer and editor. It is able to read the master.cf file (which is one style) and files in the style of main.cf (which is a different style, that is used in multiple postfix configuration files).
The design of this module is such that when files are edited, a minimum of changes are made to them. Each file should look as if it has been edited by hand; order, comments and whitespace are all preserved.

salt.modules.postfix.delete(queue_id)
Delete message(s) from the mail queue

CLI Example:
salt '*' postfix.delete 5C33CA0DEA
salt '*' postfix.delete ALL

salt.modules.postfix.hold(queue_id)
Put message(s) on hold from the mail queue

CLI Example:
salt '*' postfix.hold 5C33CA0DEA
salt '*' postfix.hold ALL

salt.modules.postfix.requeue(queue_id)
Requeue message(s) in the mail queue

CLI Example:
salt '*' postfix.requeue 5C33CA0DEA
salt '*' postfix.requeue ALL

salt.modules.postfix.set_main(key, value, path='/etc/postfix/main.cf')
Set a single config value in the main.cf file. If the value does not already exist, it will be appended to the end.

CLI Example:
Salt Documentation, Release 2016.3.6

salt <minion> postfix.set_main mailq_path /usr/bin/mailq

salt.modules.postfix.set_master(service, conn_type, private='y', unpriv='y', chroot='y',
                                 wakeup='n', maxproc='100', command='`', write_conf=True,
                                 path='/etc/postfix/master.cf')

Set a single config value in the master.cf file. If the value does not already exist, it will be appended to the end.

Because of shell parsing issues, `-` cannot be set as a value, as is normal in the master.cf file; either `y`, `n` or
a number should be used when calling this function from the command line. If the value used matches the
default, it will internally be converted to a `-`. Calling this function from the Python API is not affected by
this limitation

The settings and their default values, in order, are: service (required), conn_type (required), private (y), unpriv
(y), chroot (y), wakeup (n), maxproc (100), command (required).

By default, this function will write out the changes to the master.cf file, and then returns the full contents of
the file. By setting the write_conf option to False, it will skip writing the file.

CLI Example:
  salt <minion> postfix.set_master smtp inet n y n n 100 smtpd

salt.modules.postfix.show_main(path='/etc/postfix/main.cf')

Return a dict of active config values. This does not include comments, spacing or order. Bear in mind that order
is functionally important in the main.cf file, since keys can be referred to as variables. This means that the
data returned from this function should not be used for direct modification of the main.cf file; other functions
are available for that.

CLI Examples:
  salt <minion> postfix.show_main
  salt <minion> postfix.show_main path=/path/to/main.cf

salt.modules.postfix.show_master(path='/etc/postfix/master.cf')

Return a dict of active config values. This does not include comments, spacing or order.

The data returned from this function should not be used for direct modification of the main.cf file; other
functions are available for that.

CLI Examples:
  salt <minion> postfix.show_master
  salt <minion> postfix.show_master path=/path/to/master.cf

salt.modules.postfix.show_queue()

Show contents of the mail queue

CLI Example:
  salt '*' postfix.show_queue

salt.modules.postfix.unhold(queue_id)

Set held message(s) in the mail queue to unheld

CLI Example:
  salt '*' postfix.unhold 5C33CA0DEA
  salt '*' postfix.unhold ALL

13.6.231 salt.modules.postgres

Module to provide Postgres compatibility to salt.

13.6. execution modules
In order to connect to Postgres, certain configuration is required in /etc/salt/minion on
the relevant minions. Some sample configs might look like:

```
postgres.host: 'localhost'
postgres.port: '5432'
postgres.user: 'postgres' -> db user
postgres.pass: ''
postgres.maintenance_db: 'postgres'
```

The default for the maintenance_db is 'postgres' and in most cases it can be left at the default
setting. This data can also be passed into pillar. Options passed into opts will overwrite options
passed into pillar.

**note** This module uses MD5 hashing which may not be compliant with certain security audits.

### `salt.modules.postgres.available_extensions`

```python
salt.modules.postgres.available_extensions(user=None, host=None, port=None, 
maintenance_db=None, password=None, runas=None)
```

List available postgresql extensions

**CLI Example:**

```
salt '*' postgres.available_extensions
```

### `salt.modules.postgres.create_extension`

```python
salt.modules.postgres.create_extension(name, if_not_exists=None, schema=None, 
ext_version=None, from_version=None, user=None, host=None, port=None, maintenance_db=None, 
password=None, runas=None)
```

Install a postgresql extension

**CLI Example:**

```
salt '*' postgres.create_extension 'adminpack'
```

### `salt.modules.postgres.create_metadata`

```python
salt.modules.postgres.create_metadata(name, ext_version=None, schema=None, 
user=None, host=None, port=None, maintenance_db=None, 
password=None, runas=None)
```

Get lifecycle information about an extension

**CLI Example:**

```
salt '*' postgres.create_metadata adminpack
```

### `salt.modules.postgres.datadir_exists`

```python
salt.modules.postgres.datadir_exists(name)
```

New in version 2016.3.0.

Checks if postgres data directory has been initialized

**CLI Example:**

```
salt '*' postgres.datadir_exists '/var/lib/pgsql/data'
```

**name** Name of the directory to check

### `salt.modules.postgres.datadir_init`

```python
salt.modules.postgres.datadir_init(name, auth='password', user=None, password=None, encoding='UTF8', locale=None, runas=None)
```

New in version 2016.3.0.

Initializes a postgres data directory

**CLI Example:**
salt '*' postgres.datadir_init '/var/lib/pgsql/data'

name  The name of the directory to initialize
auth  The default authentication method for local connections
password  The password to set for the postgres user
user  The database superuser name
encoding  The default encoding for new databases
locale  The default locale for new databases
runas  The system user the operation should be performed on behalf of

salt.modules.postgres.db_alter(name, user=None, host=None, port=None, maintenance_db=None, password=None, tablespace=None, owner=None, owner_recurse=False, runas=None)

Change tablespace or/and owner of database.

CLI Example:
salt '*' postgres.db_alter dbname owner=otheruser

salt.modules.postgres.db_create(name, user=None, host=None, port=None, maintenance_db=None, password=None, tablespace=None, encoding=None, lc_collate=None, lc_ctype=None, owner=None, template=None, runas=None)

Adds a databases to the Postgres server.

CLI Example:
salt '*' postgres.db_create 'dbname'
salt '*' postgres.db_create 'dbname' template=template_postgis

salt.modules.postgres.db_exists(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Checks if a database exists on the Postgres server.

CLI Example:
salt '*' postgres.db_exists 'dbname'

salt.modules.postgres.db_list(user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Return dictionary with information about databases of a Postgres server.

CLI Example:
salt '*' postgres.db_list

salt.modules.postgres.db_remove(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Removes a databases from the Postgres server.

CLI Example:
salt '*' postgres.db_remove 'dbname'

salt.modules.postgres.drop_extension(name, if_exists=None, restrict=None, cascade=None, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Drop an installed postgresql extension
CLI Example:
```
salt '*' postgres.drop_extension 'adminpack'
```

```
salt.modules.postgres.get_available_extension(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)
```

Get info about an available postgresql extension

CLI Example:
```
salt '*' postgres.get_available_extension plpgsql
```

```
salt.modules.postgres.get_installed_extension(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)
```

Get info about an installed postgresql extension

CLI Example:
```
salt '*' postgres.get_installed_extension plpgsql
```

```
salt.modules.postgres.group_create(groupname, user=None, host=None, port=None, maintenance_db=None, password=None, createdb=None, createuser=None, createroles=None, encrypted=None, login=None, inherit=None, superuser=None, replication=None, rolepassword=None, groups=None, runas=None)
```

Creates a Postgres group. A group is postgres is similar to a user, but cannot login.

CLI Example:
```
salt '*' postgres.group_create 'groupname' user='user' \ 
    host='hostname' port='port' password='password' \ 
    rolepassword='rolepassword'
```

```
salt.modules.postgres.group_remove(groupname, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)
```

Removes a group from the Postgres server.

CLI Example:
```
salt '*' postgres.group_remove 'groupname'
```

```
salt.modules.postgres.group_update(groupname, user=None, host=None, port=None, maintenance_db=None, password=None, createdb=None, createuser=None, createroles=None, encrypted=None, inherit=None, login=None, superuser=None, replication=None, rolepassword=None, groups=None, runas=None)
```

Updates a postgres group

CLI Examples:
```
salt '*' postgres.group_update 'username' user='user' \ 
    host='hostname' port='port' password='password' \ 
    rolepassword='rolepassword'
```
salt.modules.postgres.has_privileges(name, object_name, object_type, privileges=None,
grant_option=None, prepend='public', maintenance_db=None, user=None, host=None, port=None,
password=None, runas=None)

New in version 2016.3.0.
Check if a role has the specified privileges on an object

CLI Example:
```
salt '*' postgresahas_privileges user_name table_name table \
  SELECT,INSERT maintenance_db=db_name
```

- **name**: Name of the role whose privileges should be checked on object_type
- **object_name**: Name of the object on which the check is to be performed
- **object_type**: The object type, which can be one of the following:
  - table
  - sequence
  - schema
  - tablespace
  - language
  - database
  - group
- **privileges**: Comma separated list of privileges to check, from the list below:
  - INSERT
  - CREATE
  - TRUNCATE
  - CONNECT
  - TRIGGER
  - SELECT
  - USAGE
  - TEMPORARY
  - UPDATE
  - EXECUTE
  - REFERENCES
  - DELETE
  - ALL
- **grant_option**: If grant_option is set to True, the grant option check is performed
- **prepend**: Table and Sequence object types live under a schema so this should be provided if the object is not under the default public schema
- **maintenance_db**: The database to connect to
- **user**: Database username if different from config or default
- **password**: User password if any password for a specified user
- **host**: Database host if different from config or default
- **port**: Database port if different from config or default
- **runas**: System user all operations should be performed on behalf of

salt.modules.postgres.installed_extensions(user=None, host=None, port=None,
maintenance_db=None, password=None, runas=None)

List installed postgresql extensions

CLI Example:
```
salt '*' postgres.installed_extensions
```
salt.modules.postgres.is_available_extension

Test if a specific extension is available

CLI Example:
```
salt '*' postgres.is_available_extension
```

salt.modules.postgres.is_installed_extension

Test if a specific extension is installed

CLI Example:
```
salt '*' postgres.is_installed_extension
```

salt.modules.postgres.language_create

New in version 2016.3.0.
Installs a language into a database

CLI Example:
```
salt '*' postgres.language_create plpgsql dbname
```

name  Language to install
maintenance_db  The database to install the language in
user  database username if different from config or default
password  user password if any password for a specified user
host  Database host if different from config or default
port  Database port if different from config or default
runas  System user all operations should be performed on behalf of

salt.modules.postgres.language_exists

New in version 2016.3.0.
Checks if language exists in a database.

CLI Example:
```
salt '*' postgres.language_exists plpgsql dbname
```

name  Language to check for
maintenance_db  The database to check in
user  database username if different from config or default
password  user password if any password for a specified user
host  Database host if different from config or default
port  Database port if different from config or default
runas  System user all operations should be performed on behalf of

salt.modules.postgres.language_list

New in version 2016.3.0.
Return a list of languages in a database.

CLI Example:
Salt Documentation, Release 2016.3.6

```python
salt '*' postgres.language_list dbname
```

**maintenance_db** The database to check
**user** database username if different from config or default
**password** user password if any password for a specified user
**host** Database host if different from config or default
**port** Database port if different from config or default
**runas** System user all operations should be performed on behalf of

```python
salt.modules.postgres.language_remove(name, maintenance_db, user=None, host=None, port=None, password=None, runas=None)
```

New in version 2016.3.0.

Removes a language from a database

CLI Example:

```python
salt '*' postgres.language_remove plpgsql dbname
```

**name** Language to remove
**maintenance_db** The database to install the language in
**user** database username if different from config or default
**password** user password if any password for a specified user
**host** Database host if different from config or default
**port** Database port if different from config or default
**runas** System user all operations should be performed on behalf of

```python
salt.modules.postgres.owner_to(dbname, ownername, user=None, host=None, port=None, password=None, runas=None)
```

Set the owner of all schemas, functions, tables, views and sequences to the given username.

CLI Example:

```python
salt '*' postgres.owner_to 'dbname' 'username'
```

```python
salt.modules.postgres.privileges_grant(name, object_name, object_type, privileges=None, grant_option=None, prepend='public', maintenance_db=None, user=None, host=None, port=None, password=None, runas=None)
```

New in version 2016.3.0.

Grant privileges on a postgres object

CLI Example:

```python
salt '*' postgres.privileges_grant user_name table_name table \SELECT,UPDATE maintenance_db=db_name
```

**name** Name of the role to which privileges should be granted
**object_name** Name of the object on which the grant is to be performed
**object_type** The object type, which can be one of the following:
- table
- sequence
- schema
- tablespace
- language
- database
- group

13.6. execution modules
privileges  Comma separated list of privileges to grant, from the list below:
  •  INSERT
  •  CREATE
  •  TRUNCATE
  •  CONNECT
  •  TRIGGER
  •  SELECT
  •  USAGE
  •  TEMPORARY
  •  UPDATE
  •  EXECUTE
  •  REFERENCES
  •  DELETE
  •  ALL

grant_option  If grant_option is set to True, the recipient of the privilege can in turn grant it to others
prepending  Table and Sequence object types live under a schema so this should be provided if the object is not
under the default public schema
maintenance_db  The database to connect to
user  database username if different from config or default
password  user password if any password for a specified user
host  Database host if different from config or default
port  Database port if different from config or default
runas  System user all operations should be performed on behalf of

salt.modules.postgres.privileges_list(name, object_type, prepend='public', maintenance_db=None, user=None, host=None, port=None, password=None, runas=None)

New in version 2016.3.0.

Return a list of privileges for the specified object.

CLI Example:

```
salt '*' postgres.privileges_list table_name table maintenance_db=db_name
```

name  Name of the object for which the permissions should be returned
object_type  The object type, which can be one of the following:
  •  table
  •  sequence
  •  schema
  •  tablespace
  •  language
  •  database
  •  group

prepending  Table and Sequence object types live under a schema so this should be provided if the object is not
under the default public schema
maintenance_db  The database to connect to
user  database username if different from config or default
password  user password if any password for a specified user
host  Database host if different from config or default
port  Database port if different from config or default
runas  System user all operations should be performed on behalf of

salt.modules.postgres.privileges_revoke(name, object_name, object_type, privileges=None, prepend='public', maintenance_db=None, user=None, host=None, port=None, password=None, runas=None)
New in version 2016.3.0.

Revoke privileges on a postgres object

CLI Example:

```bash
salt '*' postgres.privileges_revoke user_name table_name table \
SELECT,UPDATE maintenance_db=db_name
```

- **name**  Name of the role whose privileges should be revoked
- **object_name**  Name of the object on which the revoke is to be performed
- **object_type**  The object type, which can be one of the following:
  - table
  - sequence
  - schema
  - tablespace
  - language
  - database
  - group
- **privileges**  Comma separated list of privileges to revoke, from the list below:
  - INSERT
  - CREATE
  - TRUNCATE
  - CONNECT
  - TRIGGER
  - SELECT
  - USAGE
  - TEMPORARY
  - UPDATE
  - EXECUTE
  - REFERENCES
  - DELETE
  - ALL
- **maintenance_db**  The database to connect to
- **user**  Database username if different from config or default
- **password**  User password if any password for a specified user
- **host**  Database host if different from config or default
- **port**  Database port if different from config or default

salt.modules.postgres.psql_query(query, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Run an SQL-Query and return the results as a list. This command only supports SELECT statements. This limitation can be worked around with a query like this:

```
WITH updated AS (UPDATE pg_authid SET rolconnlimit = 2000 WHERE rolname = `rolename` RETURNING rolconnlimit) SELECT * FROM updated;
```

- **query**  The query string.
- **user**  Database username, if different from config or default.
- **host**  Database host, if different from config or default.
- **port**  Database port, if different from config or default.
- **maintenance_db**  The database to run the query against.
- **password**  User password, if different from the config or default.
- **runas**  User to run the command as.

CLI Example:
salt '‘*’‘ postgres.psql_query 'select * from pg_stat_activity'
salt.modules.postgres.role_get(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None, return_password=False)
Return a dict with information about users of a Postgres server.
Set return_password to True to get password hash in the result.
CLI Example:
salt '‘*’‘ postgres.role_get postgres
salt.modules.postgres.schema_create(dbname, name, owner=None, user=None, db_user=None, db_password=None, db_host=None, db_port=None)
Creates a Postgres schema.
CLI Example:
salt '‘*’‘ postgres.schema_create dbname name owner='owner' \ user='user' \ db_user='user' db_password='password' \ db_host='hostname' db_port='port'
salt.modules.postgres.schema_exists(dbname, name, db_user=None, db_password=None, db_host=None, db_port=None)
Checks if a schema exists on the Postgres server.
CLI Example:
salt '‘*’‘ postgres.schema_exists dbname schemaname
dbname Database name we query on
name Schema name we look for
db_user database username if different from config or default
db_password user password if any password for a specified user
db_host Database host if different from config or default
db_port Database port if different from config or default
salt.modules.postgres.schema_get(dbname, name, db_user=None, db_password=None, db_host=None, db_port=None)
Return a dict with information about schemas in a database.
CLI Example:
salt '‘*’‘ postgres.schema_get dbname name
dbname Database name we query on
name Schema name we look for
db_user database username if different from config or default
db_password user password if any password for a specified user
db_host Database host if different from config or default
db_port Database port if different from config or default
salt.modules.postgres.schema_list(dbname, db_user=None, db_password=None, db_host=None, db_port=None)
Return a dict with information about schemas in a Postgres database.
CLI Example:
salt '*(postgres.schema_list dbname

<table>
<thead>
<tr>
<th>dbname</th>
<th>Database name we query on</th>
</tr>
</thead>
<tbody>
<tr>
<td>db_user</td>
<td>database username if different from config or default</td>
</tr>
<tr>
<td>db_password</td>
<td>user password if any password for a specified user</td>
</tr>
<tr>
<td>db_host</td>
<td>Database host if different from config or default</td>
</tr>
<tr>
<td>db_port</td>
<td>Database port if different from config or default</td>
</tr>
</tbody>
</table>

salt.modules.postgres.schema_remove(dbname, name, user=None, db_user=None, 
   db_password=None, db_host=None, db_port=None)

Removes a schema from the Postgres server.

CLI Example:

```
salt '*' postgres.schema_remove dbname schemaname
```

dbname | Database name we work on |
schemaname | The schema's name we'll remove |
user | System user all operations should be performed on behalf of |

salt.modules.postgres.tablespace_alter(name, user=None, host=None, port=None, maintenance_db=None, password=None, new_name=None, new_owner=None, set_option=None, reset_option=None, runas=None)

Change tablespace name, owner, or options.

CLI Example:

```
salt '*' postgres.tablespace_alter tsname new_owner=otheruser
salt '*' postgres.tablespace_alter index_space new_name=fast_raid
salt '*' postgres.tablespace_alter test set_option="{'seq_page_cost': '1.1'}"
```

New in version 2015.8.0.

salt.modules.postgres.tablespace_create(name, location, options=None, owner=None, 
   user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Adds a tablespace to the Postgres server.

CLI Example:

```
salt '*' postgres.tablespace_create tablespacename '/path/datadir'
```

New in version 2015.8.0.

salt.modules.postgres.tablespace_exists(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Checks if a tablespace exists on the Postgres server.

CLI Example:

```
salt '*' postgres.tablespace_exists 'dbname'
```

New in version 2015.8.0.
salt.modules.postgres.tablespace_list(user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Return dictionary with information about tablespaces of a Postgres server.

CLI Example:
```
salt '*' postgres.tablespace_list
```

New in version 2015.8.0.

salt.modules.postgres.tablespace_remove(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Removes a tablespace from the Postgres server.

CLI Example:
```
salt '*' postgres.tablespace_remove tsname
```

New in version 2015.8.0.

salt.modules.postgres.user_create(username, user=None, host=None, port=None, maintenance_db=None, password=None, createdb=None, createuser=None, createroles=None, inherit=None, login=None, connlimit=None, encrypted=None, superuser=None, replication=None, rolepassword=None, groups=None, runas=None)

Creates a Postgres user.

CLI Examples:
```
salt '*' postgres.user_create 'username' user='user' \
    host='hostname' port='port' password='password' \
    rolepassword='rolepassword'
```

salt.modules.postgres.user_exists(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Checks if a user exists on the Postgres server.

CLI Example:
```
salt '*' postgres.user_exists 'username'
```

salt.modules.postgres.user_list(user=None, host=None, port=None, maintenance_db=None, password=None, runas=None, return_password=False)

Return a dict with information about users of a Postgres server.

Set return_password to True to get password hash in the result.

CLI Example:
```
salt '*' postgres.user_list
```

salt.modules.postgres.user_remove(username, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Removes a user from the Postgres server.

CLI Example:
```
salt '*' postgres.user_remove 'username'
```
salt.modules.postgres.user_update(username, user=None, host=None, port=None, maintenance_db=None, password=None, createdb=None, createdbuser=None, createdbroles=None, encrypted=None, superuser=None, inherit=None, login=None, connlimit=None, replication=None, rolepassword=None, groups=None, runas=None)

Updates a Postgres user.

CLI Examples:

```
salt '*' postgres.user_update 'username' user='user' \ host='hostname' port='port' password='password' \ rolepassword='rolepassword'
```

salt.modules.postgres.version(user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Return the version of a Postgres server.

CLI Example:

```
salt '*' postgres.version
```

### 13.6.232 salt.modules.poudriere

Support for poudriere

salt.modules.poudriere.bulk_build(jail, pkg_file, keep=False)

Run bulk build on poudriere server.

Return number of pkg builds, failures, and errors, on error dump to CLI

CLI Example:

```
salt -N buildbox_group poudriere.bulk_build 90amd64 /root/pkg_list
```

salt.modules.poudriere.create_jail(name, arch, version=’9.0-RELEASE’)

Creates a new poudriere jail if one does not exist

NOTE creating a new jail will take some time the master is not hanging

CLI Example:

```
salt '*' poudriere.create_jail 90amd64 amd64
```

salt.modules.poudriere.create_ports_tree()

Not working need to run portfetch non interactive

salt.modules.poudriere.delete_jail(name)

Deletes poudriere jail with name

CLI Example:

```
salt '*' poudriere.delete_jail 90amd64
```

salt.modules.poudriere.is_jail(name)

Return True if jail exists False if not

CLI Example:
```
salt '*' poudriere.is_jail <jail name>
```

salt.modules.poudriere.list_jails()
Return a list of current jails managed by poudriere

CLI Example:
```
salt '*' poudriere.list_jails
```

salt.modules.poudriere.list_ports()
Return a list of current port trees managed by poudriere

CLI Example:
```
salt '*' poudriere.list_ports
```

salt.modules.poudriere.make_pkgng_aware(jname)
Make jail jname pkgng aware

CLI Example:
```
salt '*' poudriere.make_pkgng_aware <jail name>
```

salt.modules.poudriere.parse_config(config_file=None)
Returns a dict of poudriere main configuration definitions

CLI Example:
```
salt '*' poudriere.parse_config
```

salt.modules.poudriere.update_jail(name)
Run freebsd-update on name poudriere jail

CLI Example:
```
salt '*' poudriere.update_jail freebsd:10:x86:64
```

salt.modules.poudriere.update_ports_tree(ports_tree)
Updates the ports tree, either the default or the ports_tree specified

CLI Example:
```
salt '*' poudriere.update_ports_tree staging
```

salt.modules.poudriere.version()
Return poudriere version

CLI Example:
```
salt '*' poudriere.version
```

13.6.233 salt.modules.powerpath
powerpath support.
Assumes RedHat

salt.modules.powerpath.add_license(key)
Add a license
salt.modules.powerpath\texttt{.has\_powerpath}()

\begin{verbatim}
salt.modules.powerpath.list\_licenses()
    returns a list of applied powerpath license keys
\end{verbatim}

\begin{verbatim}
salt.modules.powerpath.remove\_license(key)
    Remove a license
\end{verbatim}

\section*{13.6.234 \texttt{salt.modules.proxy} module}

This module allows you to manage proxy settings

\begin{verbatim}
salt '*' network.get_http_proxy
\end{verbatim}

\begin{verbatim}
salt.modules.proxy.get\_ftp\_proxy\texttt{(network\_service='Ethernet')}
    Returns the current ftp proxy settings

    network\_service  The network service to apply the changes to, this only necessary on OSX

    CLI Example:

    \begin{verbatim}
salt '*' proxy.get\_ftp\_proxy Ethernet
    \end{verbatim}
\end{verbatim}

\begin{verbatim}
salt.modules.proxy.get\_http\_proxy\texttt{(network\_service='Ethernet')}
    Returns the current http proxy settings

    network\_service  The network service to apply the changes to, this only necessary on OSX

    CLI Example:

    \begin{verbatim}
salt '*' proxy.get\_http\_proxy Ethernet
    \end{verbatim}
\end{verbatim}

\begin{verbatim}
salt.modules.proxy.get\_https\_proxy\texttt{(network\_service='Ethernet')}
    Returns the current https proxy settings

    network\_service  The network service to apply the changes to, this only necessary on OSX

    CLI Example:

    \begin{verbatim}
salt '*' proxy.get\_https\_proxy Ethernet
    \end{verbatim}
\end{verbatim}

\begin{verbatim}
salt.modules.proxy.get\_proxy\_bypass\texttt{(network\_service='Ethernet')}
    Returns the current domains that can bypass the proxy

    network\_service  The network service to get the bypass domains from, this is only necessary on OSX

    CLI Example:

    \begin{verbatim}
salt '*' proxy.get\_proxy\_bypass
    \end{verbatim}
\end{verbatim}

\begin{verbatim}
salt.modules.proxy.get\_proxy\_win()
    Gets all of the proxy settings in one call, only available on Windows

    CLI Example:

    \begin{verbatim}
salt '*' proxy.get\_proxy\_win
    \end{verbatim}
\end{verbatim}

\begin{verbatim}
salt.modules.proxy.set\_ftp\_proxy\texttt{(server, port, user=None, password=None, net-
    work\_service='Ethernet', bypass\_hosts=None)}
    Sets the ftp proxy settings

    server  The proxy server to use

    port  The port used by the proxy server

    user  The username to use for the proxy server if required

    password  The password to use if required by the server
\end{verbatim}
**network_service**  The network service to apply the changes to, this only necessary on OSX

**bypass_hosts**  The hosts that are allowed to by pass the proxy. Only used on Windows for other OS’s use `set_proxy_bypass` to edit the bypass hosts.

CLI Example:

```bash
salt '*' proxy.set_ftp_proxy example.com 1080 user=proxy_user password=proxy_pass
```

```
...network_service='Ethernet'
```

**salt.modules.proxy.set_http_proxy** *(server, port, user=None, password=None, network_service='Ethernet', bypass_hosts=None)*

Sets the http proxy settings. Note: On Windows this will override any other proxy settings you have, the preferred method of updating proxies on windows is using `set_proxy`.

**server**  The proxy server to use

**port**  The port used by the proxy server

**user**  The username to use for the proxy server if required

**password**  The password to use if required by the server

**network_service**  The network service to apply the changes to, this only necessary on OSX

**bypass_hosts**  The hosts that are allowed to by pass the proxy. Only used on Windows for other OS’s use `set_proxy_bypass` to edit the bypass hosts.

CLI Example:

```bash
salt '*' proxy.set_http_proxy example.com 1080 user=proxy_user password=proxy_
```

```bash
...pass network_service='Ethernet'
```

**salt.modules.proxy.set_https_proxy** *(server, port, user=None, password=None, network_service='Ethernet', bypass_hosts=None)*

Sets the https proxy settings. Note: On Windows this will override any other proxy settings you have, the preferred method of updating proxies on windows is using `set_proxy`.

**server**  The proxy server to use

**port**  The port used by the proxy server

**user**  The username to use for the proxy server if required

**password**  The password to use if required by the server

**network_service**  The network service to apply the changes to, this only necessary on OSX

**bypass_hosts**  The hosts that are allowed to by pass the proxy. Only used on Windows for other OS’s use `set_proxy_bypass` to edit the bypass hosts.

CLI Example:

```bash
salt '*' proxy.set_https_proxy example.com 1080 user=proxy_user password=proxy_
```

```bash
...pass network_service='Ethernet'
```

**salt.modules.proxy.set_proxy_bypass** *(domains, network_service='Ethernet')*

Sets the domains that can bypass the proxy

**domains**  An array of domains allowed to bypass the proxy

**network_service**  The network service to apply the changes to, this only necessary on OSX

CLI Example:

```bash
salt '*' proxy.set_proxy_bypass "["127.0.0.1", 'localhost']"
```

**salt.modules.proxy.set_proxy_win** *(server, port, types=None, bypass_hosts=None)*

Sets the http proxy settings, only works with Windows.

**server**  The proxy server to use

**password**  The password to use if required by the server

**types**  The types of proxy connections should be setup with this server. Valid types are http and https.

**bypass_hosts**  The hosts that are allowed to by pass the proxy.

CLI Example:
salt 'salt' proxy.set_http_proxy example.com 1080 types="['http', 'https']"

13.6.235 salt.modules.ps

A salt interface to psutil, a system and process library. See http://code.google.com/p/psutil.

depends

- psutil Python module, version 0.3.0 or later
- python-utmp package (optional)

salt.modules.ps.boot_time(time_format=None)
Return the boot time in number of seconds since the epoch began.

CLI Example:

```
salt '*' ps.boot_time
```

time_format Optionally specify a strftime format string. Use time_format='%c' to get a nicely-formatted locale specific date and time (i.e. Fri May 2 19:08:32 2014).

New in version 2014.1.4.

salt.modules.ps.cpu_percent(interval=0.1, per_cpu=False)
Return the percent of time the CPU is busy.
interval the number of seconds to sample CPU usage over
per_cpu if True return an array of CPU percent busy for each CPU, otherwise aggregate all percents into one number

CLI Example:

```
salt '*' ps.cpu_percent
```

salt.modules.ps.cpu_times(per_cpu=False)
Return the percent of time the CPU spends in each state, e.g. user, system, idle, nice, iowait, irq, softirq.
per_cpu if True return an array of percents for each CPU, otherwise aggregate all percents into one number

CLI Example:

```
salt '*' ps.cpu_times
```

salt.modules.ps.disk_io_counters(device=None)
Return disk I/O statistics.

CLI Example:

```
salt '*' ps.disk_io_counters
```
```
salt '*' ps.disk_io_counters device=sda1
```

salt.modules.ps.disk_partition_usage(all=False)
Return a list of disk partitions plus the mount point, filesystem and usage statistics.

CLI Example:

```
salt '*' ps.disk_partition_usage
```

salt.modules.ps.disk_partitions(all=False)
Return a list of disk partitions and their device, mount point, and filesystem type.
all if set to False, only return local, physical partitions (hard disk, USB, CD/DVD partitions). If True, return all filesystems.

CLI Example:
```
salt '*' ps.disk_partitions
```

salt.modules.ps.disk_usage(path)
Given a path, return a dict listing the total available space as well as the free space, and used space.

CLI Example:
```
salt '*' ps.disk_usage /home
```

salt.modules.ps.get_pid_list()
Return a list of process ids (PIDs) for all running processes.

CLI Example:
```
salt '*' ps.get_pid_list
```

salt.modules.ps.get_users()
Return logged-in users.

CLI Example:
```
salt '*' ps.get_users
```

salt.modules.ps.kill_pid(pid, signal=15)
Kill a process by PID.

```
salt 'minion' ps.kill_pid pid [signal=signal_number]
```

pid PID of process to kill.

signal Signal to send to the process. See manpage entry for kill for possible values. Default: 15 (SIGTERM).

Example:
Send SIGKILL to process with PID 2000:
```
salt 'minion' ps.kill_pid 2000 signal=9
```

salt.modules.ps.network_io_counters(interface=None)
Return network I/O statistics.

CLI Example:
```
salt '*' ps.network_io_counters
salt '*' ps.network_io_counters interface=eth0
```

salt.modules.ps.num_cpus()
Return the number of CPUs.

CLI Example:
```
salt '*' ps.num_cpus
```

salt.modules.ps.pgrep(pattern, user=None, full=False)
Return the pids for processes matching a pattern.
If full is true, the full command line is searched for a match, otherwise only the name of the command is searched.

```
salt 'x' ps.pgrep pattern [user=username] [full=(true|false)]
```

**pattern** Pattern to search for in the process list.
**user** Limit matches to the given username. Default: All users.
**full** A boolean value indicating whether only the name of the command or the full command line should be matched against the pattern.

**Examples:**
Find all httpd processes on all `www` minions:
```
salt 'www.*' ps.pgrep httpd
```

Find all bash processes owned by user `tom`:
```
salt 'x' ps.pgrep bash user=tom
```

```
salt.modules.ps.pkill(pattern, user=None, signal=15, full=False)
```
Kill processes matching a pattern.

```
salt 'x' ps.pkill pattern [user=username] [signal=signal_number] \\
[full=(true|false)]
```

**pattern** Pattern to search for in the process list.
**user** Limit matches to the given username. Default: All users.
**signal** Signal to send to the process(es). See manpage entry for kill for possible values. Default: 15 (SIGTERM).
**full** A boolean value indicating whether only the name of the command or the full command line should be matched against the pattern.

**Examples:**
Send SIGHUP to all httpd processes on all `www` minions:
```
salt 'www.*' ps.pkill httpd signal=1
```

Send SIGKILL to all bash processes owned by user `tom`:
```
salt 'x' ps.pkill bash signal=9 user=tom
```

```
salt.modules.ps.proc_info(pid, attrs=None)
```
Return a dictionary of information for a process id (PID).

CLI Example:
```
salt 'x' ps.proc_info 2322
salt 'x' ps.proc_info 2322 attrs='["pid", "name"]'
```

**pid** PID of process to query.
**attrs** Optional list of desired process attributes. The list of possible attributes can be found here: [http://pythonhosted.org/psutil/#psutil.Process](http://pythonhosted.org/psutil/#psutil.Process)

```
salt.modules.ps.swap_memory()
```
New in version 2014.7.0.

Return a dict that describes swap memory statistics.
Note: This function is only available in psutil version 0.6.0 and above.

CLI Example:
```bash
salt '*' ps.swap_memory
```

`salt.modules.ps.top(num_processes=5, interval=3)`
Return a list of top CPU consuming processes during the interval. `num_processes` = return the top N CPU consuming processes `interval` = the number of seconds to sample CPU usage over

CLI Examples:
```bash
salt '*' ps.top
salt '*' ps.top 5 10
```

`salt.modules.ps.total_physical_memory()`
Return the total number of bytes of physical memory.

CLI Example:
```bash
salt '*' ps.total_physical_memory
```

`salt.modules.ps.virtual_memory()`
New in version 2014.7.0.
Return a dict that describes statistics about system memory usage.

Note: This function is only available in psutil version 0.6.0 and above.

CLI Example:
```bash
salt '*' ps.virtual_memory
```

13.6.236 `salt.modules.publish`

Publish a command from a minion to a target

`salt.modules.publish.full_data(tgt, fun, arg=None, expr_form='glob', returner='', timeout=5)`
Return the full data about the publication, this is invoked in the same way as the publish function

CLI Example:
```bash
salt system.example.com publish.full_data '*' cmd.run 'ls -la /tmp'
```

Attention
If you need to pass a value to a function argument and that value contains an equal sign, you **must** include the argument name. For example:
```bash
salt '*' publish.full_data test.kwarg arg='cheese=spam'
```
Publish a command from the minion out to other minions.

Publications need to be enabled on the Salt master and the minion needs to have permission to publish the command. The Salt master will also prevent a recursive publication loop, this means that a minion cannot command another minion to command another minion as that would create an infinite command loop.

The `expr_form` argument is used to pass a target other than a glob into the execution, the available options are:

- `glob`
- `pcre`
- `grain`
- `grain_pcre`
- `pillar`
- `pillar_pcre`
- `ipcidr`
- `range`
- `compound`

Note that for pillar matches must be exact, both in the pillar matcher and the compound matcher. No globbing is supported.

The arguments sent to the minion publish function are separated with commas. This means that for a minion executing a command with multiple args it will look like this:

```
salt system.example.com publish.publish '*' user.add 'foo,1020,1020'
salt system.example.com publish.publish 'os:Fedora' network.interfaces '' grain
```

**CLI Example:**

```
salt system.example.com publish.publish '*' cmd.run 'ls -la /tmp'
```

**Attention**

If you need to pass a value to a function argument and that value contains an equal sign, you **must** include the argument name. For example:

```
salt '*' publish.publish test.kwarg arg='cheese=spam'
```

Multiple keyword arguments should be passed as a list.

```
salt '*' publish.publish test.kwarg arg="['cheese=spam','spam=cheese']"
```

When running via salt-call, the `via_master` flag may be set to specific which master the publication should be sent to. Only one master may be specified. If unset, the publication will be sent only to the first master in minion configuration.

```
salt.modules.publish.runner(fun, arg=None, timeout=5)
```

Execute a runner on the master and return the data from the runner function

**CLI Example:**

```
salt publish.runner manage.down
```
13.6.237 salt.modules.puppet

Execute puppet routines

salt.modules.puppet.disable(message=None)
    New in version 2014.7.0.
    Disable the puppet agent
    message  New in version 2015.5.2.
        Disable message to send to puppet
    CLI Example:
    
    salt '*' puppet.disable
    salt '*' puppet.disable 'Disabled, contact XYZ before enabling'

salt.modules.puppet.enable()
    New in version 2014.7.0.
    Enable the puppet agent
    
    salt '*' puppet.enable

salt.modules.puppet.fact(name, puppet=False)
    Run facter for a specific fact
    
    salt '*' puppet.fact kernel

salt.modules.puppet.facts(puppet=False)
    Run facter and return the results
    
    salt '*' puppet.facts

salt.modules.puppet.noop(*args, **kwargs)
    Execute a puppet noop run and return a dict with the stderr, stdout, return code, etc. Usage is the same as for puppet.run.
    
    salt '*' puppet.noop
    salt '*' puppet.noop tags=basefiles::edit,apache::server
    salt '*' puppet.noop debug
    salt '*' puppet.noop apply /a/b/manifest.pp modulepath=/a/b/modules -tags=basefiles::edit,apache::server

salt.modules.puppet.plugin_sync()
    Runs a plugin sync between the puppet master and agent
    
    salt '*' puppet.plugin_sync

salt.modules.puppet.run(*args, **kwargs)
    Execute a puppet run and return a dict with the stderr, stdout, return code, etc. The first positional argument
given is checked as a subcommand. Following positional arguments should be ordered with arguments re-
quired by the subcommand first, followed by non-keyword arguments. Tags are specified by a tag keyword
and comma separated list of values. -- http://docs.puppetlabs.com/puppet/latest/reference/lang_tags.html

CLI Examples:

```
salt '*' puppet.run
salt '*' puppet.run tags=basefiles::edit,apache::server
salt '*' puppet.run agent onetime no-daemonize no-usecacheonfailure no-splay ignorecache
salt '*' puppet.run debug
salt '*' puppet.run apply /a/b/manifest.pp modulepath=/a/b/modules tags=basefiles::edit,apache::server
```

salt.modules.puppet.status()
New in version 2014.7.0.
Display puppet agent status
CLI Example:

```
salt '*' puppet.status
```

salt.modules.puppet.summary()
New in version 2014.7.0.
Show a summary of the last puppet agent run
CLI Example:

```
salt '*' puppet.summary
```

13.6.238 salt.modules.pushbullet module

Module for sending messages to Pushbullet (https://www.pushbullet.com)
New in version 2015.8.0.
Requires an api_key in /etc/salt/minion:

For example:

```
pushbullet:
  device: "Chrome"
  title: "Example push message"
  body: "Message body."
```

salt.modules.pushbullet.push_note(device=None, title=None, body=None)
Pushing a text note.
Parameters

- **device** -- Pushbullet target device
- **title** -- Note title
- **body** -- Note body

Returns Boolean if message was sent successfully.
CLI Example:
13.6.239 salt.modules.pushover_notify

Module for sending messages to Pushover (https://www.pushover.net)

New in version 2016.3.0.

**configuration** This module can be used by either passing an api key and version directly or by specifying both in a configuration profile in the salt master/minion config.

For example:

```
pushover:
  token: abAHuZyCLtdH8P4zhmFZmgUHUsv1ei8
```

salt.modules.pushover_notify.post_message(user=None, device=None, message=None, title=None, priority=None, expire=None, retry=None, sound=None, api_version=1, token=None)

Send a message to a Pushover user or group.

**Parameters**

- `user` -- The user or group to send to, must be key of user or group not email address.
- `message` -- The message to send to the PushOver user or group.
- `title` -- Specify who the message is from.
- `priority` -- The priority of the message, defaults to 0.
- `expire` -- The message should expire after N number of seconds.
- `retry` -- The number of times the message should be retried.
- `sound` -- The sound to associate with the message.
- `api_version` -- The PushOver API version, if not specified in the configuration.
- `token` -- The PushOver token, if not specified in the configuration.

**Returns** Boolean if message was sent successfully.

CLI Example:

```
salt '*' pushover.post_message user='xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx' title='Message from Salt' message='Build is done'
```

```
salt '*' pushover.post_message user='xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx' title='Message from Salt' message='Build is done' priority='2' expire='720' retry='5'
```

13.6.240 salt.modules.pw_group

Manage groups on FreeBSD

**Important**: If you feel that Salt should be using this module to manage groups on a minion, and it is using a different module (or gives an error similar to `group.info` is not available), see here.
salt.modules.pw_group.add(name, gid=None,**kwargs)
Add the specified group

CLI Example:
```
salt '*' group.add foo 3456
```

salt.modules.pw_group.adduser(name, username)
Add a user in the group.

CLI Example:
```
salt '*' group.adduser foo bar
```

Verifies if a valid username `bar' as a member of an existing group `foo', if not then adds it.

salt.modules.pw_group.chgid(name, gid)
Change the gid for a named group

CLI Example:
```
salt '*' group.chgid foo 4376
```

salt.modules.pw_group.delete(name)
Remove the named group

CLI Example:
```
salt '*' group.delete foo
```

salt.modules.pw_group.deluser(name, username)
Remove a user from the group.

CLI Example:
```
salt '*' group.deluser foo bar
```

Removes a member user `bar' from a group `foo'. If group is not present then returns True.

salt.modules.pw_group.getent(refresh=False)
Return info on all groups

CLI Example:
```
salt '*' group.getent
```

salt.modules.pw_group.info(name)
Return information about a group

CLI Example:
```
salt '*' group.info foo
```

salt.modules.pw_group.members(name, members_list)
Replaces members of the group with a provided list.

New in version 2015.5.4.

CLI Example:
```
salt '*' group.members foo `user1,user2,user3,...'
```

Replaces a membership list for a local group `foo'. foo:x:1234:user1,user2,user3,...
13.6.241  salt.modules.pw_user

Manage users with the `pw` command

**Important**: If you feel that Salt should be using this module to manage users on a minion, and it is using a different module (or gives an error similar to `user.info` is not available), see here.

```
salt.modules.pw_user.add(name, uid=None, gid=None, groups=None, home=None, shell=None, unique=True, fullname='', roomnumber='', workphone='', homephone='', createhome=True, loginclass=None, **kwargs)
```

Add a user to the minion

CLI Example:
```
salt '*' user.add name <uid> <gid> <groups> <home> <shell>
```

```
salt.modules.pw_user.chfullname(name, fullname)
```

Change the user's Full Name

CLI Example:
```
salt '*' user.chfullname foo "Foo Bar"
```

```
salt.modules.pw_user.chgid(name, gid)
```

Change the default group of the user

CLI Example:
```
salt '*' user.chgid foo 4376
```

```
salt.modules.pw_user.chgroups(name, groups, append=False)
```

Change the groups to which a user belongs

**name**  
Username to modify

**groups**  
List of groups to set for the user. Can be passed as a comma-separated list or a Python list.

**append**  
[False]  
Set to `True` to append these groups to the user's existing list of groups. Otherwise, the specified groups will replace any existing groups for the user.

CLI Example:
```
salt '*' user.chgroups foo wheel,root True
```

```
salt.modules.pw_user.chhome(name, home, persist=False)
```

Set a new home directory for an existing user

**name**  
Username to modify

**home**  
New home directory to set

**persist**  
[False]  
Set to `True` to prevent configuration files in the new home directory from being overwritten by the files from the skeleton directory.

CLI Example:
```
salt '*' user.chhome foo /home/users/foo True
```

```
salt.modules.pw_user.chhomephone(name, homephone)
```

Change the user's Home Phone

CLI Example:
```
salt '*' user.chhomephone foo "7735551234"
```
salt.modules.pw_user.chloginclass(name, loginclass, root=None)
Change the default login class of the user

New in version 2016.3.5.

CLI Example:
```
salt '*' user.chloginclass foo staff
```

salt.modules.pw_user.chroomnumber(name, roomnumber)
Change the user's Room Number

CLI Example:
```
salt '*' user.chroomnumber foo 123
```

salt.modules.pw_user.chshell(name, shell)
Change the default shell of the user

CLI Example:
```
salt '*' user.chshell foo /bin/zsh
```

salt.modules.pw_user.chuid(name, uid)
Change the uid for a named user

CLI Example:
```
salt '*' user.chuid foo 4376
```

salt.modules.pw_user.chworkphone(name, workphone)
Change the user's Work Phone

CLI Example:
```
salt '*' user.chworkphone foo "7735550123"
```

salt.modules.pw_user.delete(name, remove=False, force=False)
Remove a user from the minion

CLI Example:
```
salt '*' user.delete name remove=True force=True
```

salt.modules.pw_user.get_loginclass(name)
Get the login class of the user

New in version 2016.3.0.

CLI Example:
```
salt '*' user.get_loginclass foo
```

salt.modules.pw_user.getent(refresh=False)
Return the list of all info for all users

CLI Example:
```
salt '*' user.getent
```
salt.modules.pw_user.info(name)
  Return user information
  CLI Example:
  
  ```
  salt '*' user.info root
  ```

salt.modules.pw_user.list_groups(name)
  Return a list of groups the named user belongs to
  CLI Example:
  
  ```
  salt '*' user.list_groups foo
  ```

salt.modules.pw_user.list_users()
  Return a list of all users
  CLI Example:
  
  ```
  salt '*' user.list_users
  ```

salt.modules.pw_user.rename(name, new_name)
  Change the username for a named user
  CLI Example:
  
  ```
  salt '*' user.rename name new_name
  ```

13.6.242 salt.modules.pyenv

Manage python installations with pyenv.
New in version v2014.04.

salt.modules.pyenv.default(python=None, runas=None)
  Returns or sets the currently defined default python.
    python=None The version to set as the default. Should match one of the versions listed by
                `pyenv.versions`. Leave blank to return the current default.
  CLI Example:
  
  ```
  salt '*' pyenv.default
  salt '*' pyenv.default 2.0.0-p0
  ```

salt.modules.pyenv.do(cmdline=None, runas=None)
  Execute a python command with pyenv's shims from the user or the system.
  CLI Example:
  
  ```
  salt '*' pyenv.do 'gem list bundler'
  salt '*' pyenv.do 'gem list bundler' deploy
  ```

salt.modules.pyenv.do_with_python(python, cmdline, runas=None)
  Execute a python command with pyenv's shims using a specific python version.
  CLI Example:
  
  ```
  salt '*' pyenv.do_with_python 2.0.0-p0 'gem list bundler'
  salt '*' pyenv.do_with_python 2.0.0-p0 'gem list bundler' deploy
  ```
salt.modules.pyenv.install(runas=None, path=None)
Install pyenv systemwide

CLI Example:
```
salt '*' pyenv.install
```

salt.modules.pyenv.install_python(python, runas=None)
Install a python implementation.
**python** The version of python to install, should match one of the versions listed by pyenv.list

CLI Example:
```
salt '*' pyenv.install_python 2.0.0-p0
```

salt.modules.pyenv.is_installed(runas=None)
Check if pyenv is installed.

CLI Example:
```
salt '*' pyenv.is_installed
```

salt.modules.pyenv.list(runas=None)
List the installable versions of python.

CLI Example:
```
salt '*' pyenv.list
```

salt.modules.pyenv.rehash(runas=None)
Run pyenv rehash to update the installed shims.

CLI Example:
```
salt '*' pyenv.rehash
```

salt.modules.pyenv.uninstall_python(python, runas=None)
Uninstall a python implementation.
**python** The version of python to uninstall. Should match one of the versions listed by pyenv.versions

CLI Example:
```
salt '*' pyenv.uninstall_python 2.0.0-p0
```

salt.modules.pyenv.update(runas=None, path=None)
Updates the current versions of pyenv and python-Build

CLI Example:
```
salt '*' pyenv.update
```

salt.modules.pyenv.versions(runas=None)
List the installed versions of python.

CLI Example:
```
salt '*' pyenv.versions
```
13.6.243 salt.modules.qemu_img

Qemu-img Command Wrapper

The qemu img command is wrapped for specific functions.

depends qemu-img

salt.modules.qemu_img.convert(orig, dest, fmt)

Convert an existing disk image to another format using qemu-img

CLI Example:

```bash
salt '*' qemu_img.convert /path/to/original.img /path/to/new.img qcow2
```

salt.modules.qemu_img.make_image(location, size, fmt)

Create a blank virtual machine image file of the specified size in megabytes. The image can be created in any format supported by qemu

CLI Example:

```bash
salt '*' qemu_img.make_image /tmp/image.qcow /dev/null 2048 qcow2
salt '*' qemu_img.make_image /tmp/image.raw /dev/null 10240 raw
```

13.6.244 salt.modules.qemu_nbd

Qemu Command Wrapper

The qemu system comes with powerful tools, such as qemu-img and qemu-nbd which are used here to build up kvm images.

salt.modules.qemu_nbd.clear(mnt)

Pass in the mnt dict returned from nbd_mount to unmount and disconnect the image from nbd. If all of the partitions are unmounted return an empty dict, otherwise return a dict containing the still mounted partitions

CLI Example:

```bash
salt '*' qemu_nbd.clear '{"/mnt/foo": "/dev/nbd0p1"}"
```

salt.modules.qemu_nbd.connect(image)

Activate nbd for an image file.

CLI Example:

```bash
salt '*' qemu_nbd.connect /tmp/image.raw
```

salt.modules.qemu_nbd.init(image, root=None)

Mount the named image via qemu-nbd and return the mounted roots

CLI Example:

```bash
salt '*' qemu_nbd.init /srv/image.qcow2
```

salt.modules.qemu_nbd.mount(nbd, root=None)

Pass in the nbd connection device location, mount all partitions and return a dict of mount points

CLI Example:
13.6.245 salt.modules.quota

Module for managing quotas on POSIX-like systems.

salt.modules.quota.get_mode(device)
    Report whether the quota system for this device is on or off
    CLI Example:
    ```
salt '*' quota.get_mode
```

salt.modules.quota.off(device)
    Turns off the quota system
    CLI Example:
    ```
salt '*' quota.off
```

salt.modules.quota.on(device)
    Turns on the quota system
    CLI Example:
    ```
salt '*' quota.on
```

salt.modules.quota.report(mount)
    Report on quotas for a specific volume
    CLI Example:
    ```
salt '*' quota.report /media/data
```

salt.modules.quota.set(device, **kwargs)
    Calls out to setquota, for a specific user or group
    CLI Example:
    ```
salt '*' quota.set /media/data user=larry block-soft-limit=1048576
salt '*' quota.set /media/data group=painters file-hard-limit=1000
```

salt.modules.quota.stats()
    Runs the quotastats command, and returns the parsed output
    CLI Example:
    ```
salt '*' quota.stats
```

salt.modules.quota.warn()
    Runs the warnquota command, to send warning emails to users who are over their quota limit.
    CLI Example:
    ```
salt '*' quota.warn
```
13.6.246 salt.modules.rabbitmq

Module to provide RabbitMQ compatibility to Salt. Todo: A lot, need to add cluster support, logging, and minion configuration data.

salt.modules.rabbitmq.add_user(name, password=None, runas=None)
Add a rabbitMQ user via rabbitmqctl user_add <user> <password>

CLI Example:
```
salt '*' rabbitmq.add_user rabbit_user password
```

salt.modules.rabbitmq.add_vhost(vhost, runas=None)
Adds a vhost via rabbitmqctl add_vhost.

CLI Example:
```
salt '*' rabbitmq add_vhost '<vhost_name>'
```

salt.modules.rabbitmq.change_password(name, password, runas=None)
Changes a user's password.

CLI Example:
```
salt '*' rabbitmq.change_password rabbit_user password
```

salt.modules.rabbitmq.check_password(name, password, runas=None)
New in version 2016.3.0.
Checks if a user's password is valid.

CLI Example:
```
salt '*' rabbitmq.check_password rabbit_user password
```

salt.modules.rabbitmq.clear_password(name, runas=None)
Removes a user's password.

CLI Example:
```
salt '*' rabbitmq.clear_password rabbit_user
```

salt.modules.rabbitmq.cluster_status(runas=None)
return rabbitmq cluster_status

CLI Example:
```
salt '*' rabbitmq.cluster_status
```

salt.modules.rabbitmq.delete_policy(vhost, name, runas=None)
Delete a policy based on rabbitmqctl clear_policy.

Reference: http://www.rabbitmq.com/ha.html

CLI Example:
```
salt '*' rabbitmq.delete_policy / HA'
```

salt.modules.rabbitmq.delete_user(name, runas=None)
Deletes a user via rabbitmqctl delete_user.
CLI Example:
```
salt '*' rabbitmq.delete_user rabbit_user
```

```python
salt.modules.rabbitmq.delete_vhost( vhost, runas=None )
```
Deletes a vhost rabbitmqctl delete_vhost.

CLI Example:
```
salt '*' rabbitmq.delete_vhost '<vhost_name>'
```

```python
salt.modules.rabbitmq.disable_plugin( name, runas=None )
```
Disable a RabbitMQ plugin via the rabbitmq-plugins command.

CLI Example:
```
salt '*' rabbitmq.disable_plugin foo
```

```python
salt.modules.rabbitmq.enable_plugin( name, runas=None )
```
Enable a RabbitMQ plugin via the rabbitmq-plugins command.

CLI Example:
```
salt '*' rabbitmq.enable_plugin foo
```

```python
salt.modules.rabbitmq.force_reset( runas=None )
```
Forcefully Return a RabbitMQ node to its virgin state

CLI Example:
```
salt '*' rabbitmq.force_reset
```

```python
salt.modules.rabbitmq.join_cluster( host, user='rabbit', ram_node=None, runas=None )
```
Join a rabbit cluster

CLI Example:
```
salt '*' rabbitmq.join_cluster 'rabbit.example.com' 'rabbit'
```

```python
salt.modules.rabbitmq.list_permissions( vhost, runas=None )
```
Lists permissions for vhost via rabbitmqctl list_permissions

CLI Example:
```
salt '*' rabbitmq.list_permissions '/myvhost'
```

```python
salt.modules.rabbitmq.list_policies( vhost='/', runas=None )
```
Return a dictionary of policies nested by vhost and name based on the data returned from rabbitmqctl list_policies.

Reference: http://www.rabbitmq.com/ha.html

CLI Example:
```
salt '*' rabbitmq.list_policies'
```

```python
salt.modules.rabbitmq.list_queues( runas=None, *args )
```
Returns queue details of the / virtual host

CLI Example:
salt '*/' rabbitmq.list_queues messages consumers

salt.modules.rabbitmq.list_queues_vhost(vhost, runas=None, *args)
Returns queue details of specified virtual host. This command will consider first parameter as the vhost name and rest will be treated as queueinfoitem. For getting details on vhost /, use list_queues instead.

CLI Example:
salt '*/' rabbitmq.list_queues messages consumers

salt.modules.rabbitmq.list_user_permissions(name, runas=None)
List permissions for a user via rabbitmqctl list_user_permissions

CLI Example:
salt '*/' rabbitmq.list_user_permissions 'user'.

salt.modules.rabbitmq.list_users(runas=None)
Return a list of users based off of rabbitmqctl user_list.

CLI Example:
salt '*/' rabbitmq.list_users

salt.modules.rabbitmq.list_vhosts(runas=None)
Return a list of vhost based on rabbitmqctl list_vhosts.

CLI Example:
salt '*/' rabbitmq.list_vhosts

salt.modules.rabbitmq.plugin_is_enabled(name, runas=None)
Return whether the plugin is enabled.

CLI Example:
salt '*/' rabbitmq.plugin_is_enabled foo

salt.modules.rabbitmq.policy_exists(vhost, name, runas=None)
Return whether the policy exists based on rabbitmqctl list_policies.

Reference: http://www.rabbitmq.com/ha.html

CLI Example:
salt '*/' rabbitmq.policy_exists / HA

salt.modules.rabbitmq.reset(runas=None)
Return a RabbitMQ node to its virgin state

CLI Example:
salt '*/' rabbitmq.reset

salt.modules.rabbitmq.set_permissions(vhost, user, conf='.*', write='.*', read='.*', runas=None)
Sets permissions for vhost via rabbitmqctl set_permissions

CLI Example:
salt.modules.rabbitmq.set_permissions('myvhost', 'myuser')

salt.modules.rabbitmq.set_policy(vhost, name, pattern, definition, priority=None, runas=None)
Set a policy based on rabbitmqctl set_policy.
Reference: http://www.rabbitmq.com/ha.html
CLI Example:
salt '*' rabbitmq.set_policy / HA '.*' '{"ha-mode":"all"}'

salt.modules.rabbitmq.set_user_tags(name, tags, runas=None)
Add user tags via rabbitmqctl set_user_tags
CLI Example:
salt '*' rabbitmq.set_user_tags 'myadmin' 'administrator'

salt.modules.rabbitmq.start_app(runas=None)
Start the RabbitMQ application.
CLI Example:
salt '*' rabbitmq.start_app

salt.modules.rabbitmq.status(runas=None)
return rabbitmq status
CLI Example:
salt '*' rabbitmq.status

salt.modules.rabbitmq.stop_app(runas=None)
Stops the RabbitMQ application, leaving the Erlang node running.
CLI Example:
salt '*' rabbitmq.stop_app

salt.modules.rabbitmq.user_exists(name, runas=None)
Return whether the user exists based on rabbitmqctl list_users.
CLI Example:
salt '*' rabbitmq.user_exists rabbit_user

salt.modules.rabbitmq.vhost_exists(name, runas=None)
Return whether the vhost exists based on rabbitmqctl list_vhosts.
CLI Example:
salt '*' rabbitmq.vhost_exists rabbit_host

**13.6.247 salt.modules.raet_publish**

Publish a command from a minion to a target
salt.modules.raet_publish.full_data(tgt, fun, arg=None, expr_form='glob', returner='`', timeout=5)

Return the full data about the publication, this is invoked in the same way as the publish function

CLI Example:

```
salt system.example.com publish.full_data '*' cmd.run 'ls -la /tmp'
```

**Attention**

If you need to pass a value to a function argument and that value contains an equal sign, you must include the argument name. For example:

```
salt '*' publish.full_data test.kwarg arg='cheese=spam'
```

called_module raet_publish.publish(tgt, fun, arg=None, expr_form='glob', returner='`', timeout=5)

Publish a command from the minion out to other minions.

Publications need to be enabled on the Salt master and the minion needs to have permission to publish the command. The Salt master will also prevent a recursive publication loop, this means that a minion cannot command another minion to command another minion as that would create an infinite command loop.

The expr_form argument is used to pass a target other than a glob into the execution, the available options are:

- `glob`
- `pcre`
- `grain`
- `grain_pcre`
- `pillar`
- `pillar_pcre`
- `ipcidr`
- `range`
- `compound`

The arguments sent to the minion publish function are separated with commas. This means that for a minion executing a command with multiple args it will look like this:

```
salt system.example.com publish.publish '*' user.add 'foo,1020,1020'
salt system.example.com publish.publish 'os:Fedora' network.interfaces '' grain
```

**CLI Example:**

```
salt system.example.com publish.publish '*' cmd.run 'ls -la /tmp'
```

**Attention**

If you need to pass a value to a function argument and that value contains an equal sign, you must include the argument name. For example:

```
salt '*' publish.publish test.kwarg arg='cheese=spam'
```

called_module raet_publish.runner(fun, arg=None, timeout=5)

Execute a runner on the master and return the data from the runner function

**CLI Example:**

```
```
13.6.248 **salt.modules.rallydev**

Support for RallyDev

New in version 2015.8.0.

Requires a **username** and a **password** in `/etc/salt/minion`:

```
salt.modules.rallydev.list_items(name)
    List items of a particular type
    CLI Examples:
    salt myminion rallydev.list_<item name>s
    salt myminion rallydev.list_users
    salt myminion rallydev.list_artifacts
```

```
salt.modules.rallydev.list_users()
    List the users
    CLI Example:
    salt myminion rallydev.list_users
```

```
salt.modules.rallydev.query_item(name, query_string, order='Rank')
    Query a type of record for one or more items. Requires a valid query string. See https://rally1.rallydev.com/slm/doc/webservice/introduction.jsp for information on query syntax.
    CLI Example:
    salt myminion rallydev.query_<item name> <query string> [order='Rank']
    salt myminion rallydev.query_task '(Name contains github)'
    salt myminion rallydev.query_task '(Name contains reactor)' Rank
```

```
salt.modules.rallydev.query_user(query_string, order='UserName')
    Update a user
    CLI Example:
    salt myminion rallydev.query_user '(Name contains Jo)'
```

```
salt.modules.rallydev.show_artifact(id_)
    Show an artifact
    CLI Example:
    salt myminion rallydev.show_artifact <artifact id>
```

```
salt.modules.rallydev.show_item(name, id_)
    Show an item
    CLI Example:
    salt myminion rallydev.show_<item name> <item id>
```
salt.modules.rallydev.show_user(id_)
Show a user

CLI Example:
salt myminion rallydev.show_user <user id>

salt.modules.rallydev.update_item(name, id_, field=None, value=None, postdata=None)
Update an item. Either a field and a value, or a chunk of POST data, may be used, but not both.

CLI Example:
salt myminion rallydev.update_<item name> <item id>

salt.modules.rallydev.update_user(id_, field, value)
Update a user

CLI Example:
salt myminion rallydev.update_user <user id> <field> <new value>

13.6.249 salt.modules.random_org

Module for retrieving random information from Random.org

New in version 2015.5.0.

configuration This module can be used by either passing an api key and version directly or by specifying both in a configuration profile in the salt master/minion config.

For example:

```
grandon:  
  api_key: 7be1402d-5719-5bd3-a306-3def9f135da5 
  api_version: 1 
```

salt.modules.random_org.generateBlobs(api_key=None, api_version=None, **kwargs)
List all Slack users.

Parameters

- **api_key** -- The Random.org api key.
- **api_version** -- The Random.org api version.
- **format** -- Specifies the format in which the blobs will be returned. Values allowed are base64 and hex.

Returns The user list.

CLI Example:

```
salt '*' get_integers number=5 min=1 max=6 
salt '*' get_integers number=5 min=1 max=6 
```

salt.modules.random_org.generateDecimalFractions(api_key=None, api_version=None, **kwargs)
Generates true random decimal fractions

Parameters

- **api_key** -- The Random.org api key.
- **api_version** -- The Random.org api version.
- **number** -- How many random decimal fractions you need. Must be within the [1,1e4] range.
- **decimalPlaces** -- The number of decimal places to use. Must be within the [1,20] range.
- **replacement** -- Specifies whether the random numbers should be picked with replacement. The default (true) will cause the numbers to be picked with replacement, i.e., the resulting numbers may contain duplicate values (like a series of dice rolls). If you want the numbers picked to be unique (like raffle tickets drawn from a container), set this value to false.

**Returns** A list of decimal fraction

CLI Example:

```bash
salt '*' random_org.generateDecimalFractions number=10 decimalPlaces=4
```

```bash
salt '*' random_org.generateDecimalFractions number=10 decimalPlaces=4 replacement=True
```

**salt.modules.random_org.generateGaussians(api_key=None, api_version=None, **kwargs)**

This method generates true random numbers from a Gaussian distribution (also known as a normal distribution).

**Parameters**

- **api_key** -- The Random.org api key.
- **api_version** -- The Random.org api version.
- **number** -- How many random numbers you need. Must be within the [1,1e4] range.
- **mean** -- The distribution’s mean. Must be within the [-1e6,1e6] range.
- **standardDeviation** -- The distribution’s standard deviation. Must be within the [-1e6,1e6] range.
- **significantDigits** -- The number of significant digits to use. Must be within the [2,20] range.

**Returns** The user list.

CLI Example:

```bash
salt '*' random_org.generateGaussians number=10 mean=0.0 standardDeviation=1.0
```

```bash
salt '*' random_org.generateGaussians number=10 mean=0.0 standardDeviation=1.0
```

**salt.modules.random_org.generateIntegers(api_key=None, api_version=None, **kwargs)**

Generate random integers

**Parameters**

- **api_key** -- The Random.org api key.
- **api_version** -- The Random.org api version.
- **number** -- The number of integers to generate
- **minimum** -- The lower boundary for the range from which the random numbers will be picked. Must be within the [-1e9,1e9] range.
- **maximum** -- The upper boundary for the range from which the random numbers will be picked. Must be within the [-1e9,1e9] range.
• **replacement** -- Specifies whether the random numbers should be picked with replacement. The default (true) will cause the numbers to be picked with replacement, i.e., the resulting numbers may contain duplicate values (like a series of dice rolls). If you want the numbers picked to be unique (like raffle tickets drawn from a container), set this value to false.

• **base** -- Specifies the base that will be used to display the numbers. Values allowed are 2, 8, 10 and 16. This affects the JSON types and formatting of the resulting data as discussed below.

**Returns** A list of integers.

**CLI Example:**

```
salt '*' random_org.generateIntegers number=5 minimum=1 maximum=6
salt '*' random_org.generateIntegers number=5 minimum=2 maximum=255 base=2
```

salt.modules.random_org.generateStrings

Generate random strings.

**Parameters**

- **api_key** -- The Random.org api key.
- **api_version** -- The Random.org api version.
- **number** -- The number of strings to generate.
- **length** -- The length of each string. Must be within the [1,20] range. All strings will be of the same length
- **characters** -- A string that contains the set of characters that are allowed to occur in the random strings. The maximum number of characters is 80.
- **replacement** -- Specifies whether the random strings should be picked with replacement. The default (true) will cause the strings to be picked with replacement, i.e., the resulting list of strings may contain duplicates (like a series of dice rolls). If you want the strings to be unique (like raffle tickets drawn from a container), set this value to false.

**Returns** A list of strings.

**CLI Example:**

```
salt '*' random_org.generateStrings number=5 length=8 characters='abcdefghijklmnopqrstuvwxyz'
salt '*' random_org.generateStrings number=10 length=16 characters='abcdefghijklmnopqrstuvwxyz'
```

salt.modules.random_org.generateUUIDs

Generate a list of random UUIDs

**Parameters**

- **api_key** -- The Random.org api key.
- **api_version** -- The Random.org api version.
- **number** -- How many random UUIDs you need. Must be within the [1,1e3] range.

**Returns** A list of UUIDs

**CLI Example:**

```
salt '*' random_org.generateUUIDs number=5
```
salt.modules.random_org.getUsage(api_key=None, api_version=None)

Show current usages statistics

**Parameters**

- *api_key* -- The Random.org api key.
- *api_version* -- The Random.org api version.

**Returns**
The current usage statistics.

CLI Example:

```
salt '*' random_org.getUsage
salt '*' random_org.getUsage api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15 api_version=1
```

### 13.6.250 salt.modules.rbenv

Manage ruby installations with rbenv. rbenv is supported on Linux and Mac OS X. rbenv doesn't work on Windows (and isn't really necessary on Windows as there is no system Ruby on Windows). On Windows, the RubyInstaller and/or Pik are both good alternatives to work with multiple versions of Ruby on the same box.

http://misheska.com/blog/2013/06/15/using-rbenv-to-manage-multiple-versions-of-ruby/

New in version 0.16.0.

salt.modules.rbenv.default(ruby=None, runas=None)

Returns or sets the currently defined default ruby

ruby  The version to set as the default. Should match one of the versions listed by `rbenv.versions`. Leave blank to return the current default.

CLI Example:

```
salt '*' rbenv.default
salt '*' rbenv.default 2.0.0-p0
```

salt.modules.rbenv.do(cmdline, runas=None, env=None)

Execute a ruby command with rbenv's shims from the user or the system

CLI Example:

```
salt '*' rbenv.do 'gem list bundler'
salt '*' rbenv.do 'gem list bundler' deploy
```

salt.modules.rbenv.do_with_ruby(ruby, cmdline, runas=None)

Execute a ruby command with rbenv's shims using a specific ruby version

CLI Example:

```
salt '*' rbenv.do_with_ruby 2.0.0-p0 'gem list bundler'
salt '*' rbenv.do_with_ruby 2.0.0-p0 'gem list bundler' runas=deploy
```

salt.modules.rbenv.install(runas=None, path=None)

Install rbenv systemwide

CLI Example:

```
salt '*' rbenv.install
```

salt.modules.rbenv.install_ruby(ruby, runas=None)

Install a ruby implementation.
The version of Ruby to install, should match one of the versions listed by `rbenv.list`.

The user under which to run rbenv. If not specified, then rbenv will be run as the user under which Salt is running.

Additional environment variables can be configured in pillar / grains / master:

```ruby
build_env: 'CONFIGURE_OPTS="--no-tcmalloc" CFLAGS="-fno-tree-dce"'
```

CLI Example:

```bash
salt '*' rbenv.install_ruby 2.0.0-p0
```

```ruby
salt.modules.rbenv.is_installed(runas=None)
```

Check if rbenv is installed

CLI Example:

```bash
salt '*' rbenv.is_installed
```

```ruby
salt.modules.rbenv.list(runas=None)
```

List the installable versions of ruby

CLI Example:

```bash
salt '*' rbenv.list
```

```ruby
salt.modules.rbenv.rehash(runas=None)
```

Run rbenv rehash to update the installed shims

CLI Example:

```bash
salt '*' rbenv.rehash
```

```ruby
salt.modules.rbenv.uninstall_ruby(ruby, runas=None)
```

Uninstall a ruby implementation.

The version of ruby to uninstall. Should match one of the versions listed by `rbenv.versions`.

The user under which to run rbenv. If not specified, then rbenv will be run as the user under which Salt is running.

CLI Example:

```bash
salt '*' rbenv.uninstall_ruby 2.0.0-p0
```

```ruby
salt.modules.rbenv.update(runas=None, path=None)
```

Updates the current versions of rbenv and ruby-build

CLI Example:

```bash
salt '*' rbenv.update
```

```ruby
salt.modules.rbenv.versions(runas=None)
```

List the installed versions of ruby

CLI Example:
13.6.251 salt.modules.rdp

Manage RDP Service on Windows servers

salt.modules.rdp.disable()
    Disable RDP the service on the server
    CLI Example:
    salt '*' rdp.disable

salt.modules.rdp.enable()
    Enable RDP the service on the server
    CLI Example:
    salt '*' rdp.enable

salt.modules.rdp.status()
    Show if rdp is enabled on the server
    CLI Example:
    salt '*' rdp.status

13.6.252 salt.modules.redis

Module to provide redis functionality to Salt

New in version 2014.7.0.

configuration This module requires the redis python module and uses the following defaults which may be overridden in the minion configuration:

    redis.host: 'localhost'
    redis.port: 6379
    redis.db: 0
    redis.password: None

salt.modules.redismod.bgrewriteaof(host=None, port=None, db=None, password=None)
    Asynchronously rewrite the append-only file
    CLI Example:
    salt '*' redis.bgrewriteaof

salt.modules.redismod.bgsave(host=None, port=None, db=None, password=None)
    Asynchronously save the dataset to disk
    CLI Example:
    salt '*' redis.bgsave
salt.modules.redismod.config_get(pattern='*', host=None, port=None, db=None, password=None)
Get redis server configuration values

CLI Example:
```
salt '*' redis.config_get
salt '*' redis.config_get port
```

salt.modules.redismod.config_set(name, value, host=None, port=None, db=None, password=None)
Set redis server configuration values

CLI Example:
```
salt '*' redis.config_set masterauth luv_kittens
```

salt.modules.redismod.dbsize(host=None, port=None, db=None, password=None)
Return the number of keys in the selected database

CLI Example:
```
salt '*' redis.dbsize
```

salt.modules.redismod.delete(*keys, **connection_args)
Deletes the keys from redis, returns number of keys deleted

CLI Example:
```
salt '*' redis.delete foo
```

salt.modules.redismod.exists(key, host=None, port=None, db=None, password=None)
Return true if the key exists in redis

CLI Example:
```
salt '*' redis.exists foo
```

salt.modules.redismod.expire(key, seconds, host=None, port=None, db=None, password=None)
Set a keys time to live in seconds

CLI Example:
```
salt '*' redis.expire foo 300
```

salt.modules.redismod.expireat(key, timestamp, host=None, port=None, db=None, password=None)
Set a keys expire at given UNIX time

CLI Example:
```
salt '*' redis.expireat foo 1400000000
```

salt.modules.redismod.flushall(host=None, port=None, db=None, password=None)
Remove all keys from all databases

CLI Example:
```
salt '*' redis.flushall
```
salt.modules.redismod.flushdb(host=None, port=None, db=None, password=None)
   Remove all keys from the selected database
   CLI Example:
   salt '*' redis.flushdb

salt.modules.redismod.get_key(key, host=None, port=None, db=None, password=None)
   Get redis key value
   CLI Example:
   salt '*' redis.get_key foo

salt.modules.redismod.get_master_ip(host=None, port=None, password=None)
   Get host information about slave
   CLI Example:
   salt '*' redis.get_master_ip

salt.modules.redismod.hget(key, field, host=None, port=None, db=None, password=None)
   Get specific field value from a redis hash, returns dict
   CLI Example:
   salt '*' redis.hget foo_hash bar_field

salt.modules.redismod.hgetall(key, host=None, port=None, db=None, password=None)
   Get all fields and values from a redis hash, returns dict
   CLI Example:
   salt '*' redis.hgetall foo_hash

salt.modules.redismod.info(host=None, port=None, db=None, password=None)
   Get information and statistics about the server
   CLI Example:
   salt '*' redis.info

salt.modules.redismod.key_type(key, host=None, port=None, db=None, password=None)
   Get redis key type
   CLI Example:
   salt '*' redis.type foo

salt.modules.redismod.keys(pattern='*', host=None, port=None, db=None, password=None)
   Get redis keys, supports glob style patterns
   CLI Example:
   salt '*' redis.keys
   salt '*' redis.keys test*

salt.modules.redismod.lastsave(host=None, port=None, db=None, password=None)
   Get the UNIX time in seconds of the last successful save to disk
   CLI Example:
salt 'salt '*' redis.lastsave'

salt.modules.redismod.llen(key, host=None, port=None, db=None, password=None)
Get the length of a list in Redis
CLI Example:
salt 'salt '*' redis.llen foo_list'

salt.modules.redismod.lrange(key, start, stop, host=None, port=None, db=None, password=None)
Get a range of values from a list in Redis
CLI Example:
salt 'salt '*' redis.lrange foo_list 0 10'

salt.modules.redismod.ping(host=None, port=None, db=None, password=None)
Ping the server, returns False on connection errors
CLI Example:
salt 'salt '*' redis.ping'

salt.modules.redismod.save(host=None, port=None, db=None, password=None)
Synchronously save the dataset to disk
CLI Example:
salt 'salt '*' redis.save'

salt.modules.redismod.sentinel_get_master_ip(master, host=None, port=None, password=None)
Get ip for sentinel master
CLI Example:
salt 'salt '*' redis.sentinel_get_master_ip 'mymaster''

salt.modules.redismod.set_key(key, value, host=None, port=None, db=None, password=None)
Set redis key value
CLI Example:
salt 'salt '*' redis.set_key foo bar'

salt.modules.redismod.shutdown(host=None, port=None, db=None, password=None)
Synchronously save the dataset to disk and then shut down the server
CLI Example:
salt 'salt '*' redis.shutdown'

salt.modules.redismod.slaveof(master_host=None, master_port=None, host=None, port=None, db=None, password=None)
Make the server a slave of another instance, or promote it as master
CLI Example:
salt.modules.redismod.smembers(key, host=None, port=None, db=None, password=None)
Get members in a Redis set

CLI Example:
salt '*' redis.smembers foo_set

salt.modules.redismod.time(host=None, port=None, db=None, password=None)
Return the current server UNIX time in seconds

CLI Example:
salt '*' redis.time

salt.modules.redismod.zcard(key, host=None, port=None, db=None, password=None)
Get the length of a sorted set in Redis

CLI Example:
salt '*' redis.zcard foo_sorted

salt.modules.redismod.zrange(key, start, stop, host=None, port=None, db=None, password=None)
Get a range of values from a sorted set in Redis by index

CLI Example:
salt '*' redis.zrange foo_sorted 0 10

13.6.253 salt.modules.reg

Manage the Windows registry

The read_key and set_key functions will be updated in Carbon to reflect proper registry usage. The registry has three main components. Hives, Keys, and Values.

Hives

Hives are the main sections of the registry and all begin with the word HKEY. - HKEY_LOCAL_MACHINE - HKEY_CURRENT_USER - HKEY_USER

Keys

Keys are the folders in the registry. Keys can have many nested subkeys. Keys can have a value assigned to them under the (Default)
Values or Entries

Values/Entries are name/data pairs. There can be many values in a key. The (Default) value corresponds to the Key, the rest are their own value pairs.

depends

- winreg Python module

class salt.modules.reg.Registry
    Delay `_winreg' usage until this module is used
salt.modules.reg.broadcast_change()
    Refresh the windows environment.
:return:
salt.modules.reg.create_key(hkey, path, key=None, value=None, reflection=True, use_32bit_registry=False)

**Important:** The name of this function is misleading and will be changed to reflect proper usage in the Carbon release of Salt. The path option will be removed and the key will be the actual key. See the following issue: https://github.com/saltstack/salt/issues/25618

In order to not break existing state files this function will call the set_value function if key is passed. Key will be passed as the value name. If key is not passed, this function will return the default value for the key.

In the Carbon release path will be removed and key will be the path. You will not pass value.

Create a registry key

CLI Example:

```
salt '*' reg.create_key HKEY_CURRENT_USER 'SOFTWARE\Salt' 'version' '0.97'
```

salt.modules.reg.delete_key(hkey, path, key=None, reflection=True, force=False, use_32bit_registry=False)

**Important:** The name of this function is misleading and will be changed to reflect proper usage in the Carbon release of Salt. The path option will be removed and the key will be the actual key. See the following issue: https://github.com/saltstack/salt/issues/25618

In order to not break existing state files this function will call the delete_value function if a key is passed. Key will be passed as the value name. If key is not passed, this function will return the default value for the key.

In the Carbon release path will be removed and key will be the path. reflection will also be removed.

Delete a registry key

CLI Example:

```
salt '*' reg.delete_key HKEY_CURRENT_USER 'SOFTWARE\Salt'
```

Parameters

- **hkey (str)** -- (will be changed to hive) The name of the hive. Can be one of the following
  - HKEY_LOCAL_MACHINE or HKLM
- HKEY_CURRENT_USER or HKCU
- HKEY_USER or HKU

- **path (str)** -- (will be changed to key) The key (looks like a path) to remove.
- **key (str)** -- (used incorrectly) Will be removed in Carbon
- **reflection (bool)** -- A boolean value indicating that the value should also be removed from the Wow6432Node portion of the registry. Only applies to 64 bit Windows. This setting is ignored for 32 bit Windows.

  Only applies to delete value. If the key parameter is passed, this function calls delete_value instead. Will be changed in Carbon.
- **force (bool)** -- A boolean value indicating that all subkeys should be removed as well. If this is set to False (default) and there are subkeys, the delete_key function will fail.

  Returns: Returns True if successful, False if not. If force=True, the results of delete_key_recursive are returned.

  Return type: bool

salt.modules.reg.delete_key_recursive(hive, key, use_32bit_registry=False)

New in version 2015.5.4.

Delete a registry key to include all subkeys.

Parameters

- **hive** -- The name of the hive. Can be one of the following
  - HKEY_LOCAL_MACHINE or HKLM
  - HKEY_CURRENT_USER or HKCU
  - HKEY_USER or HKU

- **key** -- The key to remove (looks like a path)

  Returns: A dictionary listing the keys that deleted successfully as well as those that failed to delete.

  Return type: dict

The following example will remove salt and all its subkeys from the SOFTWARE key in HKEY_LOCAL_MACHINE:

CLI Example:

```
salt '*' reg.delete_key_recursive HKLM SOFTWARE\salt
```

salt.modules.reg.delete_value(hive, key, vname=None, reflection=True, use_32bit_registry=False)

Delete a registry value entry or the default value for a key.

Parameters

- **hive (str)** -- The name of the hive. Can be one of the following
  - HKEY_LOCAL_MACHINE or HKLM
  - HKEY_CURRENT_USER or HKCU
  - HKEY_USER or HKU

- **key (str)** -- The key (looks like a path) to the value name.

- **vname (str)** -- The value name. These are the individual name/data pairs under the key. If not passed, the key (Default) value will be deleted.
- **reflection** *(bool)* -- A boolean value indicating that the value should also be set in the Wow6432Node portion of the registry. Only applies to 64 bit Windows. This setting is ignored for 32 bit Windows.

Deprecated since version 2015.8.2: Use `use_32bit_registry` instead. The parameter seems to have no effect since Windows 7 / Windows 2008R2 removed support for reflection. This parameter will be removed in Carbon.

Returns True if successful, False if not

Return type `bool`

CLI Example:

```salt
salt '*' reg.delete_value HKEY_CURRENT_USER 'SOFTWARE\Salt' 'version'
```

salt.modules.reg.list_keys *(hive, key=None, use_32bit_registry=False)*

Enumerates the subkeys in a registry key or hive.

Parameters

- **hive** *(str)* -- The name of the hive. Can be one of the following
  - HKEY_LOCAL_MACHINE or HKLM
  - HKEY_CURRENT_USER or HKCU
  - HKEY_USER or HKU

- **key** *(str)* -- The key (looks like a path) to the value name. If a key is not passed, the keys under the hive will be returned.

- **use_32bit_registry** *(bool)* -- Accesses the 32bit portion of the registry on 64 bit installations. On 32bit machines this is ignored.

Returns A list of keys/subkeys under the hive or key.

Return type `list`

CLI Example:

```salt
salt '*' reg.list_keys HKLM 'SOFTWARE'
```

salt.modules.reg.read_key *(hkey, path, key=None, use_32bit_registry=False)*

Read registry key value

Returns the first unnamed value (Default) as a string. Returns none if first unnamed value is empty. Returns False if key not found.

CLI Example:

```salt
salt '*' reg.read_key HKEY_LOCAL_MACHINE 'SOFTWARE\Salt' 'version'
```

salt.modules.reg.read_value *(hive, key, vname=None, use_32bit_registry=False)*

Reads a registry value entry or the default value for a key.
Parameters

- **hive (str)** -- The name of the hive. Can be one of the following
  - HKEY_LOCAL_MACHINE or HKLM
  - HKEY_CURRENT_USER or HKCU
  - HKEY_USER or HKU
- **key (str)** -- The key (looks like a path) to the value name.
- **vname (str)** -- The value name. These are the individual name/data pairs under the key. If not passed, the key (Default) value will be returned
- **use_32bit_registry (bool)** -- Accesses the 32bit portion of the registry on 64 bit installations. On 32bit machines this is ignored.

Returns A dictionary containing the passed settings as well as the value_data if successful. If unsuccessful, sets success to False

Return type dict

If vname is not passed:
- Returns the first unnamed value (Default) as a string.
- Returns none if first unnamed value is empty.
- Returns False if key not found.

CLI Example:

```
salt '*' reg.read_value HKEY_LOCAL_MACHINE 'SOFTWARE\Salt' 'version'
```

salt.modules.reg.set_key(hkey, path, value, key=None, vtype='REG_DWORD', reflection=True, use_32bit_registry=False)

**Important**: The name of this function is misleading and will be changed to reflect proper usage in the Carbon release of Salt. The path option will be removed and the key will be the actual key. See the following issue:

https://github.com/saltstack/salt/issues/25618

In order to not break existing state files this function will call the set_value function if a key is passed. Key will be passed as the value name. If key is not passed, this function will return the default value for the key.

In the Carbon release this function will be removed in favor of set_value.

Set a registry key

vtype: [http://docs.python.org/2/library/_winreg.html#value-types](http://docs.python.org/2/library/_winreg.html#value-types)

CLI Example:

```
salt '*' reg.set_key HKEY_CURRENT_USER 'SOFTWARE\Salt' 'version' '0.97' REG_DWORD
```

salt.modules.reg.set_value(hive, key, vname=None, vdata=None, vtype='REG_SZ', reflection=True, use_32bit_registry=False)

Sets a registry value entry or the default value for a key.

Parameters

- **hive (str)** -- The name of the hive. Can be one of the following
  - HKEY_LOCAL_MACHINE or HKLM
  - HKEY_CURRENT_USER or HKCU
  - HKEY_USER or HKU

13.6. execution modules 1437
• **key** *(str)* -- The key (looks like a path) to the value name.

• **vname** *(str)* -- The value name. These are the individual name/data pairs under the key. If not passed, the key (Default) value will be set.

• **vdata** *(str)* -- The value data to be set.

• **vtype** *(str)* -- The value type. Can be one of the following:
  - REG_BINARY
  - REG_DWORD
  - REG_EXPAND_SZ
  - REG_MULTI_SZ
  - REG_SZ

• **reflection** *(bool)* -- A boolean value indicating that the value should also be set in the Wow6432Node portion of the registry. Only applies to 64 bit Windows. This setting is ignored for 32 bit Windows.

Deprecated since version 2015.8.2: Use `use_32bit_registry` instead. The parameter seems to have no effect since Windows 7 / Windows 2008R2 removed support for reflection. The parameter will be removed in Carbon.

Returns  Returns True if successful, False if not

Return type  bool

CLI Example:

```bash
salt '*' reg.set_value HKEY_LOCAL_MACHINE 'SOFTWARE\Salt' 'version' '2015.5.2'
```

### 13.6.254 salt.modules.rest_package

Package support for the REST example

salt.modules.rest_package.install(*name=None, refresh=False, fromrepo=None, pkgs=None, **kwargs*)

salt.modules.rest_package.installed(*name, version=None, refresh=False, fromrepo=None, skip_verify=False, pkgs=None, sources=None, **kwargs*)

salt.modules.rest_package.list_pkgs(*versions_as_list=False, **kwargs*)

salt.modules.rest_package.remove(*name=None, pkgs=None, **kwargs*)

salt.modules.rest_package.upgrade(*refresh=True, skip_verify=True, **kwargs*)

salt.modules.rest_package.version(*names, **kwargs*)

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```bash
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

### 13.6.255 salt.modules.rest_service

Provide the service module for the proxy-minion REST sample
Salt Documentation, Release 2016.3.6

salt.modules.rest_service.enabled(name, sig=None)
   Only the `redbull' service is `enabled' in the test

salt.modules.rest_service.get_all()
   Return a list of all available services

   New in version 2015.8.0.

   CLI Example:
   
   salt '*' service.get_all

salt.modules.rest_service.list()
   Return a list of all available services.

   CLI Example:
   
   salt '*' service.list

salt.modules.rest_service.restart(name, sig=None)
   Restart the specified service with rest_sample

   New in version 2015.8.0.

   CLI Example:
   
   salt '*' service.restart <service name>

salt.modules.rest_service.running(name, sig=None)
   Return whether this service is running.

   New in version 2015.8.0.

salt.modules.rest_service.start(name, sig=None)
   Start the specified service on the rest_sample

   New in version 2015.8.0.

   CLI Example:
   
   salt '*' service.start <service name>

salt.modules.rest_service.status(name, sig=None)
   Return the status for a service via rest_sample, returns a bool whether the service is running.

   New in version 2015.8.0.

   CLI Example:
   
   salt '*' service.status <service name>

salt.modules.rest_service.stop(name, sig=None)
   Stop the specified service on the rest_sample

   New in version 2015.8.0.

   CLI Example:
   
   salt '*' service.stop <service name>
13.6.256 salt.modules.restartcheck module

checkrestart functionality for Debian and Red Hat Based systems

Identifies services (processes) that are linked against deleted files (for example after downloading an updated binary of a shared library).

Based on checkrestart script from debian-goodies (written by Matt Zimmerman for the Debian GNU/Linux distribution, https://packages.debian.org/debian-goodies) and psdel by Sam Morris.

codeauthor Jiri Kotlin <jiri.kotlin@ultimum.io>

salt.modules.restartcheck.restartcheck(ignorelist=None, blacklist=None, excludepid=None, verbose=True)

Analyzes files opened by running processes and seeks for packages which need to be restarted.

Args:
- ignorelist: string or list of packages to be ignored
- blacklist: string or list of file paths to be ignored
- excludepid: string or list of process IDs to be ignored
- verbose: boolean, enables extensive output

Returns:
- True if no packages for restart found. False on failure. String with checkrestart output if some package seems to need to be restarted.

New in version 2015.8.3.

CLI Example: .. code-block:: bash
   salt '*' restartcheck.restartcheck

13.6.257 salt.modules.ret

Module to integrate with the returner system and retrieve data sent to a salt returner

salt.modules.ret.get_fun(returner, fun)
   Return info about last time fun was called on each minion

   CLI Example:
   salt '*' ret.get_fun mysql network.interfaces

salt.modules.ret.get_jid(returner, jid)
   Return the information for a specified job id

   CLI Example:
   salt '*' ret.get_jid redis 20421104181954700505

salt.modules.ret.get_jids(returner)
   Return a list of all job ids

   CLI Example:
   salt '*' ret.get_jids mysql

salt.modules.ret.get_minions(returner)
   Return a list of all minions

   CLI Example:
   salt '*' ret.get_minions mysql
13.6.258  salt.modules.rh_ip

The networking module for RHEL/Fedora based distros

salt.modules.rh_ip.apply_network_settings(**settings)
Apply global network configuration.

CLI Example:
```
salt '*' ip.apply_network_settings
```

salt.modules.rh_ip.build_bond(iface, **settings)
Create a bond script in /etc/modprobe.d with the passed settings and load the bonding kernel module.

CLI Example:
```
salt '*' ip.build_bond  bond0  mode=balance-alb
```

salt.modules.rh_ip.build_interface(iface, iface_type, enabled, **settings)
Build an interface script for a network interface.

CLI Example:
```
salt '*' ip.build_interface eth0  eth <settings>
```

salt.modules.rh_ip.build_network_settings(**settings)
Build the global network script.

CLI Example:
```
salt '*' ip.build_network_settings <settings>
```

salt.modules.rh_ip.build_routes(iface, **settings)
Build a route script for a network interface.

CLI Example:
```
salt '*' ip.build_routes eth0 <settings>
```

salt.modules.rh_ip.down(iface, iface_type)
Shutdown a network interface

CLI Example:
```
salt '*' ip.down  eth0
```

salt.modules.rh_ip.get_bond(iface)
Return the content of a bond script

CLI Example:
```
salt '*' ip.get_bond  bond0
```

salt.modules.rh_ip.get_interface(iface)
Return the contents of an interface script

CLI Example:
```
salt '*' ip.get_interface eth0
```
salt.modules.rh_ip.get_network_settings()  
Return the contents of the global network script.

CLI Example:

```bash
salt '*' ip.get_network_settings
```

salt.modules.rh_ip.get_routes(iface)  
Return the contents of the interface routes script.

CLI Example:

```bash
salt '*' ip.get_routes eth0
```

salt.modules.rh_ip.up(iface, iface_type)  
Start up a network interface

CLI Example:

```bash
salt '*' ip.up eth0
```

### 13.6.259 salt.modules.rh_service

Service support for RHEL-based systems, including support for both upstart and sysvinit

**Important**: If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `service.start' is not available), see [here](#).

salt.modules.rh_service.available(name, limit='')  
Return True if the named service is available. Use the limit param to restrict results to services of that type.

CLI Examples:

```bash
salt '*' service.available sshd
salt '*' service.available sshd limit=upstart
salt '*' service.available sshd limit=sysvinit
```

salt.modules.rh_service.delete(name, **kwargs)  
Delete the named service

New in version 2016.3.

CLI Example:

```bash
salt '*' service.delete <service name>
```

salt.modules.rh_service.disable(name, **kwargs)  
Disable the named service to start at boot

CLI Example:

```bash
salt '*' service.disable <service name>
```

salt.modules.rh_service.disabled(name)  
Check to see if the named service is disabled to start on boot

CLI Example:
salt.modules.rh_service.enable(name, **kwargs)
   Enable the named service to start at boot
   CLI Example:
   
   salt '*' service.enable <service name>

salt.modules.rh_service.enabled(name, **kwargs)
   Check to see if the named service is enabled to start on boot
   CLI Example:
   
   salt '*' service.enabled <service name>

salt.modules.rh_service.get_all(limit='')
   Return all installed services. Use the limit param to restrict results to services of that type.
   CLI Example:
   
   salt '*' service.get_all
   salt '*' service.get_all limit=upstart
   salt '*' service.get_all limit=sysvinit

salt.modules.rh_service.get_disabled(limit='')
   Return the disabled services. Use the limit param to restrict results to services of that type.
   CLI Example:
   
   salt '*' service.get_disabled
   salt '*' service.get_disabled limit=upstart
   salt '*' service.get_disabled limit=sysvinit

salt.modules.rh_service.get_enabled(limit='')
   Return the enabled services. Use the limit param to restrict results to services of that type.
   CLI Examples:
   
   salt '*' service.get_enabled
   salt '*' service.get_enabled limit=upstart
   salt '*' service.get_enabled limit=sysvinit

salt.modules.rh_service.missing(name, limit='')
   The inverse of service.available. Return True if the named service is not available. Use the limit param to restrict results to services of that type.
   CLI Examples:
   
   salt '*' service.missing sshd
   salt '*' service.missing sshd limit=upstart
   salt '*' service.missing sshd limit=sysvinit

salt.modules.rh_service.reload(name)
   Reload the named service
   CLI Example:
salt '*' service.reload <service name>

salt.modules.rh_service.restart(name)

  Restart the named service

  CLI Example:

  salt '*' service.restart <service name>

salt.modules.rh_service.start(name)

  Start the specified service

  CLI Example:

  salt '*' service.start <service name>

salt.modules.rh_service.status(name, sig=None)

  Return the status for a service, returns a bool whether the service is running.

  CLI Example:

  salt '*' service.status <service name>

salt.modules.rh_service.stop(name)

  Stop the specified service

  CLI Example:

  salt '*' service.stop <service name>

13.6.260 salt.modules.riak

Riak Salt Module

salt.modules.riak.cluster_commit()

  Commit Cluster Changes

  Changed in version 2015.8.0.

  CLI Example:

  salt '*' riak.cluster_commit

salt.modules.riak.cluster_join(username, hostname)

  Join a Riak cluster

  Changed in version 2015.8.0.

  CLI Example:

  salt '*' riak.cluster_join <user> <host>

  username - The riak username to join the cluster
  hostname - The riak hostname you are connecting to

salt.modules.riak.cluster_leave(username, hostname)

  Leave a Riak cluster

  New in version 2015.8.0.

  CLI Example:
salt '.*' riak.cluster_leave <username> <host>

username - The riak username to join the cluster
hostname - The riak hostname you are connecting to

click.modules.riak.cluster_plan()
Review Cluster Plan

Changed in version 2015.8.0.

CLI Example:

salt '.*' riak.cluster_plan

click.modules.riak.member_status()
Get cluster member status

Changed in version 2015.8.0.

CLI Example:

salt '.*' riak.member_status

click.modules.riak.services()
List available services on a node

New in version 2015.8.0.

CLI Example:

salt '.*' riak.services

click.modules.riak.start()
Start Riak

CLI Example:

salt '.*' riak.start

click.modules.riak.status()
Current node status

New in version 2015.8.0.

CLI Example:

salt '.*' riak.status

click.modules.riak.stop()
Stop Riak

Changed in version 2015.8.0.

CLI Example:

salt '.*' riak.stop

click.modules.riak.test()
Runs a test of a few standard Riak operations

New in version 2015.8.0.

CLI Example:
salt '*' riak.test

13.6.261 salt.modules.rpm

Support for rpm

salt.modules.rpm.bin_pkg_info(path, saltenv='base')

New in version 2015.8.0.

Parses RPM metadata and returns a dictionary of information about the package (name, version, etc.).

path Path to the file. Can either be an absolute path to a file on the minion, or a salt fileserv er URL (e.g. salt://path/to/file.rpm). If a salt fileserver URL is passed, the file will be cached to the minion so that it can be examined.

saltenv [base] Salt fileserver environment from which to retrieve the package. Ignored if path is a local file path on the minion.

CLI Example:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt '*' lowpkg.bin_pkg_info /root/salt-2015.5.1-2.el7.noarch.rpm</td>
<td>Returns dictionary of package information</td>
</tr>
<tr>
<td>salt '*' lowpkg.bin_pkg_info salt://salt-2015.5.1-2.el7.noarch.rpm</td>
<td>Returns dictionary of package information</td>
</tr>
</tbody>
</table>

salt.modules.rpm.checksum(*paths)

Return if the signature of a RPM file is valid.

CLI Example:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt '*' lowpkg.checksum /path/to/package1.rpm</td>
<td>Returns True if signature is valid</td>
</tr>
<tr>
<td>salt '*' lowpkg.checksum /path/to/package1.rpm /path/to/package2.rpm</td>
<td>Returns False if signature is invalid</td>
</tr>
</tbody>
</table>

salt.modules.rpm.diff(package, path)

Return a formatted diff between current file and original in a package. NOTE: this function includes all files (configuration and not), but does not work on binary content.

Parameters

- package -- The name of the package
- path -- Full path to the installed file

Returns Difference or empty string. For binary files only a notification.

CLI example:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt '*' lowpkg.diff apache2 /etc/apache2/httpd.conf</td>
<td>Returns formatted diff of apache2 file</td>
</tr>
</tbody>
</table>

salt.modules.rpm.file_dict(*packages)

List the files that belong to a package, sorted by group. Not specifying any packages will return a list of _every_ file on the system's rpm database (not generally recommended).

CLI Examples:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt '*' lowpkg.file_dict httpd</td>
<td>Returns list of files in httpd package</td>
</tr>
<tr>
<td>salt '*' lowpkg.file_dict httpd postfix</td>
<td>Returns list of files in httpd and postfix packages</td>
</tr>
<tr>
<td>salt '*' lowpkg.file_dict</td>
<td>Returns list of <em>every</em> file on the system's rpm database (not generally recommended)</td>
</tr>
</tbody>
</table>

salt.modules.rpm.file_list(*packages)

List the files that belong to a package. Not specifying any packages will return a list of _every_ file on the system's rpm database (not generally recommended).

CLI Examples:
salt.modules.rpm.info(’packages’, **attr)
Return a detailed package(s) summary information. If no packages specified, all packages will be returned.

Parameters
• packages --
• attr -- Comma-separated package attributes. If no `attr` is specified, all available attributes returned.

Valid attributes are: version, vendor, release, build_date, build_date_time_t, install_date, install_date_time_t, build_host, group, source_rpm, arch, epoch, size, license, signature, packager, url, summary, description.

Returns
CLI example:
salt '*' lowpkg.info apache2 bash
salt '*' lowpkg.info apache2 bash attr=version
salt '*' lowpkg.info apache2 bash attr=version,build_date_iso,size

salt.modules.rpm.list_pkgs(’packages’)
List the packages currently installed in a dict:

```json
{’<package_name>’: ’<version>’}
```

CLI Example:
salt '*' lowpkg.list_pkgs

salt.modules.rpm.modified(’packages’, **flags)
List the modified files that belong to a package. Not specifying any packages will return a list of _all_ modified files on the system’s RPM database.

New in version 2015.5.0.

CLI examples:
salt '*' lowpkg.modified httpd
salt '*' lowpkg.modified httpd postfix
salt '*' lowpkg.modified

salt.modules.rpm.owner(’paths’)
Return the name of the package that owns the file. Multiple file paths can be passed. If a single path is passed, a string will be returned, and if multiple paths are passed, a dictionary of file/package name pairs will be returned.

If the file is not owned by a package, or is not present on the minion, then an empty string will be returned for that path.

CLI Examples:
salt '*' lowpkg.owner /usr/bin/apachectl
salt '*' lowpkg.owner /usr/bin/apachectl /etc/httpd/conf/httpd.conf

salt.modules.rpm.verify(’packages’, **kwargs)
Runs an rpm -Va on a system, and returns the results in a dict
Files with an attribute of config, doc, ghost, license or readme in the package header can be ignored using the `ignore_types` keyword argument

CLI Example:

```
salt '*' lowpkg.verify
salt '*' lowpkg.verify httpd
salt '*' lowpkg.verify httpd postfix
salt '*' lowpkg.verify httpd postfix ignore_types=['config','doc']
```

**salt.modules.rpm.version_cmp** *(ver1, ver2, ignore_epoch=False)*

New in version 2015.8.9.

Do a cmp-style comparison on two packages. Return -1 if ver1 < ver2, 0 if ver1 == ver2, and 1 if ver1 > ver2. Return None if there was a problem making the comparison.

`ignore_epoch` [False] Set to True to ignore the epoch when comparing versions

New in version 2015.8.10,2016.3.2.

CLI Example:

```
salt '*' pkg.version_cmp '0.2-001' '0.2.0.1-002'
```

### 13.6.262 salt.modules.rpmbuild

RPM Package builder system

New in version 2015.8.0.

This system allows for all of the components to build rpms safely in chrooted environments. This also provides a function to generate yum repositories

This module implements the pkgbuild interface

**salt.modules.rpmbuild.build** *(runas, tgt, dest_dir, spec, sources, deps, env, template, saltenv='base', log_dir='/var/log/salt/pkgbuild')*

Given the package destination directory, the spec file source and package sources, use mock to safely build the rpm defined in the spec file

CLI Example:

```
salt '*' pkgbuild.build mock epel-7-x86_64 /var/www/html https://raw.githubusercontent.com/saltstack/libnacl/master/pkg/rpm/python-libnacl.spec
https://pypi.python.org/packages/source/l/libnacl/libnacl-1.3.5.tar.gz
```

This example command should build the libnacl package for rhel 7 using user mock and place it in /var/www/html/ on the minion

**salt.modules.rpmbuild.make_repo** *(repodir, keyid=None, env=None, use_passphrase=False, gpgphome='/etc/salt/gpgkeys', runas='root', timeout=15.0)*

Make a package repository and optionally sign packages present

Given the repodir, create a yum repository out of the rpms therein and optionally sign it and packages present, the name is directory to turn into a repo. This state is best used with onchanges linked to your package building states.

`repodir` The directory to find packages that will be in the repository.

`keyid` Changed in version 2016.3.0.

Optional Key ID to use in signing packages and repository. Utilizes Public and Private keys associated with keyid which have been loaded into the minion’s Pillar data.
For example, contents from a Pillar data file with named Public and Private keys as follows:

```bash
env

A dictionary of environment variables to be utilized in creating the repository.

**Note:** This parameter is not used for making yum repositories.

### use_passphrase [False] New in version 2016.3.0.

Use a passphrase with the signing key presented in `keyid`. Passphrase is received from Pillar data which could be passed on the command line with `pillar` parameter. For example:

```bash
pillar= '{ "gpg_passphrase" : "my_passphrase" }'
```

### gnuiphone [/etc/salt/gpgkeys] New in version 2016.3.0.

Location where GPG related files are stored, used with `keyid`.

### runas [root] New in version 2016.3.0.

User to create the repository as, and optionally sign packages.

**Note:** Ensure the user has correct permissions to any files and directories which are to be utilized.

### timeout [15.0] New in version 2016.3.4.

Timeout in seconds to wait for the prompt for inputting the passphrase.

CLI Example:
salt '***' pkgbuild.make_repo /var/www/html/

salt.modules.rpmbuild.make_src_pkg(dest_dir, spec, sources, env=None, template=None, saltenv='base')

Create a source rpm from the given spec file and sources

CLI Example:

This example command should build the libnacl SOURCE package and place it in /var/www/html/ on the minion

13.6.263 salt.modules.rsync

Wrapper for rsync

New in version 2014.1.0.

This data can also be passed into pillar. Options passed into opts will overwrite options passed into pillar.

salt.modules.rsync.config(conf_path='/etc/rsyncd.conf')

Changed in version 2016.3.0: Return data now contains just the contents of the rsyncd.conf as a string, instead of a dictionary as returned from cmd.run_all.

Returns the contents of the rsync config file

conf_path [/etc/rsyncd.conf] Path to the config file

CLI Example:

salt '***' rsync.config

salt.modules.rsync.rsync(src, dst, delete=False, force=False, update=False, passwordfile=None, exclude=None, excludefrom=None, dryrun=False)

Changed in version 2016.3.0: Return data now contains just the output of the rsync command, instead of a dictionary as returned from cmd.run_all.

Rsync files from src to dst

CLI Example:

salt '***' rsync.rsync {src} {dst} {delete=True} {update=True} {passwordfile=/etc/pass.crt} {exclude=xx}
salt '***' rsync.rsync {src} {dst} {delete=True} {excludefrom=/xx.ini}

salt.modules.rsync.version()

Changed in version 2016.3.0: Return data now contains just the version number as a string, instead of a dictionary as returned from cmd.run_all.

Returns rsync version

CLI Example:

salt '***' rsync.version
13.6.264 salt.modules.runit

runit service module

This module is compatible with the service states, so it can be used to maintain services using the provider argument:

```yaml
myservice:
    service:
      - running
      - provider: runit
```

Note that the enabled argument is not available with this provider.

salt.modules.runit.available(name)

Returns True if the specified service is available, otherwise returns False.

CLI Example:

```
salt '*' runit.available foo
```

salt.modules.runit.full_restart(name)

Calls runit.restart() function

CLI Example:

```
salt '*' runit.full_restart <service name>
```

salt.modules.runit.get_all()

Return a list of all available services

CLI Example:

```
salt '*' runit.get_all
```

salt.modules.runit.missing(name)

The inverse of runit.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:

```
salt '*' runit.missing foo
```

salt.modules.runit.reload(name)

Send a HUP to service via runit

CLI Example:

```
salt '*' runit.reload <service name>
```

salt.modules.runit.restart(name)

Restart service via runit. This will stop/start service

CLI Example:

```
salt '*' runit.restart <service name>
```

salt.modules.runit.start(name)

Starts service via runit

CLI Example:
salt '*' runit.start <service name>

salt.modules.runit.status(name, sig=None)
Return the status for a service via runit, return pid if running

CLI Example:
```
salt '*' runit.status <service name>
```

salt.modules.runit.stop(name)
Stops service via runit

CLI Example:
```
salt '*' runit.stop <service name>
```

salt.modules.runit.term(name)
Send a TERM to service via runit

CLI Example:
```
salt '*' runit.term <service name>
```

13.6.265 salt.modules.rvm

Manage ruby installations and gemsets with RVM, the Ruby Version Manager.

salt.modules.rvm.do(ruby, command, runas=None, cwd=None)
Execute a command in an RVM controlled environment.
ruby Which ruby to use
command The rvm command to execute
runas The user under which to run rvm. If not specified, then rvm will be run as the user under which Salt is running.
cwd The directory from which to run the rvm command. Defaults to the user’s home directory.

CLI Example:
```
salt '*' rvm.do 2.0.0 <command>
```

salt.modules.rvm.gemset_copy(source, destination, runas=None)
Copy all gems from one gemset to another.
source The name of the gemset to copy, complete with ruby version
destination The destination gemset
runas The user under which to run rvm. If not specified, then rvm will be run as the user under which Salt is running.

CLI Example:
```
salt '*' rvm.gemset_copy foobar bazquo
```

salt.modules.rvm.gemset_create(ruby, gemset, runas=None)
Creates a gemset.
ruby The ruby version for which to create the gemset
gemset The name of the gemset to create
runas The user under which to run rvm. If not specified, then rvm will be run as the user under which Salt is running.

CLI Example:
salt '***' rvm.gemset_create 2.0.0 foobar

salt.modules.rvm.gemset_delete(ruby, gemset, runas=None)
Delete a gemset
- **ruby** The ruby version to which the gemset belongs
- **gemset** The gemset to delete
- **runas** The user under which to run rvm. If not specified, then rvm will be run as the user under which Salt is running.

CLI Example:

```
salt '***' rvm.gemset_delete 2.0.0 foobar
```

salt.modules.rvm.gemset_empty(ruby, gemset, runas=None)
Remove all gems from a gemset.
- **ruby** The ruby version to which the gemset belongs
- **gemset** The gemset to empty
- **runas** The user under which to run rvm. If not specified, then rvm will be run as the user under which Salt is running.

CLI Example:

```
salt '***' rvm.gemset_empty 2.0.0 foobar
```

salt.modules.rvm.gemset_list(ruby='default', runas=None)
List all gemsets for the given ruby.
- **ruby** [default] The ruby version for which to list the gemsets
- **runas** The user under which to run rvm. If not specified, then rvm will be run as the user under which Salt is running.

CLI Example:

```
salt '***' rvm.gemset_list
```

salt.modules.rvm.gemset_list_all(runas=None)
List all gemsets for all installed rubies.

Note that you must have set a default ruby before this can work.
- **runas** The user under which to run rvm. If not specified, then rvm will be run as the user under which Salt is running.

CLI Example:

```
salt '***' rvm.gemset_list_all
```

salt.modules.rvm.get(version='stable', runas=None)
Update RVM
- **version** [stable] Which version of RVM to install, (e.g. stable or head)

CLI Example:

```
salt '***' rvm.get
```

salt.modules.rvm.install(runas=None)
Install RVM system-wide
- **runas** The user under which to run the rvm installer script. If not specified, then it be run as the user under which Salt is running.

CLI Example:
salt '.*' rvm.install

salt.modules.rvm.install_ruby(ruby, runas=None)
    Install a ruby implementation.
    ruby The version of ruby to install
    runas The user under which to run rvm. If not specified, then rvm will be run as the user under which Salt is running.
    CLI Example:
    salt '.*' rvm.install_ruby 1.9.3-p385

salt.modules.rvm.is_installed(runas=None)
    Check if RVM is installed.
    CLI Example:
    salt '.*' rvm.is_installed

salt.modules.rvm.list(runas=None)
    List all rvm-installed rubies
    runas The user under which to run rvm. If not specified, then rvm will be run as the user under which Salt is running.
    CLI Example:
    salt '.*' rvm.list

salt.modules.rvm.reinstall_ruby(ruby, runas=None)
    Reinstall a ruby implementation
    ruby The version of ruby to reinstall
    runas The user under which to run rvm. If not specified, then rvm will be run as the user under which Salt is running.
    CLI Example:
    salt '.*' rvm.reinstall_ruby 1.9.3-p385

salt.modules.rvm.rubygems(ruby, version, runas=None)
    Installs a specific rubygems version in the given ruby
    ruby The ruby for which to install rubygems
    version The version of rubygems to install, or `remove` to use the version that ships with 1.9
    runas The user under which to run rvm. If not specified, then rvm will be run as the user under which Salt is running.
    CLI Example:
    salt '.*' rvm.rubygems 2.0.0 1.8.24

salt.modules.rvm.set_default(ruby, runas=None)
    Set the default ruby
    ruby The version of ruby to make the default
    runas The user under which to run rvm. If not specified, then rvm will be run as the user under which Salt is running.
    CLI Example:
    salt '.*' rvm.set_default 2.0.0

salt.modules.rvm.wrapper(ruby_string, wrapper_prefix, runas=None, *binaries)
    Install RVM wrapper scripts
ruby_string  Ruby/gemset to install wrappers for
wrapper_prefix  What to prepend to the name of the generated wrapper binaries
runas  The user under which to run rvm. If not specified, then rvm will be run as the user under which Salt is running.
binaries  [None]  The names of the binaries to create wrappers for. When nothing is given, wrappers for ruby, gem, rake, irb, rdoc, ri and testrb are generated.

CLI Example:
```
salt '*' rvm.wrapper <ruby_string> <wrapper_prefix>
```

13.6.266 salt.modules.s3

Connection module for Amazon S3

configuration  This module accepts explicit s3 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
s3.keyid: GKTADJGHEIQSXMKKRBJ08H
s3.key: askdjghsdfjkgHwupUjasdflkdfklgjsdfjajkghs
```

A service_url may also be specified in the configuration:

```
s3.service_url: s3.amazonaws.com
```

A role_arn may also be specified in the configuration:

```
s3.role_arn: arn:aws:iam::111111111111:role/my-role-to-assume
```

If a service_url is not specified, the default is s3.amazonaws.com. This may appear in various documentation as an `endpoint`. A comprehensive list for Amazon S3 may be found at:

```
http://docs.aws.amazon.com/general/latest/gr/rande.html#s3_region
```

The service_url will form the basis for the final endpoint that is used to query the service.

SSL verification may also be turned off in the configuration:

```
s3.verify_ssl: False
```

This is required if using S3 bucket names that contain a period, as these will not match Amazon's S3 wildcard certificates. Certificate verification is enabled by default.

AWS region may be specified in the configuration:

```
s3.location: eu-central-1
```

Default is us-east-1.

This module should be usable to query other S3-like services, such as Eucalyptus.

depends  requests
salt.modules.s3.delete(bucket, path=None, action=None, key=None, keyid=None, service_url=None, verify_ssl=None, kms_keyid=None, location=None, role_arn=None)

Delete a bucket, or delete an object from a bucket.

CLI Example to delete a bucket:
```
salt myminion s3.delete mybucket
```

CLI Example to delete an object from a bucket:
```
salt myminion s3.delete mybucket remoteobject
```

salt.modules.s3.get(bucket=None, path=None, return_bin=False, action=None, local_file=None, key=None, keyid=None, service_url=None, verify_ssl=None, kms_keyid=None, location=None, role_arn=None)

List the contents of a bucket, or return an object from a bucket. Set return_bin to True in order to retrieve an object wholesale. Otherwise, Salt will attempt to parse an XML response.

CLI Example to list buckets:
```
salt myminion s3.get
```

CLI Example to list the contents of a bucket:
```
salt myminion s3.get mybucket
```

CLI Example to return the binary contents of an object:
```
salt myminion s3.get mybucket myfile.png return_bin=True
```

CLI Example to save the binary contents of an object to a local file:
```
salt myminion s3.get mybucket myfile.png local_file=/tmp/myfile.png
```

It is also possible to perform an action on a bucket. Currently, S3 supports the following actions:

- acl
- cors
- lifecycle
- policy
- location
- logging
- notification
- tagging
- versions
- requestPayment
- versioning
- website

To perform an action on a bucket:
```
salt myminion s3.get mybucket myfile.png action=acl
```

salt.modules.s3.head(bucket, path=None, key=None, keyid=None, service_url=None, verify_ssl=None, kms_keyid=None, location=None, role_arn=None)

Return the metadata for a bucket, or an object in a bucket.

CLI Examples:
salt.myminion.s3.head mybucket
salt.myminion.s3.head mybucket myfile.png

```
salt.modules.s3.put(bucket, path=None, return_bin=False, action=None, local_file=None, key=None, keyid=None, service_url=None, verify_ssl=None, kms_keyid=None, location=None, role_arn=None)
```

Create a new bucket, or upload an object to a bucket.

CLI Example to create a bucket:
```
salt myminion s3.put mybucket
```

CLI Example to upload an object to a bucket:
```
salt myminion s3.put mybucket remotepath local_file=/path/to/file
```

### 13.6.267 `salt.modules.s6` module

**s6 service module**

This module is compatible with the `service` states, so it can be used to maintain services using the `provider` argument:

```
myservice:
  service:
    - running
    - provider: s6
```

Note that the `enabled` argument is not available with this provider.

**codeauthor** :email:`Marek Skrobacki <skrobul@skrobul.com>`

**salt.modules.s6.available(name)**

Returns `True` if the specified service is available, otherwise returns `False`.

CLI Example:
```
salt '*' s6.available foo
```

**salt.modules.s6.full_restart(name)**

Calls `s6.restart()` function

CLI Example:
```
salt '*' s6.full_restart <service name>
```

**salt.modules.s6.get_all()**

Return a list of all available services

CLI Example:
```
salt '*' s6.get_all
```

**salt.modules.s6.missing(name)**

The inverse of `s6.available`. Returns `True` if the specified service is not available, otherwise returns `False`.

CLI Example:
salt '*' s6.missing foo

salt.modules.s6.reload(name)
Send a HUP to service via s6

CLI Example:
salt '*' s6.reload <service name>

salt.modules.s6.restart(name)
Restart service via s6. This will stop/start service

CLI Example:
salt '*' s6.restart <service name>

salt.modules.s6.start(name)
Starts service via s6

CLI Example:
salt '*' s6.start <service name>

salt.modules.s6.status(name, sig=None)
Return the status for a service via s6, return pid if running

CLI Example:
salt '*' s6.status <service name>

salt.modules.s6.stop(name)
Stops service via s6

CLI Example:
salt '*' s6.stop <service name>

salt.modules.s6.term(name)
Send a TERM to service via s6

CLI Example:
salt '*' s6.term <service name>

13.6.268  salt.modules.salt_proxy module

Salt proxy module

New in version 2015.8.3.

Module to deploy and manage salt-proxy processes on a minion.

salt.modules.salt_proxy.configure_proxy(proxynname, start=True)
Create the salt proxy file and start the proxy process if required

Parameters:
    proxynname: Name to be used for this proxy (should match entries in pillar)
    start: Boolean indicating if the process should be started default = True

CLI Example:
salt.deviceminion salt_proxy.configure_proxy p8000

salt.modules.salt_proxy.is_running(proxyname)
Check if the salt-proxy process associated with this proxy (name) is running.
Returns True if the process is running False otherwise
Parameters:
  proxyname: String name of the proxy (p8000 for example)
CLI Example:
salt deviceminion salt_proxy.is_running p8000

13.6.269 salt.modules.saltcloudmod

Control a salt cloud system
salt.modules.saltcloudmod.create(name, profile)
Create the named vm
CLI Example:
salt <minion-id> saltcloud.create webserver rackspace_centos_512

13.6.270 salt.modules.saltutil

The Saltutil module is used to manage the state of the salt minion itself. It is used to manage minion modules as well as automate updates to the salt minion.

  depends
  • esky Python module for update functionality

salt.modules.saltutil.clear_cache()
Forcibly removes all caches on a minion.
New in version 2014.7.0.
WARNING: The safest way to clear a minion cache is by first stopping the minion and then deleting the cache files before restarting it.
CLI Example:
salt '*' saltutil.clear_cache

salt.modules.saltutil.cmd(tgt, fun, arg=(), timeout=none, expr_form='glob', ret='', kwarg=none, ssh=False, **kwargs)
Assuming this minion is a master, execute a salt command
CLI Example:
salt '*' saltutil.cmd

salt.modules.saltutil.cmd_iter(tgt, fun, arg=(), timeout=none, expr_form='glob', ret='', kwarg=none, ssh=False, **kwargs)
Assuming this minion is a master, execute a salt command
CLI Example:
salt '*

```python
salt.modules.saltutil.find_cached_job(jid)
```

Return the data for a specific cached job id. Note this only works if cache_jobs has previously been set to True on the minion.

CLI Example:

```bash
salt '*
```

```python
salt.modules.saltutil.find_job(jid)
```

Return the data for a specific job id that is currently running.

`jid` The job id to search for and return data.

CLI Example:

```bash
salt '*
```

Note that the find_job function only returns job information when the job is still running. If the job is currently running, the output looks something like this:

```bash
# salt my-minion saltutil.find_job 20160503150049487736
my-minion:  
  arg:  
    - 30  
  fun:  
    test.sleep  
  jid:  
    20160503150049487736  
  pid:  
    9601  
  ret:  
    tgt:  
      my-minion  
    tgt_type:  
      glob  
    user:  
      root
```

If the job has already completed, the job cannot be found and therefore the function returns an empty dictionary, which looks like this on the CLI:

```bash
# salt my-minion saltutil.find_job 20160503150049487736
my-minion:  
```

```python
salt.modules.saltutil.is_running(fun)
```

If the named function is running return the data associated with it/them. The argument can be a glob

CLI Example:

```bash
salt '*
```

```python
salt.modules.saltutil.kill_job(jid)
```

Sends a kill signal (SIGKILL 9) to the named salt job's process

CLI Example:
salt 's' saltutil.kill_job <job id>

salt.modules.saltutil.mmodule(saltenv, fun, *args, **kwargs)
Loads minion modules from an environment so that they can be used in pillars for that environment

CLI Example:
salt 's' saltutil.mmodule base test.ping

salt.modules.saltutil.refresh_beacons()
Signal the minion to refresh the beacons.

CLI Example:
salt 's' saltutil.refresh_beacons

salt.modules.saltutil.refresh_grains(**kwargs)
New in version 2016.3.6,2016.11.4,Nitrogen.
Refresh the minion’s grains without syncing custom grains modules from salt://_grains.

Note: The available execution modules will be reloaded as part of this process, as grains can affect which modules are available.

refresh_pillar [True] Set to False to keep pillar data from being refreshed.

CLI Examples:
salt 's' saltutil.refresh_grains

salt.modules.saltutil.refresh_modules(async=True)
Signal the minion to refresh the module and grain data.

The default is to refresh module asynchronously. To block until the module refresh is complete, set the `async' flag to False.

CLI Example:
salt 's' saltutil.refresh_modules

salt.modules.saltutil.refresh_pillar()
Signal the minion to refresh the pillar data.

CLI Example:
salt 's' saltutil.refresh_pillar

salt.modules.saltutil.regen_keys()
Used to regenerate the minion keys.

CLI Example:
salt 's' saltutil.regen_keys

salt.modules.saltutil.revoke_auth(preserve_minion_cache=False)
The minion sends a request to the master to revoke its own key. Note that the minion session will be revoked and the minion may not be able to return the result of this command back to the master.

If the `preserve_minion_cache' flag is set to True, the master cache for this minion will not be removed.
CLI Example:

```
salt '*' saltutil.revoke_auth
```

salt.modules.saltutil.runner(name, **kwargs)

Execute a runner module (this function must be run on the master)

New in version 2014.7.0.

- **name**  The name of the function to run
- **kwargs**  Any keyword arguments to pass to the runner function

CLI Example:

```
salt '*' saltutil.runner jobs.list_jobs
```

salt.modules.saltutil.running()

Return the data on all running salt processes on the minion

CLI Example:

```
salt '*' saltutil.running
```

salt.modules.saltutil.signal_job(jid, sig)

Sends a signal to the named salt job's process

CLI Example:

```
salt '*' saltutil.signal_job <job id> 15
```

salt.modules.saltutil.sync_all(saltenv=None, refresh=True)

Changed in version 2015.8.11, 2016.3.2: On masterless minions, pillar modules are now synced, and refreshed when refresh is set to True.

Sync down all of the dynamic modules from the file server for a specific environment. This function synchronizes custom modules, states, beacons, grains, returners, output modules, renderers, and utils.

- **refresh** [True]  Also refresh the execution modules and recompile pillar data available to the minion. This refresh will be performed even if no new dynamic modules are synced. Set to False to prevent this refresh.

**Important:** If this function is executed using a module.run state, the SLS file will not have access to newly synced execution modules unless a refresh argument is added to the state, like so:

```
load_my_custom_module:
  module.run:
    - name: saltutil.sync_all
    - refresh: True
```

See here for a more detailed explanation of why this is necessary.

CLI Examples:

```
salt '*' saltutil.sync_all
salt '*' saltutil.sync_all saltenv=dev
salt '*' saltutil.sync_all saltenv=base,dev
```

salt.modules.saltutil.sync_beacons(saltenv=None, refresh=True)

New in version 2015.5.1.

Sync beacons from salt://_beacons to the minion
**saltenv** [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

**refresh** [True] If True, refresh the available beacons on the minion. This refresh will be performed even if no new beacons are synced. Set to False to prevent this refresh.

CLI Example:

```
salt '*' saltutil.sync_beacons
salt '*' saltutil.sync_beacons saltenv=dev
salt '*' saltutil.sync_beacons saltenv=base,dev
```

salt.modules.saltutil.sync_engines(saltenv=None, refresh=False)

New in version 2016.3.0.

Sync engine modules from `salt://_engines` to the minion

**saltenv** [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

**refresh** [True] If True, refresh the available execution modules on the minion. This refresh will be performed even if no new engine modules are synced. Set to False to prevent this refresh.

CLI Examples:

```
salt '*' saltutil.sync_engines
salt '*' saltutil.sync_engines saltenv=base,dev
```

salt.modules.saltutil.sync_grains(saltenv=None, refresh=True)

New in version 0.10.0.

Sync grains modules from `salt://_grains` to the minion

**saltenv** [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

**refresh** [True] If True, refresh the available execution modules and recompile pillar data for the minion. This refresh will be performed even if no new grains modules are synced. Set to False to prevent this refresh.

CLI Examples:

```
salt '*' saltutil.sync_grains
salt '*' saltutil.sync_grains saltenv=dev
salt '*' saltutil.sync_grains saltenv=base,dev
```

salt.modules.saltutil.sync_log_handlers(saltenv=None, refresh=True)

New in version 2015.8.0.

Sync log handlers from `salt://_log_handlers` to the minion

**saltenv** [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

**refresh** [True] If True, refresh the available execution modules on the minion. This refresh will be performed even if no new log handlers are synced. Set to False to prevent this refresh.

CLI Examples:

```
salt '*' saltutil.sync_log_handlers
salt '*' saltutil.sync_log_handlers saltenv=dev
salt '*' saltutil.sync_log_handlers saltenv=base,dev
```

salt.modules.saltutil.sync_modules(saltenv=None, refresh=True)

New in version 0.10.0.

Sync execution modules from `salt://_modules` to the minion

**saltenv** [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
refresh  [True] If True, refresh the available execution modules on the minion. This refresh will be performed even if no new execution modules are synced. Set to False to prevent this refresh.

Important: If this function is executed using a module.run state, the SLS file will not have access to newly synced execution modules unless a refresh argument is added to the state, like so:

```
load_my_custom_module:
  module.run:
    - name: saltutil.sync_modules
    - refresh: True
```

See here for a more detailed explanation of why this is necessary.

CLI Example:
```
salt '*' saltutil.sync_modules
salt '*' saltutil.sync_modules saltenv=dev
salt '*' saltutil.sync_modules saltenv=base,dev
```

salt.modules.saltutil.sync_output(saltenv=None, refresh=True)
Sync outputters from salt://_output to the minion
- saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
- refresh [True] If True, refresh the available execution modules on the minion. This refresh will be performed even if no new outputters are synced. Set to False to prevent this refresh.

CLI Examples:
```
salt '*' saltutil.sync_output
salt '*' saltutil.sync_output saltenv=dev
salt '*' saltutil.sync_output saltenv=base,dev
```

salt.modules.saltutil.sync_outputters(saltenv=None, refresh=True)
This function is an alias of sync_output.
- saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
- refresh [True] If True, refresh the available execution modules on the minion. This refresh will be performed even if no new outputters are synced. Set to False to prevent this refresh.

CLI Examples:
```
salt '*' saltutil.sync_output
salt '*' saltutil.sync_output saltenv=dev
salt '*' saltutil.sync_output saltenv=base,dev
```

salt.modules.saltutil.sync_pillar(saltenv=None, refresh=True)
New in version 2015.8.11,2016.3.2.
- saltenv [base] Also refresh the execution modules available to the minion, and refresh pillar data.

Note: This function will raise an error if executed on a traditional (i.e. not masterless) minion.

CLI Examples:
salt.modules.saltutil.sync_proxymodules *(saltenv=None, refresh=False)*

New in version 2015.8.2.

Sync proxy modules from `salt://_proxy` to the minion

- **saltenv** [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
- **refresh** [True] If True, refresh the available execution modules on the minion. This refresh will be performed even if no new proxy modules are synced. Set to False to prevent this refresh.

CLI Examples:

```
salt '*' saltutil.sync_proxymodules
salt '*' saltutil.sync_proxymodules saltenv=dev
```

salt.modules.saltutil.sync_renderers *(saltenv=None, refresh=True)*

New in version 0.10.0.

Sync renderers from `salt://_renderers` to the minion

- **saltenv** [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
- **refresh** [True] If True, refresh the available execution modules on the minion. This refresh will be performed even if no new renderers are synced. Set to False to prevent this refresh. Set to False to prevent this refresh.

CLI Examples:

```
salt '*' saltutil.sync_renderers
salt '*' saltutil.sync_renderers saltenv=dev
salt '*' saltutil.sync_renderers saltenv=base,dev
```

salt.modules.saltutil.sync_returners *(saltenv=None, refresh=True)*

New in version 0.10.0.

Sync beacons from `salt://_returners` to the minion

- **saltenv** [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
- **refresh** [True] If True, refresh the available execution modules on the minion. This refresh will be performed even if no new returners are synced. Set to False to prevent this refresh.

CLI Examples:

```
salt '*' saltutil.sync_returners
salt '*' saltutil.sync_returners saltenv=dev
```

salt.modules.saltutil.sync_sdb *(saltenv=None)*

New in version 2015.5.8,2015.8.3.

Sync sdb modules from `salt://_sdb` to the minion

- **saltenv** [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
- **refresh** [False] This argument has no affect and is included for consistency with the other sync functions.

CLI Example:

```
salt '*' saltutil.sync_sdb
salt '*' saltutil.sync_sdb saltenv=dev
salt '*' saltutil.sync_sdb saltenv=base,dev
```
salt.modules.saltutil.sync_states(saltenv=None, refresh=True)

New in version 0.10.0.
Sync state modules from salt://_states to the minion

saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
refresh [True] If True, refresh the available states on the minion. This refresh will be performed even if no new state modules are synced. Set to False to prevent this refresh.

CLI Examples:

```
salt '*' saltutil.sync_states
salt '*' saltutil.sync_states saltenv=dev
salt '*' saltutil.sync_states saltenv=base,dev
```

salt.modules.saltutil.sync_utils(saltenv=None, refresh=True)

New in version 2014.7.0.
Sync utility modules from salt://_utils to the minion

saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
refresh [True] If True, refresh the available execution modules on the minion. This refresh will be performed even if no new utility modules are synced. Set to False to prevent this refresh.

CLI Examples:

```
salt '*' saltutil.sync_utils
salt '*' saltutil.sync_utils saltenv=dev
salt '*' saltutil.sync_utils saltenv=base,dev
```

salt.modules.saltutil.term_job(jid)

Sends a termination signal (SIGTERM 15) to the named salt job's process

CLI Example:

```
salt '*' saltutil.term_job <job id>
```

salt.modules.saltutil.update(version=None)

Update the salt minion from the URL defined in opts['update_url'] SaltStack, Inc provides the latest builds here:
update_url: https://repo.saltstack.com/windows/

Be aware that as of 2014-8-11 there's a bug in esky such that only the latest version available in the update_url can be downloaded and installed.

This feature requires the minion to be running a bdist_esky build.

The version number is optional and will default to the most recent version available at opts['update_url'].

Returns details about the transaction upon completion.

CLI Examples:

```
salt '*' saltutil.update
salt '*' saltutil.update 0.10.3
```

salt.modules.saltutil.wheel(name, *args, **kwargs)

Execute a wheel module and function. This function must be run against a minion that is local to the master.

New in version 2014.7.0.

name The name of the function to run
args Any positional arguments to pass to the wheel function. A common example of this would be the match arg needed for key functions.
New in version v2015.8.11.

**kwargs**  Any keyword arguments to pass to the wheel function

CLI Example:

```
salt my-local-minion saltutil.wheel key.accept jerry
salt my-local-minion saltutil.wheel minions.connected
```

---

**Note:** Since this function must be run against a minion that is running locally on the master in order to get accurate returns, if this function is run against minions that are not local to the master, "empty" returns are expected. The remote minion does not have access to wheel functions and their return data.

### 13.6.271 salt.modules.schedule

Module for managing the Salt schedule on a minion

New in version 2014.7.0.

**salt.modules.schedule.add**(name, **kwargs)

Add a job to the schedule

CLI Example:

```
salt '*' schedule.add job1 function='test.ping' seconds=3600
# If function have some arguments, use job_args
salt '*' schedule.add job2 function='cmd.run' job_args="['date >> /tmp/date.log']"
```

**salt.modules.schedule.build_schedule_item**(name, **kwargs)

Build a schedule job

CLI Example:

```
salt '*' schedule.build_schedule_item job1 function='test.ping' seconds=3600
```

**salt.modules.schedule.copy**(name, target, **kwargs)

Copy scheduled job to another minion or minions.

CLI Example:

```
salt '*' schedule.copy jobname target
```

**salt.modules.schedule.delete**(name, **kwargs)

Delete a job from the minion's schedule

CLI Example:

```
salt '*' schedule.delete job1
```

**salt.modules.schedule.disable**( **kwargs)

Disable all scheduled jobs on the minion

CLI Example:

```
salt '*' schedule.disable
```
salt.modules.schedule.disable_job(name, **kwargs)
    Disable a job in the minion's schedule
    CLI Example:
    salt '*' schedule.disable_job job1

salt.modules.schedule.enable(**kwargs)
    Enable all scheduled jobs on the minion
    CLI Example:
    salt '*' schedule.enable

salt.modules.schedule.enable_job(name, **kwargs)
    Enable a job in the minion's schedule
    CLI Example:
    salt '*' schedule.enable_job job1

salt.modules.schedule.is_enabled(name)
    List a Job only if its enabled
    New in version 2015.5.3.
    CLI Example:
    salt '*' schedule.is_enabled name=job_name

salt.modules.schedule.list(show_all=False, show_disabled=True, where=None, return_yaml=True)
    List the jobs currently scheduled on the minion
    CLI Example:
    salt '*' schedule.list
    # Show all jobs including hidden internal jobs
    salt '*' schedule.list show_all=True
    # Hide disabled jobs from list of jobs
    salt '*' schedule.list show_disabled=False

salt.modules.schedule.modify(name, **kwargs)
    Modify an existing job in the schedule
    CLI Example:
    salt '*' schedule.modify job1 function='test.ping' seconds=3600

salt.modules.schedule.move(name, target, **kwargs)
    Move scheduled job to another minion or minions.
    CLI Example:
    salt '*' schedule.move jobname target

salt.modules.schedule.purge(**kwargs)
    Purge all the jobs currently scheduled on the minion
    CLI Example:
salt '*' schedule.purge

salt.modules.schedule.reload()
Reload saved scheduled jobs on the minion

CLI Example:
salt '*' schedule.reload

salt.modules.schedule.run_job(name, force=False)
Run a scheduled job on the minion immediately

CLI Example:
salt '*' schedule.run_job job1
salt '*' schedule.run_job job1 force=True
Force the job to run even if it is disabled.

salt.modules.schedule.save(**kwargs)
Save all scheduled jobs on the minion

CLI Example:
salt '*' schedule.save

13.6.272 salt.modules.scsi

SCSI administration module

salt.modules.scsi.ls(get_size=True)
List SCSI devices, with details

CLI Examples:
salt '*' scsi.ls
salt '*' scsi.ls get_size=False

get_size [True] Get the size information for scsi devices. This option should be set to False for older OS distributions (RHEL6 and older) due to lack of support for the `-s` option in lsscsi.

New in version 2015.5.10.

salt.modules.scsi.rescan_all(host)
List scsi devices

CLI Example:
salt '*' scsi.rescan_all 0

13.6.273 salt.modules.sdb

Module for Manipulating Data via the Salt DB API

salt.modules.sdb.get(uri)
Get a value from a db, using a uri in the form of sdb://<profile>/<key>. If the uri provided does not start with sdb://, then it will be returned as-is.
CLI Example:

```bash
salt '*' sdb.get sdb://mymemcached/foo
```

`salt.modules.sdb.set(uri, value)`

Set a value in a db, using a uri in the form of `sdb://<profile>/<key>`. If the uri provided does not start with `sdb://` or the value is not successfully set, return `False`.

CLI Example:

```bash
salt '*' sdb.set sdb://mymemcached/foo bar
```

### 13.6.274 salt.modules.seed

Virtual machine image management tools

`salt.modules.seed.apply(path, id_=None, config=None, approve_key=True, install=True, prep_install=False, pub_key=None, priv_key=None, mount_point=None)`

Seed a location (disk image, directory, or block device) with the minion config, approve the minion's key, and/or install salt-minion.

CLI Example:

```bash
salt 'minion' seed.apply path id [config=config_data] \ 
   [gen_key=(true|false)] [approve_key=(true|false)] \ 
   [install=(true|false)]
```

- `path` Full path to the directory, device, or disk image on the target minion's file system.
- `id_` Minion id with which to seed the path.
- `config` Minion configuration options. By default, the `master` option is set to the target host's `master`.
- `approve_key` Request a pre-approval of the generated minion key. Requires that the salt-master be configured to either auto-accept all keys or expect a signing request from the target host. Default: true.
- `install` Install salt-minion, if absent. Default: true.
- `prep_install` Prepare the bootstrap script, but don't run it. Default: false

`salt.modules.seed.mkconfig(config=None, tmp=None, id_=None, approve_key=True, pub_key=None, priv_key=None)`

Generate keys and config and put them in a tmp directory.

- `pub_key` absolute path or file content of an optional preseeded salt key
- `priv_key` absolute path or file content of an optional preseeded salt key

CLI Example:

```bash
salt 'minion' seed.mkconfig [config=config_data] [tmp=tmp_dir] \ 
   [id_=minion_id] [approve_key=(true|false)]
```

`salt.modules.seed.prep_bootstrap(mpt)`

Update and get the random script to a random place

CLI Example:

```bash
salt '*' seed.prep_bootstrap /tmp
```

### 13.6.275 salt.modules.selinux

Execute calls on selinux
Note: This module requires the semanage, setsebool, and semodule commands to be available on the minion. On RHEL-based distributions, ensure that the policycoreutils and policycoreutils-python packages are installed. If not on a Fedora or RHEL-based distribution, consult the selinux documentation for your distribution to ensure that the proper packages are installed.

salt.modules.selinux.getenforce()
Return the mode selinux is running in

CLI Example:
```
salt '*' selinux.getenforce
```

salt.modules.selinux.getsebool(boolean)
Return the information on a specific selinux boolean

CLI Example:
```
salt '*' selinux.getsebool virt_use_usb
```

salt.modules.selinux.getsemod(module)
Return the information on a specific selinux module

CLI Example:
```
salt '*' selinux.getsemod mysql
```

New in version 2016.3.0.

salt.modules.selinux.list_sebool()
Return a structure listing all of the selinux booleans on the system and what state they are in

CLI Example:
```
salt '*' selinux.list_sebool
```

salt.modules.selinux.list_semod()
Return a structure listing all of the selinux modules on the system and what state they are in

CLI Example:
```
salt '*' selinux.list_semod
```

New in version 2016.3.0.

salt.modules.selinux.selinux_fs_path('args)
Return the location of the SELinux VFS directory

CLI Example:
```
salt '*' selinux.selinux_fs_path
```

salt.modules.selinux.setenforce(mode)
Set the SELinux enforcing mode

CLI Example:
```
salt '*' selinux.setenforce enforcing
salt.modules.selinux.setsebool(boolean, value, persist=False)
   Set the value for a boolean
   CLI Example:
   ```
   salt '*' selinux.setsebool virt_use_usb off
   ```

salt.modules.selinux.setsebools(pairs, persist=False)
   Set the value of multiple booleans
   CLI Example:
   ```
   salt '*' selinux.setsebools '{virt_use_usb: on, squid_use_tproxy: off}'
   ```

salt.modules.selinux.setsemod(module, state)
   Enable or disable an SELinux module.
   CLI Example:
   ```
   salt '*' selinux.setsemod nagios Enabled
   ```
   New in version 2016.3.0.

**13.6.276 salt.modules.sensors**

Read lm-sensors
New in version 2014.1.3.

salt.modules.sensors.sense(chip, fahrenheit=False)
   Gather lm-sensors data from a given chip
   To determine the chip to query, use the `sensors' command and see the leading line in the block.
   Example:
   ```
   /usr/bin/sensors
   coretemp-isa-0000 Adapter: ISA adapter Physical id 0: +56.0°C (high = +87.0°C, crit = +105.0°C) Core 0: +52.0°C (high = +87.0°C, crit = +105.0°C) Core 1: +50.0°C (high = +87.0°C, crit = +105.0°C) Core 2: +56.0°C (high = +87.0°C, crit = +105.0°C) Core 3: +53.0°C (high = +87.0°C, crit = +105.0°C)
   Given the above, the chip is `coretemp-isa-0000'.
```

**13.6.277 salt.modules.serverdensity_device**

Wrapper around Server Density API
New in version 2014.7.0.

salt.modules.serverdensity_device.create(name, **params)
   Function to create device in Server Density. For more info, see the API docs.
   CLI Example:
   ```
   salt '*' serverdensity_device.create lama
   salt '*' serverdensity_device.create rich_lama group=lama_band installedRAM=32768
   ```
**salt.modules.serverdensity_device.delete** *(device_id)*

Delete a device from Server Density. For more information, see the API docs.

CLI Example:
```
salt '*' serverdensity_device.delete 51f7eafcdba4bb235e000ae4
```

**salt.modules.serverdensity_device.get_sd_auth** *(val, sd_auth_pillar_name='serverdensity')*

Returns requested Server Density authentication value from pillar.

CLI Example:
```
salt '*' serverdensity_device.get_sd_auth <val>
```

**salt.modules.serverdensity_device.install_agent** *(agent_key, agent_version=1)*

Function downloads Server Density installation agent, and installs sd-agent with agent_key. Optionally the agent_version would select the series to use (defaults on the v1 one).

CLI Example:
```
salt '*' serverdensity_device.install_agent c2bbdd6689ff46282bdaa07555641498
salt '*' serverdensity_device.install_agent c2bbdd6689ff46282bdaa07555641498 2
```

**salt.modules.serverdensity_device.ls** *(**params**)*

List devices in Server Density

Results will be filtered by any params passed to this function. For more information, see the API docs on listing and searching.

CLI Example:
```
salt '*' serverdensity_device.ls
salt '*' serverdensity_device.ls name=lama
salt '*' serverdensity_device.ls name=lama group=lama_band installedRAM=32768
```

**salt.modules.serverdensity_device.update** *(device_id, **params)*

Updates device information in Server Density. For more information see the API docs.

CLI Example:
```
salt '*' serverdensity_device.update 51f7eafcdba4bb235e000ae4 name=lama·
  ·group=lama_band
salt '*' serverdensity_device.update 51f7eafcdba4bb235e000ae4 name=better_lama·
  ·group=rock_lamas swapSpace=512
```

13.6.278 **salt.modules.service**

service is a virtual module that is fulfilled by one of the following modules:
<table>
<thead>
<tr>
<th>Execution Module</th>
<th>Used for</th>
</tr>
</thead>
<tbody>
<tr>
<td>debian_service</td>
<td>Debian Wheezy and earlier</td>
</tr>
<tr>
<td>freebsd-service</td>
<td>FreeBSD-based OSes using service(8)</td>
</tr>
<tr>
<td>gentoo_service</td>
<td>Gentoo Linux using sysvinit and rc-update(8)</td>
</tr>
<tr>
<td>launchctl</td>
<td>Mac OS hosts using Launchctl(1)</td>
</tr>
<tr>
<td>netbsd-service</td>
<td>NetBSD-based OSes</td>
</tr>
<tr>
<td>openbsd-service</td>
<td>OpenBSD-based OSes</td>
</tr>
<tr>
<td>rh_service</td>
<td>RedHat-based distros and derivatives using service(8) and chkconfig(8). Supports both pure sysvinit and mixed sysvinit/upstart systems.</td>
</tr>
<tr>
<td>service</td>
<td>Fallback which simply wraps sysvinit scripts</td>
</tr>
<tr>
<td>smf</td>
<td>Solaris-based OSes which use SMF</td>
</tr>
<tr>
<td>systemd</td>
<td>Linux distros which use systemd</td>
</tr>
<tr>
<td>upstart</td>
<td>Ubuntu-based distros using upstart</td>
</tr>
<tr>
<td>win_service</td>
<td>Windows</td>
</tr>
</tbody>
</table>

If Salt's OS detection does not identify a different virtual service module, the minion will fall back to using this basic module, which simply wraps sysvinit scripts.

**salt.modules.service.available(name)**

Returns True if the specified service is available, otherwise returns False.

CLI Example:

```
salt '*' service.available sshd
```

**salt.modules.service.get_all()**

Return a list of all available services

CLI Example:

```
salt '*' service.get_all
```

**salt.modules.service.missing(name)**

The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:

```
salt '*' service.missing sshd
```

**salt.modules.service.reload(name)**

Refreshes config files by calling service reload. Does not perform a full restart.

CLI Example:

```
salt '*' service.reload <service name>
```
salt.modules.service.restart(name)

    Restart the specified service

    CLI Example:

    salt '*' service.restart <service name>

salt.modules.service.run(name, action)

    Run the specified service with an action.

    name  Service name.

    action  Action name (like start, stop, reload, restart).

    CLI Example:

    salt '*' service.run apache2 reload
    salt '*' service.run postgresql initdb

salt.modules.service.start(name)

    Start the specified service

    CLI Example:

    salt '*' service.start <service name>

salt.modules.service.status(name, sig=None)

    Return the status for a service, returns the PID or an empty string if the service is running or not, pass a signature to use to find the service via ps

    CLI Example:

    salt '*' service.status <service name> [service signature]

salt.modules.service.stop(name)

    Stop the specified service

    CLI Example:

    salt '*' service.stop <service name>

13.6.279 salt.modules.shadow

shadow is a virtual module that is fulfilled by one of the following modules:

<table>
<thead>
<tr>
<th>Execution Module</th>
<th>Used for</th>
</tr>
</thead>
<tbody>
<tr>
<td>shadow</td>
<td>Linux</td>
</tr>
<tr>
<td>bsd_shadow</td>
<td>FreeBSD, OpenBSD, NetBSD</td>
</tr>
<tr>
<td>solaris_shadow</td>
<td>Solaris-based OSes</td>
</tr>
<tr>
<td>win_shadow</td>
<td>Windows</td>
</tr>
</tbody>
</table>

Manage the shadow file on Linux systems

13.6. execution modules
Important: If you feel that Salt should be using this module to manage passwords on a minion, and it is using a different module (or gives an error similar to `shadow.info' is not available), see here.

salt.modules.shadow.default_hash()
Returns the default hash used for unset passwords

CLI Example:
```
salt '*' shadow.default_hash
```

salt.modules.shadow.del_password(name)
New in version 2014.7.0.
Delete the password from name user

CLI Example:
```
salt '*' shadow.del_password username
```

salt.modules.shadow.gen_password(password, crypt_salt=None, algorithm='sha512')
New in version 2014.7.0.
Generate hashed password

Note: When called this function is called directly via remote-execution, the password argument may be displayed in the system's process list. This may be a security risk on certain systems.

password  Plaintext password to be hashed.
crypt_salt Cryptographic salt. If not given, a random 8-character salt will be generated.
algorithm The following hash algorithms are supported:
  • md5
  • blowfish (not in mainline glibc, only available in distros that add it)
  • sha256
  • sha512 (default)

CLI Example:
```
salt '*' shadow.gen_password 'I_am_password'
salt '*' shadow.gen_password 'I_am_password' crypt_salt='I_am_salt'
  algorithm=sha256
```

salt.modules.shadow.info(name)
Return information for the specified user

CLI Example:
```
salt '*' shadow.info root
```

salt.modules.shadow.set_date(name, date)
Sets the value for the date the password was last changed to days since the epoch (January 1, 1970). See man chage.

CLI Example:
```
salt '*' shadow.set_date username 0
```
salt.modules.shadow.set_expire(name, expire)
   Changed in version 2014.7.0.
   Sets the value for the date the account expires as days since the epoch (January 1, 1970). Using a value of -1 will clear expiration. See man chage.
   CLI Example:
   ```
salt '*' shadow.set_expire username -1
   ```

salt.modules.shadow.set_inactdays(name, inactdays)
   Set the number of days of inactivity after a password has expired before the account is locked. See man chage.
   CLI Example:
   ```
salt '*' shadow.set_inactdays username 7
   ```

salt.modules.shadow.set_maxdays(name, maxdays)
   Set the maximum number of days during which a password is valid. See man chage.
   CLI Example:
   ```
salt '*' shadow.set_maxdays username 90
   ```

salt.modules.shadow.set_mindays(name, mindays)
   Set the minimum number of days between password changes. See man chage.
   CLI Example:
   ```
salt '*' shadow.set_mindays username 7
   ```

salt.modules.shadow.set_password(name, password, use_usermod=False)
   Set the password for a named user. The password must be a properly defined hash. The password hash can be generated with this command:
   ```
   python -c "import crypt; print crypt.crypt('password','\$6\$SALTsalt')"
   ```
   SALTsalt is the 8-character cryptgraphic salt. Valid characters in the salt are ../, and any alphanumeric character.
   Keep in mind that the $6 represents a sha512 hash, if your OS is using a different hashing algorithm this needs to be changed accordingly
   CLI Example:
   ```
salt '*' shadow.set_password root '$1$UYCIxa628.9qXjpQCjM4a..'
   ```

salt.modules.shadow.set_warndays(name, warndays)
   Set the number of days of warning before a password change is required. See man chage.
   CLI Example:
   ```
salt '*' shadow.set_warndays username 7
   ```

13.6.280  salt.modules.slack_notify

Module for sending messages to Slack
New in version 2015.5.0.
configuration This module can be used by either passing an api key and version directly or by specifying both in a configuration profile in the salt master/minion config.

For example:

```
slack:
  api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

salt.modules.slack_notify.find_room(name, api_key=None)

Find a room by name and return it.

Parameters

- **name** -- The room name.
- **api_key** -- The Slack admin api key.

Returns The room object.

CLI Example:

```
salt '*' slack.find_room name="random"
salt '*' slack.find_room name="random" api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

salt.modules.slack_notify.find_user(name, api_key=None)

Find a user by name and return it.

Parameters

- **name** -- The user name.
- **api_key** -- The Slack admin api key.

Returns The user object.

CLI Example:

```
salt '*' slack.find_user name="ThomasHatch"
salt '*' slack.find_user name="ThomasHatch" api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

salt.modules.slack_notify.list_rooms(api_key=None)

List all Slack rooms.

Parameters **api_key** -- The Slack admin api key.

Returns The room list.

CLI Example:

```
salt '*' slack.list_rooms
salt '*' slack.list_rooms api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

salt.modules.slack_notify.list_users(api_key=None)

List all Slack users.

Parameters **api_key** -- The Slack admin api key.

Returns The user list.

CLI Example:

```
salt '*' slack.list_users
salt '*' slack.list_users api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```
salt.modules.slack_notify.post_message(channel, message, from_name, api_key=None, icon=None)

Send a message to a Slack channel.

Parameters

- **channel** -- The channel name, either will work.
- **message** -- The message to send to the Slack channel.
- **from_name** -- Specify who the message is from.
- **api_key** -- The Slack api key, if not specified in the configuration.
- **icon** -- URL to an image to use as the icon for this message

Returns Boolean if message was sent successfully.

CLI Example:

```
salt '*' slack.post_message channel="Development Room" message="Build is done" from_name="Build Server"
```

### 13.6.281 salt.modules.slsutil

Utility functions for use with or in SLS files

#### 13.6.282 salt.modules.smartos_imgadm

Module for running imgadm command on SmartOS

salt.modules.smartos_imgadm.avail(search=None, verbose=False)

Return a list of available images

- **search** [string] search keyword
- **verbose** [boolean (False)] toggle verbose output

CLI Example:

```
salt '*' imgadm.avail [percona]
salt '*' imgadm.avail verbose=True
```

salt.modules.smartos_imgadm.delete(uuid)

Remove an installed image

- **uuid** [string] Specifies uuid to import

CLI Example:

```
salt '*' imgadm.delete e42f8c84-bbea-11e2-b920-078fab2aab1f
```

salt.modules.smartos_imgadm.get(uuid)

Return info on an installed image

- **uuid** [string] uuid of image

CLI Example:

```
salt '*' imgadm.get e42f8c84-bbea-11e2-b920-078fab2aab1f
```

salt.modules.smartos_imgadm.import(uuid, verbose=False)

Import an image from the repository

- **uuid** [string] uuid to import
- **verbose** [boolean (False)] toggle verbose output

CLI Example:
salt 'x' imgadm.import e42f8c84-bbea-11e2-b920-078fab2aab1f [verbose=True]
salt.modules.smartos_imgadm.list(verbos=False)
   Return a list of installed images
   verbose [boolean (False)] toggle verbose output
   CLI Example:
   salt 'x' imgadm.list [verbose=True]
salt.modules.smartos_imgadm.show(uuid)
   Show manifest of a given image
   uuid [string] uuid of image
   CLI Example:
   salt 'x' imgadm.show e42f8c84-bbea-11e2-b920-078fab2aab1f
salt.modules.smartos_imgadm.update(uuid='
   Gather info on unknown image(s) (locally installed)
   uuid [string] optional uuid of image
   CLI Example:
   salt 'x' imgadm.update [uuid]
salt.modules.smartos_imgadm.vacuum(verbos=False)
   Remove unused images
   verbose [boolean (False)] toggle verbose output
   CLI Example:
   salt 'x' imgadm.vacuum [verbose=True]
salt.modules.smartos_imgadm.version()
   Return imgadm version
   CLI Example:
   salt 'x' imgadm.version

13.6.283 salt.modules.smartos_virt

virt compatibility module for managing VMs on SmartOS
salt.modules.smartos_virt.create(domain)
   Deprecated since version 2016.3.0: Use start() instead.
   Start a defined domain
   CLI Example:
   salt 'x' virt.create <domain>
salt.modules.smartos_virt.destroy(domain)
   Deprecated since version 2016.3.0: Use stop() instead.
   Power off a defined domain
   CLI Example:
salt '*/' virt.destroy <domain>

salt.modules.smartos_virt.get_macs(domain)
Return a list off MAC addresses from the named VM

CLI Example:
salt '*/' virt.get_macs <domain>

salt.modules.smartos_virt.init(**kwargs)
Initialize a new VM

CLI Example:
salt '*/' virt.init image_uuid='...' alias='...' [..]

salt.modules.smartos_virt.list_active_vms()
Return a list of uuids for active virtual machine on the minion

CLI Example:
salt '*/' virt.list_active_vms

salt.modules.smartos_virt.list_domains()
Return a list of virtual machine names on the minion

CLI Example:
salt '*/' virt.list_domains

salt.modules.smartos_virt.list_inactive_vms()
Return a list of uuids for inactive virtual machine on the minion

CLI Example:
salt '*/' virt.list_inactive_vms

salt.modules.smartos_virt.list_vms()
Deprecated since version 2016.3.0: Use list_domains() instead.
List all virtual machines.

CLI Example:
salt '*/' virt.list_vms <domain>

salt.modules.smartos_virt.reboot(domain)
Reboot a domain via ACPI request

CLI Example:
salt '*/' virt.reboot <domain>

salt.modules.smartos_virt.setmem(domain, memory)
Change the amount of memory allocated to VM. <memory> is to be specified in MB.

Note for KVM : this would require a restart of the VM.

CLI Example:
Salt Documentation, Release 2016.3.6

```yaml
salt '*' virt.setmem <domain> 512
```

**virt.setmem**

This function sets the memory limit of a virtual machine.

```python
salt.modules.smartos_virt.setmem(domain, memory_limit)
```

**CLI Example:**

```bash
salt '*' virt.setmem <domain> 512
```

**virt.shutdown**

This function send a soft shutdown signal to the named vm.

```python
salt.modules.smartos_virt.shutdown(domain)
```

**CLI Example:**

```bash
salt '*' virt.shutdown <domain>
```

**virt.start**

This function starts a defined domain.

```python
salt.modules.smartos_virt.start(domain)
```

**CLI Example:**

```bash
salt '*' virt.start <domain>
```

**virt.stop**

This function stops a defined domain.

```python
salt.modules.smartos_virt.stop(domain)
```

**CLI Example:**

```bash
salt '*' virt.stop <domain>
```

**virt.destroy**

This function hard power down the virtual machine, this is equivalent to powering off the hardware.

```python
salt.modules.smartos_virt.destroy(domain)
```

**CLI Example:**

```bash
salt '*' virt.destroy <domain>
```

**virt.vm_info**

This function returns a dict with information about the specified VM on this CN.

```python
salt.modules.smartos_virt.vm_info(domain)
```

**CLI Example:**

```bash
salt '*' virt.vm_info <domain>
```

**virt.vm_virt_type**

This function returns VM virtualization type : OS or KVM.

```python
salt.modules.smartos_virt.vm_virt_type(domain)
```

**CLI Example:**

```bash
salt '*' virt.vm_virt_type <domain>
```

### 13.6.284 salt.modules.smartos_vmadm

Module for running vmadm command on SmartOS

**create**

This function creates a new vm.

```python
salt.modules.smartos_vmadm.create(from_file=None, **kwargs)
```

**CLI Example:**

```bash
salt '*' vmadm.create from_file=/tmp/new_vm.json
salt '*' vmadm.create image_uuid='...' alias='...' nics='[[ "nic_tag": "admin", "ip": "198.51.100.123", ...}, {...]]' [...]
```

**create_snapshot**

This function creates a snapshot of a vm.

```python
salt.modules.smartos_vmadm.create_snapshot(vm, name, key='uuid')
```

**CLI Example:**

```bash
salt '*' vmadm.create_snapshot vm=<vm_name> name=<snapshot_name>
```
key [string [uuid|alias|hostname]] value type of `vm' parameter

CLI Example:

```
salt '*' vmadm.create_snapshot 186da9ab-7392-4f55-91a5-b8f1fe770543 baseline
salt '*' vmadm.create_snapshot nacl baseline key=alias
```

**salt.modules.smartos_vmadm.delete**(vm, key='uuid')
Delete a vm

**vm** [string] vm to be deleted

**key** [string [uuid|alias|hostname]] value type of `vm' parameter

CLI Example:

```
salt '*' vmadm.delete 186da9ab-7392-4f55-91a5-b8f1fe770543
salt '*' vmadm.delete nacl key=alias
```

**salt.modules.smartos_vmadm.delete_snapshot**(vm, name, key='uuid')
Delete snapshot of a vm

**vm** [string] vm to be targeted

**name** [string] snapshot name

The snapname must be 64 characters or less and must only contain alphanumeric characters and characters in the set [-_::%] to comply with ZFS restrictions.

**key** [string [uuid|alias|hostname]] value type of `vm' parameter

CLI Example:

```
salt '*' vmadm.delete_snapshot 186da9ab-7392-4f55-91a5-b8f1fe770543 baseline
salt '*' vmadm.delete_snapshot nacl baseline key=alias
```

**salt.modules.smartos_vmadm.get**(vm, key='uuid')
Output the JSON object describing a VM

**vm** [string] vm to be targeted

**key** [string [uuid|alias|hostname]] value type of `vm' parameter

CLI Example:

```
salt '*' vmadm.get 186da9ab-7392-4f55-91a5-b8f1fe770543
salt '*' vmadm.get nacl key=alias
```

**salt.modules.smartos_vmadm.info**(vm, info_type='all', key='uuid')
Lookup info on running kvm

**vm** [string] vm to be targeted

**info_type** [string [all|block|blockstats|chardev|cpus|kvm|pci|spice|version|vnc]] info type to return

**key** [string [uuid|alias|hostname]] value type of `vm' parameter

CLI Example:

```
salt '*' vmadm.info 186da9ab-7392-4f55-91a5-b8f1fe770543
salt '*' vmadm.info 186da9ab-7392-4f55-91a5-b8f1fe770543 vnc
salt '*' vmadm.info nacl key=alias
salt '*' vmadm.info vnc nacl vnc key=alias
```

**salt.modules.smartos_vmadm.list**(search=None, sort=None, order='uuid, type, ram, state, alias', keyed=True)
Return a list of VMs

**search** [string] vmadm filter property

**sort** [string] vmadm sort (-s) property

**order** [string] vmadm order (-o) property -- Default: uuid,type,ram,state,alias

**keyed** [boolean]
specified if the output should be an array (False) or dict (True) For a dict the key is the first item from the order parameter. Note: If key is not unique last vm wins.

CLI Example:

```
salt '*' vmadm.list
salt '*' vmadm.list order=alias,ram,cpu_cap sort=-ram,-cpu_cap
salt '*' vmadm.list search='type=KVM'
```

salt.modules.smartos_vmadm lookup(search=None, order=None, one=False)
Return a list of VMs using lookup
search [string] vmadm filter property
order [string] vmadm order (-o) property -- Default: uuid,type,ram,state,alias
one [boolean] return only one result (vmadm's -1)

CLI Example:

```
salt '*' vmadm.lookup search='state=running'
salt '*' vmadm.lookup search='state=running' order=uuid,alias,hostname
salt '*' vmadm.lookup search='alias=nacl' one=True
```

salt.modules.smartos_vmadm reboot(vm, force=False, key='uuid')
Reboot a vm
vm [string] vm to be rebooted
force [boolean] force reboot of vm if true
key [string [uuid|alias|hostname]] value type of `vm` parameter

CLI Example:

```
salt '*' vmadm.reboot 186da9ab-7392-4f55-91a5-b8f1fe770543
salt '*' vmadm.reboot 186da9ab-7392-4f55-91a5-b8f1fe770543 True
salt '*' vmadm.reboot vm=nacl key=alias
salt '*' vmadm.reboot vm=nina.example.org key=hostname
```

salt.modules.smartos_vmadm receive(uuid, source)
Receive a vm from a directory
uuid [string] uuid of vm to be received
source [string] source directory

CLI Example:

```
salt '*' vmadm.receive 186da9ab-7392-4f55-91a5-b8f1fe770543 /opt/backups
```

salt.modules.smartos_vmadm reprovision(vm, image, key='uuid')
Reprovision a vm
vm [string] vm to be reprovisioned
image [string] uuid of new image
key [string [uuid|alias|hostname]] value type of `vm` parameter

CLI Example:

```
salt '*' vmadm.reprovision 186da9ab-7392-4f55-91a5-b8f1fe770543 c02a2044-c1bd-11e4-bd8c-dfc1db8b0182
salt '*' vmadm.reprovision nacl c02a2044-c1bd-11e4-bd8c-dfc1db8b0182 key=alias
```

salt.modules.smartos_vmadm rollback_snapshot(vm, name, key='uuid')
Rollback snapshot of a vm
vm [string] vm to be targeted
name [string] snapshot name The snapshot name must be 64 characters or less and must only contain alphanumeric characters and characters in the set [-_:%] to comply with ZFS restrictions.
**Key** [string [uuid|alias|hostname]] value type of `vm' parameter

**CLI Example:**
```
salt '*' vmadm.rollback_snapshot 186da9ab-7392-4f55-91a5-b8f1fe770543 baseline
salt '*' vmadm.rollback_snapshot nacl baseline key=alias
```

---

**salt.modules.smartos_vmadm**.send(*vm, target, **key=’uuid’*)

Send a vm to a directory

- **vm** [string] vm to be sent
- **target** [string] target directory
- **key** [string [uuid|alias|hostname]] value type of `vm' parameter

**CLI Example:**
```
salt '*' vmadm.send 186da9ab-7392-4f55-91a5-b8f1fe770543 /opt/backups
salt '*' vmadm.send vm=nacl target=/opt/backups key=alias
```

---

**salt.modules.smartos_vmadm**.start(*vm, options=None, **key=’uuid’*)

Start a vm

- **vm** [string] vm to be started
- **options** [string] optional additional options
- **key** [string [uuid|alias|hostname]] value type of `vm' parameter

**CLI Example:**
```
salt '*' vmadm.start 186da9ab-7392-4f55-91a5-b8f1fe770543
salt '*' vmadm.start 186da9ab-7392-4f55-91a5-b8f1fe770543 order=c,once=d cdrom=/!
path/to/image.iso,ide'
salt '*' vmadm.start vm=nacl key=alias
salt '*' vmadm.start vm=nina.example.org key=hostname
```

---

**salt.modules.smartos_vmadm**.stop(*vm, force=False, **key=’uuid’*)

Stop a vm

- **vm** [string] vm to be stopped
- **force** [boolean] force stop of vm if true
- **key** [string [uuid|alias|hostname]] value type of `vm' parameter

**CLI Example:**
```
salt '*' vmadm.stop 186da9ab-7392-4f55-91a5-b8f1fe770543
salt '*' vmadm.stop 186da9ab-7392-4f55-91a5-b8f1fe770543 True
salt '*' vmadm.stop vm=nacl key=alias
salt '*' vmadm.stop vm=nina.example.org key=hostname
```

---

**salt.modules.smartos_vmadm**.sysrq(*vm, action=’nmi’, **key=’uuid’*)

Send non-maskable interrupt to vm or capture a screenshot

- **vm** [string] vm to be targeted
- **action** [string] nmi or screenshot -- Default: nmi
- **key** [string [uuid|alias|hostname]] value type of `vm' parameter

**CLI Example:**
```
salt '*' vmadm.sysrq 186da9ab-7392-4f55-91a5-b8f1fe770543 nmi
salt '*' vmadm.sysrq 186da9ab-7392-4f55-91a5-b8f1fe770543 screenshot
```

---

**salt.modules.smartos_vmadm**.update(*vm, from_file=None, **key=’uuid’, **kwargs)

Update a new vm

- **vm** [string] vm to be updated
- **from_file** [string] json file to update the vm with -- if present, all other options will be ignored
key  [string [uuid|alias|hostname]] value type of `vm' parameter
kwarg  [string|int|...] options to update for the vm

CLI Example:
salt '*' vmadm.update vm=186da9ab-7392-4f55-91a5-b8f1fe770543 from_file=/tmp/new_.vm.json
salt '*' vmadm.update vm=nacl key=alias from_file=/tmp/new_vm.json
salt '*' vmadm.update vm=186da9ab-7392-4f55-91a5-b8f1fe770543 max_physical_memory=1024

13.6.285 salt.modules.smbios

Interface to SMBIOS/DMI
(Parsing through dmidecode)

External References

Desktop Management Interface (DMI)
System Management BIOS
DMIdecode

salt.modules.smbios.get(string, clean=True)
Get an individual DMI string from SMBIOS info

string
The string to fetch. DMIdecode supports:

  - bios-vendor
  - bios-version
  - bios-release-date
  - system-manufacturer
  - system-product-name
  - system-version
  - system-serial-number
  - system-uuid
  - baseboard-manufacturer
  - baseboard-product-name
  - baseboard-version
  - baseboard-serial-number
  - baseboard-asset-tag
  - chassis-manufacturer
  - chassis-type
  - chassis-version
  - chassis-serial-number
• chassis-asset-tag
• processor-family
• processor-manufacturer
• processor-version
• processor-frequency

clean

Don’t return well-known false information
(invalid UUID’s, serial 000000000’s, etcetera)
Defaults to True

CLI Example:
salt '*

smbios.get system-uuid clean=False

salt.modules.smbios.records(rec_type=None, fields=None, clean=True)

Return DMI records from SMBIOS

type Return only records of type(s) The SMBIOS specification defines the following DMI types:

<table>
<thead>
<tr>
<th>Type</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>BIOS</td>
</tr>

**clean**

Don’t return well-known false information
(invalid UUID’s, serial 000000000’s, etcetera)

Defaults to True

CLI Example:

```
salt '*' smbios.records clean=False
salt '*' smbios.records 14
salt '*' smbios.records 4 core_count,thread_count,current_speed
```

13.6.286 `salt.modules.smf`

Service support for Solaris 10 and 11, should work with other systems that use SMF also. (e.g. SmartOS)

**Important:** If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `service.start' is not available), see here.

`salt.modules.smf.available(name)`

Returns True if the specified service is available, otherwise returns False.

We look up the name with the svcs command to get back the FMRI This allows users to use simpler service names

CLI Example:

```
salt '*' service.available net-snmp
```

`salt.modules.smf.disable(name, **kwargs)`

Disable the named service to start at boot

CLI Example:

```
salt '*' service.disable <service name>
```

`salt.modules.smf.disabled(name)`

Check to see if the named service is disabled to start on boot

CLI Example:
salt 'salt' service.disabled <service name>

salt.modules.smf.enable(name, **kwargs)
   Enable the named service to start at boot
   CLI Example:
   salt '*' service.enable <service name>

salt.modules.smf.enabled(name, **kwargs)
   Check to see if the named service is enabled to start on boot
   CLI Example:
   salt '*' service.enabled <service name>

salt.modules.smf.get_all()
   Return all installed services
   CLI Example:
   salt '*' service.get_all

salt.modules.smf.get_disabled()
   Return the disabled services
   CLI Example:
   salt '*' service.get_disabled

salt.modules.smf.get_enabled()
   Return the enabled services
   CLI Example:
   salt '*' service.get_enabled

salt.modules.smf.get_running()
   Return the running services
   CLI Example:
   salt '*' service.get_running

salt.modules.smf.get_stopped()
   Return the stopped services
   CLI Example:
   salt '*' service.get_stopped

salt.modules.smf.missing(name)
   The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.
   CLI Example:
   salt '*' service.missing net-snmp
salt.modules.smf.reload(name)
Reload the named service

CLI Example:
salt '*' service.reload <service name>

salt.modules.smf.restart(name)
Restart the named service

CLI Example:
salt '*' service.restart <service name>

salt.modules.smf.start(name)
Start the specified service

CLI Example:
salt '*' service.start <service name>

salt.modules.smf.status(name, sig=None)
Return the status for a service, returns a bool whether the service is running.

CLI Example:
salt '*' service.status <service name>

salt.modules.smf.stop(name)
Stop the specified service

CLI Example:
salt '*' service.stop <service name>

13.6.287  salt.modules.smtp

Module for Sending Messages via SMTP

New in version 2014.7.0.

depends
  • smtplib python module

configuration  This module can be used by either passing a jid and password directly to send_message, or by specifying the name of a configuration profile in the minion config, minion pillar, or master config.

For example:

```yaml
my-smtp-login:
  smtp.server: smtp.domain.com
  smtp.tls: True
  smtp.sender: admin@domain.com
  smtp.username: myuser
  smtp.password: verybadpass
```

The resourcename refers to the resource that is using this account. It is user-definable, and optional. The following configurations are both valid:
my-smtp-login:
    smtp.server: smtp.domain.com
    smtp.tls: True
    smtp.sender: admin@domain.com
    smtp.username: myuser
    smtp.password: verybadpass

another-smtp-login:
    smtp.server: smtp.domain.com
    smtp.tls: True
    smtp.sender: admin@domain.com
    smtp.username: myuser
    smtp.password: verybadpass

salt.modules.smtp.send_msg(recipient, message, subject='Message from Salt', sender=None, server=None, use_ssl='True', username=None, password=None, profile=None)

Send a message to an SMTP recipient. Designed for use in states.

CLI Examples:

```
salt.modules.smtp.send_msg 'admin@example.com' 'This is a salt module test' profile='my-smtp-account'
salt.modules.smtp.send_msg 'admin@example.com' 'This is a salt module test' username='myuser' password='verybadpass' sender='admin@example.com'
```

13.6.288 salt.modules.solaris_fmadm

Module for running fmadm and fmdump on Solaris

- maintainer Jorge Schrauwen <sjorge@blackdot.be>
- maturity new
- platform solaris,illumos

New in version 2016.3.0.

salt.modules.solaris_fmadm.acquit(fmri)

Acquit resource or acquit case

```
fmri: string fmri or uuid
```

CLI Example:

```
salt '*' fmadm.acquit fmri | uuid
```

salt.modules.solaris_fmadm.config()

Display fault manager configuration

CLI Example:

```
salt '*' fmadm.config
```

salt.modules.solaris_fmadm.faulty()

Display list of faulty resources

CLI Example:
salt 'salt '*' fmadm.flush fmri"

salt.modules.solaris_fmadm.flush(fmri)
    Flush cached state for resource
    fmri: string fmri
    CLI Example:
    
    salt 'salt '*' fmadm.flush fmri"

salt.modules.solaris_fmadm.healthy()
    Return whether fmadm is reporting faults
    CLI Example:
    
    salt 'salt '*' fmadm.healthy"

salt.modules.solaris_fmadm.list(after=None, before=None)
    Display fault management logs
    after [string] filter events after time, see man fmdump for format
    before [string] filter events before time, see man fmdump for format
    CLI Example:
    
    salt 'salt '*' fmadm.list"

salt.modules.solaris_fmadm.load(path)
    Load specified fault manager module
    path: string path of fault manager module
    CLI Example:
    
    salt 'salt '*' fmadm.load /module/path"

salt.modules.solaris_fmadm.repaired(fmri)
    Notify fault manager that resource has been repaired
    fmri: string fmri
    CLI Example:
    
    salt 'salt '*' fmadm.repaired fmri"

salt.modules.solaris_fmadm.replaced(fmri)
    Notify fault manager that resource has been replaced
    fmri: string fmri
    CLI Example:
    
    salt 'salt '*' fmadm.replaced fmri"

salt.modules.solaris_fmadm.reset(module, serd=None)
    Reset module or sub-component
    module: string module to unload
    serd [string] serd sub module
    CLI Example:
    
    salt 'salt '*' fmadm.reset software-response"

salt.modules.solaris_fmadm.show(uuid)
    Display log details
    uuid: string uuid of fault
CLI Example:
```
salt '*' fmadm.show 11b4070f-4358-62fa-9e1e-998f485977e1
```

```
salt.modules.solaris_fmadm.unload(module)
Unload specified fault manager module
module: string  module to unload
```

CLI Example:
```
salt '*' fmadm.unload software-response
```

### 13.6.289 salt.modules.solaris_group

Manage groups on Solaris

**Important:** If you feel that Salt should be using this module to manage groups on a minion, and it is using a different module (or gives an error similar to `group.info' is not available), see [here](#).

```
salt.modules.solaris_group.add(name, gid=None, **kwargs)
Add the specified group
```

CLI Example:
```
salt '*' group.add foo 3456
```

```
salt.modules.solaris_group.chgid(name, gid)
Change the gid for a named group
```

CLI Example:
```
salt '*' group.chgid foo 4376
```

```
salt.modules.solaris_group.delete(name)
Remove the named group
```

CLI Example:
```
salt '*' group.delete foo
```

```
salt.modules.solaris_group.getent(refresh=False)
Return info on all groups
```

CLI Example:
```
salt '*' group.getent
```

```
salt.modules.solaris_group.info(name)
Return information about a group
```

CLI Example:
```
salt '*' group.info foo
```

13.6. execution modules 1493
13.6.290 salt.modules.solaris_shadow

Manage the password database on Solaris systems

**Important:** If you feel that Salt should be using this module to manage passwords on a minion, and it is using a different module (or gives an error similar to `shadow.info' is not available), see [here](#).

```python
salt.modules.solaris_shadow.default_hash()
Returns the default hash used for unset passwords

CLI Example:
salt '*' shadow.default_hash
```

```python
salt.modules.solaris_shadow.del_password(name)
Delete the password from name user

CLI Example:
salt '*' shadow.del_password username
```

```python
salt.modules.solaris_shadow.gen_password(password, crypt_salt=None, algorithm='sha512')
Generate hashed password

**Note:** When called this function is called directly via remote-execution, the password argument may be displayed in the system's process list. This may be a security risk on certain systems.

- **password** Plaintext password to be hashed.
- **crypt_salt** Cryptographic salt. If not given, a random 8-character salt will be generated.
- **algorithm** The following hash algorithms are supported:
  - md5
  - blowfish (not in mainline glibc, only available in distros that add it)
  - sha256
  - sha512 (default)

CLI Example:

```python
salt '*' shadow.gen_password 'I_am_password'
salt '*' shadow.gen_password 'I_am_password' crypt_salt='I_am_salt'
   algorithm=sha256
```

```python
salt.modules.solaris_shadow.info(name)
Return information for the specified user

CLI Example:

```python
salt '*' shadow.info root
```

```python
salt.modules.solaris_shadow.set_maxdays(name, maxdays)
Set the maximum number of days during which a password is valid. See man passwd.

CLI Example:
```
salt '*' shadow.set_maxdays username 90

```python
salt.modules.solaris_shadow.set_mindays(name, mindays)
```
Set the minimum number of days between password changes. See man passwd.

CLI Example:

```bash
salt '*' shadow.set_mindays username 7
```

```python
salt.modules.solaris_shadow.set_password(name, password)
```
Set the password for a named user. The password must be a properly defined hash, the password hash can be generated with this command: `openssl passwd -1 <plaintext password>`

CLI Example:

```bash
salt '*' shadow.set_password root $1$UYCIxa628.9qXjpQCjM4a..
```

```python
salt.modules.solaris_shadow.set_warndays(name, warndays)
```
Set the number of days of warning before a password change is required. See man passwd.

CLI Example:

```bash
salt '*' shadow.set_warndays username 7
```

### 13.6.291 `salt.modules.solaris_system`

Support for reboot, shutdown, etc

This module is assumes we are using solaris-like shutdown

New in version 2016.3.0.

```python
salt.modules.solaris_system.halt()
```
Halt a running system

CLI Example:

```bash
salt '*' system.halt
```

```python
salt.modules.solaris_system.init(state)
```
Change the system runlevel on sysV compatible systems

CLI Example:

```bash
state [string] Init state
salt '*' system.init 3
```

```python
salt.modules.solaris_system.poweroff()
```
Poweroff a running system

CLI Example:

```bash
salt '*' system.poweroff
```

```python
salt.modules.solaris_system.reboot(delay=0, message=None)
```
Reboot the system

delay [int] Optional wait time in seconds before the system will be rebooted.

message [string] Optional message to broadcast before rebooting.
13.6.292 salt.modules.solaris_user

Manage users with the useradd command

**Important:** If you feel that Salt should be using this module to manage users on a minion, and it is using a different module (or gives an error similar to `user.info` is not available), see [here](#).
salt.modules.solaris_user.chhome(name, home, persist=False)
Set a new home directory for an existing user
name Username to modify
home New home directory to set
persist [False] Set to True to prevent configuration files in the new home directory from being overwritten by the files from the skeleton directory.
CLI Example:
```
salt '*' user.chhome foo /home/users/foo True
```

salt.modules.solaris_user.chhomephone(name, homephone)
Change the user's Home Phone
CLI Example:
```
salt '*' user.chhomephone foo "7735551234"
```

salt.modules.solaris_user.chroomnumber(name, roomnumber)
Change the user's Room Number
CLI Example:
```
salt '*' user.chroomnumber foo 123
```

salt.modules.solaris_user.chshell(name, shell)
Change the default shell of the user
CLI Example:
```
salt '*' user.chshell foo /bin/zsh
```

salt.modules.solaris_user.chuid(name, uid)
Change the uid for a named user
CLI Example:
```
salt '*' user.chuid foo 4376
```

salt.modules.solaris_user.chworkphone(name, workphone)
Change the user's Work Phone
CLI Example:
```
salt '*' user.chworkphone foo "7735550123"
```

salt.modules.solaris_user.delete(name, remove=False, force=False)
Remove a user from the minion
CLI Example:
```
salt '*' user.delete name remove=True force=True
```

salt.modules.solaris_user.getent(refresh=False)
Return the list of all info for all users
CLI Example:
```
salt '*' user.getent
```

13.6. execution modules
salt.modules.solaris_user.info(name)
Return user information

CLI Example:
salt '*' user.info root

salt.modules.solaris_user.list_groups(name)
Return a list of groups the named user belongs to

CLI Example:
salt '*' user.list_groups foo

salt.modules.solaris_user.list_users()
Return a list of all users

CLI Example: ..

salt.modules.solaris_user.rename(name, new_name)
Change the username for a named user

CLI Example:
salt '*' user.rename name new_name

13.6.293 salt.modules.solarisips

IPS pkg support for Solaris

Important: If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to 'pkg.install' is not available), see here.

This module provides support for Solaris 11 new package management - IPS (Image Packaging System). This is the default pkg module for Solaris 11 (and later).

If you want to use also other packaging module (e.g. pkgutil) together with IPS, you need to override the pkg provider in sls for each package:

mypackage:
pkg.installed:
  - provider: pkgutil

Or you can override it globally by setting the providers parameter in your Minion config file like this:

providers:
pkg: pkgutil

Or you can override it globally by setting the providers parameter in your Minion config file like this:

providers:
pkg: pkgutil

salt.modules.solarisips.available_version(name, **kwargs)
This function is an alias of latest_version.
The available version of the package in the repository. In case of multiple matches, it returns list of all matched packages. Accepts full or partial FMRI. Please use pkg.latest_version as pkg.available_version is being deprecated.

CLI Example:
```
salt '*' pkg.latest_version pkg://solaris/entire
```

```python
salt.modules.solarisips.get_fmri(name, **kwargs)
```
Returns FMRI from partial name. Returns empty string ("") if not found. In case of multiple match, the function returns list of all matched packages.

CLI Example:
```
salt '*' pkg.get_fmri bash
```

```python
salt.modules.solarisips.install(name=None, refresh=False, pkgs=None, version=None, test=False, **kwargs)
```
Install the named package using the IPS pkg command. Accepts full or partial FMRI.

Returns a dict containing the new package names and versions:

```json
{ '<package>': { 'old': '<old-version>', 'new': '<new-version>' }}
```

Multiple Package Installation Options:

**pkgs** A list of packages to install. Must be passed as a python list.

CLI Example:
```
salt '*' pkg.install vim
salt '*' pkg.install pkg://solaris/editor/vim
salt '*' pkg.install pkg://solaris/editor/vim refresh=True
salt '*' pkg.install pkgs='["foo", "bar"]'
```

```python
salt.modules.solarisips.is_installed(name, **kwargs)
```
Returns True if the package is installed. Otherwise returns False. Name can be full or partial FMRI. In case of multiple match from partial FMRI name, it returns True.

CLI Example:
```
salt '*' pkg.is_installed bash
```

```python
salt.modules.solarisips.latest_version(name, **kwargs)
```
The available version of the package in the repository. In case of multiple matches, it returns list of all matched packages. Accepts full or partial FMRI. Please use pkg.latest_version as pkg.available_version is being deprecated.

CLI Example:
```
salt '*' pkg.latest_version pkg://solaris/entire
```

```python
salt.modules.solarisips.list_pkgs(versions_as_list=False, **kwargs)
```
List the currently installed packages as a dict:

```json
{ '<package_name>': '<version>' }
```

CLI Example:
salt '*' pkg.list_pkgs

```python
salt.modules.solarisips.list_upgrades(refresh=False, **kwargs)
```

Lists all packages available for update.

- When run in global zone, it reports only upgradable packages for the global zone.
- When run in non-global zone, it can report more upgradable packages than `pkg update -vn`, because `pkg update` hides packages that require newer version of `pkg://solaris/entire` (which means that they can be upgraded only from the global zone). If `pkg://solaris/entire` is found in the list of upgrades, then the global zone should be updated to get all possible updates. Use `refresh=True` to refresh the package database.

- **refresh** [False] Set to True to force a full pkg DB refresh before listing

```bash
salt '*' pkg.list_upgrades
salt '*' pkg.list_upgrades refresh=True
```

```python
salt.modules.solarisips.normalize_name(name, **kwargs)
```

Internal function. Normalizes pkg name to full FMRI before running `pkg.install`. In case of multiple matches or no match, it returns the name without modifications.

```bash
salt '*' pkg.normalize_name vim
```

```python
salt.modules.solarisips.purge(name, **kwargs)
```

Remove specified package. Accepts full or partial FMRI.

Returns a list containing the removed packages.

```bash
salt '*' pkg.purge <package name>
```

```python
salt.modules.solarisips.refresh_db(full=False)
```

Updates the remote repos database.

- **full** : False
-  Set to True to force a refresh of the pkg DB from all publishers, regardless of the last refresh time.

```bash
salt '*' pkg.refresh_db
salt '*' pkg.refresh_db full=True
```

```python
salt.modules.solarisips.remove(name=None, pkgs=None, **kwargs)
```

Remove specified package. Accepts full or partial FMRI. In case of multiple match, the command fails and won't modify the OS.

- **name** The name of the package to be deleted.
- Multiple Package Options:
- **pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

Returns a list containing the removed packages.

```bash
salt '*' pkg.remove <package name>
salt '*' pkg.remove tcsh
```
salt.modules.solarisips.search(name, versions_as_list=False, **kwargs)
Searches the repository for given pkg name. The name can be full or partial FMRI. All matches are printed. Globs are also supported.

CLI Example:
```
salt '*' pkg.search bash
```

salt.modules.solarisips.upgrade(refresh=False, **kwargs)
Upgrade all packages to the latest possible version. When run in global zone, it updates also all non-global zones. In non-global zones upgrade is limited by dependency constrains linked to the version of pkg://solaris/entire.

Returns also the raw output of the pkg update command (because if update creates a new boot environment, no immediate changes are visible in pkg list).

CLI Example:
```
salt '*' pkg.upgrade
```

salt.modules.solarisips.upgrade_available(name)
Check if there is an upgrade available for a certain package Accepts full or partial FMRI. Returns all matches found.

CLI Example:
```
salt '*' pkg.upgrade_available apache-22
```

salt.modules.solarisips.version(*names, **kwargs)
Common interface for obtaining the version of installed packages. Accepts full or partial FMRI. If called using pkg_resource, full FMRI is required.

CLI Example:
```
salt '*' pkg.version vim
salt '*' pkg.version foo bar baz
salt '*' pkg_resource.version pkg://solaris/entire
```

13.6.294 salt.modules.solarispkg

Package support for Solaris

Important: If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install' is not available), see here.

salt.modules.solarispkg.install(name=None, sources=None, saltenv='base', **kwargs)
Install the passed package. Can install packages from the following sources:
- Locally (package already exists on the minion
- HTTP/HTTPS server
- FTP server
- Salt master

Returns a dict containing the new package names and versions:
CLI Examples:

# Installing a data stream pkg that already exists on the minion

```
salt '*' pkg.install sources='["<pkg name": "/dir/on/minion/<pkg filename>"]'
salt '*' pkg.install sources='["<SMClgcc346": "/var/spool/pkg/gcc-3.4.6-sol10-sparc-local.pkg"]'
```

# Installing a data stream pkg that exists on the salt master

```
salt '*' pkg.install sources='["<pkg name": ":salt://pkgs/<pkg filename>"]'
salt '*' pkg.install sources='["<SMClgcc346": ":salt://pkgs/gcc-3.4.6-sol10-sparc-local.pkg"]'
```

CLI Example:

# Installing a data stream pkg that exists on a HTTP server

```
salt '*' pkg.install sources='["<pkg name": ":http://packages.server.com/<pkg filename>"]'
salt '*' pkg.install sources='["<SMClgcc346": ":http://packages.server.com/gcc-3.4.6-sol10-sparc-local.pkg"]'
```

If working with solaris zones and you want to install a package only in the global zone you can pass `current_zone_only=True` to salt to have the package only installed in the global zone. (Behind the scenes this is passing `-G` to the pkgadd command.) Solaris default when installing a package in the global zone is to install it in all zones. This overrides that and installs the package only in the global.

CLI Example:

```
salt 'global_zone' pkg.install sources='["<SMClgcc346": "/var/spool/pkg/gcc-3.4.6-sol10-sparc-local.pkg"]' current_zone_only=True
```

By default salt automatically provides an adminfile, to automate package installation, with these options set:

```
email=
instance=quit
partial=nocheck
runlevel=nocheck
idepend=nocheck
rdepend=nocheck
space=nocheck
setuid=nocheck
conflict=nocheck
action=nocheck
basedir=default
```

You can override any of these options in two ways. First you can optionally pass any of the options as a kwarg to the module/state to override the default value or you can optionally pass the `admin_source` option providing your own adminfile to the minions.

Note: You can find all of the possible options to provide to the adminfile by reading the admin man page:

```
man -s 4 admin
```
CLI Example:

```python
# Overriding the 'instance' adminfile option when calling the module directly
salt '*' pkg.install sources='["<pkg name>": "salt://pkgs/<pkg filename>"]'
  → instance="overwrite"
```

SLS Example:

```python
# Overriding the 'instance' adminfile option when used in a state
SMClgcc346:
  pkg.installed:
    - sources:
      - SMClgcc346: salt://srv/salt/pkgs/gcc-3.4.6-sol10-sparc-local.pkg
      - instance: overwrite
```

Note: The ID declaration is ignored, as the package name is read from the sources parameter.

CLI Example:

```python
# Providing your own adminfile when calling the module directly
salt '*' pkg.install sources='["<pkg name>": "salt://pkgs/<pkg filename>"]'
  → admin_source='salt://pkgs/<adminfile filename>'

# Providing your own adminfile when using states
<pkg name>:
  pkg.installed:
    - sources:
      - <pkg name>: salt://pkgs/<pkg filename>
      - admin_source: salt://pkgs/<adminfile filename>
```

Note: The ID declaration is ignored, as the package name is read from the sources parameter.

```python
salt.modules.solarispkg.latest_version(*names, **kwargs)
```

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:

```python
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

NOTE: As package repositories are not presently supported for Solaris pkgadd, this function will always return an empty string for a given package.

```python
salt.modules.solarispkg.list_pkgs(versions_as_list=False, **kwargs)
```

List the packages currently installed as a dict:

```python
{"<package_name>": '<version>'
```

CLI Example:
salt '*/' pkg.list_pkgs

salt.modules.solarispkg.purge(name=None, pkgs=None, **kwargs)
Package purges are not supported, this function is identical to remove().

name  The name of the package to be deleted
Multiple Package Options:
   pkgs  A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this
         option is passed.
New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

salt '*/' pkg.purge <package name>
salt '*/' pkg.purge <package1>,<package2>,<package3>
salt '*/' pkg.purge pkgs='["foo", "bar"]'

salt.modules.solarispkg.remove(name=None, pkgs=None, saltenv='base', **kwargs)
Remove packages with pkgrm

name  The name of the package to be deleted
By default salt automatically provides an adminfile, to automate package removal, with these options set:

    email=
    instance=quit
    partial=nocheck
    runlevel=nocheck
    idepend=nocheck
    rdepend=nocheck
    space=nocheck
    setuid=nocheck
    conflict=nocheck
    action=nocheck
    basedir=default

You can override any of these options in two ways. First you can optionally pass any of the options as a
kwarg to the module/state to override the default value or you can optionally pass the 'admin_source' option
providing your own adminfile to the minions.

Note: You can find all of the possible options to provide to the adminfile by reading the admin man page:

man -s 4 admin

Multiple Package Options:
   pkgs  A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this
         option is passed.
New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

salt '*/' pkg.remove <package name>
salt '*/' pkg.remove SUNWgit
salt '*/' pkg.remove <package1>,<package2>,<package3>
salt '*/' pkg.remove pkgs='["foo", "bar"]'

salt.modules.solarispkg.upgrade_available(name)
Check whether or not an upgrade is available for a given package
**CLI Example:**

```bash
salt '*' pkg.upgrade_available <package name>
```

**salt.modules.solarispkg.version(**`names`, **kwargs**)**

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

**CLI Example:**

```bash
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

---

**13.6.295 salt.modules.solr**

Apache Solr Salt Module

Author: Jed Glazner Version: 0.2.1 Modified: 12/09/2011

This module uses HTTP requests to talk to the apache solr request handlers to gather information and report errors. Because of this the minion doesn't necessarily need to reside on the actual slave. However if you want to use the signal function the minion must reside on the physical solr host.

This module supports multi-core and standard setups. Certain methods are master/slave specific. Make sure you set the solr.type. If you have questions or want a feature request please ask.

**Coming Features in 0.3**

1. Add command for checking for replication failures on slaves
2. Improve match_index_versions since it's pointless on busy solr masters
3. Add additional local fs checks for backups to make sure they succeeded

**Override these in the minion config**

- **solr.cores** A list of core names e.g. ['core1','core2']. An empty list indicates non-multicore setup.
- **solr.baseurl** The root level URL to access solr via HTTP
- **solr.request_timeout** The number of seconds before timing out an HTTP/HTTPS/FTP request. If nothing is specified then the python global timeout setting is used.
- **solr.type** Possible values are `master` or `slave`
- **solr.backup_path** The path to store your backups. If you are using cores and you can specify to append the core name to the path in the backup method.
- **solr.num_backups** For versions of solr >= 3.5. Indicates the number of backups to keep. This option is ignored if your version is less.
- **solr.init_script** The full path to your init script with start/stop options
- **solr.dih.options** A list of options to pass to the DIH.
Required Options for DIH

**clean** [False] Clear the index before importing

**commit** [True] Commit the documents to the index upon completion

**optimize** [True] Optimize the index after commit is complete

**verbose** [True] Get verbose output

```python
salt.modules.solr.abort_import(handler, host=None, core_name=None, verbose=False)
```

MASTER ONLY Aborts an existing import command to the specified handler. This command can only be run if the minion is configured with solr.type=master

**handler** [str] The name of the data import handler.

**host** [str (None)] The solr host to query. __opts__['host'] is default.

**core** [str (None)] The core the handler belongs to.

**verbose** [boolean (False)] Run the command with verbose output.

Return : dict<str,obj>:

```
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```
salt '*' solr.abort_import dataimport None music {'clean':True}
```

```python
salt.modules.solr.backup(host=None, core_name=None, append_core_to_path=False)
```

Tell solr make a backup. This method can be mis-leading since it uses the backup API. If an error happens during the backup you are not notified. The status: `OK` in the response simply means that solr received the request successfully.

**host** [str (None)] The solr host to query. __opts__['host'] is default.

**core_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

**append_core_to_path** [boolean (False)] If True add the name of the core to the backup path. Assumes that minion backup path is not None.

Return : dict<str,obj>:

```
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```
salt '*' solr.backup music
```
**handler** [str] The name of the data import handler.

**host** [str (None)] The solr host to query. `__opts__['host']` is default.

**core** [str (None)] The core the handler belongs to.

**options** [dict (_) A list of options such as clean, optimize commit, verbose, and pause_replication. Leave blank to use `__opts__` defaults. options will be merged with `__opts__`.

**extra** [dict ([])] Extra name value pairs to pass to the handler. e.g. `["name=value"]`

Return : dict<str,obj>:

```python
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```
salt '*' solr.delta_import dataimport None music {'clean':True}
```

**salt.modules.solr.full_import(handler, host=None, core_name=None, options=None, extra=None)**

MASTER ONLY Submits an import command to the specified handler using specified options. This command can only be run if the minion is configured with `solr.type=master`

**handler** [str] The name of the data import handler.

**host** [str (None)] The solr host to query. `__opts__['host']` is default.

**core** [str (None)] The core the handler belongs to.

**options** [dict (_) A list of options such as clean, optimize commit, verbose, and pause_replication. Leave blank to use `__opts__` defaults. options will be merged with `__opts__`.

**extra** [dict ([])] Extra name value pairs to pass to the handler. e.g. `["name=value"]`

Return : dict<str,obj>:

```python
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```
salt '*' solr.full_import dataimport None music {'clean':True}
```

**salt.modules.solr.import_status(handler, host=None, core_name=None, verbose=False)**

Submits an import command to the specified handler using specified options. This command can only be run if the minion is configured with `solr.type=master`

**handler** [str] The name of the data import handler.

**host** [str (None)] The solr host to query. `__opts__['host']` is default.

**core** [str (None)] The core the handler belongs to.

**verbose** [boolean (False)] Specifies verbose output

Return : dict<str,obj>:

```python
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```
salt '*' solr.import_status dataimport None music False
```

**salt.modules.solr.is_replication_enabled(host=None, core_name=None)**

SLAVE CALL Check for errors, and determine if a slave is replicating or not.

**host** [str (None)] The solr host to query. `__opts__['host']` is default.

**core_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return : dict<str,obj>:

```python
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```
salt '*' solr.is_replication_enabled
```

13.6. execution modules
salt '*' solr.is_replication_enabled

salt.modules.solr.lucene_version(core_name=None)

Gets the lucene version that solr is using. If you are running a multi-core setup you should specify a core name since all the cores run under the same servlet container, they will all have the same version.

core_name [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return: dict<str,obj>:
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}

CLI Example:

salt '*' solr.lucene_version

salt.modules.solr.match_index_versions(host=None, core_name=None)

SLAVE CALL Verifies that the master and the slave versions are in sync by comparing the index version. If you are constantly pushing updates the index the master and slave versions will seldom match. A solution to this is pause indexing every so often to allow the slave to replicate and then call this method before allowing indexing to resume.

host [str (None)] The solr host to query. __opts__['host'] is default.

core_name [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return : dict<str,obj>:
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}

CLI Example:

salt '*' solr.match_index_versions

salt.modules.solr.optimize(host=None, core_name=None)

Search queries fast, but it is a very expensive operation. The ideal process is to run this with a master/slave configuration. Then you can optimize the master, and push the optimized index to the slaves. If you are running a single solr instance, or if you are going to run this on a slave be aware that search performance will be horrible while this command is being run. Additionally it can take a LONG time to run and your HTTP request may timeout. If that happens adjust your timeout settings.

host [str (None)] The solr host to query. __opts__['host'] is default.

core_name [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return : dict<str,obj>:
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}

CLI Example:

salt '*' solr.optimize

salt.modules.solr.ping(host=None, core_name=None)

Does a health check on solr, makes sure solr can talk to the indexes.

host [str (None)] The solr host to query. __opts__['host'] is default.

core_name [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return : dict<str,obj>:
{'success': boolean, 'data': dict, 'errors': list, 'warnings': list}

CLI Example:
```
salt '*' solr.ping music
```

`salt.modules.solr.reload_core(host=None, core_name=None)`
MULTI-CORE HOSTS ONLY Load a new core from the same configuration as an existing registered core. While the "new" core is initializing, the "old" one will continue to accept requests. Once it has finished, all new request will go to the "new" core, and the "old" core will be unloaded.

- **host** [str (None)] The solr host to query. __opts__['host'] is default.
- **core_name** [str] The name of the core to reload

Return : dict<str,obj>:
```
{'success': boolean, 'data': dict, 'errors': list, 'warnings': list}
```

CLI Example:
```
salt '*' solr.reload_core None music
```

Return data is in the following format:
```
{'success': bool, 'data': dict, 'errors': list, 'warnings': list}
```

`salt.modules.solr.reload_import_config(handler, host=None, core_name=None, verbose=False)`
MASTER ONLY re-loads the handler config XML file. This command can only be run if the minion is a `master` type

- **handler** [str] The name of the data import handler.
- **host** [str (None)] The solr host to query. __opts__['host'] is default.
- **core** [str (None)] The core the handler belongs to.
- **verbose** [boolean (False)] Run the command with verbose output.

Return : dict<str,obj>:
```
{'success': boolean, 'data': dict, 'errors': list, 'warnings': list}
```

CLI Example:
```
salt '*' solr.reload_import_config dataimport None music {'clean':True}
```

`salt.modules.solr.replication_details(host=None, core_name=None)`
Get the full replication details.

- **host** [str (None)] The solr host to query. __opts__['host'] is default.
- **core_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return : dict<str,obj>:
```
{'success': boolean, 'data': dict, 'errors': list, 'warnings': list}
```

CLI Example:
```
salt '*' solr.replication_details music
```

`salt.modules.solr.set_is_polling(polling, host=None, core_name=None)`
SLAVE CALL Prevent the slaves from polling the master for updates.

- **polling** [boolean] True will enable polling. False will disable it.
host  [str (None)] The solr host to query. __opts__['host'] is default.
core_name  [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.
Return : dict<str,obj>:

{ 'success':boolean, 'data':dict, 'errors':list, 'warnings':list }

CLI Example:
salt '*' solr.set_is_polling False

salt.modules.solr.set_replication_enabled( status, host= None, core_name= None)
MASTER ONLY Sets the master to ignore poll requests from the slaves. Useful when you don't want the slaves replicating during indexing or when clearing the index.
status  [boolean] Sets the replication status to the specified state.
host  [str (None)] The solr host to query. __opts__['host'] is default.
core_name  [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to set the status on all cores.
Return : dict<str,obj>:

{ 'success':boolean, 'data':dict, 'errors':list, 'warnings':list }

CLI Example:
salt '*' solr.set_replication_enabled false, None, music

salt.modules.solr.signal( signal=None)
Signals Apache Solr to start, stop, or restart. Obviously this is only going to work if the minion resides on the solr host. Additionally Solr doesn't ship with an init script so one must be created.
signal  [str (None)] The command to pass to the apache solr init valid values are `start`, `stop`, and `restart`

CLI Example:
salt '*' solr.signal restart

salt.modules.solr.version( core_name=None)
Gets the solr version for the core specified. You should specify a core here as all the cores will run under the same servlet container and so will all have the same version.
core_name  [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.
Return : dict<str,obj>:

{ 'success':boolean, 'data':dict, 'errors':list, 'warnings':list }

CLI Example:
salt '*' solr.version

13.6.296  salt.modules.splunk

Module for interop with the Splunk API
New in version 2016.3.0..

depends
- splunk-sdk python module
**configuration**  Configure this module by specifying the name of a configuration profile in the minion config, minion pillar, or master config. The module will use the `splunk` key by default, if defined.

For example:

```yaml
splunk:
  username: alice
  password: abc123
  host: example.splunkcloud.com
  port: 8080
```

```python
salt.modules.splunk.create_user(email, profile='splunk', **kwargs)
```
create a splunk user by name/email

CLI Example:

```bash
salt myminion splunk.create_user user@example.com roles=['user'] realname="Test User" name=testuser
```

```python
salt.modules.splunk.delete_user(email, profile='splunk')
```
Delete a splunk user by email

CLI Example:

```bash
salt myminion splunk_user.delete 'user@example.com'
```

```python
salt.modules.splunk.get_user(email, profile='splunk', **kwargs)
```
Get a splunk user by name/email

CLI Example:

```bash
salt myminion splunk.get_user 'user@example.com' user_details=false salt myminion splunk.get_user 'user@example.com' user_details=true
```

```python
salt.modules.splunk.list_users(profile='splunk')
```
List all users in the splunk DB

CLI Example:

```bash
salt myminion splunk.list_users
```

```python
salt.modules.splunk.update_user(email, profile='splunk', **kwargs)
```
Create a splunk user by email

CLI Example:

```bash
salt myminion splunk.update_user example@domain.com roles=['user'] realname="Test User"
```

### 13.6.297 *salt.modules.splunk_search*

Module for interop with the Splunk API

New in version 2015.5.0.

**depends**
- splunk-sdk python module

**configuration**  Configure this module by specifying the name of a configuration profile in the minion config, minion pillar, or master config. The module will use the `splunk` key by default, if defined.

For example:

```yaml
splunk:
  username: alice
  password: abc123
```
**Salt Documentation, Release 2016.3.6**

```
host: example.splunkcloud.com
port: 8080
```

**salt.modules.splunk_search.create**(name, profile='splunk', **kwargs)
Create a splunk search

CLI Example:
splunk_search.create `my search name` search='error msg'

**salt.modules.splunk_search.delete**(name, profile='splunk')
Delete a splunk search

CLI Example:
splunk_search.delete `my search name`

**salt.modules.splunk_search.get**(name, profile='splunk')
Get a splunk search

CLI Example:
splunk_search.get `my search name`

**salt.modules.splunk_search.list**(profile='splunk')
List splunk searches (names only)

CLI Example: splunk_search.list

**salt.modules.splunk_search.list_all**(prefix=None, app=None, owner=None, description_contains=None, name_not_contains=None, profile='splunk')
Get all splunk search details. Produces results that can be used to create an sls file.

if app or owner are specified, results will be limited to matching saved searches.

if description_contains is specified, results will be limited to those where `description_contains in description` is true if name_not_contains is specified, results will be limited to those where `name_not_contains not in name` is true.

If prefix parameter is given, alarm names in the output will be prepended with the prefix; alarms that have the prefix will be skipped. This can be used to convert existing alarms to be managed by salt, as follows:

CLI example:

1. Make a `backup` of all existing searches
   $ salt-call splunk_search.list_all --out=txt | sed `s/local: //" > legacy_searches.sls

2. Get all searches with new prefixed names
   $ salt-call splunk_search.list_all `"prefix="MANAGED BY SALT"" --out=txt | sed `s/local: //" > managed_searches.sls

3. Insert the managed searches into splunk
   $ salt-call state.sls managed_searches.sls

4. Manually verify that the new searches look right

5. Delete the original searches
   $ sed s/present/absent/ legacy_searches.sls > remove_legacy_searches.sls
   $ salt-call state.sls remove_legacy_searches.sls

6. Get all searches again, verify no changes
   $ salt-call splunk_search.list_all --out=txt | sed `s/local: //" > final_searches.sls
   $ diff final_searches.sls managed_searches.sls

**salt.modules.splunk_search.update**(name, profile='splunk', **kwargs)
Update a splunk search

CLI Example:
splunk_search.update `my search name` sharing=app
13.6.298 salt.modules.sqlite3

Support for SQLite3

salt.modules.sqlite3.fetch(db=None, sql=None)

Retrieve data from an sqlite3 db (returns all rows, be careful!)

CLI Example:

```
salt '*' sqlite3.fetch /root/test.db 'SELECT * FROM test;'
```

salt.modules.sqlite3.indexes(db=None)

Show all indices in the database, for people with poor spelling skills

CLI Example:

```
salt '*' sqlite3.indexes /root/test.db
```

salt.modules.sqlite3.indices(db=None)

Show all indices in the database

CLI Example:

```
salt '*' sqlite3.indices /root/test.db
```

salt.modules.sqlite3.modify(db=None, sql=None)

Issue an SQL query to sqlite3 (with no return data), usually used to modify the database in some way (insert, delete, create, etc)

CLI Example:

```
salt '*' sqlite3.modify /root/test.db 'CREATE TABLE test(id INT, testdata TEXT);'
```

salt.modules.sqlite3.sqlite_version()

Return version of sqlite

CLI Example:

```
salt '*' sqlite3.sqlite_version
```

salt.modules.sqlite3.tables(db=None)

Show all tables in the database

CLI Example:

```
salt '*' sqlite3.tables /root/test.db
```

salt.modules.sqlite3.version()

Return version of pysqlite

CLI Example:

```
salt '*' sqlite3.version
```

13.6.299 salt.modules.ssh

Manage client ssh components
Note: This module requires the use of MD5 hashing. Certain security audits may not permit the use of MD5. For those cases, this module should be disabled or removed.

`salt.modules.ssh.auth_keys(user=None, config='ssh/authorized_keys')`
Return the authorized keys for users

CLI Example:
```
salt '*' ssh.auth_keys
salt '*' ssh.auth_keys root
salt '*' ssh.auth_keys user=root
salt '*' ssh.auth_keys user="[user1, user2]"
```

`salt.modules.ssh.check_key(user, key, enc, comment, options, config='ssh/authorized_keys', cache_keys=None)`
Check to see if a key needs updating, returns `"update", "add" or "exists"`

CLI Example:
```
salt '*' ssh.check_key <user> <key> <enc> <comment> <options>
```

`salt.modules.ssh.check_key_file(user, source, config='ssh/authorized_keys', saltenv='base', env=None)`
Check a keyfile from a source destination against the local keys and return the keys to change

CLI Example:
```
salt '*' ssh.check_key_file root salt://ssh/keyfile
```

`salt.modules.ssh.check_known_host(user=None, hostname=None, key=None, fingerprint=None, config=None, port=None)`
Check the record in known_hosts file, either by its value or by fingerprint (it’s enough to set up either key or fingerprint, you don’t need to set up both).

If provided key or fingerprint doesn’t match with stored value, return `"update"`, if no value is found for a given host, return `"add"`, otherwise return `"exists"`.

If neither key, nor fingerprint is defined, then additional validation is not performed.

CLI Example:
```
salt '*' ssh.check_known_host <user> <hostname> key='AAAA...FAaQ=='
```

`salt.modules.ssh.get_known_host(user, hostname, config=None, port=None)`
Return information about known host from the configfile, if any. If there is no such key, return None.

CLI Example:
```
salt '*' ssh.get_known_host <user> <hostname>
```

`salt.modules.ssh.hash_known_hosts(user=None, config=None)`
Hash all the hostnames in the known hosts file.

New in version 2014.7.0.

user hash known hosts of this user
config path to known hosts file: can be absolute or relative to user’s home directory

CLI Example:
salt '*r' ssh.hash_known_hosts

salt.modules.ssh.host_keys(keydir=None, private=True)
Return the minion’s host keys
CLI Example:

```
salt 'r' ssh.host_keys
salt 'r' ssh.host_keys keydir=/etc/ssh
salt 'r' ssh.host_keys keydir=/etc/ssh private=False
```

salt.modules.ssh.key_is_encrypted(key)
Function to determine whether or not a private key is encrypted with a passphrase.
Checks key for a Proc-Type header with ENCRYPTED in the value. If found, returns True, otherwise returns False.
CLI Example:

```
salt 'r' ssh.key_is_encrypted /root/id_rsa
```

salt.modules.ssh.recv_known_host(hostname, enc=None, port=None, hash_hostname=True, hash_known_hosts=True, timeout=5)
Retrieve information about host public key from remote server
hostname The name of the remote host (e.g. `github.com`)
enc Defines what type of key is being used, can be ed25519, ecdsa ssh-rsa or ssh-dss
port optional parameter, denoting the port of the remote host, which will be used in case, if the public key will be requested from it. By default the port 22 is used.
hash_hostname [True] Hash all hostnames and addresses in the known hosts file.

Depreciated since version Carbon: Please use hash_known_hosts instead.
hash_known_hosts [True] Hash all hostnames and addresses in the known hosts file.
timeout [int] Set the timeout for connection attempts. If timeout seconds have elapsed since a connection was initiated to a host or since the last time anything was read from that host, then the connection is closed and the host in question considered unavailable. Default is 5 seconds.

New in version 2016.3.0.
CLI Example:

```
salt 'r' ssh.recv_known_host <hostname> enc=<enc> port=<port>
```

salt.modules.ssh.rm_auth_key(user, key, config='.ssh/authorized_keys')
Remove an authorized key from the specified user's authorized key file
CLI Example:

```
salt 'r' ssh.rm_auth_key <user> <key>
```

salt.modules.ssh.rm_auth_key_from_file(user, source, config='.ssh/authorized_keys', saltenv='base', env=None)
Remove an authorized key from the specified user's authorized key file, using a file as source
CLI Example:

```
salt 'r' ssh.rm_auth_key_from_file <user> salt://ssh_keys/<user>.id_rsa.pub
```
salt.modules.ssh.rm_known_host(user=None, hostname=None, config=None, port=None)

Remove all keys belonging to hostname from a known_hosts file.

CLI Example:
```
salt '*' ssh.rm_known_host <user> <hostname>
```

salt.modules.ssh.set_auth_key(user, key, enc='ssh-rsa', comment='`', options=None, config='.ssh/authorized_keys', cache_keys=None)

Add a key to the authorized_keys file. The `key` parameter must only be the string of text that is the encoded key. If the key begins with `ssh-rsa` or ends with `user@host`, remove those from the key before passing it to this function.

CLI Example:
```
salt '*' ssh.set_auth_key <user> '<key>' enc='dsa'
```

salt.modules.ssh.set_auth_key_from_file(user, source, config='.ssh/authorized_keys', saltenv='base', env=None)

Add a key to the authorized_keys file, using a file as the source.

CLI Example:
```
salt '*' ssh.set_auth_key_from_file <user> salt://ssh_keys/<user>.id_rsa.pub
```

salt.modules.ssh.set_known_host(user=None, hostname=None, fingerprint=None, key=None, port=None, enc=None, hash_hostname=True, config=None, hash_known_hosts=True, timeout=5)

Download SSH public key from remote host `hostname`, optionally validate its fingerprint against `fingerprint` variable and save the record in the known_hosts file.

If such a record does already exists in there, do nothing.

user The user who owns the ssh authorized keys file to modify
hostname The name of the remote host (e.g. `github.com`)
fingerprint The fingerprint of the key which must be presented in the known_hosts file (optional if key specified)
key The public key which must be presented in the known_hosts file (optional if fingerprint specified)
port optional parameter, denoting the port of the remote host, which will be used in case, if the public key will be requested from it. By default the port 22 is used.
enc Defines what type of key is being used, can be ed25519, ecdsa ssh-rsa or ssh-dss
hashhostname [True] Hash all hostnames and addresses in the known hosts file.
hashknownhosts [True] Hash all hostnames and addresses in the known hosts file.
timeout [int] Set the timeout for connection attempts. If timeout seconds have elapsed since a connection was initiated to a host or since the last time anything was read from that host, then the connection is closed and the host in question considered unavailable. Default is 5 seconds.

Deprecated since version Carbon: Please use hash_known_hosts instead.

config The location of the authorized keys file relative to the user's home directory, defaults to `~/.ssh/known_hosts`. If no user is specified, defaults to `~/etc/ssh/ssh_known_hosts`. If present, must be an absolute path when a user is not specified.

New in version 2016.3.0.

CLI Example:
```
salt '*' ssh.set_known_host <user> fingerprint='xx:xx:..:xx' enc='ssh-rsa' config='~/.ssh/known_hosts'
```

salt.modules.ssh.user_keys(user=None,.pubfile=None,prvfile=None)

Return the user's ssh keys on the minion
New in version 2014.7.0.

CLI Example:

```
salt '*' ssh.user_keys
salt '*' ssh.user_keys user=user1
salt '*' ssh.user_keys user=user1 pubfile=/home/user1/.ssh/id_rsa.pub prvfile=/
~home/user1/.ssh/id_rsa
salt '*' ssh.user_keys user=user1 prvfile=False
salt '*' ssh.user_keys user=['user1','user2'] pubfile=id_rsa.pub prvfile=id_rsa
```

As you can see you can tell Salt not to read from the user's private (or public) key file by setting the file path to `False`. This can be useful to prevent Salt from publishing private data via Salt Mine or others.

### 13.6.300 `salt.modules.ssh_package` module

Service support for the REST example

```
salt.modules.ssh_package.install(name=None, refresh=False, fromrepo=None, pkgs=None, sources=None, **kwargs)
salt.modules.ssh_package.list_pkgs(versions_as_list=False, **kwargs)
salt.modules.ssh_package.remove(name=None, pkgs=None, **kwargs)
```

### 13.6.301 `salt.modules.ssh_service` module

Provide the service module for the proxy-minion SSH sample ...

```
salt.modules.ssh_service.enabled(name, sig=None)
    Only the `redbull' service is `enabled' in the test
salt.modules.ssh_service.get_all()
    Return a list of all available services
    CLI Example:
    ```
salt '*' service.get_all
    ```
salt.modules.ssh_service.list()
    Return a list of all available services.
    CLI Example:
    ```
salt '*' service.list
    ```
salt.modules.ssh_service.restart(name, sig=None)
    Restart the specified service with rest_sample CLI Example:
    ```
salt '*' service.restart <service name>
    ```
salt.modules.ssh_service.running(name, sig=None)
    Return whether this service is running.
    salt.modules.ssh_service.start(name, sig=None)
    Start the specified service on the rest_sample
    CLI Example:
    ```
Salt Documentation, Release 2016.3.6

salt '*' service.start <service name>

salt.modules.ssh_service.status(name, sig=None)
Return the status for a service via rest_sample, returns a bool whether the service is running.
CLI Example:
salt '*' service.status <service name>

salt.modules.ssh_service.stop(name, sig=None)
Stop the speciﬁed service on the rest_sample
CLI Example:
salt '*' service.stop <service name>

13.6.302 salt.modules.state
Control the state system on the minion.
State Caching
When a highstate is called, the minion automatically caches a copy of the last high data. If you then run a highstate
with cache=True it will use that cached highdata and won't hit the ﬁleserver except for salt:// links in the states
themselves.
salt.modules.state.apply(mods=None, **kwargs)
New in version 2015.5.0.
is function will call state.highstate or state.sls based on the arguments passed to this function.
It exists as a more intuitive way of applying states.
APPLYING ALL STATES CONFIGURED IN TOP.SLS (A.K.A. HIGHSTATE)
To apply all conﬁgured states, simply run state.apply:
salt '*' state.apply

e following additional arguments are also accepted when applying all states conﬁgured in top.sls:
test Run states in test-only (dry-run) mode
pillar Custom Pillar values, passed as a dictionary of key-value pairs
salt '*' state.apply test pillar='{"foo": "bar"}'

Note: Values passed this way will override Pillar values set via pillar_roots or an external Pillar
source.
queue [False] Instead of failing immediately when another state run is in progress, queue the new state run
to begin running once the other has ﬁnished.
is option starts a new thread for each queued state run, so use this option sparingly.

1518

Chapter 13. Salt Module Reference


Salt Documentation, Release 2016.3.6

localconﬁg Optionally, instead of using the minion conﬁg, load minion opts from the ﬁle speciﬁed by this
argument, and then merge them with the options from the minion conﬁg. is functionality allows
for speciﬁc states to be run with their own custom minion conﬁguration, including diﬀerent pillars,
ﬁle_roots, etc.
salt '*' state.apply localconfig=/path/to/minion.yml

APPLYING INDIVIDUAL SLS FILES (A.K.A. STATE.SLS)
To apply individual SLS ﬁles, pass them as a comma-separated list:
# Run the states configured in salt://test.sls (or salt://test/init.sls)
salt '*' state.apply test
# Run the states configured in salt://test.sls (or salt://test/init.sls)
# and salt://pkgs.sls (or salt://pkgs/init.sls).
salt '*' state.apply test,pkgs

e following additional arguments are also accepted when applying individual SLS ﬁles:
test Run states in test-only (dry-run) mode
pillar Custom Pillar values, passed as a dictionary of key-value pairs
salt '*' state.apply test pillar='{"foo": "bar"}'

Note: Values passed this way will override Pillar values set via pillar_roots or an external Pillar
source.
queue [False] Instead of failing immediately when another state run is in progress, queue the new state run
to begin running once the other has ﬁnished.
is option starts a new thread for each queued state run, so use this option sparingly.
concurrent [False] Execute state runs concurrently instead of serially
Warning: is ﬂag is potentially dangerous. It is designed for use when multiple state runs can
safely be run at the same time. Do not use this ﬂag for performance optimization.
saltenv [None] Specify a salt ﬁleserver environment to be used when applying states
Changed in version 0.17.0: Argument name changed from env to saltenv
Changed in version 2014.7.0: If no saltenv is speciﬁed, the minion conﬁg will be checked for an environment parameter and if found, it will be used. If none is found, base will be used. In prior
releases, the minion conﬁg was not checked and base would always be assumed when the saltenv was
not explicitly set.
pillarenv Specify a Pillar environment to be used when applying states. By default, all Pillar environments
will be merged together and used.
localconﬁg Optionally, instead of using the minion conﬁg, load minion opts from the ﬁle speciﬁed by this
argument, and then merge them with the options from the minion conﬁg. is functionality allows
for speciﬁc states to be run with their own custom minion conﬁguration, including diﬀerent pillars,
ﬁle_roots, etc.
salt '*' state.apply test localconfig=/path/to/minion.yml

salt.modules.state.check_request(name=None)
New in version 2015.5.0.
13.6. execution modules

1519


Return the state request information, if any

CLI Example:

```bash
salt '*' state.check_request
```

**salt.modules.state.clear_cache()**

Clear out cached state files, forcing even cache runs to refresh the cache on the next state execution.

Remember that the state cache is completely disabled by default, this execution only applies if cache=True is used in states

CLI Example:

```bash
salt '*' state.clear_cache
```

**salt.modules.state.clear_request(name=None)**

New in version 2015.5.0.

Clear out the state execution request without executing it

CLI Example:

```bash
salt '*' state.clear_request
```

**salt.modules.state.disable(states)**

Disable state runs.

CLI Example:

```bash
salt '*' state.disable highstate
salt '*' state.disable highstate,test.succeed_without_changes
```

**Note:** To disable a state file from running provide the same name that would be passed in a state.sls call.

```
salt '*' state.disable bind.config
```

**salt.modules.state.enable(states)**

Enable state function or sls run

CLI Example:

```bash
salt '*' state.enable highstate
salt '*' state.enable test.succeed_without_changes
```

**Note:** To enable a state file from running provide the same name that would be passed in a state.sls call.

```
salt '*' state.enable bind.config
```

**salt.modules.state.event(tagmatch='*', count=-1, quiet=False, sock_dir=None, pretty=False, node='minion')**

Watch Salt's event bus and block until the given tag is matched

New in version 2016.3.0.

This is useful for utilizing Salt's event bus from shell scripts or for taking simple actions directly from the CLI.
Enable debug logging to see ignored events.

Parameters

- **tagmatch** -- the event is written to stdout for each tag that matches this pattern; uses the same matching semantics as Salt's Reactor.
- **count** -- this number is decremented for each event that matches the **tagmatch** parameter; pass -1 to listen forever.
- **quiet** -- do not print to stdout; just block
- **sock_dir** -- path to the Salt master's event socket file.
- **pretty** -- Output the JSON all on a single line if False (useful for shell tools); pretty-print the JSON output if True.
- **node** -- Watch the minion-side or master-side event bus.

CLI Example:

```
salt-call --local state.event pretty=True
```

**salt.modules.state.high**(data=None, test=None, queue=False, **kwargs)

Execute the compound calls stored in a single set of high data

This function is mostly intended for testing the state system and is not likely to be needed in everyday usage.

CLI Example:

```
salt '*' state.high '{{"vim":{"pkg": ["installed"]}}}'
```

**salt.modules.state.highstate**(test=None, queue=False, **kwargs)

Retrieve the state data from the salt master for this minion and execute it

test Run states in test-only (dry-run) mode

pillar Custom Pillar values, passed as a dictionary of key-value pairs

```
salt '*' state.apply test pillar='{"foo": "bar"}''
```

**Note:** Values passed this way will override Pillar values set via pillar_roots or an external Pillar source.

Changed in version 2016.3.0: GPG-encrypted CLI Pillar data is now supported via the GPG renderer. See [here](#) for details.

**pillar_enc** Specify which renderer to use to decrypt encrypted data located within the pillar value. Currently, only gpg is supported.

New in version 2016.3.0.

**queue** [False] Instead of failing immediately when another state run is in progress, queue the new state run to begin running once the other has finished.

This option starts a new thread for each queued state run, so use this option sparingly.

**localconfig** Optionally, instead of using the minion config, load minion opts from the file specified by this argument, and then merge them with the options from the minion config. This functionality allows for specific states to be run with their own custom minion configuration, including different pillars, file_roots, etc.

**mock** The mock option allows for the state run to execute without actually calling any states. This then returns a mocked return which will show the requisite ordering as well as fully validate the state run.

New in version 2015.8.4.
CLI Examples:

```python
salt ',*' state.highstate
salt ',*' state.highstate whitelist=sls1_to_run,sls2_to_run
salt ',*' state.highstate exclude=sls_to_exclude
salt ',*' state.highstate exclude='[{'id': 'id_to_exclude'}, {'sls': 'sls_to_exclude'}]'
salt ',*' state.highstate pillar='{{foo: 'Foo!', bar: 'Bar!'}}'
```

```python
salt.modules.state.list_disabled()
List the states which are currently disabled
```

```python
salt ',*' state.list_disabled
```

```python
salt.modules.state.low(data, queue=False, **kwargs)
Execute a single low data call
```

```python
salt.modules.state.low '{"state": "pkg", "fun": "installed", "name": "vi"}"
```

```python
salt.modules.state.pkg(pkg_path, pkg_sum, hash_type, test=None, **kwargs)
Execute a packaged state run, the packaged state run will exist in a tarball available locally. This packaged state can be generated using salt-ssh.
```

```python
salt.modules.state.pkg /tmp/state_pkg.tgz
```

```python
salt.modules.state.request(mods=None, **kwargs)
New in version 2015.5.0.
```

```python
salt.modules.state.request test,pkgs
```

```python
salt.modules.state.run_request(name='default', **kwargs)
New in version 2015.5.0.
```

```python
salt.modules.state.run_request
```

```python
salt.modules.state.running(concurrent=False)
Return a list of strings that contain state return data if a state function is already running. This function is used to prevent multiple state calls from being run at the same time.
```

```python
salt ',*' state.run_request
```
```python
salt '*' state.running

salt.modules.state.show_highstate(queue=False, **kwargs)
Retrieve the highstate data from the salt master and display it
Custom Pillar data can be passed with the pillar kwarg.
CLI Example:
```

```python
salt '*' state.show_highstate

salt.modules.state.show_low_sls(mods, saltenv='base', test=None, queue=False, env=None, **kwargs)
Display the low data from a specific sls. The default environment is base, use saltenv (env in Salt 0.17.x and older) to specify a different environment.
CLI Example:
```

```python
salt '*' state.show_low_sls foo

salt.modules.state.show_lowstate(queue=False, **kwargs)
List out the low data that will be applied to this minion
CLI Example:
```

```python
salt '*' state.show_lowstate

salt.modules.state.show_sls(mods, saltenv=None, test=None, queue=False, env=None, **kwargs)
Display the state data from a specific sls or list of sls files on the master. The default environment is base, use saltenv (env in Salt 0.17.x and older) to specify a different environment.
This function does not support topfiles. For top.sls please use show_top instead.
Custom Pillar data can be passed with the pillar kwarg.
CLI Example:
```

```python
salt '*' state.show_sls core,edit.vim dev

salt.modules.state.show_top(queue=False, **kwargs)
Return the top data that the minion will use for a highstate
CLI Example:
```

```python
salt '*' state.show_top

salt.modules.state.single(fun, name, test=None, queue=False, **kwargs)
Execute a single state function with the named kwargs, returns False if insufficient data is sent to the command
By default, the values of the kwargs will be parsed as YAML. So, you can specify lists values, or lists of single entry key-value maps, as you would in a YAML salt file. Alternatively, JSON format of keyword values is also supported.
CLI Example:
```

```python
salt '*' state.single pkg.installed name=vim

salt.modules.state.sls(mods, saltenv=None, test=None, exclude=None, queue=False, env=None, pillarenv=None, **kwargs)
Execute the states in one or more SLS files
```
Salt Documentation, Release 2016.3.6

test Run states in test-only (dry-run) mode
pillar Custom Pillar values, passed as a dictionary of key-value pairs
salt '*' state.apply test pillar='{"foo": "bar"}'

Note: Values passed this way will override Pillar values set via pillar_roots or an external Pillar
source.
Changed in version 2016.3.0: GPG-encrypted CLI Pillar data is now supported via the GPG renderer. See
here for details.
pillar_enc Specify which renderer to use to decrypt encrypted data located within the pillar value. Currently, only gpg is supported.
New in version 2016.3.0.
queue [False] Instead of failing immediately when another state run is in progress, queue the new state run
to begin running once the other has ﬁnished.
is option starts a new thread for each queued state run, so use this option sparingly.
concurrent [False] Execute state runs concurrently instead of serially
Warning: is ﬂag is potentially dangerous. It is designed for use when multiple state runs can
safely be run at the same time. Do not use this ﬂag for performance optimization.
saltenv [None] Specify a salt ﬁleserver environment to be used when applying states
Changed in version 0.17.0: Argument name changed from env to saltenv.
Changed in version 2014.7.0: If no saltenv is speciﬁed, the minion conﬁg will be checked for an environment parameter and if found, it will be used. If none is found, base will be used. In prior
releases, the minion conﬁg was not checked and base would always be assumed when the saltenv was
not explicitly set.
pillarenv
Specify a Pillar environment to be used when applying states. By default, all Pillar environments
will be merged together and used.
localconﬁg
Optionally, instead of using the minion conﬁg, load minion opts from the ﬁle speciﬁed by this
argument, and then merge them with the options from the minion conﬁg. is functionality
allows for speciﬁc states to be run with their own custom minion conﬁguration, including diﬀerent
pillars, ﬁle_roots, etc.
mo: e mock option allows for the state run to execute without actually calling any states. is then
returns a mocked return which will show the requisite ordering as well as fully validate the state run.
New in version 2015.8.4.
CLI Example:
salt '*' state.sls core,edit.vim dev
salt '*' state.sls core exclude="[{'id': 'id_to_exclude'}, {'sls': 'sls_to_exclude
,→'}]"
salt '*' state.sls myslsfile pillar="{foo: 'Foo!', bar: 'Bar!'}"

salt.modules.state.sls_id(id_, mods, saltenv='base', test=None, queue=False, **kwargs)
Call a single ID from the named module(s) and handle all requisites

1524

Chapter 13. Salt Module Reference


New in version 2014.7.0.

CLI Example:

```
salt '*' state.sls_id apache http
```

**salt.modules.state.template** *(tem, queue=False, **kwargs)*

Execute the information stored in a template file on the minion.

This function does not ask a master for a SLS file to render but instead directly processes the file at the provided path on the minion.

CLI Example:

```
salt '*' state.template '<Path to template on the minion>'
```

**salt.modules.state.template_str** *(tem, queue=False, **kwargs)*

Execute the information stored in a string from an sls template

CLI Example:

```
salt '*' state.template_str '<Template String>'
```

**salt.modules.state.top** *(topfn, test=None, queue=False, saltenv=None, **kwargs)*

Execute a specific top file instead of the default. This is useful to apply configurations from a different environment (for example, dev or prod), without modifying the default top file.

CLI Example:

```
salt '*' state.top reverse_top.sls
salt '*' state.top prod_top.sls exclude=sls_to_exclude
salt '*' state.top dev_top.sls exclude="[{'id': 'id_to_exclude'}, {'sls': 'sls_to_!exclude'}]"
```

### 13.6.303  **salt.modules.status**

Module for returning various status data about a minion. These data can be useful for compiling into stats later.

**salt.modules.status.all_status()**

Return a composite of all status data and info for this minion. Warning: There is a LOT here!

CLI Example:

```
salt '*' status.all_status
```

**salt.modules.status.cpuinfo()**

.. versionchanged:: 2016.3.2 Return the CPU info for this minion

CLI Example:

```
salt '*' status.cpuinfo
```

**salt.modules.status.cpustats()**

Return the CPU stats for this minion

CLI Example:

```
salt '*' status.cpustats
```
salt.modules.status.custom()

Return a custom composite of status data and info for this minion, based on the minion config file. An example config like might be:

```
status.cpustats.custom: [ 'cpu', 'ctxt', 'btime', 'processes' ]
```

Where status refers to status.py, cpustats is the function where we get our data, and custom is this function. It is followed by a list of keys that we want returned.

This function is meant to replace all_status(), which returns anything and everything, which we probably don’t want.

By default, nothing is returned. Warning: Depending on what you include, there can be a LOT here!

CLI Example:

```
salt '*' status.custom
```

salt.modules.status.diskstats()

.. versionchanged:: 2016.3.2 Return the disk stats for this minion

CLI Example:

```
salt '*' status.diskstats
```

salt.modules.status.diskusage(*args)

Return the disk usage for this minion

Usage:

```
salt '*' status.diskusage [paths and/or filesystem types]
```

CLI Example:

```
salt '*' status.diskusage    # usage for all filesystems
salt '*' status.diskusage / /tmp # usage for / and /tmp
salt '*' status.diskusage ext? # usage for ext[234] filesystems
salt '*' status.diskusage / ext? # usage for / and all ext filesystems
```

salt.modules.status.loadavg()

Return the load averages for this minion

CLI Example:

```
salt '*' status.loadavg
```

salt.modules.status.master(master=None, connected=True)

New in version 2014.7.0.

Fire an event if the minion gets disconnected from its master. This function is meant to be run via a scheduled job from the minion. If master_ip is an FQDN/Hostname, it must be resolvable to a valid IPv4 address.

CLI Example:

```
salt '*' status.master
```

salt.modules.status.meminfo()

Return the memory info for this minion

CLI Example:
salt '*' status.meminfo

salt.modules.status.netdev()  
.versionchanged:: 2016.3.2 Return the network device stats for this minion  

CLI Example:

    salt '*' status.netdev

salt.modules.status.netstats()  
Return the network stats for this minion  

CLI Example:

    salt '*' status.netstats

salt.modules.status.nproc()  
Return the number of processing units available on this system  

CLI Example:

    salt '*' status.nproc

salt.modules.status.pid(sig)  
Return the PID or an empty string if the process is running or not. Pass a signature to use to find the process via ps. Note you can pass a Python-compatible regular expression to return all pids of processes matching the regexp.  

CLI Example:

    salt '*' status.pid <sig>

salt.modules.status.ping_master(master)  
New in version 2016.3.0.  
Sends ping request to the given master. Fires `__master_alive' event on success. Returns bool result.  

CLI Example:

    salt '*' status.ping_master localhost

salt.modules.status.procs()  
Return the process data  

CLI Example:

    salt '*' status.procs

salt.modules.status.time(format='\%A, \%d. \%B \%Y \%I:\%M\%p')  
New in version 2016.3.0.  
Return the current time on the minion, formatted based on the format parameter.  
Default date format: Monday, 27. July 2015 07:55AM  

CLI Example:

    salt '*' status.time

    salt '*' status.time '%s'
salt.modules.status.version()
Return the system version for this minion

CLI Example:
```
salt '*' status.version
```

salt.modules.status.vmstats()
.. versionchanged:: 2016.3.2 Return the virtual memory stats for this minion

CLI Example:
```
salt '*' status.vmstats
```

salt.modules.status.w()
Return a list of logged in users for this minion, using the w command

CLI Example:
```
salt '*' status.w
```

13.6.304 salt.modules.stormpath

Support for Stormpath
New in version 2015.8.0.

salt.modules.stormpath.create_account(directory_id, email, password, givenName, surname, **kwargs)
Create an account

CLI Examples:
salt myminion stormpath.create_account <directory_id> shemp@example.com letmein Shemp Howard

salt.modules.stormpath.delete_account(account_id)
Delete an account.

CLI Examples:
salt myminion stormpath.delete_account <account_id>

salt.modules.stormpath.list_accounts()
Show all accounts.

CLI Example:
salt myminion stormpath.list_accounts

salt.modules.stormpath.list_directories()
Show all directories.

CLI Example:
salt myminion stormpath.list_directories

salt.modules.stormpath.show_account(account_id=None, email=None, directory_id=None, application_id=None, group_id=None, **kwargs)
Show a specific account.

CLI Example:
salt myminion stormpath.show_account <account_id>
salt.modules.stormpath.show_tenant()
Get the tenant for the login being used.

salt.modules.stormpath.update_account(account_id, key=None, value=None, items=None)
Update one or more items for this account. Specifying an empty value will clear it for that account.

CLI Examples:
```
salt myminion stormpath.update_account <account_id> givenName shemp
salt myminion stormpath.update_account <account_id> middleName "salt
salt myminion stormpath.update_account <account_id> items='{`givenName": "Shemp"}"
salt myminion stormpath.update_account <account_id> items='{`middleName": ""}"
```

13.6.305 salt.modules.supervisord

Provide the service module for system supervisord or supervisord in a virtualenv

salt.modules.supervisord.add(name, user=None, conf_file=None, bin_env=None)
Activates any updates in config for process/group.
user user to run supervisorctl
conf_file path to supervisord config file
bin_env path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:
```
salt '*' supervisord.add <name>
```

salt.modules.supervisord.custom(command, user=None, conf_file=None, bin_env=None)
Run any custom supervisord command
user user to run supervisorctl
conf_file path to supervisord config file
bin_env path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:
```
salt '*' supervisord.custom "mstop '*gunicorn*'"
```

salt.modules.supervisord.options(name, conf_file=None)
New in version 2014.1.0.
Read the config file and return the config options for a given process
name Name of the configured process
conf_file path to supervisord config file

CLI Example:
```
salt '*' supervisord.options foo
```

salt.modules.supervisord.remove(name, user=None, conf_file=None, bin_env=None)
Removes process/group from active config
user user to run supervisorctl
conf_file path to supervisord config file
bin_env path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:
```
salt '*' supervisord.remove <name>
```

salt.modules.supervisord.reread(user=None, conf_file=None, bin_env=None)
Reload the daemon's configuration files
user user to run supervisorctl

13.6. execution modules
conf_file  path to supervisord config file
bin_env  path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:

```
salt 'salt' supervisorctl.reread
```

salt.modules.supervisord.restart(name='all', user=None, conf_file=None, bin_env=None)

Restart the named service. Process group names should not include a trailing asterisk.

user  user to run supervisorctl as
conf_file  path to supervisord config file
bin_env  path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:

```
salt 'salt' supervisorctl.restart <service>
salt 'salt' supervisorctl.restart <group>:
```

salt.modules.supervisord.start(name='all', user=None, conf_file=None, bin_env=None)

Start the named service. Process group names should not include a trailing asterisk.

user  user to run supervisorctl as
conf_file  path to supervisord config file
bin_env  path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:

```
salt 'salt' supervisorctl.start <service>
salt 'salt' supervisorctl.start <group>:
```

salt.modules.supervisord.status(name=None, user=None, conf_file=None, bin_env=None)

List programs and its state

user  user to run supervisorctl as
conf_file  path to supervisord config file
bin_env  path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:

```
salt 'salt' supervisorctl.status
```

salt.modules.supervisord.status_raw(name=None, user=None, conf_file=None, bin_env=None)

Display the raw output of status

user  user to run supervisorctl as
conf_file  path to supervisord config file
bin_env  path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:

```
salt 'salt' supervisorctl.status_raw
```

salt.modules.supervisord.stop(name='all', user=None, conf_file=None, bin_env=None)

Stop the named service. Process group names should not include a trailing asterisk.

user  user to run supervisorctl as
conf_file  path to supervisord config file
bin_env  path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:

```
salt 'salt' supervisorctl.stop <service>
salt 'salt' supervisorctl.stop <group>:
```

salt.modules.supervisord.update(user=None, conf_file=None, bin_env=None)

Reload config and add/remove as necessary
user  user to run supervisorctl as
conf_file  path to supervisord config file
bin_env  path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:
salt '*/' supervisord.update

13.6.306  salt.modules.svn

Subversion SCM

salt.modules.svn.add(cwd, targets=None, user=None, username=None, password=None, *opts)
Add files to be tracked by the Subversion working-copy checkout

cwd  The path to the Subversion repository

targets  [None] files and directories to pass to the command as arguments

CLI Example:
salt '*/' svn.add /path/to/repo /path/to/new/file

salt.modules.svn.checkout(cwd, remote=None, target=None, user=None, username=None, password=None, *opts)
Download a working copy of the remote Subversion repository directory or file

cwd  The path to the Subversion repository

remote  [None] URL to checkout
target  [None] The name to give the file or directory working copy Default: svn uses the remote basename

CLI Example:
salt '*/' svn.checkout /path/to/repo svn://remote/repo

salt.modules.svn.commit(cwd, targets=None, msg=None, user=None, username=None, password=None, *opts)
Commit the current directory, files, or directories to the remote Subversion repository

cwd  The path to the Subversion repository

CLI Example:
salt '*/' svn.commit /path/to/repo

salt.modules.svn.diff(cwd, targets=None, user=None, username=None, password=None, *opts)
Return the diff of the current directory, files, or directories from the remote Subversion repository
cwd  The path to the Subversion repository

targets  [None] files and directories to pass to the command as arguments Default: svn uses ‘.’

user  [None] Run svn as a user other than what the minion runs as

username  [None] Connect to the Subversion server as another user

password  [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:

```bash
salt '*' svn.diff /path/to/repo
```

salt.modules.svn.export(cwd, remote, target=None, user=None, username=None, password=None, revision='HEAD', *opts)

Create an unversioned copy of a tree.

cwd  The path to the Subversion repository

remote  [None] URL and path to file or directory checkout

target  [None] The name to give the file or directory working copy Default: svn uses the remote basename

user  [None] Run svn as a user other than what the minion runs as

username  [None] Connect to the Subversion server as another user

password  [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:

```bash
salt '*' svn.export /path/to/repo svn://remote/repo
```

salt.modules.svn.info(cwd, targets=None, user=None, username=None, password=None, fmt='str')

Display the Subversion information from the checkout.

cwd  The path to the Subversion repository

targets  [None] files, directories, and URLs to pass to the command as arguments svn uses ‘.’ by default

user  [None] Run svn as a user other than what the minion runs as

username  [None] Connect to the Subversion server as another user

password  [None] Connect to the Subversion server with this password

New in version 0.17.0.

fmt  [str] How to fmt the output from info. (str, xml, list, dict)

CLI Example:

```bash
salt '*' svn.info /path/to/svn/repo
```

salt.modules.svn.remove(cwd, targets, msg=None, user=None, username=None, password=None, *opts)

Remove files and directories from the Subversion repository

cwd  The path to the Subversion repository

targets  [None] files, directories, and URLs to pass to the command as arguments

msg  [None] Message to attach to the commit log

user  [None] Run svn as a user other than what the minion runs as

username  [None] Connect to the Subversion server as another user

password  [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:

```bash
salt '*' svn.remove /path/to/repo /path/to/repo/remove
```

salt.modules.svn.status(cwd, targets=None, user=None, username=None, password=None, *opts)

Display the status of the current directory, files, or directories in the Subversion repository
cwd  The path to the Subversion repository

targets  [None] files, directories, and URLs to pass to the command as arguments Default: svn uses ".":

user  [None] Run svn as a user other than what the minion runs as

username  [None] Connect to the Subversion server as another user

password  [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:

```
salt '*' svn.status /path/to/repo
```

salt.modules.svn.switch(cwd, remote, target=None, user=None, username=None, password=None, *opts)

New in version 2014.1.0.

Switch a working copy of a remote Subversion repository directory

```
cwd  The path to the Subversion repository
remote  [None] URL to switch
target  [None] The name to give the file or directory working copy Default: svn uses the remote basename
user  [None] Run svn as a user other than what the minion runs as
username  [None] Connect to the Subversion server as another user
password  [None] Connect to the Subversion server with this password
```

CLI Example:

```
salt '*' svn.switch /path/to/repo svn://remote/repo
```

salt.modules.svn.update(cwd, targets=None, user=None, username=None, password=None, *opts)

Update the current directory, files, or directories from the remote Subversion repository

```
cwd  The path to the Subversion repository
targets  [None] files and directories to pass to the command as arguments Default: svn uses ".":
user  [None] Run svn as a user other than what the minion runs as
password  [None] Connect to the Subversion server with this password
```

New in version 0.17.0.

```
username  [None] Connect to the Subversion server as another user
```

CLI Example:

```
salt '*' svn.update /path/to/repo
```

13.6.307  salt.modules.swift

Module for handling OpenStack Swift calls

Author: Anthony Stanton <anthony.stanton@gmail.com>

Inspired by the S3 and Nova modules

```
depends
```

```
  - swiftclient Python module
```

configuration  This module is not usable until the user, tenant, auth URL, and password or auth_key are specified either in a pillar or in the minion's config file. For example:

```
keystone.user: admin
keystone.tenant: admin
keystone.auth_url: 'http://127.0.0.1:5000/v2.0/
keystone.password: verybadpass
# or
keystone.auth_key: 203802934809284k2j34lkj2l3kj43k
```
If configuration for multiple OpenStack accounts is required, they can be set up as different configuration profiles: For example:

openstack1:
  keystone.user: admin
  keystone.tenant: admin
  keystone.auth_url: 'http://127.0.0.1:5000/v2.0/'
  keystone.password: verybadpass
  # or
  keystone.auth_key: 203802934809284k2j34lkj2l3kj43k

openstack2:
  keystone.user: admin
  keystone.tenant: admin
  keystone.auth_url: 'http://127.0.0.2:5000/v2.0/'
  keystone.password: verybadpass
  # or
  keystone.auth_key: 303802934809284k2j34lkj2l3kj43k

With this configuration in place, any of the swift functions can make use of a configuration profile by declaring it explicitly. For example:

salt 'salt' swift.get mycontainer myfile /tmp/file profile=openstack1

NOTE: For Rackspace cloud files setting keystone.auth_version = 1 is recommended.

salt.modules.swift.delete(cont, path=None, profile=None)
Delete a container, or delete an object from a container.

CLI Example to delete a container:
salt myminion swift.delete mycontainer

CLI Example to delete an object from a container:
salt myminion swift.delete mycontainer remoteobject

salt.modules.swift.get(cont=None, path=None, local_file=None, return_bin=False, profile=None)
List the contents of a container, or return an object from a container. Set return_bin to True in order to retrieve an object wholesale. Otherwise, Salt will attempt to parse an XML response.

CLI Example to list containers:
salt myminion swift.get

CLI Example to list the contents of a container:
salt myminion swift.get mycontainer

CLI Example to return the binary contents of an object:
salt myminion swift.get mycontainer myfile.png return_bin=True

CLI Example to save the binary contents of an object to a local file:
salt myminion swift.get mycontainer myfile.png local_file=/tmp/myfile.png
salt.modules.swift.head()
salt.modules.swift.put(cont, path=None, local_file=None, profile=None)

Create a new container, or upload an object to a container.

CLI Example to create a container:
```
salt myminion swift.put mycontainer
```

CLI Example to upload an object to a container:
```
salt myminion swift.put mycontainer remotepath local_file=/path/to/file
```

13.6.308 salt.modules.sysbench

The 'sysbench' module is used to analyze the performance of the minions, right from the master! It measures various system parameters such as CPU, Memory, File I/O, Threads and Mutex.

salt.modules.sysbench.cpu()
Tests for the CPU performance of minions.
CLI Examples:
```
salt '*' sysbench.cpu
```

salt.modules.sysbench.fileio()
This tests for the file read and write operations. Various modes of operations are:
- sequential write
- sequential rewrite
- sequential read
- random read
- random write
- random read and write
The test works with 32 files with each file being 1Gb in size. The test consumes a lot of time. Be patient!
CLI Examples:
```
salt '*' sysbench.fileio
```

salt.modules.sysbench.memory()
This tests the memory for read and write operations.
CLI Examples:
```
salt '*' sysbench.memory
```

salt.modules.sysbench.mutex()
Tests the implementation of mutex
CLI Examples:
```
salt '*' sysbench.mutex
```

salt.modules.sysbench.ping()
salt.modules.sysbench.threads()
This tests the performance of the processor's scheduler
CLI Example:
13.6.309  salt.modules.sysfs module

Module for interfacing with SysFS

See also:
https://www.kernel.org/doc/Documentation/filesystems/sysfs.txt

New in version 2016.3.0.

salt.modules.sysfs.attr(key, value=None)
Access/write a SysFS attribute. If the attribute is a symlink, its destination is returned

Returns  value or bool

CLI example:
salt '*' sysfs.attr block/sda/queue/logical_block_size

salt.modules.sysfs.interfaces(root)
Generate a dictionary with all available interfaces relative to root. Symlinks are not followed.

CLI example:
salt '*' sysfs.interfaces block/bcache0/bcache

Output example:

```json
{
    "r": [
        "state",
        "partial_stripes_expensive",
        "writeback_rate_debug",
        "stripe_size",
        "dirty_data",
        "stats_total/cache_hits",
        "stats_total/cache_bypass_misses",
        "stats_total/bypassed",
        "stats_total/cache_readahead",
        "stats_total/cache_hit_ratio",
        "stats_total/cache_miss_collisions",
        "stats_total/cache_misses",
        "stats_total/cache_bypass_hits",
    ],
    "rw": [
        "writeback_rate",
        "writeback_rate_update_seconds",
        "cache_mode",
        "writeback_delay",
        "label",
        "writeback_running",
        "writeback_metadata",
        "running",
        "writeback_rate_p_term_inverse",
        "sequential_cutoff",
        "writeback_percent",
        "writeback_rate_d_term",
        "readahead"
    ]
}
```
Note:
• `r` interfaces are read-only
• `w` interfaces are write-only (e.g. actions)
• `rw` are interfaces that can both be read or written

salt.modules.sysfs.read(key, root='')
Read from SysFS
Parameters
key -- file or path in SysFS; if key is a list then root will be prefixed on each key
Returns the full (tree of) SysFS attributes under key

CLI example:
salt '*' sysfs.read class/net/em1/statistics

salt.modules.sysfs.target(key, full=True)
Return the basename of a SysFS key path
Parameters
  • key -- the location to resolve within SysFS
  • full -- full path instead of basename
Returns fullpath or basename of path

CLI example:
salt '*' sysfs.read class/ttyS0

salt.modules.sysfs.write(key, value)
Write a SysFS attribute/action

CLI example:
salt '*' sysfs.write devices/system/cpus/cpu0/cpufreq/scaling_governor
  ~'performance'

13.6.310 salt.modules.syslog_ng

Module for getting information about syslog-ng

maintainer Tibor Benke <btibi@sch.bme.hu>
maturity new
depends cmd
platform all
This module is capable of managing syslog-ng instances which were installed via a package manager or from source. Users can use a directory as a parameter in the case of most functions, which contains the syslog-ng and syslog-ng-ctl binaries.

Syslog-ng can be installed via a package manager or from source. In the latter case, the syslog-ng and syslog-ng-ctl binaries are not available from the PATH, so users should set location of the sbin directory with `syslog_ng.set_binary_path`.

Similarly, users can specify the location of the configuration file with `syslog_ng.set_config_file`, then the module will use it. If it is not set, syslog-ng uses the default configuration file.

class salt.modules.syslog_ng.Ar...ng.NamedStatement

It represents a configuration statement, which has a name, e.g. a source.

Does not need examples.

class salt.modules.syslog_ng.Option

A Statement class contains Option instances.

An instance of Option can represent a file(), tcp(), udp(), etc. option.

Does not need examples.

class salt.modules.syslog_ng.Parameter

An Option has one or more Parameter instances.

Does not need examples.
class salt.modules.syslog_ng.ParameterValue
    iterable=None, join_body_on='`

A TypedParameter can have one or more values.

Does not need examples.

class salt.modules.syslog_ng.SimpleParameter
    value='`

A Parameter is a SimpleParameter, if it's just a simple type, like a string.

For example:

destination d_file {
    file( '/var/log/messages'
    );
};

/var/log/messages is a SimpleParameter.

Does not need examples.

build()

class salt.modules.syslog_ng.SimpleParameterValue
    value='`

A ParameterValue which holds a simple type, like a string or a number.

For example in ip(127.0.0.1) 127.0.0.1 is a SimpleParameterValue.

Does not need examples.

build()

class salt.modules.syslog_ng.Statement
    type='`, id='`, options=None, has_name=True

It represents a syslog-ng configuration statement, e.g. source, destination, filter.

Does not need examples.

add_child(option)
build_header()
build_tail()

exception salt.modules.syslog_ng.SyslogNgError

class salt.modules.syslog_ng.TypedParameter
    type='`, values=None

A Parameter, which has a type:

destination d_tcp {
    tcp( 
        ip(127.0.0.1)
    );
};

ip(127.0.0.1) is a TypedParameter.

Does not need examples.

add_value(value)
build()

class salt.modules.syslog_ng.TypedParameterValue
    type='`, arguments=None

We have to go deeper...

A TypedParameter can have a `parameter`, which also have a type. For example key_file and cert_file:
source demo_tls_source {
  tcp(
    ip(0.0.0.0)
    port(1999)
    tls(
      key_file('/opt/syslog-ng/etc/syslog-ng/key.d/syslog-ng.key')
      cert_file('/opt/syslog-ng/etc/syslog-ng/cert.d/syslog-ng.cert')
    )
  );
};

Does not need examples.

add_argument(arg)

build()

class salt.modules.syslog_ng.UnnamedStatement(type, options=None)
  It represents a configuration statement, which doesn't have a name, e.g. a log path.

  Does not need examples.

salt.modules.syslog_ng.config(name, config, write=True)
  Builds syslog-ng configuration. This function is intended to be used from the state module, users should not use it directly!

  name : the id of the Salt document or it is the format of <statement name>.id
  config : the parsed YAML code
  write : if True, it writes the config into the configuration file, otherwise just returns it

  CLI Example:

  salt '*' syslog_ng.config name='s_local' config="[{'tcp':[{'ip':'127.0.0.1'},
       {'port':1233}]}]"

salt.modules.syslog_ng.config_test(syslog_ng_sbin_dir=None, cfgfile=None)
  Runs syntax check against cfgfile. If syslog_ng_sbin_dir is specified, it is added to the PATH during the test.

  CLI Example:

  salt '*' syslog_ng.config_test
  salt '*' syslog_ng.config_test /home/user/install/syslog-ng/sbin
  salt '*' syslog_ng.config_test /home/user/install/syslog-ng/sbin /etc/syslog-ng/
      syslog-ng.conf

salt.modules.syslog_ng.get_config_file()
  Returns the configuration directory, which contains syslog-ng.conf.

  CLI Example:

  salt '*' syslog_ng.get_config_file

salt.modules.syslog_ng.modules(syslog_ng_sbin_dir=None)
  Returns the available modules. If syslog_ng_sbin_dir is specified, it is added to the PATH during the execution of the command syslog-ng.

  CLI Example:

  salt '*' syslog_ng.modules
  salt '*' syslog_ng.modules /home/user/install/syslog-ng/sbin
salt.modules.syslog_ng.reload(name)
Reloads syslog-ng. This function is intended to be used from states.

If syslog_ng.set_config_file, is called before, this function will use the set binary path.

CLI Example:
```
salt '*' syslog_ng.reload
```

salt.modules.syslog_ng.set_binary_path(name)
Sets the path, where the syslog-ng binary can be found. This function is intended to be used from states.

If syslog-ng is installed via a package manager, users don’t need to use this function.

CLI Example:
```
salt '*' syslog_ng.set_binary_path name=/usr/sbin
```

salt.modules.syslog_ng.set_config_file(name)
Sets the configuration’s name. This function is intended to be used from states.

CLI Example:
```
salt '*' syslog_ng.set_config_file name=/etc/syslog-ng
```

salt.modules.syslog_ng.set_parameters(version=None, binary_path=None, config_file=None, *args, **kwargs)
Sets variables.

CLI Example:
```
salt '*' syslog_ng.set_parameters version='3.6'
salt '*' syslog_ng.set_parameters binary_path=/home/user/install/syslog-ng/sbin
  config_file=/home/user/install/syslog-ng/etc/syslog-ng.conf
```

salt.modules.syslog_ng.start(name=None, user=None, group=None, chroot=None, caps=None, no_caps=False, pidfile=None, enable_core=False, fd_limit=None, verbose=False, debug=False, trace=False, yydebug=False, persist_file=None, control=None, worker_threads=None)
Ensures, that syslog-ng is started via the given parameters. This function is intended to be used from the state module.

Users shouldn’t use this function, if the service module is available on their system. If syslog_ng.set_config_file, is called before, this function will use the set binary path.

CLI Example:
```
salt '*' syslog_ng.start
```

salt.modules.syslog_ng.stats(syslog_ng_sbin_dir=None)
Returns statistics from the running syslog-ng instance. If syslog_ng_sbin_dir is specified, it is added to the PATH during the execution of the command syslog-ng-ctl.

CLI Example:
```
salt '*' syslog_ng.stats
salt '*' syslog_ng.stats /home/user/install/syslog-ng/sbin
```

salt.modules.syslog_ng.stop(name=None)
Kills syslog-ng. This function is intended to be used from the state module.
Users shouldn't use this function, if the service module is available on their system. If `syslog_ng.set_config_file` is called before, this function will use the set binary path.

CLI Example:
```
salt '*' syslog_ng.stop
```

**salt.modules.syslog_ng.version** *(syslog_ng_sbin_dir=None)*  
Returns the version of the installed syslog-ng. If syslog_ng_sbin_dir is specified, it is added to the PATH during the execution of the command syslog-ng.

CLI Example:
```
salt '*' syslog_ng.version
salt '*' syslog_ng.version /home/user/install/syslog-ng/sbin
```

**salt.modules.syslog_ng.write_config** *(config, newlines=2)*  
Writes the given parameter config into the config file. This function is intended to be used from states.

If `syslog_ng.set_config_file`, is called before, this function will use the set config file.

CLI Example:
```
salt '*' syslog_ng.write_config config=# comment
```

**salt.modules.syslog_ng.write_version** *(name)*  
Removes the previous configuration file, then creates a new one and writes the name line. This function is intended to be used from states.

If `syslog_ng.set_config_file`, is called before, this function will use the set config file.

CLI Example:
```
salt '*' syslog_ng.write_version name="3.6"
```

### 13.6.311 salt.modules.sysmod

The sys module provides information about the available functions on the minion

**salt.modules.sysmod.argspec** *(module='')*  
Return the argument specification of functions in Salt execution modules.

CLI Example:
```
salt '*' sys.argspec pkg.install
salt '*' sys.argspec sys
salt '*' sys.argspec
```

Module names can be specified as globs.

New in version 2015.5.0.
```
salt '*' sys.argspec 'pkg.*'
```

**salt.modules.sysmod.doc** *(args)*  
Return the docstrings for all modules. Optionally, specify a module or a function to narrow the selection.

The strings are aggregated into a single document on the master for easy reading.

Multiple modules/functions can be specified.
CLI Example:

```shell
salt '*' sys.doc
salt '*' sys.doc sys
salt '*' sys.doc sys.doc
salt '*' sys.doc network.traceroute user.info
```

Modules can be specified as globs.

New in version 2015.5.0.

```shell
salt '*' sys.doc 'sys.*'
salt '*' sys.doc 'sys.list_*'
```

```

salt.modules.sysmod.list_functions(*args, **kwargs)

List the functions for all modules. Optionally, specify a module or modules from which to list.

CLI Example:

```shell
salt '*' sys.list_functions
salt '*' sys.list_functions sys
salt '*' sys.list_functions sys user
```

Function names can be specified as globs.

New in version 2015.5.0.

```shell
salt '*' sys.list_functions 'sys.list_*'
```

```

salt.modules.sysmod.list_modules(*args)

List the modules loaded on the minion

New in version 2015.5.0.

CLI Example:

```shell
salt '*' sys.list_modules
```

Module names can be specified as globs.

```shell
salt '*' sys.list_modules 's*' 
```

```

salt.modules.sysmod.list_renderers(*args)

List the renderers loaded on the minion

New in version 2015.5.0.

CLI Example:

```shell
salt '*' sys.list_renderers
```

Render names can be specified as globs.

```shell
salt '*' sys.list_renderers 'yaml*'
```

```

salt.modules.sysmod.list_returner_functions(*args, **kwargs)

List the functions for all returner modules. Optionally, specify a returner module or modules from which to list.

New in version 2014.7.0.

```

13.6. execution modules 1543
CLI Example:

```
salt '*' sys.list_returner_functions
salt '*' sys.list_returner_functions mysql
salt '*' sys.list_returner_functions mysql etcd
```

Returner names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.list_returner_functions 'sqlite3.get_*'
```

**salt.modules.sysmod.list_returners**(*args*)

List the returners loaded on the minion

New in version 2014.7.0.

CLI Example:

```
salt '*' sys.list_returners
```

Returner names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.list_returners 's*'`
```

**salt.modules.sysmod.list_runner_functions**(*args, **kwargs*)

List the functions for all runner modules. Optionally, specify a runner module or modules from which to list.

New in version 2014.7.0.

CLI Example:

```
salt '*' sys.list_runner_functions
salt '*' sys.list_runner_functions state
salt '*' sys.list_runner_functions state virt
```

Runner function names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.list_runner_functions 'state.*' 'virt.*'
```

**salt.modules.sysmod.list_runners**(*args*)

List the runners loaded on the minion

New in version 2014.7.0.

CLI Example:

```
salt '*' sys.list_runners
```

Runner names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.list_runners 'm*'
```

**salt.modules.sysmod.list_state_functions**(*args, **kwargs*)

List the functions for all state modules. Optionally, specify a state module or modules from which to list.
New in version 2014.7.0.

CLI Example:

```
salt '*' sys.list_state_functions
salt '*' sys.list_state_functions file
salt '*' sys.list_state_functions pkg user
```

State function names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.list_state_functions 'file.*'
salt '*' sys.list_state_functions 'file.s*' 
```

```
salt.modules.sysmod.list_state_modules(*args)
List the modules loaded on the minion
New in version 2014.7.0.

CLI Example:

```
salt '*' sys.list_state_modules
```

State module names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.list_state_modules 'mysql_*'
```

```
salt.modules.sysmod.reload_modules()
Tell the minion to reload the execution modules
New in version 2014.7.0.

CLI Example:

```
salt '*' sys.reload_modules
```

```
salt.modules.sysmod.renderer_doc(*args)
Return the docstrings for all renderers. Optionally, specify a renderer or a function to narrow the selection.
The strings are aggregated into a single document on the master for easy reading.
Multiple renderers can be specified.
New in version 2015.5.0.

CLI Example:

```
salt '*' sys.renderer_doc
salt '*' sys.renderer_doc cheetah
salt '*' sys.renderer_doc jinja json
```

Renderer names can be specified as globs.

```
salt '*' sys.renderer_doc 'c*' 'j*'
```

```
salt.modules.sysmod.returner_argspec(module='')
Return the argument specification of functions in Salt returner modules.
New in version 2015.5.0.

CLI Example:
Returner names can be specified as globs.

```
salt '*' sys.returner_argspec '*sqlite3.*'
```

```
salt.modules.sysmod.returner_doc(*args)
Return the docstrings for all returners. Optionally, specify a returner or a function to narrow the selection.

The strings are aggregated into a single document on the master for easy reading.

Multiple returners/functions can be specified.

New in version 2014.7.0.

CLI Example:
```
salt '*' sys.returner_doc
salt '*' sys.returner_doc sqlite3
salt '*' sys.returner_doc sqlite3.get_fun
salt '*' sys.returner_doc sqlite3.get_fun etcd.get_fun
```

Returner names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.returner_doc '*sqlite3.get_*'
```

```
salt.modules.sysmod.runner_argspec(module='`)
Return the argument specification of functions in Salt runner modules.

New in version 2015.5.0.

CLI Example:
```
salt '*' sys.runner_argspec state
salt '*' sys.runner_argspec http
salt '*' sys.runner_argspec
```

Runner names can be specified as globs.

```
salt '*' sys.runner_argspec '*winrepo.*'
```

```
salt.modules.sysmod.runner_doc(*args)
Return the docstrings for all runners. Optionally, specify a runner or a function to narrow the selection.

The strings are aggregated into a single document on the master for easy reading.

Multiple runners/functions can be specified.

New in version 2014.7.0.

CLI Example:
```
salt '*' sys.runner_doc
salt '*' sys.runner_doc cache
salt '*' sys.runner_doc cache.grains
salt '*' sys.runner_doc cache.grains mine.get
```
Runner names can be specified as globs.

New in version 2015.5.0.

```
salt '* sys.runner_doc 'cache.clear_*'`
```

```
salt.modules.sysmod.state_argspec(module='')
Return the argument specification of functions in Salt state modules.
New in version 2015.5.0.

CLI Example:
```
salt '*' sys.state_argspec pkg.installed
salt '*' sys.state_argspec file
salt '*' sys.state_argspec
```

State names can be specified as globs.

```
salt '*' sys.state_argspec 'pkg.*'
```

```
salt.modules.sysmod.state_doc("args")
Return the docstrings for all states. Optionally, specify a state or a function to narrow the selection.
The strings are aggregated into a single document on the master for easy reading.
Multiple states/functions can be specified.
New in version 2014.7.0.

CLI Example:
```
salt '*' sys.state_doc
salt '*' sys.state_doc service
salt '*' sys.state_doc service.running
salt '*' sys.state_doc service.running_ipables.append
```

State names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.state_doc 'service.*' 'iptables.*'
```

```
salt.modules.sysmod.state_schema(module='')
Return a JSON Schema for the given state function(s)
New in version 2016.3.0.

CLI Example:
```
salt '*' sys.state_schema
salt '*' sys.state_schema pkg.installed
```

13.6.312 salt.modules.sysrc

sysrc module for FreeBSD

```
salt.modules.sysrc.get(**kwargs)
Return system rc configuration variables
```

CLI Example:
salt '*' sysrc.get includeDefaults=True

salt.modules.sysrc.remove(name, **kwargs)
Remove system rc configuration variables

CLI Example:

    salt '*' sysrc.remove name=sshd_enable

salt.modules.sysrc.set(name, value, **kwargs)
Set system rc configuration variables

CLI Example:

    salt '*' sysrc.set name=sshd_flags value="-p 2222"

13.6.313 salt.modules.system

Support for reboot, shutdown, etc

salt.modules.system.halt()
Halt a running system

CLI Example:

    salt '*' system.halt

salt.modules.system.init(runlevel)
Change the system runlevel on sysV compatible systems

CLI Example:

    salt '*' system.init 3

salt.modules.system.poweroff()
Poweroff a running system

CLI Example:

    salt '*' system.poweroff

salt.modules.system.reboot(at_time=None)
Reboot the system
at_time  The wait time in minutes before the system will be rebooted.

CLI Example:

    salt '*' system.reboot

salt.modules.system.shutdown(at_time=None)
Shutdown a running system
at_time  The wait time in minutes before the system will be shutdown.

CLI Example:

    salt '*' system.shutdown 5
13.6.314  salt.modules.system_profiler

System Profiler Module

Interface with Mac OSX's command-line System Profiler utility to get information about package receipts and installed applications.

New in version 2015.5.0.

salt.modules.system_profiler.applications()

Return the results of a call to `system_profiler -xml -detail full SPApplicationsDataType` as a dictionary. Top-level keys of the dictionary are the names of each set of install receipts, since there can be multiple receipts with the same name. Contents of each key are a list of dictionaries.

Note that this can take a long time depending on how many applications are installed on the target Mac.

CLI Example:

```
salt '*' systemprofiler.applications
```

salt.modules.system_profiler.receipts()

Return the results of a call to `system_profiler -xml -detail full SPInstallHistoryDataType` as a dictionary. Top-level keys of the dictionary are the names of each set of install receipts, since there can be multiple receipts with the same name. Contents of each key are a list of dictionaries.

CLI Example:

```
salt '*' systemprofiler.receipts
```

13.6.315  salt.modules.systemd

Provides the service module for systemd

New in version 0.10.0.

**Important:** If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `service.start' is not available), see [here](#).

salt.modules.systemd.available(name)

New in version 0.10.4.

Check that the given service is available taking into account template units.

CLI Example:

```
salt '*' service.available sshd
```

salt.modules.systemd.disable(name, **kwargs)

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands run by this function from the `salt-minion` daemon's control group. This is done to avoid a race condition in cases where the `salt-minion` service is restarted while a service is being modified. If desired, usage of `systemd-run(1)` can be suppressed by setting a config option called `systemd.scope`, with a value of `False` (no quotes).

Disable the named service to not start when the system boots

CLI Example:
salt 's' service.disable <service name>

salt.modules.systemd.disabled(name)
   Return if the named service is disabled from starting on boot
   
   CLI Example:
   
   salt 's' service.disabled <service name>

salt.modules.systemd.enable(name, **kwargs)
   Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205,
   systemd-run(1) is now used to isolate commands run by this function from the salt-minion daemon's control group. This is
done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of systemd-run(1) can be suppressed by setting a config option called
systemd.scope, with a value of False (no quotes).

   Enable the named service to start when the system boots
   
   CLI Example:
   
   salt 's' service.enable <service name>

salt.modules.systemd.enabled(name, **kwargs)
   Return if the named service is enabled to start on boot
   
   CLI Example:
   
   salt 's' service.enabled <service name>

salt.modules.systemd.execs()
   New in version 2014.7.0.

   Return a list of all files specified as ExecStart for all services.

   CLI Example:
   
   salt 's' service.execs

salt.modules.systemd.force_reload(name)
   Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, systemd-run(1) is now
   used to isolate commands run by this function from the salt-minion daemon's control group. This is
done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of systemd-run(1) can be suppressed by setting a config option called
systemd.scope, with a value of False (no quotes).

   New in version 0.12.0.

   Force-reload the specified service with systemd

   CLI Example:
   
   salt 's' service.force_reload <service name>

salt.modules.systemd.get_all()
   Return a list of all available services

   CLI Example:
   
   salt 's' service.get_all
salt.modules.systemd.get_disabled()
Return a list of all disabled services

CLI Example:
salt '*' service.get_disabled

salt.modules.systemd.get_enabled()
Return a list of all enabled services

CLI Example:
salt '*' service.get_enabled

salt.modules.systemd.get_static()
New in version 2015.8.5.
Return a list of all static services

CLI Example:
salt '*' service.get_static

salt.modules.systemd.mask(name, runtime=False)
New in version 2015.5.0.
Changed in version 2015.8.12,2016.3.3,2016.11.0: On minions running systemd>=205, systemd-run(1) is now used to isolate commands run by this function from the salt-minion daemon's control group. This is done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Mask the specified service with systemd
runtime [False] Set to True to mask this service only until the next reboot

New in version 2015.8.5.
CLI Example:
salt '*' service.mask <service name>

salt.modules.systemd.masked(name)
New in version 2015.8.0.
Changed in version 2015.8.5: The return data for this function has changed. If the service is masked, the return value will now be the output of the systemctl is-enabled command (so that a persistent mask can be distinguished from a runtime mask). If the service is not masked, then False will be returned.

Check whether or not a service is masked

CLI Example:
salt '*' service.masked <service name>

salt.modules.systemd.missing(name)
New in version 2014.1.0.
The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:
salt `*` service.missing sshd

salt.modules.systemd.reload(name)
Changed in version 2015.8.12,2016.3.3,2016.11.0: On minions running systemd>=205, systemd-run(1) is now used to isolate commands run by this function from the salt-minion daemon's control group. This is done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Reload the specified service with systemd

CLI Example:
```
salt `*` service.reload <service name>
```

salt.modules.systemd.restart(name)
Changed in version 2015.8.12,2016.3.3,2016.11.0: On minions running systemd>=205, systemd-run(1) is now used to isolate commands run by this function from the salt-minion daemon's control group. This is done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Restart the specified service with systemd

CLI Example:
```
salt `*` service.restart <service name>
```

salt.modules.systemd.show(name)
New in version 2014.7.0.

Show properties of one or more units/jobs or the manager

CLI Example:
```
salt `*` service.show <service name>
```

salt.modules.systemd.start(name)
Changed in version 2015.8.12,2016.3.3,2016.11.0: On minions running systemd>=205, systemd-run(1) is now used to isolate commands run by this function from the salt-minion daemon's control group. This is done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Start the specified service with systemd

CLI Example:
```
salt `*` service.start <service name>
```

salt.modules.systemd.status(name, sig=None)

Return the status for a service via systemd, returns True if the service is running and False if it is not.

CLI Example:
```
salt `*` service.status <service name>
```

salt.modules.systemd.stop(name)
Changed in version 2015.8.12,2016.3.3,2016.11.0: On minions running systemd>=205, systemd-run(1) is now used to isolate commands run by this function from the salt-minion daemon's control group. This is
done to avoid a race condition in cases where the `salt-minion` service is restarted while a service is being modified. If desired, usage of `systemd-run(1)` can be suppressed by setting a config option called `systemd.scope`, with a value of False (no quotes).

Stop the specified service with systemd

CLI Example:

```
salt '*' service.stop <service name>
```

```
salt.modules.systemd.systemctl_reload()
```

New in version 0.15.0.

Reloads systemctl, an action needed whenever unit files are updated.

CLI Example:

```
salt '*' service.systemctl_reload
```

```
salt.modules.systemd.unmask(name)
```

New in version 2015.5.0.

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands run by this function from the `salt-minion` daemon's control group. This is done to avoid a race condition in cases where the `salt-minion` service is restarted while a service is being modified. If desired, usage of `systemd-run(1)` can be suppressed by setting a config option called `systemd.scope`, with a value of False (no quotes).

Unmask the specified service with systemd

CLI Example:

```
salt '*' service.unmask <service name>
```

### 13.6.316 salt.modules.telemetry

Connection module for Telemetry

New in version 2016.3.0.

https://github.com/mongolab/mongolab-telemetry-api-docs/blob/master/alerts.md

**configuration** This module accepts explicit telemetry credentials or can also read api key credentials from a pillar. More Information available at:

https://github.com/mongolab/mongolab-telemetry-api-docs/blob/master/alerts.md

In the minion's config file:

```
telemetry.telemetry_api_keys:
  - abc123  # Key 1
  - efg321  # Backup Key 1
```

```
telemetry_api_base_url: https://telemetry-api.mongolab.com/v0
```

**depends** requests

```
salt.modules.telemetry.create_alarm(deployment_id, metric_name, data, api_key=None, profile='telemetry')
```

create an telemetry alarms.

data is a dict of alert configuration data.
Returns (bool success, str message) tuple.

CLI Example:
salt myminion telemetry.create_alarm rs-ds033197 {} profile=telemetry

salt.modules.telemetry.delete_alarms(deployment_id, alert_id=None, metric_name=None, api_key=None, profile='telemetry')
delete an alert specified by alert_id or if not specified blows away all the alerts in the current deployment.
Returns (bool success, str message) tuple.

CLI Example:
salt myminion telemetry.delete_alarms rs-ds033197 profile=telemetry

salt.modules.telemetry.get_alarms(deployment_id, profile='telemetry')
get all the alarms set up against the current deployment
Returns dictionary of alarm information

CLI Example:
salt myminion telemetry.get_alarms rs-ds033197 profile=telemetry

salt.modules.telemetry.get_alert_config(deployment_id, metric_name=None, api_key=None, profile='telemetry')
Get all alert definitions associated with a given deployment or if metric_name is specified, obtain the specific alert config
Returns dictionary or list of dictionaries.

CLI Example:
salt myminion telemetry.get_alert_config rs-ds033197 currentConnections profile=telemetry salt myminion telemetry.get_alert_config rs-ds033197 profile=telemetry

salt.modules.telemetry.get_notification_channel_id(notify_channel, profile='telemetry')
Given an email address, creates a notification-channel if one is not found and also returns the corresponding notification channel id.
notify_channel Email escalation policy
profile A dict of telemetry config information.

CLI Example:
salt myminion telemetry.get_notification_channel_id userx@company.com profile=telemetry

salt.modules.telemetry.update_alarm(deployment_id, metric_name, data, api_key=None, profile='telemetry')
update an telemetry alarms. data is a dict of alert configuration data.
Returns (bool success, str message) tuple.

CLI Example:
salt myminion telemetry.update_alarm rs-ds033197 {} profile=telemetry

13.6.317 salt.modules.temp

Simple module for creating temporary directories and files
This is a thin wrapper around Pythons tempfile module
New in version 2015.8.0.
salt.modules.temp.dir(suffix='', prefix='tmp', parent=None)
Create a temporary directory

CLI Example:
salt.modules.temp.file(suffix='*', prefix='tmp', parent=None)

Create a temporary file

CLI Example:

```
salt '*' temp.file
salt '*' temp.file prefix='mytemp-' parent='/var/run/
```

13.6.318 salt.modules.test

Module for running arbitrary tests

salt.modules.test.arg(*args, **kwargs)

Print out the data passed into the function args and kwargs, this is used to both test the publication data and cli argument passing, but also to display the information available within the publication data. Returns {``args'': args, ``kwargs'': kwargs}.

CLI Example:

```
salt '*' test.arg 1 "two" 3.1 txt="hello" wow={a: 1, b: "hello"}
```

salt.modules.test.arg_repr(*args, **kwargs)

Print out the data passed into the function args and kwargs, this is used to both test the publication data and cli argument passing, but also to display the information available within the publication data. Returns {``args'': repr(args), ``kwargs'': repr(kwargs)}.

CLI Example:

```
salt '*' test.arg_repr 1 "two" 3.1 txt="hello" wow={a: 1, b: "hello"}
```

salt.modules.test.arg_type(*args, **kwargs)

Print out the types of the args and kwargs. This is used to test the types of the args and kwargs passed down to the minion

CLI Example:

```
salt '*' test.arg_type 1 'int'
```

salt.modules.test.assertion(assertion)

Assert the given argument

CLI Example:

```
salt '*' test.assertion False
```

salt.modules.test.attr_call()

Call grains.items via the attribute

CLI Example:

```
salt '*' test.attr_call
```

salt.modules.test.collatz(start)

Execute the collatz conjecture from the passed starting number, returns the sequence and the time it took to compute. Used for performance tests.
salt.modules.test.conf_test()
Return the value for test.foo in the minion configuration file, or return the default value

CLI Example:
salt '*' test.conf_test

salt.modules.test.cross_test(func, args=None)
Execute a minion function via the __salt__ object in the test module, used to verify that the minion functions can be called via the __salt__ module.

CLI Example:
salt '*' test.cross_test file.gid_to_group 0

salt.modules.test.echo(text)
Return a string - used for testing the connection

CLI Example:
salt '*' test.echo 'foo bar baz quo qux'

salt.modules.test.exception(message='Test Exception')
Raise an exception
Optionally provide an error message or output the full stack.

CLI Example:
salt '*' test.exception 'Oh noes!'

salt.modules.test.false()
Always return False

CLI Example:
salt '*' test.false

salt.modules.test.fib(num)
Return the num-th Fibonacci number, and the time it took to compute in seconds. Used for performance tests.
This function is designed to have terrible performance.

CLI Example:
salt '*' test.fib 3

salt.modules.test.get_opts()
Return the configuration options passed to this minion

CLI Example:
salt '*' test.get_opts

salt.modules.test.kwarg(**kwargs)
Print out the data passed into the function **kwargs, this is used to both test the publication data and cli kwarg passing, but also to display the information available within the publication data.
CLI Example:

```bash
salt '*' test.kwarg num=1 txt="two" env='{"a: 1, b: "hello"}"'
```

```
salt.modules.test.missing_func()
```

```
salt.modules.test.module_report()

Return a dict containing all of the execution modules with a report on the overall availability via different references

CLI Example:

```bash
salt '*' test.module_report
```

```
salt.modules.test.not_loaded()

List the modules that were not loaded by the salt loader system

CLI Example:

```bash
salt '*' test.not_loaded
```

```
salt.modules.test.opts_pkg()

Return an opts package with the grains and opts for this minion. This is primarily used to create the options used for master side state compiling routines

CLI Example:

```bash
salt '*' test.opts_pkg
```

```
salt.modules.test.outputter(data)

Test the outputter, pass in data to return

CLI Example:

```bash
salt '*' test.outputter foobar
```

```
salt.modules.test.ping()

Used to make sure the minion is up and responding. Not an ICMP ping.

Returns True.

CLI Example:

```bash
salt '*' test.ping
```

```
salt.modules.test.provider(module)

Pass in a function name to discover what provider is being used

CLI Example:

```bash
salt '*' test.provider service
```

```
salt.modules.test.providers()

Return a dict of the provider names and the files that provided them

CLI Example:

```bash
salt '*' test.providers
```
salt.modules.test.rand_sleep(max=60)
Sleep for a random number of seconds, used to test long-running commands and minions returning at differing intervals

CLI Example:
```
salt '*' test.rand_sleep 60
```

salt.modules.test.rand_str(size=9999999999, hash_type=None)
Return a random string
- `size`: size of the string to generate
- `hash_type`: hash type to use

New in version 2015.5.2.

CLI Example:
```
salt '*' test.rand_str
```

salt.modules.test.retcode(code=42)
Test that the returncode system is functioning correctly

CLI Example:
```
salt '*' test.retcode 42
```

salt.modules.test.sleep(length)
Instruct the minion to initiate a process that will sleep for a given period of time.

CLI Example:
```
salt '*' test.sleep 20
```

salt.modules.test.stack()
Return the current stack trace

CLI Example:
```
salt '*' test.stack
```

salt.modules.test.true()
Always return True

CLI Example:
```
salt '*' test.true
```

salt.modules.test.try_(module, return_try_exception=False, **kwargs)
Try to run a module command. On an exception return None. If `return_try_exception` is set True return the exception. This can be helpful in templates where running a module might fail as expected.

CLI Example:
```
<pre>
{% for i in range(0,230) %}
    {{ salt['test.try'](module='ipmi.get_users', bmc_host='172.2.2.' + i)|yaml(False) }}
{% endfor %}
</pre>
```
salt.modules.test.tty(*args, **kwargs)
    Deprecated! Moved to cmdmod.
    
    CLI Example:
    
    salt '*' test.tty tty0 'This is a test'
salt '*' test.tty pts3 'This is a test'

salt.modules.test.version()
    Return the version of salt on the minion
    
    CLI Example:
    
    salt '*' test.version

salt.modules.test.versions()
    This function is an alias of versions_report.
    Returns versions of components used by salt
    
    CLI Example:
    
    salt '*' test.versions_report

salt.modules.test.versions_information()
    Report the versions of dependent and system software
    
    CLI Example:
    
    salt '*' test.versions_information

salt.modules.test.versions_report()
    Returns versions of components used by salt
    
    CLI Example:
    
    salt '*' test.versions_report

13.6.319  salt.modules.test_virtual

Module for running arbitrary tests with a __virtual__ function

salt.modules.test_virtual.ping()

13.6.320  salt.modules.timezone

Module for managing timezone on POSIX-like systems.

salt.modules.timezone.get_hwclock()
    Get current hardware clock setting (UTC or localtime)
    
    CLI Example:
    
    salt '*' timezone.get_hwclock

salt.modules.timezone.get_offset()
    Get current numeric timezone offset from UCT (i.e. -0700)
    
    CLI Example:
salt '*' timezone.get_offset

salt.modules.timezone.get_zone()
   Get current timezone (i.e. America/Denver)
   CLI Example:
   ```
   salt '*' timezone.get_zone
   ```

salt.modules.timezone.get_zonecode()
   Get current timezone (i.e. PST, MDT, etc)
   CLI Example:
   ```
   salt '*' timezone.get_zonecode
   ```

salt.modules.timezone.set_hwclock(clock)
   Sets the hardware clock to be either UTC or localtime
   CLI Example:
   ```
   salt '*' timezone.set_hwclock UTC
   ```

salt.modules.timezone.set_zone(timezone)
   Unlinks, then symlink /etc/localtime to the set timezone.
   The timezone is crucial to several system processes, each of which SHOULD be restarted (for instance, whatever you system uses as its cron and syslog daemons). This will not be automagically done and must be done manually!
   CLI Example:
   ```
   salt '*' timezone.set_zone 'America/Denver'
   ```

salt.modules.timezone.zone_compare(timezone)
   Compares the given timezone name with the system timezone name. Checks the hash sum between the given timezone, and the one set in /etc/localtime. Returns True if names and hash sums match, and False if not. Mostly useful for running state checks.
   Changed in version 2016.3.0.
   Note: On Solaris-link operating systems only a string comparison is done.
   CLI Example:
   ```
   salt '*' timezone.zone_compare 'America/Denver'
   ```

13.6.321 salt.modules.tls

A salt module for SSL/TLS. Can create a Certificate Authority (CA) or use Self-Signed certificates.

depends
   • PyOpenSSL Python module (0.10 or later, 0.14 or later for X509 extension support)
configuration Add the following values in /etc/salt/minion for the CA module to function properly:

```plaintext
c.a.cert_base_path: '/etc/pki'
```

CLI Example #1 Creating a CA, a server request and its signed certificate:

```bash
# salt-call tls.create_ca my_little \
  days=5 \
  CN='My Little CA' \
  C=US \
  ST=Utah \
  L=Salt Lake City \
  O=Saltstack \
  emailAddress=pleasedontemail@example.com

Created Private Key: "/etc/pki/my_little/my_little_ca_cert.key"
Created CA "my_little_ca": "/etc/pki/my_little_ca/my_little_ca_cert.crt"

# salt-call tls.create_csr my_little CN=www.example.com

Created Private Key: "/etc/pki/my_little/certs/www.example.com.key"
Created CSR for "www.example.com": "/etc/pki/my_little/certs/www.example.com.csr"

# salt-call tls.create_ca_signed_cert my_little CN=www.example.com

Created Certificate for "www.example.com": "/etc/pki/my_little/certs/www.example.com.crt"
```

CLI Example #2: Creating a client request and its signed certificate

```bash
# salt-call tls.create_csr my_little CN=DBReplica_No.1 cert_type=client

Created Private Key: "/etc/pki/my_little/certs/DBReplica_No.1.key"
Created CSR for "DBReplica_No.1": "/etc/pki/my_little/certs/DBReplica_No.1.csr"

# salt-call tls.create_ca_signed_cert my_little CN=DBReplica_No.1

Created Certificate for "DBReplica_No.1": "/etc/pki/my_little/certs/DBReplica_No.1.crt"
```

CLI Example #3: Creating both a server and client req + cert for the same CN

```bash
# salt-call tls.create_csr my_little CN=MasterDBReplica_No.2 \
  cert_type=client

Created Private Key: "/etc/pki/my_little/certs/MasterDBReplica_No.2.key"
Created CSR for "DBReplica_No.1": "/etc/pki/my_little/certs/MasterDBReplica_No.2.csr"

# salt-call tls.create_ca_signed_cert my_little CN=MasterDBReplica_No.2

Certificate "MasterDBReplica_No.2" already exists

(doh!)# salt-call tls.create_csr my_little CN=MasterDBReplica_No.2 \
  cert_type=server type_ext=True

Created Private Key: "/etc/pki/my_little/certs/DBReplica_No.1_client.key"
Created CSR for "DBReplica_No.1": "/etc/pki/my_little/certs/DBReplica_No.1_client.csr"

# salt-call tls.create_ca_signed_cert my_little CN=MasterDBReplica_No.2

Certificate "MasterDBReplica_No.2" already exists
```
(DOH!)

```
# salt-call tls.create_ca_signed_cert my_little CN=MasterDBReplica_No.2 \
   cert_type=server type_ext=True
Created Certificate for "MasterDBReplica_No.2": "/etc/pki/my_little/certs/\n   MasterDBReplica_No.2_server.crt"
```

CLI Example #4: Create a server req + cert with non-CN filename for the cert

```
# salt-call tls.create_csr my_little CN=www.anothersometh.ing \
   cert_type=server type_ext=True
Created Private Key: "/etc/pki/my_little/certs/www.anothersometh.ing_server.key."
Created CSR for "DBReplica_No.1": "/etc/pki/my_little/certs/www.anothersometh.ing_\n   server.csr."

# salt-call tls_create_ca_signed_cert my_little CN=www.anothersometh.ing \
   cert_type=server cert_filename="something_completely_different"
Created Certificate for "www.anothersometh.ing": /etc/pki/my_little/certs/something_\n   completely_different.crt
```

```
salt.modules.tls.ca_exists(ca_name, cacert_path=None, ca_filename=None)
    Verify whether a Certificate Authority (CA) already exists
    ca_name  name of the CA
cacert_path  absolute path to ca certificates root directory
c_filename  alternative filename for the CA

    New in version 2015.5.3.
    CLI Example:

    salt '*' tls.ca_exists test_ca /etc/certs
```

```
salt.modules.tls.cert_base_path(cacert_path=None)
    Return the base path for certs from CLI or from options
    cacert_path  absolute path to ca certificates root directory

    CLI Example:

    salt '*' tls.cert_base_path
```

```
salt.modules.tls.cert_info(cert_path, digest='sha256')
    Return information for a particular certificate
    cert_path  path to the cert file
digest  what digest to use for fingerprinting

    CLI Example:

    salt '*' tls.cert_info /dir/for/certs/cert.pem
```

```
salt.modules.tls.create_ca(ca_name, bits=2048, days=365, CN='localhost', C='US', ST='Utah', L='Salt\n   Lake City', O='SaltStack', OU=None, emailAddress='xyz@pdq.net', fix-\n   mode=False, cacert_path=None, ca_filename=None, digest='sha256', on-\n   lyif=None, unless=None, replace=False)
    Create a Certificate Authority (CA)
    ca_name  name of the CA
    bits  number of RSA key bits, default is 2048
days  number of days the CA will be valid, default is 365
    CN  common name in the request, default is ``localhost"
    C  country, default is `"US"`
```
ST state, default is `"Utah"`
L locality, default is `"Centerville"`, the city where SaltStack originated
O organization, default is `"SaltStack"
OU organizational unit, default is None
emailAddress email address for the CA owner, default is `xyz@pdq.net`
cacert_path absolute path to ca certificates root directory
cacert_path absolute path to ca certificates root directory
cacert_path absolute path to ca certificates root directory
ca_filename alternative filename for the CA

New in version 2015.5.3.
digest The message digest algorithm. Must be a string describing a digest algorithm supported by OpenSSL
(by EVP_get_digestbyname, specifically). For example, `"md5"` or `"sha1"`. Default: `sha256`
replace Replace this certificate even if it exists

New in version 2015.5.1.
Writes out a CA certificate based upon defined config values. If the file already exists, the function just returns
assuming the CA certificate already exists.
If the following values were set:

```python
c.ca.cert_base_path='/etc/pki'
c.ca_name='koji'
```

the resulting CA, and corresponding key, would be written in the following location:

```
/etc/pki/koji/koji_ca_cert.crt
/etc/pki/koji/koji_ca_cert.key
```

CLI Example:

```
salt '*' tls.create_ca test_ca
```

salt.modules.tls.create_ca_signed_cert

salt.modules.tls.create_ca_signed_cert

Create a Certificate (CERT) signed by a named Certificate Authority (CA)
If the certificate file already exists, the function just returns assuming the CERT already exists.

The CN must match an existing CSR generated by create_csr. If it does not, this method does nothing.
ca_name name of the CA
CN common name matching the certificate signing request
days number of days certificate is valid, default is 365 (1 year)
cacert_path absolute path to ca certificates root directory
cacert_path absolute path to ca certificates root directory
cacert_path absolute path to ca certificates root directory
cacert_path absolute path to ca certificates root directory
cacert_path absolute path to ca certificates root directory
cacert_path absolute path to ca certificates root directory
ca_filename alternative filename for the CA
ca_filename alternative filename for the CA
ca_filename alternative filename for the CA
ca_filename alternative filename for the CA
ca_filename alternative filename for the CA
ca_filename alternative filename for the CA

New in version 2015.5.3.
cert_path full path to the certificates directory
cert_filename alternative filename for the certificate, useful when using special characters in the CN. If this
option is set it will override the certificate filename output effects of cert_type. type_ext will be completely overridden.

cert_filename alternative filename for the certificate, useful when using special characters in the CN. If this
option is set it will override the certificate filename output effects of cert_type. type_ext will be completely overridden.

New in version 2015.5.3.
digest The message digest algorithm. Must be a string describing a digest algorithm supported by OpenSSL
(by EVP_get_digestbyname, specifically). For example, `"md5"` or `"sha1"`. Default: `sha256`
replace Replace this certificate even if it exists

New in version 2015.5.1.
cert_type string. Either 'server' or 'client' (see create_csr() for details).

    If create_csr(type_ext=True) this function must be called with the same cert_type so it can find the CSR file.

Note: create_csr() defaults to cert_type='server'; therefore, if it was also called with type_ext, cert_type becomes a required argument for create_ca_signed_cert()

type_ext bool. If set True, use cert_type as an extension to the CN when formatting the filename.

    e.g.: some_subject_CN_server.crt or some_subject_CN_client.crt

This facilitates the context where both types are required for the same subject

If cert_filename is not None, setting type_ext has no effect

If the following values were set:

    ca.cert_base_path='/etc/pki'
    ca_name='koji'
    CN='test.egavas.org'

the resulting signed certificate would be written in the following location:

    /etc/pki/koji/certs/test.egavas.org.crt

CLI Example:

salt '*' tls.create_ca_signed_cert test localhost

salt.modules.tls.create_csr(ca_name, bits=2048, CN='localhost', C='US', ST='Utah', L='Salt Lake City', O='SaltStack', OU=None, emailAddress='xyz@pdq.net', subjectAltName=None, cacert_path=None, ca_filename=None, csr_path=None, csr_filename=None, digest='sha256', type_ext=False, cert_type='server', replace=False)

Create a Certificate Signing Request (CSR) for a particular Certificate Authority (CA)

    ca_name name of the CA
    bits number of RSA key bits, default is 2048
    CN common name in the request, default is `localhost`
    C country, default is `US`
    ST state, default is `Utah`
    L locality, default is `Centerville`, the city where SaltStack originated
    O organization, default is `SaltStack` NOTE: Must the same as CA certificate or an error will be raised
    OU organizational unit, default is None
    emailAddress email address for the request, default is `xyz@pdq.net`
    subjectAltName valid subjectAltNames in full form, e.g. to add DNS entry you would call this function with this value:

        examples: ['DNS:somednsname.com', 'DNS:1.2.3.4', 'IP:1.2.3.4', 'IP:2001:4801:7821:77:be76:4eff:fe11:e51', 'email:me@i.like.pie.com']

Note: some libraries do not properly query IP: prefixes, instead looking for the given req. source with a DNS: prefix. To be thorough, you may want to include both DNS: and IP: entries if you are using subjectAltNames for destinations for your TLS connections. e.g.: requests to https://1.2.3.4 will fail from python’s requests library w/out the second entry in the above list

New in version 2015.8.0.
cert_type  Specify the general certificate type. Can be either server or client. Indicates the set of common extensions added to the CSR.

```
server: {
    'basicConstraints': 'CA:FALSE',
    'extendedKeyUsage': 'serverAuth',
    'keyUsage': 'digitalSignature, keyEncipherment'
}
client: {
    'basicConstraints': 'CA:FALSE',
    'extendedKeyUsage': 'clientAuth',
    'keyUsage': 'nonRepudiation, digitalSignature, keyEncipherment'
}
```

type_ext  boolean. Whether or not to extend the filename with CN_[cert_type] This can be useful if a server and client certificate are needed for the same CN. Defaults to False to avoid introducing an unexpected file naming pattern.

The files normally named some_subject_CN.csr and some_subject_CN.key will then be saved.

replace  Replace this signing request even if it exists

New in version 2015.5.1.

Writews out a Certificate Signing Request (CSR) If the file already exists, the function just returns assuming the CSR already exists.

If the following values were set:

```
ca.cert_base_path='/etc/pki'
ca_name='koji'
CN='test.egavas.org'
```

the resulting CSR, and corresponding key, would be written in the following location:

```
/etc/pki/koji/certs/test.egavas.org.csr
/etc/pki/koji/certs/test.egavas.org.key
```

CLI Example:

```
salt '*' tls.create_csr test
```

salt.modules.tls.create_empty_crl(ca_name, cacert_path=None, ca_filename=None, crl_file=None)

Create an empty Certificate Revocation List.

New in version 2015.8.0.

ca_name  name of the CA

cacert_path  absolute path to ca certificates root directory

cacert_filename  alternative filename for the CA

New in version 2015.5.3.

crl_file  full path to the CRL file

CLI Example:

```
salt '*' tls.create_empty_crl ca_name='koji' ca_filename='ca' crl_file='/etc/openvpn/team1/crl.pem'
```

salt.modules.tls.create_pkcs12(ca_name, CN, passphrase='', cacert_path=None, replace=False)

Create a PKCS#12 browser certificate for a particular Certificate (CN)

c_name  name of the CA

13.6. execution modules 1565
CN  common name matching the certificate signing request
passphrase  used to unlock the PKCS#12 certificate when loaded into the browser
cacert_path  absolute path to ca certificates root directory
replace  Replace this certificate even if it exists

    New in version 2015.5.1.
If the following values were set:

```python
c.a.cert_base_path='/etc/pki'
c.ca_name='koji'
CN='test.egavas.org'
```

the resulting signed certificate would be written in the following location:

```bash
/etc/pki/koji/certs/test.egavas.org.p12
```

CLI Example:

```bash
call 's' tls.create_pkcs12 test localhost
```

```
salt.modules.tls.create_self_signed_cert(tls_dir='tls', bits=2048, days=365, CN='localhost',
  C='US', ST='Utah', L='Salt Lake City', O='SaltStack', OU=None, emailAddress='xyz@pdq.net',
  cacert_path=None, cert_filename=None, digest='sha256', replace=False)
```

Create a Self-Signed Certificate (CERT)

- **tls_dir** location appended to the ca.cert_base_path, default is 'tls'
- **bits** number of RSA key bits, default is 2048
- **CN** common name in the request, default is `localhost`
- **C** country, default is `US`
- **ST** state, default is `Utah`
- **L** locality, default is `Centerville`, the city where SaltStack originated
- **O** organization, default is `SaltStack` NOTE: Must the same as CA certificate or an error will be raised
- **OU** organizational unit, default is None
- **emailAddress** email address for the request, default is `xyz@pdq.net`
- **cacert_path** absolute path to ca certificates root directory
- **digest** The message digest algorithm. Must be a string describing a digest algorithm supported by OpenSSL
  (by EVP_get_digestbyname, specifically). For example, `md5` or `sha1`. Default: `sha256`
- **replace** Replace this certificate even if it exists

    New in version 2015.5.1.
Writes out a Self-Signed Certificate (CERT). If the file already exists, the function just returns.

If the following values were set:

```python
c.a.cert_base_path='/etc/pki'
tls_dir='koji'
CN='test.egavas.org'
```

the resulting CERT, and corresponding key, would be written in the following location:

```bash
/etc/pki/koji/certs/test.egavas.org.crt
/etc/pki/koji/certs/test.egavas.org.key
```

CLI Example:
salt 'salt '*' tls.create_self_signed_cert

Passing options from the command line:
salt 'minion' tls.create_self_signed_cert CN='test.mysite.org'

salt.modules.tls.get_ca(ca_name, as_text=False, cacert_path=None)
Get the certificate path or content
ca_name name of the CA
as_text if true, return the certificate content instead of the path
cacert_path absolute path to ca certificates root directory

CLI Example:
salt 'salt '*' tls.get_ca test_ca as_text=False cacert_path=/etc/certs

salt.modules.tls.get_ca_signed_cert(ca_name, CN='localhost', as_text=False, cacert_path=None, cert_filename=None)
Get the certificate path or content
ca_name name of the CA
CN common name of the certificate
as_text if true, return the certificate content instead of the path
cacert_path absolute path to certificates root directory
cert_filename alternative filename for the certificate, useful when using special characters in the CN

New in version 2015.5.3.
CLI Example:
salt 'salt '*' tls.get_ca_signed_cert test_ca CN=localhost as_text=False cacert_path=/
/etc/certs

salt.modules.tls.get_ca_signed_key(ca_name, CN='localhost', as_text=False, cacert_path=None, key_filename=None)
Get the certificate path or content
ca_name name of the CA
CN common name of the certificate
as_text if true, return the certificate content instead of the path
cacert_path absolute path to certificates root directory
key_filename alternative filename for the key, useful when using special characters in the CN

New in version 2015.5.3.
CLI Example:
salt 'salt '*' tls.get_ca_signed_key test_ca CN=localhost as_text=False cacert_path=/
/etc/certs

salt.modules.tls.get_extensions(cert_type)
Fetch X509 and CSR extension definitions from tls:extensions: (common|server|client) or set them to standard defaults.

New in version 2015.8.0.
cert_type: The type of certificate such as server or client.
CLI Example:
salt 'salt '*' tls.get_extensions client
salt.modules.tls\textbf{.maybe_fix_ssl_version}(ca\_name, cacert\_path=None, ca\_filename=None)

Check that the X509 version is correct (was incorrectly set in previous salt versions). This will fix the version if needed.

- ca\_name: ca authority name
- cacert\_path: absolute path to ca certificates root directory
- ca\_filename: alternative filename for the CA

New in version 2015.5.3.

CLI Example:

```
salt '*' tls.maybe_fix_ssl_version test_ca /etc/certs
```

salt.modules.tls\textbf{.revoke_cert}(ca\_name, CN, cacert\_path=None, ca\_filename=None, cert\_path=None, cert\_filename=None, crl\_file=None)

Revoke a certificate.

New in version 2015.8.0.

- ca\_name: Name of the CA.
- CN: Common name matching the certificate signing request.
- cacert\_path: Absolute path to ca certificates root directory.
- ca\_filename: Alternative filename for the CA.
- cert\_path: Path to the cert file.
- cert\_filename: Alternative filename for the certificate, useful when using special characters in the CN.
- crl\_file: Full path to the CRL file.

CLI Example:

```
salt '*' tls.revoke_cert ca_name='koji' cert_filename='ca'
  crl_file='/etc/openvpn/team1/crl.pem'
```

salt.modules.tls\textbf{.set_ca_path}(cacert\_path)

If wanted, store the aforementioned cacert\_path in context to be used as the basepath for further operations.

CLI Example:

```
salt '*' tls.set_ca_path /etc/certs
```

13.6.322 salt.modules.tomcat

Support for Tomcat

This module uses the manager webapp to manage Apache tomcat webapps. If the manager webapp is not configured some of the functions won't work.

configuration

- Java bin path should be in default path
- If ipv6 is enabled make sure you permit manager access to ipv6 interface `\'0:0:0:0:0:0:0:1\'`
- If you are using tomcat.tar.gz it has to be installed or symlinked under `/opt`, preferably using name tomcat
- `\'tomcat.signal start/stop\'` works but it does not use the startup scripts

The following grains/pillar should be set:

```
tomcat-manager:
  user: <username>
  passwd: <password>
```
or the old format:

```
tomcat-manager.user: <username>
tomcat-manager.passwd: <password>
```

Also configure a user in the conf/tomcat-users.xml file:

```
<?xml version='1.0' encoding='utf-8'?>
<tomcat-users>
    <role rolename="manager-script"/>
    <user username="tomcat" password="tomcat" roles="manager-script"/>
</tomcat-users>
```

Note:
- if you use only this module for deployments you've might want to strict access to the manager only from localhost for more info: http://tomcat.apache.org/tomcat-7.0-doc/manager-howto.html#Configuring_Manager_Application_Access
- Tested on:
  JVM Vendor: Sun Microsystems Inc.
  JVM Version: 1.6.0_43-b01
  OS Architecture: amd64
  OS Name: Linux
  OS Version: 2.6.32-358.el6.x86_64
  Tomcat Version: Apache Tomcat/7.0.37

```
salt.modules.tomcat.deploy_war( war, context, force='no', url='http://localhost:8080/manager', saltenv='base', timeout=180, env=None, temp_war_location=None, version='`) 
```

Deploy a WAR file
war absolute path to WAR file (should be accessible by the user running tomcat) or a path supported by the salt.modules.cp.get_file function
context the context path to deploy
force [False] set True to deploy the webapp even one is deployed in the context
url [http://localhost:8080/manager] the URL of the server manager webapp
saltenv [base] the environment for WAR file in used by salt.modules.cp.get_url function
timeout [180] timeout for HTTP request
temp_war_location [None] use another location to temporarily copy to war file by default the system's temp directory is used
version [''] Specify the war version. If this argument is provided, it overrides the version encoded in the war file name, if one is present.

Examples:
```
salt '*' tomcat.deploy_war salt://salt-2015.8.6.war version=2015.08.r6
```

CLI Examples:
cp module
salt '...' tomcat.deploy_war salt://application.war /api
salt '...' tomcat.deploy_war salt://application.war /api no
salt '...' tomcat.deploy_war salt://application.war /api yes http://localhost:8080/

minion local file system

salt '...' tomcat.deploy_war /tmp/application.war /api
salt '...' tomcat.deploy_war /tmp/application.war /api no
salt '...' tomcat.deploy_war /tmp/application.war /api yes http://localhost:8080/

salt.modules.tomcat.fullversion()
Return all server information from catalina.sh version

CLI Example:
salt '*' tomcat.fullversion

salt.modules.tomcat.leaks(url='http://localhost:8080/manager', timeout=180)
Find memory leaks in tomcat
url [http://localhost:8080/manager] the URL of the server manager webapp
timeout [180] timeout for HTTP request

CLI Examples:
salt '*' tomcat.leaks

salt.modules.tomcat.ls(url='http://localhost:8080/manager', timeout=180)
list all the deployed webapps
url [http://localhost:8080/manager] the URL of the server manager webapp
timeout [180] timeout for HTTP request

CLI Examples:
salt '*' tomcat.ls
s"al*t '*' tomcat.ls http://localhost:8080/manager

salt.modules.tomcat.passwd(passwd, user='`, alg='sha1', realm=None)
This function replaces the $CATALINA_HOME/bin/digest.sh script convert a clear-text password to the
$CATALINA_BASE/conf/tomcat-users.xml format

CLI Examples:
salt '*' tomcat.passwd secret
salt '*' tomcat.passwd secret tomcat shal
salt '*' tomcat.passwd secret tomcat shal 'Protected Realm'

salt.modules.tomcat.reload(app, url='http://localhost:8080/manager', timeout=180)
Reload the webapp
app the webapp context path
url [http://localhost:8080/manager] the URL of the server manager webapp
timeout [180] timeout for HTTP request

CLI Examples:
salt '*' tomcat.reload /jenkins
salt '*' tomcat.reload /jenkins http://localhost:8080/manager
salt.modules.tomcat.serverinfo(url='http://localhost:8080/manager', timeout=180)
    return details about the server
    url [http://localhost:8080/manager] the URL of the server manager webapp
    timeout [180] timeout for HTTP request
    CLI Examples:

    salt '*' tomcat.serverinfo
    salt '*' tomcat.serverinfo http://localhost:8080/manager

salt.modules.tomcat.sessions(app, url='http://localhost:8080/manager', timeout=180)
    return the status of the webapp sessions
    app the webapp context path
    url [http://localhost:8080/manager] the URL of the server manager webapp
    timeout [180] timeout for HTTP request
    CLI Examples:

    salt '*' tomcat.sessions /jenkins
    salt '*' tomcat.sessions /jenkins http://localhost:8080/manager

salt.modules.tomcat.signal(signal=None)
    Signals catalina to start, stop, securestart, forcelstop.
    CLI Example:

    salt '*' tomcat.signal start

salt.modules.tomcat.start(app, url='http://localhost:8080/manager', timeout=180)
    Start the webapp
    app the webapp context path
    url [http://localhost:8080/manager] the URL of the server manager webapp
    timeout [180] timeout for HTTP request
    CLI Examples:

    salt '*' tomcat.start /jenkins
    salt '*' tomcat.start /jenkins http://localhost:8080/manager

salt.modules.tomcat.status(url='http://localhost:8080/manager', timeout=180)
    Used to test if the tomcat manager is up
    url [http://localhost:8080/manager] the URL of the server manager webapp
    timeout [180] timeout for HTTP request
    CLI Examples:

    salt '*' tomcat.status
    salt '*' tomcat.status http://localhost:8080/manager

salt.modules.tomcat.status_webapp(app, url='http://localhost:8080/manager', timeout=180)
    return the status of the webapp (stopped | running | missing)
    app the webapp context path
    url [http://localhost:8080/manager] the URL of the server manager webapp
    timeout [180] timeout for HTTP request
    CLI Examples:

    salt '*' tomcat.status_webapp /jenkins
    salt '*' tomcat.status_webapp /jenkins http://localhost:8080/manager

salt.modules.tomcat.stop(app, url='http://localhost:8080/manager', timeout=180)
    Stop the webapp
app the webapp context path
url [http://localhost:8080/manager] the URL of the server manager webapp
timeout [180] timeout for HTTP request

CLI Examples:
salt '*' tomcat.stop /jenkins
tsalt '*' tomcat.stop /jenkins http://localhost:8080/manager

salt.modules.tomcat.undeploy(app, url='http://localhost:8080/manager', timeout=180)
Undeploy a webapp
app the webapp context path
url [http://localhost:8080/manager] the URL of the server manager webapp
timeout [180] timeout for HTTP request

CLI Examples:
salt '*' tomcat.undeploy /jenkins
tsalt '*' tomcat.undeploy /jenkins http://localhost:8080/manager

salt.modules.tomcat.version()
Return server version from catalina.sh version

CLI Example:
salt '*' tomcat.version

13.6.323 salt.modules.trafficserver

Apache Traffic Server execution module.
New in version 2015.8.0.

traffic_line is used to execute individual Traffic Server commands and to script multiple commands in a shell.

salt.modules.trafficserver.alarms()
List all alarm events that have not been acknowledged (cleared).

salt '*' trafficserver.alarms

salt.modules.trafficserver.bounce_cluster()

salt '*' trafficserver.bounce_cluster

salt.modules.trafficserver.bounce_local(drain=False)

This option modifies the behavior of traffic_line -b and traffic_line -L such that traffic_server is not shut down until the number of active client connections drops to the number given by the proxy.config.restart.active_client_threshold configuration variable.

salt '*' trafficserver.bounce_local
salt '*' trafficserver.bounce_local drain=True
salt.modules.trafficserver.clear_alarms(alarm)
Clear (acknowledge) an alarm event. The arguments are “all” for all current alarms, a specific alarm number (e.g. “1”), or an alarm string identifier (e.g. “MGMT_ALARM_PROXY_CONFIG_ERROR”).

```bash
salt '*' trafficserver.clear_alarms [all | #event | name]
```

salt.modules.trafficserver.clear_cluster()
Clears accumulated statistics on all nodes in the cluster.

```bash
salt '*' trafficserver.clear_cluster
```

salt.modules.trafficserver.clear_node()
Clears accumulated statistics on the local node.

```bash
salt '*' trafficserver.clear_node
```

salt.modules.trafficserver.match_var(regex)
Display the current values of all performance statistics or configuration variables whose names match the given regular expression.

```bash
salt '*' trafficserver.match_var regex
```

salt.modules.trafficserver.offline(path)
Mark a cache storage device as offline. The storage is identified by a path which must match exactly a path specified in storage.config. This removes the storage from the cache and redirects requests that would have used this storage to other storage. This has exactly the same effect as a disk failure for that storage. This does not persist across restarts of the traffic_server process.

```bash
salt '*' trafficserver.offline /path/to/cache
```

salt.modules.trafficserver.read_var(*args)
Read variable definitions from the traffic_line command
This allows reading arbitrary key=value pairs from within trafficserver

```bash
salt '*' trafficserver.read_var proxy.process.http.tcp_hit_count_stat
```

salt.modules.trafficserver.refresh()
Initiate a Traffic Server configuration file reread. Use this command to update the running configuration after any configuration file modification.

The timestamp of the last reconfiguration event (in seconds since epoch) is published in the proxy.node.config.reconfigure_time metric.

```bash
salt '*' trafficserver.refresh
```

salt.modules.trafficserver.restart_cluster()
Restart the traffic_manager process and the traffic_server process on all the nodes in a cluster.

```bash
salt '*' trafficserver.restart_cluster
```

salt.modules.trafficserver.restart_local(drain=False)
Restart the traffic_manager and traffic_server processes on the local node.

This option modifies the behavior of traffic_line -b and traffic_line -L such that traffic_server is not shut down until the number of active client connections drops to the number given by the proxy.config.restart.active_client_threshold configuration variable.

13.6. execution modules 1573
salt '*' trafficserver.restart_local
salt '*' trafficserver.restart_local drain=True

```
salt '*' trafficserver.set_var proxy.config.http.server_ports
```

salt.modules.trafficserver.set_var(variable, value)

```
salt '*' trafficserver.set_var proxy.config.http.server_ports
```

salt.modules.trafficserver.shutdown()
Shut down Traffic Server on the local node.
```
salt '*' trafficserver.shutdown
```

salt.modules.trafficserver.startup()
Start Traffic Server on the local node.
```
salt '*' trafficserver.start
```

salt.modules.trafficserver.status()
Show the current proxy server status, indicating if we're running or not.
```
salt '*' trafficserver.status
```

salt.modules.trafficserver.zero_cluster()
Reset performance statistics to zero across the cluster.
```
salt '*' trafficserver.zero_cluster
```

salt.modules.trafficserver.zero_node()
Reset performance statistics to zero on the local node.
```
salt '*' trafficserver.zero_cluster
```

13.6.324 salt.modules.tuned

Interface to Red Hat tuned-adm module

maintainer  Syed Ali <alicsyed@gmail.com>
maturity    new
depends     tuned-adm
platform    Linux

salt.modules.tuned.active()
Return current active profile

CLI Example:
```
salt '*' tuned.active
```

salt.modules.tuned.list()
List the profiles available

CLI Example:
salt '...' tuned.list

salt.modules.tuned.off()
    Turn off all profiles
    CLI Example:
    
    salt '...' tuned.off

salt.modules.tuned.profile(profile_name)
    Activate specified profile
    CLI Example:
    
    salt '...' tuned.profile virtual-guest

13.6.325 salt.modules.twilio_notify

Module for notifications via Twilio
New in version 2014.7.0.

depends
    - twilio python module
configuration Configure this module by specifying the name of a configuration profile in the minion
    config, minion pillar, or master config.
    
    For example:
    
    my-twilio-account:
        twilio.account_sid: AC32a3c83990934481add5ce1659f04d2
        twilio.auth_token: mytoken

salt.modules.twilio_notify.send_sms(profile, body, to, from_)
    Send an sms
    CLI Example:
    
    twilio.send_sms twilio-account 'Test sms' '+18019999999' '+18011111111' 

13.6.326 salt.modules.udev

Manage and query udev info
New in version 2015.8.0.
salt.modules.udev.env(dev)
    Return all environment variables udev has for dev
    CLI Example:
    
    salt '...' udev.env /dev/sda
    salt '...' udev.env /sys/class/net/eth0

salt.modules.udev.info(dev)
    Extract all info delivered by udevadm
    CLI Example:
salt '*' udev.info /dev/sda
salt '*' udev.info /sys/class/net/eth0

salt.modules.udev.links(dev)
Return all udev-created device symlinks

CLI Example:
salt '*' udev.links /dev/sda
salt '*' udev.links /sys/class/net/eth0

salt.modules.udev.name(dev)
Return the actual dev name(s?) according to udev for dev

CLI Example:
salt '*' udev.dev /dev/sda
salt '*' udev.dev /sys/class/net/eth0

salt.modules.udev.path(dev)
Return the physical device path(s?) according to udev for dev

CLI Example:
salt '*' udev.path /dev/sda
salt '*' udev.path /sys/class/net/eth0

13.6.327 salt.modules.upstart

Module for the management of upstart systems. The Upstart system only supports service starting, stopping and restarting.

Important: If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `service.start' is not available), see here.

Currently (as of Ubuntu 12.04) there is no tool available to disable Upstart services (like update-rc.d). This[1] is the recommended way to disable an Upstart service. So we assume that all Upstart services that have not been disabled in this manner are enabled.

But this is broken because we do not check to see that the dependent services are enabled. Otherwise we would have to do something like parse the output of ``initctl show-config'' to determine if all service dependencies are enabled to start on boot. For example, see the ``start on'' condition for the lightdm service below[2]. And this would be too hard. So we wait until the upstart developers have solved this problem. :) This is to say that an Upstart service that is enabled may not really be enabled.

Also, when an Upstart service is enabled, should the dependent services be enabled too? Probably not. But there should be a notice about this, at least.

[2] example upstart configuration file:

```
lightdm
emits login-session-start
emits desktop-session-start
emits desktop-shutdown
```
start on (((filesystem and runlevel ![06]) and started dbus) and (drm-device-added!card0 PRIMARY_DEVICE_FOR_DISPLAY=1 or stopped udev-fallback-graphics)) or runlevel!PREVLEVEL=S)
stop on runlevel [016]

Warning: This module should not be used on Red Hat systems. For these, the rh_service module should be used, as it supports the hybrid upstart/sysvinit system used in RHEL/CentOS 6.

salt.modules.upstart.available(name)
Returns True if the specified service is available, otherwise returns False.

CLI Example:
salt '*' service.available sshd

salt.modules.upstart.disable(name, **kwargs)
Disable the named service from starting on boot

CLI Example:
salt '*' service.disable <service name>

salt.modules.upstart.disabled(name)
Check to see if the named service is disabled to start on boot

CLI Example:
salt '*' service.disabled <service name>

salt.modules.upstart.enable(name, **kwargs)
Enable the named service to start at boot

CLI Example:
salt '*' service.enable <service name>

salt.modules.upstart.enabled(name, **kwargs)
Check to see if the named service is enabled to start on boot

CLI Example:
salt '*' service.enabled <service name>

salt.modules.upstart.force_reload(name)
Force-reload the named service

CLI Example:
salt '*' service.force_reload <service name>

salt.modules.upstart.full_restart(name)
Do a full restart (stop/start) of the named service

CLI Example:
salt '*' service.full_restart <service name>
salt.modules.upstart.get_all()  
Return all installed services  
   CLI Example:  
       salt '*' service.get_all

salt.modules.upstart.get_disabled()  
Return the disabled services  
   CLI Example:  
       salt '*' service.get_disabled

salt.modules.upstart.get_enabled()  
Return the enabled services  
   CLI Example:  
       salt '*' service.get_enabled

salt.modules.upstart.missing(name)  
The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.  
   CLI Example:  
       salt '*' service.missing sshd

salt.modules.upstart.reload(name)  
Reload the named service  
   CLI Example:  
       salt '*' service.reload <service name>

salt.modules.upstart.restart(name)  
Restart the named service  
   CLI Example:  
       salt '*' service.restart <service name>

salt.modules.upstart.start(name)  
Start the specified service  
   CLI Example:  
       salt '*' service.start <service name>

salt.modules.upstart.status(name, sig=None)  
Return the status for a service, returns a bool whether the service is running.  
   CLI Example:  
       salt '*' service.status <service name>

salt.modules.upstart.stop(name)  
Stop the specified service  
   CLI Example:
13.6.328 salt.modules.uptime

Wrapper around uptime API

salt.modules.uptime.check_exists(name)
Check if a given URL is in being monitored by uptime

CLI Example:
```
salt '*' uptime.check_exists http://example.org
```

salt.modules.uptime.checks_list()
List URL checked by uptime

CLI Example:
```
salt '*' uptime.checks_list
```

salt.modules.uptime.create(name, **params)
Create a check on a given URL.

Additional parameters can be used and are passed to API (for example interval, maxTime, etc). See the documentation https://github.com/fzaninotto/uptime for a full list of the parameters.

CLI Example:
```
salt '*' uptime.create http://example.org
```

salt.modules.uptime.delete(name)
Delete a check on a given URL

CLI Example:
```
salt '*' uptime.delete http://example.org
```

13.6.329 salt.modules.useradd

Manage users with the useradd command

Important: If you feel that Salt should be using this module to manage users on a minion, and it is using a different module (or gives an error similar to `user.info’ is not available), see here.

salt.modules.useradd.add(name, uid=None, gid=None, groups=None, home=None, shell=None, unique=True, system=False, fullname='', roomnumber='', workphone='', homephone='', loginclass=False, loginclass=None, root=None)

Add a user to the minion

CLI Example:
```
salt '*' user.add name <uid> <gid> <groups> <home> <shell>
```
salt.modules.useradd.chfullname(name, fullname)
Change the user's Full Name

CLI Example:
salt '*' user.chfullname foo "Foo Bar"

salt.modules.useradd.chgid(name, gid, root=None)
Change the default group of the user

CLI Example:
salt '*' user.chgid foo 4376

salt.modules.useradd.chgroups(name, groups, append=False, root=None)
Change the groups to which this user belongs

name User to modify
groups Groups to set for the user
append [False] If True, append the specified group(s). Otherwise, this function will replace the user's groups with the specified group(s).

CLI Examples:
salt '*' user.chgroups foo wheel,root
salt '*' user.chgroups foo wheel,root append=True

salt.modules.useradd.chhome(name, home, persist=False, root=None)
Change the home directory of the user, pass True for persist to move files to the new home directory if the old home directory exist.

CLI Example:
salt '*' user.chhome foo /home/users/foo True

salt.modules.useradd.chhomephone(name, homephone)
Change the user's Home Phone

CLI Example:
salt '*' user.chhomephone foo 7735551234

salt.modules.useradd.chloginclass(name, loginclass, root=None)
Change the default login class of the user

Note: This function only applies to OpenBSD systems.

CLI Example:
salt '*' user.chloginclass foo staff

salt.modules.useradd.chroomnumber(name, roomnumber)
Change the user's Room Number

CLI Example:
salt '*' user.chroomnumber foo 123

salt.modules.useradd.chshell(name, shell, root=None)
Change the default shell of the user
CLI Example:
```
salt '*' user.chshell foo /bin/zsh
```

salt.modules.useradd.chuid(name, uid)
Change the uid for a named user

CLI Example:
```
salt '*' user.chuid foo 4376
```

salt.modules.useradd.chworkphone(name, workphone)
Change the user's Work Phone

CLI Example:
```
salt '*' user.chworkphone foo 773550123
```

salt.modules.useradd.delete(name, remove=False, force=False, root=None)
Remove a user from the minion

CLI Example:
```
salt '*' user.delete name remove=True force=True
```

salt.modules.useradd.get_loginclass(name)
Get the login class of the user

Note: This function only applies to OpenBSD systems.

CLI Example:
```
salt '*' user.get_loginclass foo
```

salt.modules.useradd.getent(refresh=False)
Return the list of all info for all users

CLI Example:
```
salt '*' user.getent
```

salt.modules.useradd.info(name)
Return user information

CLI Example:
```
salt '*' user.info root
```

salt.modules.useradd.list_groups(name)
Return a list of groups the named user belongs to

CLI Example:
```
salt '*' user.list_groups foo
```

salt.modules.useradd.list_users()
Return a list of all users

CLI Example:
salt user.list_users

classic

salt.modules.useradd.primary_group(name)

Return the primary group of the named user

New in version 2016.3.0.

CLI Example:

    salt '*' user.primary_group saltadmin

salt.modules.useradd.rename(name, new_name, root=None)

Change the username for a named user

CLI Example:

    salt '*' user.rename name new_name

13.6.330 salt.modules.uwsgi

maintainer Peter Baumgartner <pete@lincolnloop.com>
maturity new
platform all

salt.modules.uwsgi.stats(socket)

Return the data from uwsgi --connect-and-read as a dictionary.

socket The socket the uWSGI stats server is listening on

CLI Example:

    salt '*' uwsgi.stats /var/run/mystatsserver.sock
    salt '*' uwsgi.stats 127.0.0.1:5050

13.6.331 salt.modules.varnish

Support for Varnish

New in version 2014.7.0.

Note: These functions are designed to work with all implementations of Varnish from 3.x onwards

salt.modules.varnish.ban(ban_expression)

Add ban to the varnish cache

CLI Example:

    salt '*' varnish.ban ban_expression

classic

salt.modules.varnish.ban_list()

List varnish cache current bans

CLI Example:
salt '*' varnish.ban_list

salt.modules.varnish.param_set(param, value)
Set a param in varnish cache

CLI Example:
salt '*' varnish.param_set param value

salt.modules.varnish.param_show(param=None)
Show params of varnish cache

CLI Example:
salt '*' varnish.param_show param

salt.modules.varnish.purge()
Purge the varnish cache

CLI Example:
salt '*' varnish.purge

salt.modules.varnish.version()
Return server version from varnishd -V

CLI Example:
salt '*' varnish.version

13.6.332 salt.modules.vbox_guest

VirtualBox Guest Additions installer

salt.modules.vbox_guest.additions_install(*args, **kwargs)
Install VirtualBox Guest Additions. Uses the CD, connected by VirtualBox.

To connect VirtualBox Guest Additions via VirtualBox graphical interface press `Host+D' (`Host' is usually `Right Ctrl').

See https://www.virtualbox.org/manual/ch04.html#idp52733088 for more details.

CLI Example:
salt '*' vbox_guest.additions_install
salt '*' vbox_guest.additions_install reboot=True
salt '*' vbox_guest.additions_install upgrade_os=True

Parameters

• reboot (bool) -- reboot computer to complete installation
• upgrade_os (bool) -- upgrade OS (to ensure the latests version of kernel and developer tools are installed)

Returns version of VirtualBox Guest Additions or string with error

salt.modules.vbox_guest.additions_mount()
Mount VirtualBox Guest Additions CD to the temp directory.
To connect VirtualBox Guest Additions via VirtualBox graphical interface press `Host+D` (`Host' is usually 'Right Ctrl').

CLI Example:

```bash
salt '*' vbox_guest.additions_mount
```

**Returns** True or OSError exception

```python
salt.modules.vbox_guest.additions_remove(**kwargs)
```

Remove VirtualBox Guest Additions.

Firstly it tries to uninstall itself by executing `/opt/VBoxGuestAdditions-VERSION/uninstall.run uninstall'. It uses the CD, connected by VirtualBox if it fails.

CLI Example:

```bash
salt '*' vbox_guest.additions_remove
salt '*' vbox_guest.additions_remove force=True
```

**Parameters** `force (bool)` -- force VirtualBox Guest Additions removing

**Returns** True if VirtualBox Guest Additions were removed successfully else False

```python
salt.modules.vbox_guest.additions_umount(mount_point)
```

Unmount VirtualBox Guest Additions CD from the temp directory.

CLI Example:

```bash
salt '*' vbox_guest.additions_umount
```

**Parameters** `mount_point` -- directory VirtualBox Guest Additions is mounted to

**Returns** True or an string with error

```python
salt.modules.vbox_guest.additions_version()
```

Check VirtualBox Guest Additions version.

CLI Example:

```bash
salt '*' vbox_guest.additions_version
```

**Returns** version of VirtualBox Guest Additions or False if they are not installed

```python
salt.modules.vbox_guest.grant_access_to_shared_folders_to(name, users=None)
```

Grant access to auto-mounted shared folders to the users.

User is specified by it's name. To grant access for several users use argument `users`. Access will be denied to the users not listed in `users` argument.

CLI Example:

```bash
salt '*' vbox_guest.grant_access_to_shared_folders_to fred
salt '*' vbox_guest.grant_access_to_shared_folders_to users ['fred', 'roman']
```

**Parameters**

- `name (str)` -- name of the user to grant access to auto-mounted shared folders to
- `users (list of str)` -- list of names of users to grant access to auto-mounted shared folders to (if specified, name will not be taken into account)

**Returns** list of users who have access to auto-mounted shared folders
salt.modules.vbox_guest.list_shared_folders_users()  
List users who have access to auto-mounted shared folders.  
See https://www.virtualbox.org/manual/ch04.html#sf_mount_auto for more details.  
CLI Example:  
```
salt '*' vbox_guest.list_shared_folders_users
```

**Returns**  list of users who have access to auto-mounted shared folders

### 13.6.333 salt.modules.vboxmanage module

Support for VirtualBox using the VBoxManage command  
New in version 2016.3.0.  
If the vboxdrv kernel module is not loaded, this module can automatically load it by configuring autoload_vboxdrv in /etc/salt/minion:  
The default for this setting is False.  

depends virtualbox

salt.modules.vboxmanage.clonemedium(  
`medium`, `uuid_in=None`, `file_in=None`, `uuid_out=None`, `file_out=None`, `mformat=None`, `variant=None`, `existing=False`, **kwargs)  
Clone a new VM from an existing VM  
CLI Example:  
```
salt 'hypervisor' vboxmanage.clonemedium <name> <new_name>
```

salt.modules.vboxmanage.clonevm(  
`name=None`, `uuid=None`, `new_name=None`, `snapshot_uuid=None`, `snapshot_name=None`, `mode='machine'`, `options=None`, `basefolder=None`, `new_uuid=None`, `register=False`, `groups=None`, **kwargs)  
Clone a new VM from an existing VM  
CLI Example:  
```
salt 'hypervisor' vboxmanage.clonevm <name> <new_name>
```

salt.modules.vboxmanage.create(  
`name`, `groups=None`, `ostype=None`, `register=True`, `basefolder=None`, `new_uuid=None`, **kwargs)  
Create a new VM  
CLI Example:  
```
salt 'hypervisor' vboxmanage.create <name>
```

salt.modules.vboxmanage.destroy(  
`name`)  
Unregister and destroy a VM

salt.modules.vboxmanage.list_items(  
`item`, `details=False`, `group_by='UUID'`)  
Return a list of a specific type of item. The following items are available:  
- vms runningvms ostypes hostdvs hostfloppies innets bridgedifs hostonlyifs natnets dhcpservers hostinfo hostcpuids hddbackends hdds dvds floppies ushghost usbfilters systemproperties extpacks groups webcams screenshotformats  
CLI Example:
Some items do not display well, or at all, unless `details` is set to `True`. By default, items are grouped by the UUID field, but not all items contain that field. In those cases, another field must be specified.

```
salt 'hypervisor' vboxmanage.items <item>  
salt 'hypervisor' vboxmanage.items <item> details=True  
salt 'hypervisor' vboxmanage.items <item> details=True group_by=Name
```

salt.modules.vboxmanage.list_nodes()
Return a list of registered VMs

salt.modules.vboxmanage.list_nodes_full()
Return a list of registered VMs, with detailed information

salt.modules.vboxmanage.list_nodes_min()
Return a list of registered VMs, with minimal information

salt.modules.vboxmanage.list_ostypes()
List the available OS Types

salt.modules.vboxmanage.register(filename)
Register a VM

salt.modules.vboxmanage.start(name)
Start a VM

salt.modules.vboxmanage.stop(name)
Stop a VM

salt.modules.vboxmanage.unregister(name, delete=False)
Unregister a VM

salt.modules.vboxmanage.vboxcmd()
Return the location of the VBoxManage command

13.6.334 salt.modules.victorops

Support for VictorOps

New in version 2015.8.0.

Requires an `api_key` in `/etc/salt/minion`:

```
salt.modules.victorops.create_event(message_type=None, routing_key='everybody', **kwargs)
```
Create an event in VictorOps. Designed for use in states.

The following parameters are required:
**Parameters**

- `message_type` -- One of the following values: INFO, WARNING, ACKNOWLEDGEMENT, CRITICAL, RECOVERY.

The following parameters are optional:

- `routing_key` -- The key for where messages should be routed. By default, sent to `everyone` route.

- `entity_id` -- The name of alerting entity. If not provided, a random name will be assigned.

- `timestamp` -- Timestamp of the alert in seconds since epoch. Defaults to the time the alert is received at VictorOps.

:param timestamp_fmt: The date format for the timestamp parameter.

**Parameters**
- **state_start_time** -- The time this entity entered its current state (seconds since epoch). Defaults to the time alert is received.
- **state_start_time_fmt** -- The date format for the timestamp parameter.
- **state_message** -- Any additional status information from the alert item.
- **entity_is_host** -- Used within VictorOps to select the appropriate display format for the incident.
- **entity_display_name** -- Used within VictorOps to display a human-readable name for the entity.
- **ack_message** -- A user entered comment for the acknowledgment.
- **ack_author** -- The user that acknowledged the incident.

**Returns** A dictionary with result, entity_id, and message if result was failure.

**CLI Example:**

```bash
salt myminion victorops.create_event message_type='CRITICAL' routing_key='everyone' entity_id='hostname/diskspace'
salt myminion victorops.create_event message_type='ACKNOWLEDGEMENT' routing_key='everyone' entity_id='hostname/diskspace' ack_message='Acknowledged' ack_author='username'
salt myminion victorops.create_event message_type='RECOVERY' routing_key='everyone' entity_id='hostname/diskspace'
```

The following parameters are required: message_type

### 13.6.335 salt.modules.virt

Work with virtual machines managed by libvirt

**depends** libvirt Python module

**salt.modules.virt.cpu_baseline**(*full=False, migratable=False, out='libvirt'*)

Return the optimal 'custom' CPU baseline config for VM's on this minion

New in version 2016.3.0.

**Parameters**

- **full** -- Return all CPU features rather than the ones on top of the closest CPU model
- **migratable** -- Exclude CPU features that are unmigratable (libvirt 2.13+)
- **out** -- 'libvirt' (default) for usable libvirt XML definition, 'salt' for nice dict

**CLI Example:**

```
salt '*' virt.cpu_baseline
```

**salt.modules.virt.create**(domain)

Deprecated since version 2016.3.0: Use `start()` instead.

Start a defined domain

**CLI Example:**

```
salt '*' virt.create <domain>
```
salt.modules.virt.\texttt{create\_xml\_path}(path)
Start a domain based on the XML-file path passed to the function

CLI Example:

\begin{verbatim}
salt '*' virt.create_xml_path <path to XML file on the node>
\end{verbatim}

salt.modules.virt.\texttt{create\_xml\_str}(xml)
Start a domain based on the XML passed to the function

CLI Example:

\begin{verbatim}
salt '*' virt.create_xml_str <XML in string format>
\end{verbatim}

salt.modules.virt.\texttt{ctrl\_alt\_del}(vm_)
Sends CTRL+ALT+DEL to a VM

CLI Example:

\begin{verbatim}
salt '*' virt.ctrl_alt_del <domain>
\end{verbatim}

salt.modules.virt.\texttt{define\_vol\_xml\_path}(path)
Define a volume based on the XML-file path passed to the function

CLI Example:

\begin{verbatim}
salt '*' virt.define_vol_xml_path <path to XML file on the node>
\end{verbatim}

salt.modules.virt.\texttt{define\_vol\_xml\_str}(xml)
Define a volume based on the XML passed to the function

CLI Example:

\begin{verbatim}
salt '*' virt.define_vol_xml_str <XML in string format>
\end{verbatim}

salt.modules.virt.\texttt{define\_xml\_path}(path)
Define a domain based on the XML-file path passed to the function

CLI Example:

\begin{verbatim}
salt '*' virt.define_xml_path <path to XML file on the node>
\end{verbatim}

salt.modules.virt.\texttt{define\_xml\_str}(xml)
Define a domain based on the XML passed to the function

CLI Example:

\begin{verbatim}
salt '*' virt.define_xml_str <XML in string format>
\end{verbatim}

salt.modules.virt.\texttt{delete\_snapshots}(name, *names, **kwargs)
Delete one or more snapshots of the given VM.

Options:
- all: Remove all snapshots. Values: True or False (default False).

New in version 2016.3.0.

CLI Example:

\begin{verbatim}
salt '*' virt.delete_snapshots <domain> all=True
salt '*' virt.delete_snapshots <domain> <snapshot>
salt '*' virt.delete_snapshots <domain> <snapshot1> <snapshot2> ...
\end{verbatim}
salt.modules.virt.destroy(domain)
  Deprecated since version 2016.3.0: Use stop() instead.
  Power off a defined domain
  CLI Example:
  ```
salt '*' virt.destroy <domain>
  ```

salt.modules.virt.freecpu()
  Return an int representing the number of unallocated cpus on this hypervisor
  CLI Example:
  ```
salt '*' virt.freecpu
  ```

salt.modules.virt.freemem()
  Return an int representing the amount of memory (in MB) that has not been given to virtual machines on this node
  CLI Example:
  ```
salt '*' virt.freemem
  ```

salt.modules.virt.full_info()
  Return the node_info, vm_info and freemem
  CLI Example:
  ```
salt '*' virt.full_info
  ```

salt.modules.virt.get_disks(vm_)
  Return the disks of a named vm
  CLI Example:
  ```
salt '*' virt.get_disks <domain>
  ```

salt.modules.virt.get_graphics(vm_)
  Returns the information on vnc for a given vm
  CLI Example:
  ```
salt '*' virt.get_graphics <domain>
  ```

salt.modules.virt.get_macs(vm_)
  Return a list off MAC addresses from the named vm
  CLI Example:
  ```
salt '*' virt.get_macs <domain>
  ```

salt.modules.virt.get_nics(vm_)
  Return info about the network interfaces of a named vm
  CLI Example:
  ```
salt '*' virt.get_nics <domain>
  ```
salt.modules.virt.get_profiles(hypervisor=None)
Return the virt profiles for hypervisor.
Currently there are profiles for:
  • nic
  • disk
CLI Example:

```
salt '*' virt.get_profiles
salt '*' virt.get_profiles hypervisor=esxi
```

salt.modules.virt.get_xml(vm_)
Returns the XML for a given vm
CLI Example:

```
salt '*' virt.get_xml <domain>
```

salt.modules.virt.init(name, cpu, mem, image=None, nic='default', hypervisor='kvm', start=True, disk='default', saltenv='base', seed=True, install=True, pub_key=None, priv_key=None, seed_cmd='seed.apply', enable_vnc=False, **kwargs)
Initialize a new vm
CLI Example:

```
salt 'hypervisor' virt.init vm_name 4 512 salt://path/to/image.raw
salt 'hypervisor' virt.init vm_name 4 512 nic=profile disk=profile
```

salt.modules.virt.is_hyper()
Returns a bool whether or not this node is a hypervisor of any kind
CLI Example:

```
salt '*' virt.is_hyper
```

salt.modules.virt.is_kvm_hyper()
Returns a bool whether or not this node is a KVM hypervisor
CLI Example:

```
salt '*' virt.is_kvm_hyper
```

salt.modules.virt.is_xen_hyper()
Returns a bool whether or not this node is a XEN hypervisor
CLI Example:

```
salt '*' virt.is_xen_hyper
```

salt.modules.virt.list_active_vms()
Return a list of names for active virtual machine on the minion
CLI Example:

```
salt '*' virt.list_active_vms
```

salt.modules.virt.list_domains()  
Return a list of available domains.
CLI Example:
salt '*' virt.list_domains

salt.modules.virt.list_inactive_vms()
Return a list of names for inactive virtual machine on the minion

CLI Example:
salt '*' virt.list_inactive_vms

salt.modules.virt.list_snapshots(domain=None)
List available snapshots for certain vm or for all.
New in version 2016.3.0.

CLI Example:
salt '*' virt.list_snapshots
salt '*' virt.list_snapshots <domain>

salt.modules.virt.list_vms()
Deprecated since version 2016.3.0: Use list_domains() instead.

List all virtual machines.

CLI Example:
salt '*' virt.list_vms <domain>

salt.modules.virt.migrate(vm_, target, ssh=False)
Shared storage migration

CLI Example:
salt '*' virt.migrate <domain> <target hypervisor>

salt.modules.virt.migrate_non_shared(vm_, target, ssh=False)
Attempt to execute non-shared storage "all" migration

CLI Example:
salt '*' virt.migrate_non_shared <vm name> <target hypervisor>

salt.modules.virt.migrate_non_shared_inc(vm_, target, ssh=False)
Attempt to execute non-shared storage "all" migration

CLI Example:
salt '*' virt.migrate_non_shared_inc <vm name> <target hypervisor>

salt.modules.virt.node_info()
Return a dict with information about this node

CLI Example:
salt '*' virt.node_info

salt.modules.virt.pause(vm_)
Pause the named vm

CLI Example:
salt '*' virt.pause <domain>

salt.modules.virt.purge(vm_, dirs=False)
    Recursively destroy and delete a virtual machine, pass True for dir's to also delete the directories containing
    the virtual machine disk images - USE WITH EXTREME CAUTION!

    CLI Example:
    ```
salt '*' virt.purge <domain>
    ```

salt.modules.virt.reboot(name)
    Reboot a domain via ACPI request

    CLI Example:
    ```
salt '*' virt.reboot <domain>
    ```

salt.modules.virt.reset(vm_)
    Reset a VM by emulating the reset button on a physical machine

    CLI Example:
    ```
salt '*' virt.reset <domain>
    ```

salt.modules.virt.resume(vm_)
    Resume the named vm

    CLI Example:
    ```
salt '*' virt.resume <domain>
    ```

salt.modules.virt.revert_snapshot(name, snapshot=None, cleanup=False)
    Revert snapshot to the previous from current (if available) or to the specific.

    Options:
    - **cleanup**: Remove all newer than reverted snapshots. Values: True or False (default False).
      New in version 2016.3.0.

    CLI Example:
    ```
salt '*' virt.revert <domain>
salt '*' virt.revert <domain> <snapshot>
    ```

salt.modules.virt.seed_non_shared_migrate(disks, force=False)
    Non shared migration requires that the disks be present on the migration destination, pass the disks information
    via this function, to the migration destination before executing the migration.

    CLI Example:
    ```
salt '*' virt.seed_non_shared_migrate <disks>
    ```

salt.modules.virt.set_autostart(vm_, state='on')
    Set the autostart flag on a VM so that the VM will start with the host system on reboot.

    CLI Example:
    ```
salt "*" virt.set_autostart <domain> <on | off>
    ```
salt.modules.virt.setmem(vm_, memory, config=False)
Changes the amount of memory allocated to VM. The VM must be shutdown for this to work.
memory is to be specified in MB If config is True then we ask libvirt to modify the config as well
CLI Example:
```
salt '*' virt.setmem <domain> <size>
salt '*' virt.setmem my_domain 768
```

salt.modules.virt.setvcpus(vm_, vcpus, config=False)
Changes the amount of vcpus allocated to VM. The VM must be shutdown for this to work.
vcpus is an int representing the number to be assigned If config is True then we ask libvirt to modify the config as well
CLI Example:
```
salt '*' virt.setvcpus <domain> <amount>
salt '*' virt.setvcpus my_domain 4
```

salt.modules.virt.shutdown(vm_)
Send a soft shutdown signal to the named vm
CLI Example:
```
salt '*' virt.shutdown <domain>
```

salt.modules.virt.snapshot(domain, name=None, suffix=None)
Create a snapshot of a VM.
Options:
- **name**: Name of the snapshot. If the name is omitted, then will be used original domain name with ISO 8601 time as a suffix.
- **suffix**: Add suffix for the new name. Useful in states, where such snapshots can be distinguished from manually created.
New in version 2016.3.0.
CLI Example:
```
salt '*' virt.snapshot <domain>
```

salt.modules.virt.start(name)
Start a defined domain
CLI Example:
```
salt '*' virt.start <domain>
```

salt.modules.virt.stop(name)
Hard power down the virtual machine, this is equivalent to pulling the power.
CLI Example:
```
salt '*' virt.stop <domain>
```

salt.modules.virt.undefine(vm_)
Remove a defined vm, this does not purge the virtual machine image, and this only works if the vm is powered down
CLI Example:
salt '*' virt.undefine <domain>

salt.modules.virt.virt_type()
Returns the virtual machine type as a string

CLI Example:
salt '*' virt.virt_type

salt.modules.virt.vm_cputime(vm_=None)
Return cputime used by the vms on this hyper in a list of dicts:

```
[
    'your-vm': {
        'cputime' <int>,
        'cputime_percent' <int>,
    },
    ...
]
```

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:
salt '*' virt.vm_cputime

salt.modules.virt.vm_diskstats(vm_=None)
Return disk usage counters used by the vms on this hyper in a list of dicts:

```
[
    'your-vm': {
        'rd_req' : 0,
        'rd_bytes' : 0,
        'wr_req' : 0,
        'wr_bytes' : 0,
        'errs' : 0,
    },
    ...
]
```

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:
salt '*' virt.vm_blockstats

salt.modules.virt.vm_info(vm_=None)
Return detailed information about the vms on this hyper in a list of dicts:

```
[
    'your-vm': {
        'cpu': <int>,
        'maxMem': <int>,
        'mem': <int>,
        'state': '<state>',
        'cputime': <int>
    }
]```
If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:
```
salt '*' virt.vm_info
```

```
salt.modules.virt.vm_netstats(vm_=None)

Return combined network counters used by the vms on this hyper in a list of dicts:
```
```
['your-vm': {
  'rx_bytes' : 0,
  'rx_packets' : 0,
  'rx_errs' : 0,
  'rx_drop' : 0,
  'tx_bytes' : 0,
  'tx_packets' : 0,
  'tx_errs' : 0,
  'tx_drop' : 0
},
...
```
```
If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:
```
salt '*' virt.vm_netstats
```

```
salt.modules.virt.vm_state(vm_=None)

Return list of all the vms and their state.
```
```
If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:
```
salt '*' virt.vm_state <domain>
```

### 13.6.336 salt.modules.virtualenv

Create virtualenv environments.

New in version 0.17.0.

```
salt.modules.virtualenv_mod.create(path, venv_bin=None, system_site_packages=False, distribute=False, clear=False, python=None, extra_search_dir=None, never_download=None, prompt=None, pip=False, symlinks=None, upgrade=None, user=None, use_vt=False, saltenv='base')
```

Create a virtualenv

**path**  The path to the virtualenv to be created
venv_bin  The name (and optionally path) of the virtualenv command. This can also be set globally in the
minion config file as virtualenv.venv_bin. Defaults to virtualenv.

system_site_packages  [False] Passthrough argument given to virtualenv or pyvenv
distribute  [False] Passthrough argument given to virtualenv
pip  [False] Install pip after creating a virtual environment. Implies distribute=True
clear  [False] Passthrough argument given to virtualenv or pyvenv
python  [None (default)] Passthrough argument given to virtualenv
extra_search_dir  [None (default)] Passthrough argument given to virtualenv
never_download  [None (default)] Passthrough argument given to virtualenv if True
prompt  [None (default)] Passthrough argument given to virtualenv if not None
symlinks  [None] Passthrough argument given to pyvenv if True
upgrade  [None] Passthrough argument given to pyvenv if True
user  [None] Set ownership for the virtualenv
runas  [None] Set ownership for the virtualenv

Deprecated since version 2014.1.0: user should be used instead

use_vt  [False] Use VT terminal emulation (see output while installing)

New in version 2015.5.0.
saltenv  ['base'] Specify a different environment. The default environment is base.

New in version 2014.1.0.

Note: The runas argument is deprecated as of 2014.1.0. user should be used instead.

CLI Example:

```
salt '*' virtualenv.create /path/to/new/virtualenv
```

salt.modules.virtualenv_mod.get_distribution_path(venv, distribution)

Return the path to a distribution installed inside a virtualenv

New in version 2016.3.0.

venv  Path to the virtualenv.
distribution  Name of the distribution. Note, all non-alphanumeric characters will be converted to dashes.

CLI Example:

```
salt '*' virtualenv.get_distribution_path /path/to/my/venv my_distribution
```

salt.modules.virtualenv_mod.get_resource_content(venv, package_or_requirement=None, resource_name=None, package=None, resource=None)

Return the content of a package resource installed inside a virtualenv

venv  Path to the virtualenv
package  Name of the package in which the resource resides

New in version 2016.3.0.

package_or_requirement  Name of the package in which the resource resides

Deprecation since version 2016.3.0: Use package instead.

resource  Name of the resource of which the content is to be returned

New in version 2016.3.0.

resource_name  Name of the resource of which the content is to be returned

Deprecation since version 2016.3.0.
New in version 2015.5.0.

venv  Path to the virtualenv.
**package_or_requirement**  Name of the package where the resource resides in.
**resource_name**  Name of the resource of which the content is to be returned.

CLI Example:
```
salt '*' virtualenv.get_resource_content /path/to/my/venv my_package my/resource.xml
```

```python
salt.modules.virtualenv_mod.get_resource_path(venv, package_or_requirement=None, resource_name=None, package=None, resource=None)
```

Return the path to a package resource installed inside a virtualenv

**venv**  Path to the virtualenv

**package**  Name of the package in which the resource resides

New in version 2016.3.0.

**package_or_requirement**  Name of the package in which the resource resides

Depreciated since version 2016.3.0: Use **package** instead.

**resource**  Name of the resource of which the path is to be returned

New in version 2016.3.0.

**resource_name**  Name of the resource of which the path is to be returned

Depreciated since version 2016.3.0.

New in version 2015.5.0.

**venv**  Path to the virtualenv.

**package_or_requirement**  Name of the package where the resource resides in.

**resource_name**  Name of the resource of which the path is to be returned.

CLI Example:
```
salt '*' virtualenv.get_resource_path /path/to/my/venv my_package my/resource.xml
```

```python
salt.modules.virtualenv_mod.get_site_packages(venv)
```

Return the path to the site-packages directory of a virtualenv

**venv**  Path to the virtualenv.

CLI Example:
```
salt '*' virtualenv.get_site_packages /path/to/my/venv
```

### 13.6.337  salt.modules.vsphere

Manage VMware vCenter servers and ESXi hosts.

New in version 2015.8.4.

**Dependencies**

- pyVmomi Python Module
- ESXCLI

**pyVmomi**

PyVmomi can be installed via pip:
pip install pyVmomi

Note: Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, Python 2.6, Python 2.7.9, or newer must be present. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the following:

pip install pyVmomi==5.5.0.2014.1.1

The 5.5.0.2014.1.1 is a known stable version that this original vSphere Execution Module was developed against.

ESXCLI

Currently, about a third of the functions used in the vSphere Execution Module require the ESXCLI package be installed on the machine running the Proxy Minion process.

The ESXCLI package is also referred to as the VMware vSphere CLI, or vCLI. VMware provides vCLI package installation instructions for vSphere 5.5 and vSphere 6.0.

Once all of the required dependencies are in place and the vCLI package is installed, you can check to see if you can connect to your ESXi host or vCenter server by running the following command:

```bash
esxcli -s <host-location> -u <username> -p <password> system syslog config get
```

If the connection was successful, ESXCLI was successfully installed on your system. You should see output related to the ESXi host's syslog configuration.

Note: Be aware that some functionality in this execution module may depend on the type of license attached to a vCenter Server or ESXi host(s).

For example, certain services are only available to manipulate service state or policies with a VMware vSphere Enterprise or Enterprise Plus license, while others are available with a Standard license. The ntpd service is restricted to an Enterprise Plus license, while ssh is available via the Standard license.

Please see the vSphere Comparison page for more information.

About

This execution module was designed to be able to handle connections both to a vCenter Server, as well as to an ESXi host. It utilizes the pyVmomi Python library and the ESXCLI package to run remote execution functions against either the defined vCenter server or the ESXi host.

Whether or not the function runs against a vCenter Server or an ESXi host depends entirely upon the arguments passed into the function. Each function requires a host location, username, and password. If the credentials provided apply to a vCenter Server, then the function will be run against the vCenter Server. For example, when listing hosts using vCenter credentials, you'll get a list of hosts associated with that vCenter Server:
# salt my-minion vsphere.list_hosts <vcenter-ip> <vcenter-user> <vcenter-password>
my-minion:
  - esxi-1.example.com
  - esxi-2.example.com

However, some functions should be used against ESXi hosts, not vCenter Servers. Functionality such as getting a host's coredump network configuration should be performed against a host and not a vCenter server. If the authentication information you're using is against a vCenter server and not an ESXi host, you can provide the host name that is associated with the vCenter server in the command, as a list, using the host_names or esxi_host kwarg. For example:

```bash
# salt my-minion vsphere.get_coredump_network_config <vcenter-ip> <vcenter-user> <vcenter-password> esxi_hosts='[esxi-1.example.com, esxi-2.example.com]'
```

You can also use these functions against an ESXi host directly by establishing a connection to an ESXi host using the host's location, username, and password. If ESXi connection credentials are used instead of vCenter credentials, the host_names and esxi_host arguments are not needed.

```bash
# salt my-minion vsphere.get_coredump_network_config esxi-1.example.com root <host-password>
```

---

13.6. execution modules 1599
salt.modules.vsphere.add_host_to_dvs(host, username, password, vmknic_name, vmnic_name, dvs_name, target_portgroup_name, uplink_portgroup_name, protocol=None, port=None, host_names=None)

Adds an ESXi host to a vSphere Distributed Virtual Switch and migrates the desired adapters to the DVS from the standard switch.

- **host**: The location of the vCenter server.
- **username**: The username used to login to the vCenter server.
- **password**: The password used to login to the vCenter server.
- **vmknic_name**: The name of the virtual NIC to migrate.
- **vmnic_name**: The name of the physical NIC to migrate.
- **dvs_name**: The name of the Distributed Virtual Switch.
- **target_portgroup_name**: The name of the distributed portgroup in which to migrate the virtual NIC.
- **uplink_portgroup_name**: The name of the uplink portgroup in which to migrate the physical NIC.
- **protocol**: Optionally set to alternate protocol if the vCenter server or ESX/ESXi host is not using the default protocol. Default protocol is https.
- **port**: Optionally set to alternate port if the vCenter server or ESX/ESXi host is not using the default port. Default port is 443.
- **host_names**: An array of VMware host names to migrate

CLI Example:

```
salt some_host vsphere.add_host_to_dvs host='vsphere.corp.com' username='administrator@vsphere.corp.com' password='vsphere_password' vmknic_name='vmk0' vmnic_name='vmnic0' dvs_name='DSwitch' target_portgroup_name='DPortGroup' uplink_portgroup_name='DSwitch1-DVUplinks-181' protocol='https' port='443', host_names=['esxi1.corp.com','esxi2.corp.com','esxi3.corp.com']"
```

Return Example:

```
somehost:
    ----------
esxi1.corp.com:
    ----------
dvs:
    DSwitch
portgroup:
    DPortGroup
status:
    True
uplink:
    DSwitch-DVUplinks-181
vmknic:
    vmk0
vmnic:
    vmnic0
esxi2.corp.com:
    ----------
dvs:
    DSwitch
portgroup:
    DPortGroup
status:
    True
uplink:
    DSwitch-DVUplinks-181
```
This was very difficult to figure out. VMware's PyVmomi documentation at https://github.com/vmware/pyvmomi/blob/master/docs/vim/DistributedVirtualSwitch.rst (which is a copy of the official documentation here: https://www.vmware.com/support/developer/converter-sdk/conv60_apireference/vim.DistributedVirtualSwitch.html) says to create the DVS, create distributed portgroups, and then add the host to the DVS specifying which physical NIC to use as the port backing. However, if the physical NIC is in use as the only link from the host to vSphere, this will fail with an unhelpful "busy" error.

There is, however, a Powershell PowerCLI cmdlet called Add-VDSwitchPhysicalNetworkAdapter that does what we want. I used Onyx (https://labs.vmware.com/flings/onyx) to sniff the SOAP stream from Powershell to our vSphere server and got this snippet out:

```
<UpdateNetworkConfig xmlns="urn:vim25">
  <_this type="HostNetworkSystem">networkSystem-187</_this>
  <config>
    <vswitch>
      <changeOperation/edit><name>vSwitch0</name>
      <spec>
        <numPorts>7812</numPorts>
      </spec>
    </vswitch>
    <proxySwitch>
      <changeOperation/edit><uuid>73 a4 05 50 b0 d2 7e b9-38 80 5d 24 65 8f da 70</uuid>
      <backing xsi:type="DistributedVirtualSwitchHostMemberPnicBacking">
        <pnicSpec><pnicDevice>vmnic0</pnicDevice></pnicSpec>
      </backing>
    </proxySwitch>
    <portgroup>
      <changeOperation/remove><spec>
        <name>Management
        <vlanId>1</vlanId>
      </spec>
    </portgroup>
  </config>
</UpdateNetworkConfig>
```
The SOAP API maps closely to PyVmomi, so from there it was (relatively) easy to figure out what Python to write.

```
salt.modules.vsphere.coredump_network_enable(host, username, password, enabled, protocol=None, port=None, esxi_hosts=None)
```

Enable or disable ESXi core dump collection. Returns True if coredump is enabled and returns False if core dump is not enabled. If there was an error, the error will be the value printed in the Error key dictionary for the given host.

- **host** The location of the host.
- **username** The username used to login to the host, such as root.
- **password** The password used to login to the host.
- **enabled** Python True or False to enable or disable coredumps.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is 443.
- **esxi_hosts** If host is a vCenter host, then use esxi_hosts to execute this function on a list of one or more ESXi machines.

CLI Example:

```
# Used for ESXi host connection information
salt '*' vsphere.coredump_network_enable my.esxi.host root bad-password True

# Used for connecting to a vCenter Server
salt '*' vsphere.coredump_network_enable my.vcenter.location root bad-password True
esxi_hosts='[esxi-1.host.com, esxi-2.host.com]'
```

```
salt.modules.vsphere.enable_firewall_ruleset(host, username, password, ruleset_enable, ruleset_name, protocol=None, port=None, esxi_hosts=None)
```

Enable or disable an ESXi firewall rule set.

- **host** The location of the host.
- **username** The username used to login to the host, such as root.
- **password** The password used to login to the host.
- **ruleset_enable** True to enable the ruleset, false to disable.
- **ruleset_name** Name of ruleset to target.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is 443.
- **esxi_hosts** If host is a vCenter host, then use esxi_hosts to execute this function on a list of one or more ESXi machines.

Returns A standard cmd.run_all dictionary, per host.
CLI Example:

```yaml
# Used for ESXi host connection information
salt '*' vsphere.enable_firewall_ruleset my.esxi.host root bad-password True →'syslog'
# Used for connecting to a vCenter Server
salt '*' vsphere.enable_firewall_ruleset my.vcenter.location root bad-password
  →True 'syslog' esxi_hosts='[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.esxcli_cmd(host, username, password, cmd_str, protocol=None, port=None, esxi_hosts=None)

Run an ESXCLI command directly on the host or list of hosts.

- **host** The location of the host.
- **username** The username used to login to the host, such as `root`.
- **password** The password used to login to the host.
- **cmd_str** The ESXCLI command to run. Note: This should not include the `--protocol`, or `--portnumber` arguments that are frequently passed when using a bare ESXCLI command from the command line. Those arguments are handled by this function via the other args and kwargs.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is `443`.
- **esxi_hosts** If `host` is a vCenter host, then use esxi_hosts to execute this function on a list of one or more ESXi machines.

Returns A dictionary with the network configuration, or, if getting the network config failed, an error message retrieved from the standard cmd.run_all dictionary, per host.

CLI Example:

```yaml
# Used for ESXi host connection information
salt '*' vsphere.esxcli_cmd my.esxi.host root bad-password
  →coredump network get'
# Used for connecting to a vCenter Server
salt '*' vsphere.esxcli_cmd my.vcenter.location root bad-password
  →'system coredump network get' esxi_hosts='[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.get_coredump_network_config(host, username, password, protocol=None, port=None, esxi_hosts=None)

Retrieve information on ESXi or vCenter network dump collection and format it into a dictionary.

- **host** The location of the host.
- **username** The username used to login to the host, such as `root`.
- **password** The password used to login to the host.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is `443`.
- **esxi_hosts** If `host` is a vCenter host, then use esxi_hosts to execute this function on a list of one or more ESXi machines.

Returns A dictionary with the network configuration, or, if getting the network config failed, an error message retrieved from the standard cmd.run_all dictionary, per host.

CLI Example:
salt.modules.vsphere.get_firewall_status(host, username, password, protocol=None, port=None, esxi_hosts=None)

Show status of all firewall rule sets.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as `root`.
- **password**: The password used to login to the host.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is `443`.
- **esxi_hosts**: If `host` is a vCenter host, then use `esxi_hosts` to execute this function on a list of one or more ESXi machines.

**Returns**: Nested dictionary with two toplevel keys: `rulesets` and `success`. `success` will be True or False depending on query success. `rulesets` will list the rulesets and their statuses if `success` was true, per host.

CLI Example:

```bash
# Used for ESXi host connection information
salt '*' vsphere.get_firewall_status my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.get_firewall_status my.vcenter.location root bad-password
```

salt.modules.vsphere.get_host_datetime(host, username, password, protocol=None, port=None, host_names=None)

Get the date/time information for a given host or list of host_names.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as `root`.
- **password**: The password used to login to the host.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is `443`.
- **host_names**: List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the `host_names` argument is required to tell vCenter the hosts for which to get date/time information.

If `host_names` is not provided, the date/time information will be retrieved for the `host` location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

```bash
# Used for single ESXi host connection information
salt '*' vsphere.get_host_datetime my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.get_host_datetime my.vcenter.location root bad-password
```

salt.modules.vsphere.get_ntp_config(host, username, password, protocol=None, port=None, host_names=None)

Get the NTP configuration information for a given host or list of host_names.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as `root`.
- **password**: The password used to login to the host.
protocol  Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

port  Optionally set to alternate port if the host is not using the default port. Default port is 443.

host_names  List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter the hosts for which to get ntp configuration information.

If host_names is not provided, the NTP configuration will be retrieved for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

```
# Used for single ESXi host connection information
salt '*' vsphere.get_ntp_config my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.get_ntp_config my.vcenter.location root bad-password
  host_names=['esxi-1.host.com, esxi-2.host.com']
```

salt.modules.vsphere.get_service_policy(host, username, password, service_name, protocol=None, port=None, host_names=None)

Get the service name's policy for a given host or list of hosts.

- **host**  The location of the host.
- **username**  The username used to login to the host, such as root.
- **password**  The password used to login to the host.
- **service_name**  The name of the service for which to retrieve the policy. Supported service names are:
  - DCUI
  - TSM
  - SSH
  - lbtd
  - lsassd
  - lwiod
  - netlogond
  - ntpd
  - sfcbd-watchdog
  - snmpd
  - vprobed
  - vpax
  - xorg

protocol  Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

port  Optionally set to alternate port if the host is not using the default port. Default port is 443.

host_names  List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter the hosts for which to get service policy information.

If host_names is not provided, the service policy information will be retrieved for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:
# Used for single ESXi host connection information
salt '*' vsphere.get_service_policy my.esxi.host root bad-password 'ssh'

# Used for connecting to a vCenter Server
salt '*' vsphere.get_service_policy my.vcenter.location root bad-password 'ntpd' host_names='[esxi-1.host.com, esxi-2.host.com]'

salt.modules.vsphere.get_service_running(host, username, password, service_name, protocol=None, port=None, host_names=None)

Get the service name's running state for a given host or list of hosts.

host The location of the host.
username The username used to login to the host, such as root.
password The password used to login to the host.

service_name

The name of the service for which to retrieve the policy. Supported service names are:

- DCUI
- TSM
- SSH
- lbd
- lsassd
- lwiod
- netlogond
- ntpd
- sfcbd-watchdog
- snmpd
- vprobed
- vpxa
- xorg

protocol Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

port Optionally set to alternate port if the host is not using the default port. Default port is 443.

host_names List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter the hosts for which to get the service's running state.

If host_names is not provided, the service's running state will be retrieved for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

# Used for single ESXi host connection information
salt '*' vsphere.get_service_running my.esxi.host root bad-password 'ssh'

# Used for connecting to a vCenter Server
salt '*' vsphere.get_service_running my.vcenter.location root bad-password 'ntpd' host_names='[esxi-1.host.com, esxi-2.host.com]'

salt.modules.vsphere.get_ssh_key(host, username, password, protocol=None, port=None, certificate_verify=False)

Retrieve the authorized_keys entry for root. This function only works for ESXi, not vCenter.
Parameters

- **host** -- The location of the ESXi Host
- **username** -- Username to connect as
- **password** -- Password for the ESXi web endpoint
- **protocol** -- defaults to https, can be http if ssl is disabled on ESXi
- **port** -- defaults to 443 for https
- **certificate_verify** -- If true require that the SSL connection present a valid certificate

Returns  True if upload is successful

CLI Example:

```bash
salt '*' vsphere.get_ssh_key my.esxi.host root bad-password certificate_verify=True
```

salt.modules.vsphere.get_syslog_config(*host, username, password, protocol=None, port=None, esxi_hosts=None*)

Retrieve the syslog configuration.

- **host** The location of the host.
- **username** The username used to login to the host, such as root.
- **password** The password used to login to the host.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is 443.
- **esxi_hosts** If host is a vCenter host, then use esxi_hosts to execute this function on a list of one or more ESXi machines.

Returns Dictionary with keys and values corresponding to the syslog configuration, per host.

CLI Example:

```
# Used for ESXi host connection information
salt '*' vsphere.get_syslog_config my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.get_syslog_config my.vcenter.location root bad-password

← esxi_hosts='[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.get_vmotion_enabled(*host, username, password, protocol=None, port=None, host_names=None*)

Get the VMotion enabled status for a given host or a list of host_names. Returns True if VMotion is enabled, False if it is not enabled.

- **host** The location of the host.
- **username** The username used to login to the host, such as root.
- **password** The password used to login to the host.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is 443.
- **host_names** List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter which hosts to check if VMotion is enabled.

If host_names is not provided, the VMotion status will be retrieved for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:
salt.modules.vsphere.get_vsan_eligible_disks

```python
salt.modules.vsphere.get_vsan_eligible_disks(host, username, password, protocol=None, port=None, host_names=None)
```

Returns a list of VSAN-eligible disks for a given host or list of host_names.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as `root`.
- **password**: The password used to login to the host.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is 443.
- **host_names**: List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter which hosts to check if any VSAN-eligible disks are available.

If host_names is not provided, the VSAN-eligible disks will be retrieved for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

**CLI Example:**

```bash
# Used for single ESXi host connection information
salt 'salt/' vsphere.get_vsan_eligible_disks my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt 'salt/' vsphere.get_vsan_eligible_disks my.vcenter.location root bad-password
← host_names=['[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.get_vsan_enabled

```python
salt.modules.vsphere.get_vsan_enabled(host, username, password, protocol=None, port=None, host_names=None)
```

Get the VSAN enabled status for a given host or a list of host_names. Returns `True` if VSAN is enabled, `False` if it is not enabled, and `None` if a VSAN Host Config is unset, per host.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as `root`.
- **password**: The password used to login to the host.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is 443.
- **host_names**: List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter which hosts to check if VSAN enabled.

If host_names is not provided, the VSAN status will be retrieved for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

**CLI Example:**

```bash
# Used for single ESXi host connection information
salt 'salt/' vsphere.get_vsan_enabled my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt 'salt/' vsphere.get_vsan_enabled my.vcenter.location root bad-password
← host_names=['[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.list_clusters

```python
salt.modules.vsphere.list_clusters(host, username, password, protocol=None, port=None)
```

1608 Chapter 13. Salt Module Reference
Returns a list of clusters for the specified host.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as `root`.
- **password**: The password used to login to the host.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is 443.

```python
salt '*' vsphere.list_clusters 1.2.3.4 root bad-password
```

### vsphere.list_datacenters

Returns a list of datacenters for the specified host.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as `root`.
- **password**: The password used to login to the host.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is 443.

```python
salt '*' vsphere.list_datacenters 1.2.3.4 root bad-password
```

### vsphere.list_datastore_clusters

Returns a list of datastore clusters for the specified host.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as `root`.
- **password**: The password used to login to the host.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is 443.

```python
salt '*' vsphere.list_datastore_clusters 1.2.3.4 root bad-password
```

### vsphere.list_datastores

Returns a list of datastores for the specified host.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as `root`.
- **password**: The password used to login to the host.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is 443.

```python
salt '*' vsphere.list_datastores 1.2.3.4 root bad-password
```

### vsphere.list_dvs

Returns a list of distributed virtual switches for the specified host.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as `root`.
- **password**: The password used to login to the host.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is 443.

```python
salt '*' vsphere.list_dvs 1.2.3.4 root bad-password
```
salt.modules.vsphere.list_folders(host, username, password, protocol=None, port=None)

Returns a list of folders for the specified host.

**host** The location of the host.

**username** The username used to login to the host, such as root.

**password** The password used to login to the host.

**protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

**port** Optionally set to alternate port if the host is not using the default port. Default port is 443.

```
salt '*' vsphere.list_folders 1.2.3.4 root bad-password
```

salt.modules.vsphere.list_hosts(host, username, password, protocol=None, port=None)

Returns a list of hosts for the specified VMware environment.

**host** The location of the host.

**username** The username used to login to the host, such as root.

**password** The password used to login to the host.

**protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

**port** Optionally set to alternate port if the host is not using the default port. Default port is 443.

```
salt '*' vsphere.list_hosts 1.2.3.4 root bad-password
```

salt.modules.vsphere.list_networks(host, username, password, protocol=None, port=None)

Returns a list of networks for the specified host.

**host** The location of the host.

**username** The username used to login to the host, such as root.

**password** The password used to login to the host.

**protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

**port** Optionally set to alternate port if the host is not using the default port. Default port is 443.

```
salt '*' vsphere.list_networks 1.2.3.4 root bad-password
```

salt.modules.vsphere.list_non_ssds(host, username, password, protocol=None, port=None, host_names=None)

Returns a list of Non-SSD disks for the given host or list of host_names.

**Note:** In the pyVmomi StorageSystem, ScsiDisks may, or may not have an `ssd` attribute. This attribute indicates if the ScsiDisk is SSD backed. As this option is optional, if a relevant disk in the StorageSystem does not have `ssd = true`, it will end up in the `non_ssds` list here.

**host** The location of the host.

**username** The username used to login to the host, such as root.

**password** The password used to login to the host.

**protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

**port** Optionally set to alternate port if the host is not using the default port. Default port is 443.

**host_names** List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter the hosts for which to retrieve Non-SSD disks.

If host_names is not provided, Non-SSD disks will be retrieved for the `host` location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:
salt.modules.vsphere.list_resourcepools(host, username, password, protocol=None, port=None)

Returns a list of resource pools for the the specified host.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as `root`.
- **password**: The password used to login to the host.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is `443`.

```bash
salt '*' vsphere.list_resourcepools 1.2.3.4 root bad-password
```

salt.modules.vsphere.list_ssds(host, username, password, protocol=None, port=None, host_names=None)

Returns a list of SSDs for the given host or list of `host_names`.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as `root`.
- **password**: The password used to login to the host.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is `443`.
- **host_names**: List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the `host_names` argument is required to tell vCenter the hosts for which to retrieve SSDs.

If `host_names` is not provided, SSDs will be retrieved for the `host` location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

```bash
# Used for single ESXi host connection information
salt '*' vsphere.list_ssds my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.list_ssds my.vcenter.location root bad-password  --names='[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.list_vapps(host, username, password, protocol=None, port=None)

Returns a list of vApps for the the specified host.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as `root`.
- **password**: The password used to login to the host.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is `443`.

```bash
salt '*' vsphere.list_vapps 1.2.3.4 root bad-password
```

salt.modules.vsphere.list_vms(host, username, password, protocol=None, port=None)

Returns a list of VMs for the the specified host.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as `root`.
- **password**: The password used to login to the host.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is `443`.

```bash
salt '*' vsphere.list_vms 1.2.3.4 root bad-password
```
**salt.modules.vsphere.reset_syslog_config**

```python
salt.modules.vsphere.reset_syslog_config(host, username, password, protocol=None, port=None, syslog_config=None, esxi_hosts=None)
```

Reset the syslog service to its default settings.

*Valid syslog_config values are* `logdir`, `loghost`, `logdir-unique`, `default-rotate`, `default-size`, `default-timeout`, or `all` for all of these.

**host** The location of the host.

**username** The username used to login to the host, such as `root`.

**password** The password used to login to the host.

**protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.

**port** Optionally set to alternate port if the host is not using the default port. Default port is 443.

**syslog_config** List of parameters to reset, provided as a comma-delimited string, or `'all'` to reset all syslog configuration parameters. Required.

**esxi_hosts** If host is a vCenter host, then use esxi_hosts to execute this function on a list of one or more ESXi machines.

**Returns** Dictionary with a top-level key of `success` which indicates if all the parameters were reset, and individual keys for each parameter indicating which succeeded or failed, per host.

**CLI Example:**

```bash
salt '*' vsphere.reset_syslog_config my.esxi.host root bad-password
```

```bash
-> syslog_config='logdir,loghost'
```

```bash
salt '*' vsphere.reset_syslog_config my.vcenter.location root bad-password
```

```bash
-> syslog_config='logdir,loghost' esxi_hosts='[esxi-1.host.com, esxi-2.host.com]'
```

**salt.modules.vsphere.service_restart**

```python
salt.modules.vsphere.service_restart(host, username, password, service_name, protocol=None, port=None, host_names=None)
```

Restart the named service for the given host or list of hosts.

**host** The location of the host.

**username** The username used to login to the host, such as `root`.

**password** The password used to login to the host.

**service_name**

The name of the service for which to set the policy. Supported service names are:

- DCUI
- TSM
- SSH
- lbtd
• lsassd
• lwiod
• netlogond
• ntpd
• sfcbd-watchdog
• snmpd
• vprobed
• vpxa
• xorg

**protocol**  Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

**port**  Optionally set to alternate port if the host is not using the default port. Default port is 443.

**host_names**  List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter the hosts for which to restart the service.

If host_names is not provided, the service will be restarted for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

**CLI Example:**

```
# Used for single ESXi host connection information
salt '*' vsphere.service_restart my.esxi.host root bad-password 'ntpd'

# Used for connecting to a vCenter Server
salt '*' vsphere.service_restart my.vcenter.location root bad-password 'ntpd'  #
host_names=['esxi-1.host.com, esxi-2.host.com']
```

```python
salt.modules.vsphere.service_start(host, username, password, service_name, protocol=None, port=None, host_names=None)
```

Start the named service for the given host or list of hosts.

**host**  The location of the host.

**username**  The username used to login to the host, such as root.

**password**  The password used to login to the host.

**service_name**  The name of the service for which to set the policy. Supported service names are:

- DCUI
- TSM
- SSH
- lbtd
- lsassd
- lwiod
- netlogond
- ntpd
- sfcbd-watchdog
- snmpd
- vprobed

13.6. execution modules
salt.modules.vsphere.service_start(host, username, password, service_name, protocol=None, port=None, host_names=None)

Stop the named service for the given host or list of hosts.

- **host** The location of the host.
- **username** The username used to login to the host, such as root.
- **password** The password used to login to the host.
- **service_name** The name of the service for which to set the policy. Supported service names are:
  - DCUI
  - TSM
  - SSH
  - lbtd
  - lsassd
  - lwiod
  - netlogond
  - ntpd
  - sfchd-watchdog
  - snmpd
  - vprobed
  - vpxa
  - xorg

**protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

**port** Optionally set to alternate port if the host is not using the default port. Default port is 443.

**host_names** List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter the hosts for which to stop the service.

If host_names is not provided, the service will be started for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

```bash
# Used for single ESXi host connection information
salt '*' vsphere.service_start my.esxi.host root bad-password 'ntpd'

# Used for connecting to a vCenter Server
salt '*' vsphere.service_start my.vcenter.location root bad-password 'ntpd'  # host_names='[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.service_stop(host, username, password, service_name, protocol=None, port=None, host_names=None)

Stop the named service for the given host or list of hosts.

- **host** The location of the host.
- **username** The username used to login to the host, such as root.
- **password** The password used to login to the host.
- **service_name** The name of the service for which to set the policy. Supported service names are:
  - DCUI
  - TSM
  - SSH
  - lbtd
  - lsassd
  - lwiod
  - netlogond
  - ntpd
  - sfchd-watchdog
  - snmpd
  - vprobed
  - vpxa
  - xorg

**protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

**port** Optionally set to alternate port if the host is not using the default port. Default port is 443.

**host_names** List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter the hosts for which to stop the service.
If host_names is not provided, the service will be stopped for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

```
# Used for single ESXi host connection information
salt '*' vsphere.service_stop my.esxi.host root bad-password 'ssh'

# Used for connecting to a vCenter Server
salt '*' vsphere.service_stop my.vcenter.location root bad-password 'ssh'
  →host_names='[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.set_coredump_network_config(host, username, password, dump_ip, protocol=None, port=None, host_vnic='vmk0', dump_port=6500, esxi_hosts=None)

Set the network parameters for a network coredump collection. Note that ESXi requires that the dumps first be enabled (see coredump_network_enable) before these parameters may be set.

- **host** The location of the host.
- **username** The username used to login to the host, such as root.
- **password** The password used to login to the host.
- **dump_ip** IP address of host that will accept the dump.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is 443.
- **esxi_hosts** If host is a vCenter host, then use esxi_hosts to execute this function on a list of one or more ESXi machines.
- **host_vnic** Host VNic port through which to communicate. Defaults to vmk0.
- **dump_port** TCP port to use for the dump, defaults to 6500.

**Returns** A standard cmd.run_all dictionary with a success key added, per host. success will be True if the set succeeded, False otherwise.

CLI Example:

```
# Used for ESXi host connection information
salt '*' vsphere.set_coredump_network_config my.esxi.host root bad-password 'dump_ip.host.com'

# Used for connecting to a vCenter Server
salt '*' vsphere.set_coredump_network_config my.vcenter.location root bad-password
  →'dump_ip.host.com'  esxi_hosts='[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.set_ntp_config(host, username, password, ntp_servers, protocol=None, port=None, host_names=None)

Set NTP configuration for a given host of list of host_names.

- **host** The location of the host.
- **username** The username used to login to the host, such as root.
- **password** The password used to login to the host.
- **ntp_servers** A list of servers that should be added to and configured for the specified host's NTP configuration.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is 443.
- **host_names** List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter which hosts to configure ntp servers.

If host_names is not provided, the NTP servers will be configured for the host location instead.
is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

```bash
# Used for single ESXi host connection information
salt '*' vsphere.ntp_configure my.esxi.host root bad-password '[[192.174.1.100, 192.174.1.200]]'

# Used for connecting to a vCenter Server
salt '*' vsphere.ntp_configure my.vcenter.location root bad-password '[[192.174.1.100, 192.174.1.200]]' host_names='[esxi-1.host.com, esxi-2.host.com]'
```

```
salt.modules.vsphere.set_service_policy(host, username, password, service_name, service_policy, protocol=None, port=None, host_names=None)
```

Set the service name's policy for a given host or list of hosts.

- **host** The location of the host.
- **username** The username used to login to the host, such as root.
- **password** The password used to login to the host.
- **service_name** The name of the service for which to set the policy. Supported service names are:
  - DCUI
  - TSM
  - SSH
  - lbtd
  - lsassd
  - lwiod
  - netlogond
  - ntpd
  - sfchd-watchdog
  - snmpd
  - vprobed
  - vpxa
  - xorg
- **service_policy** The policy to set for the service. For example, `automatic`.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is 443.
- **host_names** List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter the hosts for which to set the service policy.

If host_names is not provided, the service policy information will be retrieved for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

```bash
# Used for single ESXi host connection information
salt '*' vsphere.set_service_policy my.esxi.host root bad-password 'ntpd' protocol='automatic'
```
# Used for connecting to a vCenter Server
salt '*' vsphere.set_service_policy my.vcenter.location root bad-password 'ntpd' --'automatic'  host_names='[esxi-1.host.com, esxi-2.host.com]'

salt.modules.vsphere.set_syslog_config(host, username, password, syslog_config, config_value, protocol=None, port=None, firewall=True, reset_service=True, esxi_hosts=None)

Set the specified syslog configuration parameter. By default, this function will reset the syslog service after the configuration is set.

- **host**: ESXi or vCenter host to connect to.
- **username**: User to connect as, usually root.
- **password**: Password to connect with.
- **syslog_config**: Name of parameter to set (corresponds to the command line switch for esxcli without the double dashes (--))
  - Valid syslog_config values are logdir, loghost, default-rotate`, `default-size, default-timeout, and logdir-unique.
- **config_value**: Value for the above parameter. For loghost, URLs or IP addresses to use for logging. Multiple log servers can be specified by listing them, comma-separated, but without spaces before or after commas.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is 443.
- **firewall**: Enable the firewall rule set for syslog. Defaults to True.
- **reset_service**: After a successful parameter set, reset the service. Defaults to True.
- **esxi_hosts**: If host is a vCenter host, then use esxi_hosts to execute this function on a list of one or more ESXi machines.

**Returns**: Dictionary with a top-level key of `success` which indicates if all the parameters were reset, and individual keys for each parameter indicating which succeeded or failed, per host.

CLI Example:

```
# Used for ESXi host connection information
salt '*' vsphere.set_syslog_config my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.set_service_policy my.vcenter.location root bad-password

salt.modules.vsphere.syslog_service_reload(host, username, password, protocol=None, port=None, esxi_hosts=None)

Reload the syslog service so it will pick up any changes.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as root.
- **password**: The password used to login to the host.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is 443.
- **esxi_hosts**: If host is a vCenter host, then use esxi_hosts to execute this function on a list of one or more ESXi machines.
Returns A standard cmd.run_all dictionary. This dictionary will at least have a retcode key. If retcode is 0 the command was successful.

CLI Example:

```bash
# Used for ESXi host connection information
salt '*' vsphere.syslog_service_reload my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.syslog_service_reload my.vcenter.location root bad-password
```

salt.modules.vsphere.system_info(host, username, password, protocol=None, port=None)

Return system information about a VMware environment.

- **host** The location of the host.
- **username** The username used to login to the host, such as root.
- **password** The password used to login to the host.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is 443.

CLI Example:

```bash
salt '*' vsphere.system_info 1.2.3.4 root bad-password
```

salt.modules.vsphere.update_host_datetime(host, username, password, protocol=None, port=None, host_names=None)

Update the date/time on the given host or list of host_names. This function should be used with caution since network delays and execution delays can result in time skews.

- **host** The location of the host.
- **username** The username used to login to the host, such as root.
- **password** The password used to login to the host.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is 443.
- **host_names** List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter which hosts should update their date/time.

If host_names is not provided, the date/time will be updated for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

```bash
# Used for single ESXi host connection information
salt '*' vsphere.update_date_time my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.update_date_time my.vcenter.location root bad-password
```

salt.modules.vsphere.update_host_password(host, username, password, new_password, protocol=None, port=None)

Update the password for a given host.

**Note:** Currently only works with connections to ESXi hosts. Does not work with vCenter servers.
username The username used to login to the ESXi host, such as root.
password The password used to login to the ESXi host.
new_password The new password that will be updated for the provided username on the ESXi host.
protocol Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
port Optionally set to alternate port if the host is not using the default port. Default port is 443.

CLI Example:

```bash
salt '*' vsphere.update_host_password my.esxi.host root original-bad-password new-bad-password
```

salt.modules.vsphere.upload_ssh_key(host, username, password, ssh_key=None, ssh_key_file=None, protocol=None, port=None, certificate_verify=False)

Upload an ssh key for root to an ESXi host via http PUT. This function only works for ESXi, not vCenter. Only one ssh key can be uploaded for root. Uploading a second key will replace any existing key.

Parameters

- `host` -- The location of the ESXi Host
- `username` -- Username to connect as
- `password` -- Password for the ESXi web endpoint
- `ssh_key` -- Public SSH key, will be added to authorized_keys on ESXi
- `ssh_key_file` -- File containing the SSH key. Use `ssh_key` or `ssh_key_file`, but not both.
- `protocol` -- defaults to https, can be http if ssl is disabled on ESXi
- `port` -- defaults to 443 for https
- `certificate_verify` -- If true require that the SSL connection present a valid certificate

Returns Dictionary with a `status` key, True if upload is successful. If upload is unsuccessful, `status` key will be False and an `Error` key will have an informative message.

CLI Example:

```bash
salt '*' vsphere.upload_ssh_key my.esxi.host root bad-password ssh_key_file='/etc/salt/my_keys/my_key.pub'
```

salt.modules.vsphere.vmotion_disable(host, username, password, protocol=None, port=None, host_names=None)

Disable vMotion for a given host or list of host_names.

- `host` The location of the host.
- `username` The username used to login to the host, such as root.
- `password` The password used to login to the host.
- `protocol` Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- `port` Optionally set to alternate port if the host is not using the default port. Default port is 443.
- `host_names` List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter which hosts should disable vMotion.

If host_names is not provided, VMotion will be disabled for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:
salt.modules.vsphere.vmotion_enable(host, username, password, protocol=None, port=None, host_names=None, device='vmk0')

Enable vMotion for a given host or list of host_names.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as `root`.
- **password**: The password used to login to the host.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is `443`.
- **host_names**: List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the `host_names` argument is required to tell vCenter which hosts should enable VMotion. If `host_names` is not provided, VMotion will be enabled for the `host` location instead. This is useful for when service instance connection information is used for a single ESXi host.
- **device**: The device that uniquely identifies the VirtualNic that will be used for VMotion for each host. Defaults to `vmk0`.

CLI Example:

```bash
# Used for single ESXi host connection information
salt '*' vsphere.vmotion_enable my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.vmotion_enable my.vcenter.location root bad-password
  --host-names='[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.vsan_add_disks(host, username, password, protocol=None, port=None, host_names=None)

Add any VSAN-eligible disks to the VSAN System for the given host or list of host_names.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as `root`.
- **password**: The password used to login to the host.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is `443`.
- **host_names**: List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the `host_names` argument is required to tell vCenter which hosts need to add any VSAN-eligible disks to the host's VSAN system. If `host_names` is not provided, VSAN-eligible disks will be added to the hosts's VSAN system for the `host` location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

```bash
# Used for single ESXi host connection information
salt '*' vsphere.vsan_add_disks my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.vsan_add_disks my.vcenter.location root bad-password
  --host-names='[esxi-1.host.com, esxi-2.host.com]'
```
salt.modules.vsphere.vsan_disable(**host**, **username**, **password**, **protocol=None**, **port=None**, **host_names=None**)

Disable VSAN for a given host or list of host_names.

- **host** The location of the host.
- **username** The username used to login to the host, such as root.
- **password** The password used to login to the host.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is 443.
- **host_names** List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter which hosts should disable VSAN.

If host_names is not provided, VSAN will be disabled for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

```bash
# Used for single ESXi host connection information
salt '*' vsphere.vsan_disable my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.vsan_disable my.vcenter.location root bad-password
host_names='[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.vsan_enable(**host**, **username**, **password**, **protocol=None**, **port=None**, **host_names=None**)

Enable VSAN for a given host or list of host_names.

- **host** The location of the host.
- **username** The username used to login to the host, such as root.
- **password** The password used to login to the host.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is 443.
- **host_names** List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter which hosts should enable VSAN.

If host_names is not provided, VSAN will be enabled for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

```bash
# Used for single ESXi host connection information
salt '*' vsphere.vsan_enable my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.vsan_enable my.vcenter.location root bad-password
host_names='[esxi-1.host.com, esxi-2.host.com]'
```

13.6.338 salt.modules.win_autoruns

Module for listing programs that automatically run on startup (very alpha...not tested on anything but my Win 7x64)

salt.modules.win_autoruns.list()

Get a list of automatically running programs

CLI Example:
13.6.339 salt.modules.win_certutil module

This module allows you to install certificates into the windows certificate manager.

```
salt '*' certutil.add_store salt://cert.cer "TrustedPublisher"
```

**salt.modules.win_certutil.add_store**([source, store, saltenv='base'])

Add the given cert into the given Certificate Store

- **source**: The source certificate file this can be in the form salt://path/to/file
- **store**: The certificate store to add the certificate to
- **saltenv**: The salt environment to use this is ignored if the path is local

CLI Example:
```
salt '*' certutil.add_store salt://cert.cer TrustedPublisher
```

**salt.modules.win_certutil.del_store**([source, store, saltenv='base'])

Delete the given cert into the given Certificate Store

- **source**: The source certificate file this can be in the form salt://path/to/file
- **store**: The certificate store to delete the certificate from
- **saltenv**: The salt environment to use this is ignored if the path is local

CLI Example:
```
salt '*' certutil.del_store salt://cert.cer TrustedPublisher
```

**salt.modules.win_certutil.get_cert_serial**([cert_file])

Get the serial number of a certificate file

- **cert_file**: The certificate file to find the serial for

**salt.modules.win_certutil.get_stored_cert_serials**([store])

Get all of the certificate serials in the specified store

- **store**: The store to get all the certificate serials from

13.6.340 salt.modules.win_dacl

Manage DACLs on Windows

**depends**

- winreg Python module

**salt.modules.win_dacl.add_ace**([path, objectType, user, permission, acetype, propagation])

Add an ace to an object

- **path**: path to the object (i.e. c:\temp\file, HKEY_LOCAL_MACHINE\SOFTWARE\KEY, etc)
- **user**: user to add permission
- **permission**: permissions for the user acetype: either allow/deny for each user/permission (ALLOW, DENY)
- **acetype**: how the ACE applies to children for Registry Keys and Directories(KEY, KEY&SUBKEYS, SUBKEYS)

CLI Example:
```
allow domain\fakeuser full control on HKLM\SOFTWARE\somekey, propagate to this key and subkeys
salt 'myminion' win_dacl.add_ace 'HKEY_LOCAL_MACHINE\SOFTWARE\somekey' Registry 'domain\fakeuser' 'FULLCONTROL' 'ALLOW' 'KEY&SUBKEYS'
```
salt.modules.win_dacl.check_ace(path, objectType, user, permission=None, acetype=None, propagation=None, exactPermissionMatch=False)

checks a path to verify the ACE (access control entry) specified exists returns 'Exists' true if the ACE exists, false if it does not

path: path to the file/reg key user: user that the ACL is for permission: permission to test for (READ, FULL-CONTROL, etc) acetype: the type of ACE (ALLOW or DENY) propagation: the propagation type of the ACE (FILES, FOLDERS, KEY, KEY&SUBKEYS, SUBKEYS, etc) exactPermissionMatch: the ACL must match exactly, IE if READ is specified, the user must have READ exactly and not FULLCONTROL (which also has the READ permission obviously)

salt.modules.win_dacl.check_inheritance(path, objectType, user=None)

check a specified path to verify if inheritance is enabled returns 'Inheritance' of True/False

path: path of the registry key or file system object to check user: if provided, will consider only the ACEs for that user

class salt.modules.win_dacl.daclConstants

dacl constants used throughout the module

getAceTypeBit(t)
returns the acetype bit of a text value

getAceTypeText(t)
returns the textual representation of a acetype bit

ggetObjectTypeBit(t)
returns the bit value of the string object type

getPermissionBit(t, m)
returns a permission bit of the string permission value for the specified object type

getPermissionText(t, m)
returns the permission textual representation of a specified permission bit/object type

getPropagationBit(t, p)
returns the propagation bit of a text value

getPropagationText(t, p)
returns the textual representation of a propagation bit

getSecurityHkey(s)
returns the necessary string value for an HKEY for the win32security module

processPath(path, objectType)
processes a path/object type combo and returns: registry types with the correct HKEY text representation files/directories with environment variables expanded

salt.modules.win_dacl.disable_inheritance(path, objectType, copy=True)
disable inheritance on an object

copy = True will copy the Inerhited ACEs to the DACL before disabling inheritance

salt.modules.win_dacl.enable_inheritance(path, objectType, clear=False)
enable/disable inheritance on an object

clear = True will remove non-Inherited ACEs from the ACL

salt.modules.win_dacl.get(path, objectType, user=None)
Get the acl of an object. Will filter by user if one is provided.
salt.modules.win_dacl.rm_ace(path, objectType, user, permission=None, acetype=None, propagation=None)

remove an ace to an object

path: path to the object (i.e. c:\temp\file, HKEY_LOCAL_MACHINE\SOFTWARE\KEY, etc) user: user to remove permission: permissions for the user acetyes: either allow/deny for each user/permission (ALLOW, DENY) propagation: how the ACE applies to children for Registry Keys and Directories(KEY, KEY&SUBKEYS, SUBKEYS)

If any of the optional parameters are omitted (or set to None) they act as wildcards.

CLI Example:

```
remove allow domain\fakeuser full control on HKLM\SOFTWARE\somekey propagated to this key and subkeys
salt 'myminion' win_dacl.rm_ace 'Registry' 'HKEY_LOCAL_MACHINE\SOFTWARE\somekey' 'domain\fakeuser' 'FULLCONTROL' 'ALLOW' 'KEY&SUBKEYS'
```

13.6.341 salt.modules.win_disk

Module for gathering disk information on Windows

depends

- win32api Python module

salt.modules.win_disk.usage()

Return usage information for volumes mounted on this minion

CLI Example:

```
salt '*' disk.usage
```

13.6.342 salt.modules.win_dism module

Install features/packages for Windows using DISM, which is useful for minions not running server versions of Windows. Some functions are only available on Windows 10.

salt.modules.win_dism.add_capability(capability, source=None, limit_access=False, image=None, restart=False)

Install a capability

Args:
capability (str): The capability to install source (Optional[str]): The optional source of the capability. Default is set by group policy and can be Windows Update.

limit_access (Optional[bool]): Prevent DISM from contacting Windows Update for the source package

image (Optional[str]): The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None.

restart (Optional[bool]): Reboot the machine if required by the install

Raises: NotImplementedError: For all versions of Windows that are not Windows 10 and later. Server editions of Windows use ServerManager instead.

Returns: dict: A dictionary containing the results of the command

CLI Example:
salt '*' dism.add_capability Tools.Graphics.DirectX~~~~0.0.1.0

```python
class salt.modules.win_dism.add_feature:
    def __init__(self, feature, package=None, source=None, limit_access=False, enable_parent=False, image=None, restart=False):
        pass
```

Install a feature using DISM

**Args:**
- `feature` (str): The feature to install package (Optional)[str]: The parent package for the feature. You do not have to specify the package if it is the Windows Foundation Package. Otherwise, use package to specify the parent package of the feature
- `source` (Optional[str]): The optional source of the capability. Default is set by group policy and can be Windows Update
- `limit_access` (Optional[bool]): Prevent DISM from contacting Windows Update for the source package
- `enable_parent` (Optional[bool]): True will enable all parent features of the specified feature
- `image` (Optional[str]): The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None.
- `restart` (Optional[bool]): Reboot the machine if required by the install

**Returns:** dict: A dictionary containing the results of the command

**CLI Example:**
```
salt '*' dism.add_feature NetFx3
```

```python
class salt.modules.win_dism.add_package:
    def __init__(self, package, ignore_check=False, prevent_pending=False, image=None, restart=False):
        pass
```

Install a package using DISM

**Args:**
- `package` (str): The package to install. Can be a .cab file, a .msu file, or a folder
- `ignore_check` (Optional[bool]): Skip installation of the package if the applicability checks fail
- `prevent_pending` (Optional[bool]): Skip the installation of the package if there are pending online actions
- `image` (Optional[str]): The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None.
- `restart` (Optional[bool]): Reboot the machine if required by the install

**Returns:** dict: A dictionary containing the results of the command

**CLI Example:**
```
salt '*' dism.add_package C:\Packages\package.cab
```

```python
class salt.modules.win_dism.available_capabilities:
    def __init__(self, image=None):
        pass
```

List the capabilities available on the system

**Args:**
- `image` (Optional[str]): The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None.

**Raises:** NotImplementedError: For all versions of Windows that are not Windows 10 and later. Server editions of Windows use ServerManager instead.

**Returns:** list: A list of available capabilities

**CLI Example:**
```
salt '*' dism.installed_capabilities
```

```python
class salt.modules.win_dism.available_features:
    def __init__(self, image=None):
        pass
```

List the features available on the system

**Args:**
image (Optional[str]): The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None.

Returns: list: A list of available features

CLI Example:

```bash
salt '*' dism.available_features
```

salt.modules.win_dism.get_capabilities(image=None)
List all capabilities on the system

Args:

image (Optional[str]): The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None.

Raises: NotImplementationError: For all versions of Windows that are not Windows 10 and later. Server editions of Windows use ServerManager instead.

Returns: list: A list of capabilities

CLI Example:

```bash
salt '*' dism.get_capabilities
```

salt.modules.win_dism.get_features(package=None, image=None)
List features on the system or in a package

Args:

package (Optional[str]): The full path to the package. Can be either a .cab file or a folder. Should point to the original source of the package, not to where the file is installed. You cannot use this command to get package information for .msu files

This can also be the name of a package as listed in dism.installed_packages

image (Optional[str]): The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None.

Returns: list: A list of features

CLI Example:

```bash
# Return all features on the system
salt '*' dism.get_features

# Return all features in package.cab
salt '*' dism.get_features C:\packages\package.cab

# Return all features in the calc package
salt '*' dism.get_features Microsoft.Windows.Calc.Demo~6595b6144ccf1df~,!x86~en~1.0.0.0
```

salt.modules.win_dism.installed_capabilities(image=None)
List the capabilities installed on the system

Args:

image (Optional[str]): The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None.

Raises: NotImplementationError: For all versions of Windows that are not Windows 10 and later. Server editions of Windows use ServerManager instead.

Returns: list: A list of installed capabilities

CLI Example:

```bash
salt '*' dism.installed_capabilities
```

salt.modules.win_dism.installed_features(image=None)
List the features installed on the system
**salt.modules.win_dism.installed_packages** *(image=None)*

List the packages installed on the system

**Arguments:**
- `image (Optional[str])`: The path to the root directory of an offline Windows image. If `None` is passed, the running operating system is targeted. Default is `None`.

**Returns:** list: A list of installed packages

**CLI Example:**
```
salt '*' dism.installed_packages
```

**salt.modules.win_dism.package_info** *(package, image=None)*

Display information about a package

**Arguments:**
- `package (str)`: The full path to the package. Can be either a `.cab` file or a folder. Should point to the original source of the package, not to where the file is installed. You cannot use this command to get package information for `.msu` files
- `image (Optional[str])`: The path to the root directory of an offline Windows image. If `None` is passed, the running operating system is targeted. Default is `None`.

**Returns:** dict: A dictionary containing the results of the command

**CLI Example:**
```
salt '*' dism.package_info C:\packages\package.cab
```

**salt.modules.win_dism.remove_capability** *(capability, image=None, restart=False)*

Uninstall a capability

**Arguments:**
- `capability (str)`: The capability to be removed
- `image (Optional[str])`: The path to the root directory of an offline Windows image. If `None` is passed, the running operating system is targeted. Default is `None`.
- `restart (Optional[bool])`: Reboot the machine if required by the install

**Raises:** `NotImplementedError`: For all versions of Windows that are not Windows 10 and later. Server editions of Windows use ServerManager instead.

**Returns:** dict: A dictionary containing the results of the command

**CLI Example:**
```
salt '*' dism.remove_capability Tools.Graphics.DirectX~~~0.0.1.0
```

**salt.modules.win_dism.remove_feature** *(feature, remove_payload=False, image=None, restart=False)*

Disables the feature.

**Arguments:**
- `feature (str)`: The feature to uninstall
- `remove_payload (Optional[bool])`: Remove the feature's payload. Must supply source when enabling in the future.
- `image (Optional[str])`: The path to the root directory of an offline Windows image. If `None` is passed, the running operating system is targeted. Default is `None`.
- `restart (Optional[bool])`: Reboot the machine if required by the install
Returns: dict: A dictionary containing the results of the command

CLI Example:

```
salt '*' dism.remove_feature NetFx3
```

`salt.modules.win_dism.remove_package` *(package, image=None, restart=False)*

Uninstall a package

Args:

- `package` (str): The full path to the package. Can be either a .cab file or a folder. Should point to the original source of the package, not to where the file is installed. This can also be the name of a package as listed in `dism.installed_packages`
- `image` (Optional[str]): The path to the root directory of an offline Windows image. If `None` is passed, the running operating system is targeted. Default is `None`.
- `restart` (Optional[bool]): Reboot the machine if required by the install

Returns: dict: A dictionary containing the results of the command

CLI Example:

```
# Remove the Calc Package
salt '*' dism.remove_package Microsoft.Windows.Calc.Demo~6595b6144ccf1df~x86~en~1.0.0.0

# Remove the package.cab (does not remove C:\packages\package.cab)
salt '*' dism.remove_package C:\packages\package.cab
```

`13.6.343 salt.modules.win_dns_client`

Module for configuring DNS Client on Windows systems

`salt.modules.win_dns_client.add_dns` *(ip, interface='Local Area Connection', index=1)*

Add the DNS server to the network interface (index starts from 1)

Note: if the interface DNS is configured by DHCP, all the DNS servers will be removed from the interface and the requested DNS will be the only one

CLI Example:

```
salt '*' win_dns_client.add_dns <ip> <interface> <index>
```

`salt.modules.win_dns_client.dns_dhcp` *(interface='Local Area Connection')*

Configure the interface to get its DNS servers from the DHCP server

CLI Example:

```
salt '*' win_dns_client.dns_dhcp <interface>
```

`salt.modules.win_dns_client.get_dns_config` *(interface='Local Area Connection')*

Get the type of DNS configuration (dhcp / static)

CLI Example:

```
salt '*' win_dns_client.get_dns_config 'Local Area Connection'
```

`salt.modules.win_dns_client.get_dns_servers` *(interface='Local Area Connection')*

Return a list of the configured DNS servers of the specified interface

CLI Example:
salt '*' win_dns_client.get_dns_servers 'Local Area Connection'

salt.modules.win_dns_client.rm_dns(ip, interface='Local Area Connection')
    Remove the DNS server from the network interface
    CLI Example:
    
    salt '*' win_dns_client.rm_dns <ip> <interface>

13.6.344 salt.modules.win_dsc

Module for managing PowerShell modules
    depends
        • PowerShell 5.0

Support for PowerShell

salt.modules.win_dsc.apply_config(path, source=None, salt_env='base')
    Run an compiled DSC configuration (a folder containing a .mof file). The folder can be cached from the salt master using the source option.
    Parameters path (str) -- Local path to the directory that contains the .mof configuration file to apply. Required.
    Parameters source (str) -- Path to the directory that contains the .mof file on the file_roots. The source directory will be copied to the path directory and then executed. If the path and source directories differ, the source directory will be applied. If source is not passed, the config located at path will be applied. Optional.
    Parameters salt_env (str) -- The salt environment to use when copying your source. Default is 'base'
    Returns True if successful, otherwise False
    Return type bool
    CLI Example:
    
    To apply a config that already exists on the system
    
    salt '*' dsc.run_config C:\DSC\WebSiteConfiguration

    To cache a configuration from the master and apply it:
    
    salt '*' dsc.run_config C:\DSC\WebSiteConfiguration salt://dsc/configs/\-WebSiteConfiguration

salt.modules.win_dsc.avail_modules(desc=False)
    List available modules in registered Powershell module repositories.
    desc [False] If True, the verbose description will be returned.
    CLI Example:
    
    salt 'win01' dsc.avail_modules
    salt 'win01' dsc.avail_modules desc=True

salt.modules.win_dsc.bootstrap()
    Make sure that nuget-anycpu.exe is installed. This will download the official nuget-anycpu.exe from the internet.
    CLI Example:
salt 'win01' dsc.bootstrap

```python
salt.modules.win_dsc.compile_config(path, source=None, config=None, salt_env='base')
```

Compile a config from a powershell script (.ps1)

**Parameters**

- **path** *(str)* -- Path (local) to the script that will create the .mof configuration file. If no source is passed, the file must exist locally. Required.
- **source** *(str)* -- Path to the script on file_roots to cache at the location specified by path. The source file will be cached locally and then executed. If source is not passed, the config script located at path will be compiled. Optional.
- **config** *(str)* -- The name of the Configuration within the script to apply. If the script contains multiple configurations within the file a config must be specified. If the config is not specified, the name of the file will be used as the config to run. Optional.
- **salt_env** *(str)* -- The salt environment to use when copying the source. Default is 'base'

**Returns**

A dictionary containing the results of the compilation

**Return type**

*dict*

**CLI Example:**

To compile a config from a script that already exists on the system:

```
salt '* dsc.compile_config C:\DSC\WebsiteConfig.ps1
```

To cache a config script to the system from the master and compile it:

```
salt '* dsc.compile_config C:\DSC\WebsiteConfig.ps1 salt://dsc/configs/WebsiteConfig.ps1
```

salt.modules.win_dsc.enable_scripts()

Enable Powershell Scripts

Allows all Powershell scripts to be run. Executes `"Set-ExecutionPolicy Unrestricted"` on the system.

**CLI Example:**

```
salt 'win01' dsc.enable_scripts
```

salt.modules.win_dsc.get_config()

Get the current DSC Configuration

**Returns**

A dictionary representing the DSC Configuration on the machine

**Return type**

*dict*

**CLI Example:**

```
salt '* dsc.get_config
```

salt.modules.win_dsc.get_config_status()

Get the status of the current DSC Configuration

**Returns**

A dictionary representing the status of the current DSC Configuration on the machine

**Return type**

*dict*

**CLI Example:**

```
salt '* dsc.get_config_status
```

salt.modules.win_dsc.get_lcm_config()

Get the current Local Configuration Manager settings

**Returns**

A dictionary representing the Local Configuration Manager settings on the machine

**Return type**

*dict*
salt.modules.win_dsc.install(name)

Install a Powershell DSC module on the system.

name Name of a Powershell DSC module

CLI Example:

```
salt 'win01' dsc.install PowerPlan
```

salt.modules.win_dsc.list_modules(desc=False)

List currently installed DSC Modules on the system.

desc [False] If True, the verbose description will be returned.

CLI Example:

```
salt 'win01' dsc.list_modules
dsalt 'win01' dsc.list_modules desc=True
```

salt.modules.win_dsc.psversion()

Returns the Powershell version

CLI Example:

```
salt 'win01' dsc.psversion
```

salt.modules.win_dsc.remove(name)

Remove a Powershell DSC module from the system.

name Name of a Powershell DSC module

CLI Example:

```
salt 'win01' dsc.remove PowerPlan
```

salt.modules.win_dsc.run_config(path, source=None, config=None, salt_env='base')

Compile a DSC Configuration in the form of a powershell script (.ps1) and apply it. The powershell script can be cached from the master using the source option. If there is more than one config within the powershell script, the desired configuration can be applied by passing the name in the config option.

This command would be the equivalent of running dsc.compile_config and dsc.apply_config separately.

Parameters:

- **path** (str) -- The local path to the powershell script that contains the DSC Configuration. Required.
- **source** (str) -- The path to the script on file_roots to cache at the location specified by path. The source file will be cached locally and then executed. If source is not passed, the config script located at path will be compiled. Optional.
- **config** (str) -- The name of the Configuration within the script to apply. If the script contains multiple configurations within the file a config must be specified. If the config is not specified, the name of the file will be used as the config to run. Optional.
- **salt_env** (str) -- The salt environment to use when copying the source. Default is 'base'.

Returns True if successfully compiled and applied, False if not

Return type bool

CLI Example

To compile a config from a script that already exists on the system:
salt '*' dsc.compile_apply_config C:\DSC\WebsiteConfig.ps1

To cache a config script to the system from the master and compile it:

```bash
salt '*' dsc.compile_apply_config C:\DSC\WebsiteConfig.ps1 salt://dsc/configs/WebsiteConfig.ps1
```

salt.modules.win_dsc.set_lcm_config(config_mode=None, config_mode_freq=None, refresh_freq=None, reboot_if_needed=None, action_after_reboot=None, refresh_mode=None, certificate_id=None, configuration_id=None, allow_module_overwrite=None, debug_mode=False, status_retention_days=None)

For detailed descriptions of the parameters see: https://msdn.microsoft.com/en-us/PowerShell/DSC/metaConfig

**Parameters**

- **config_mode (str)** -- How the LCM applies the configuration. Valid values are: - ApplyOnly - ApplyAndMonitor - ApplyAndAutoCorrect
- **config_mode_freq (int)** -- How often, in minutes, the current configuration is checked and applied. Ignored if config_mode is set to ApplyOnly. Default is 15.
- **refresh_mode (str)** -- How the LCM gets configurations. Valid values are:
  - Disabled
  - Push
  - Pull
- **refresh_freq (int)** -- How often, in minutes, the LCM checks for updated configurations. (pull mode only) Default is 30.

**Note:** Either `config_mode_freq` or `refresh_freq` needs to be a multiple of the other. See documentation on MSDN for more details.

- **reboot_if_needed (bool)** -- Reboot the machine if needed after a configuration is applied. Default is False.
- **action_after_reboot (str)** -- Action to take after reboot. Valid values are: - ContinueConfiguration - StopConfiguration
- **certificate_id (guid)** -- A GUID that specifies a certificate used to access the configuration: (pull mode)
- **configuration_id (guid)** -- A GUID that identifies the config file to get from a pull server. (pull mode)
- **allow_module_overwrite (bool)** -- New configs are allowed to overwrite old ones on the target node.
- **debug_mode (str)** -- Sets the debug level. Valid values are:
  - None
  - ForceModuleImport
  - All
- **status_retention_days (int)** -- Number of days to keep status of the current config.

Returns:

salt.modules.win_dsc.test_config()
Tests the current applied DSC Configuration

**Returns** True if successfully applied, otherwise False
Return type  bool

CLI Example:

```
salt '*' dsc.test_config
```

### 13.6.345  `salt.modules.win_file`

Manage information about files on the minion, set/read user, group data

**depends**

- win32api
- win32file
- win32security

```python
salt.modules.win_file.chgrp(path, group)
```

Change the group of a file

Under Windows, this will do nothing.

While a file in Windows does have a `primary group`, this rarely used attribute generally has no bearing on permissions unless intentionally configured and is only used to support Unix compatibility features (e.g. Services For Unix, NFS services).

Salt, therefore, remaps this function to do nothing while still being compatible with Unix behavior. When managing Windows systems, this function is superfluous and will generate an info level log entry if used directly.

If you do actually want to set the `primary group` of a file, use `file.chpgrp`.

CLI Example:

```
salt '*' file.chpgrp c:\temp\test.txt administrators
```

```python
salt.modules.win_file.chown(path, user, group=None, pgroup=None, follow_symlinks=True)
```

Chown a file, pass the file the desired user and group

Under Windows, the group parameter will be ignored.

This is because while files in Windows do have a `primary group` property, this is rarely used. It generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

If you do want to change the `primary group` property and understand the implications, pass the Windows only parameter, pgroup, instead.

To set the primary group to `None`, it must be specified in quotes. Otherwise Salt will interpret it as the Python value of None and no primary group changes will occur. See the example below.

CLI Example:

```
salt '*' file.chown c:\temp\test.txt myusername
salt '*' file.chown c:\temp\test.txt myusername pgroup=Administrators
salt '*' file.chown c:\temp\test.txt myusername "pgroup='None'"
```

```python
salt.modules.win_file.chpgrp(path, group)
```

Change the group of a file
Under Windows, this will set the rarely used primary group of a file. This generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

Ensure you know what you are doing before using this function.

To set the primary group to `None`, it must be specified in quotes. Otherwise Salt will interpret it as the Python value of None and no primary group changes will occur. See the example below.

CLI Example:

```bash
salt '*' file.chgrp c:\temp\test.txt Administrators
salt '*' file.chgrp c:\temp\test.txt "'None'"
```

\texttt{salt.modules.win_file.get_attributes(path)}

Return a dictionary object with the Windows file attributes for a file.

CLI Example:

```bash
salt '*' file.get_attributes c:\temp\a.txt
```

\texttt{salt.modules.win_file.get_gid(path, follow_symlinks=True)}

Return the id of the group that owns a given file.

Under Windows, this will return the uid of the file.

While a file in Windows does have a `primary group', this rarely used attribute generally has no bearing on permissions unless intentionally configured and is only used to support Unix compatibility features (e.g. Services For Unix, NFS services).

Salt, therefore, remaps this function to provide functionality that somewhat resembles Unix behavior for API compatibility reasons. When managing Windows systems, this function is superfluous and will generate an info level log entry if used directly.

If you do actually want to access the `primary group' of a file, use \texttt{file.get_pgid}.

CLI Example:

```bash
salt '*' file.get_gid c:\temp\test.txt
```

\texttt{salt.modules.win_file.get_group(path, follow_symlinks=True)}

Return the group that owns a given file.

Under Windows, this will return the user (owner) of the file.

While a file in Windows does have a `primary group', this rarely used attribute generally has no bearing on permissions unless intentionally configured and is only used to support Unix compatibility features (e.g. Services For Unix, NFS services).

Salt, therefore, remaps this function to provide functionality that somewhat resembles Unix behavior for API compatibility reasons. When managing Windows systems, this function is superfluous and will generate an info level log entry if used directly.

If you do actually want to access the `primary group' of a file, use \texttt{file.get_pgroup}.

CLI Example:

```bash
salt '*' file.get_group c:\temp\test.txt
```

\texttt{salt.modules.win_file.get_mode(path)}

Return the mode of a file.

Right now we're just returning None because Windows' doesn't have a mode like Linux.
CLI Example:

```python
salt '*' file.get_mode /etc/passwd
```

```
salt.modules.win_file.get_pgid(path, follow_symlinks=True)
```

Return the id of the primary group that owns a given file (Windows only)

This function will return the rarely used primary group of a file. This generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

Ensure you know what you are doing before using this function.

CLI Example:

```python
salt '*' file.get_pgid c:\temp\test.txt
```

```
salt.modules.win_file.get_pgroup(path, follow_symlinks=True)
```

Return the name of the primary group that owns a given file (Windows only)

This function will return the rarely used primary group of a file. This generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

Ensure you know what you are doing before using this function.

The return value may be `None`, e.g. if the user is not on a domain. This is a valid group - do not confuse this with the Salt/Python value of None which means no value was returned. To be certain, use the `get_pgid` function which will return the SID, including for the system `None` group.

CLI Example:

```python
salt '*' file.get_pgroup c:\temp\test.txt
```

```
salt.modules.win_file.get_uid(path, follow_symlinks=True)
```

Return the id of the user that owns a given file

Symlinks are followed by default to mimic Unix behavior. Specify `follow_symlinks=False` to turn off this behavior.

CLI Example:

```python
salt '*' file.get_uid c:\temp\test.txt
salt '*' file.get_uid c:\temp\test.txt follow_symlinks=False
```

```
salt.modules.win_file.get_user(path, follow_symlinks=True)
```

Return the user that owns a given file

Symlinks are followed by default to mimic Unix behavior. Specify `follow_symlinks=False` to turn off this behavior.

CLI Example:

```python
salt '*' file.get_user c:\temp\test.txt
salt '*' file.get_user c:\temp\test.txt follow_symlinks=False
```

```
salt.modules.win_file.gid_to_group(gid)
```

Convert the group id to the group name on this system

Under Windows, because groups are just another ACL entity, this function behaves the same as `uid_to_user`. 
For maintaining Windows systems, this function is superfluous and only exists for API compatibility with Unix. Use the `uid_to_user` function instead; an info level log entry will be generated if this function is used directly.

CLI Example:

```
salt '*' file.gid_to_group S-1-5-21-626487655-2533044672-482107328-1010
```

**salt.modules.win_file.group_to_gid(group)**

Convert the group to the gid on this system

Under Windows, because groups are just another ACL entity, this function behaves the same as `user_to_uid`, except if `None` is given, `''` is returned.

For maintaining Windows systems, this function is superfluous and only exists for API compatibility with Unix. Use the `user_to_uid` function instead; an info level log entry will be generated if this function is used directly.

CLI Example:

```
salt '*' file.group_to_gid administrators
```

**salt.modules.win_file.is_link(path)**

Check if the path is a symlink

This is only supported on Windows Vista or later.

Inline with Unix behavior, this function will raise an error if the path is not a symlink, however, the error raised will be a `SaltInvocationError`, not an `OSError`.

CLI Example:

```
salt '*' file.is_link /path/to/link
```

**salt.modules.win_file.lchown(path, user, group=None, pgroup=None)**

Chown a file, pass the file the desired user and group without following any symlinks.

Under Windows, the group parameter will be ignored.

This is because while files in Windows do have a `primary group` property, this is rarely used. It generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

If you do want to change the `primary group` property and understand the implications, pass the Windows only parameter, `pgroup`, instead.

To set the `primary group` to `None`, it must be specified in quotes. Otherwise Salt will interpret it as the Python value of `None` and no primary group changes will occur. See the example below.

CLI Example:

```
salt '*' file.lchown c:\temp\test.txt myusername
salt '*' file.lchown c:\temp\test.txt myusername pgroup='Administrators'
salt '*' file.lchown c:\temp\test.txt myusername "pgroup='None'"
```

**salt.modules.win_file.readlink(path)**

Return the path that a symlink points to

This is only supported on Windows Vista or later.

Inline with Unix behavior, this function will raise an error if the path is not a symlink, however, the error raised will be a `SaltInvocationError`, not an `OSError`.
CLI Example:

```
salt '*' file.readlink /path/to/link
```

**salt.modules.win_file.remove**(path, force=False)

Remove the named file or directory

**Parameters**

- **path**(str) -- The path to the file or directory to remove.
- **force**(bool) -- Remove even if marked Read-Only

**Returns**

True if successful, False if unsuccessful

**Return type**

bool

CLI Example:

```
salt '*' file.remove C:\Temp
```

**salt.modules.win_file.set_attributes**(path, archive=None, hidden=None, normal=None, notIndexed=None, readonly=None, system=None, temporary=None)

Set file attributes for a file. Note that the normal attribute means that all others are false. So setting it will clear all others.

CLI Example:

```
salt '*' file.set_attributes c:\temp\a.txt normal=True
salt '*' file.set_attributes c:\temp\a.txt readonly=True hidden=True
```

**salt.modules.win_file.set_mode**(path, mode)

Set the mode of a file

This just calls get_mode, which returns None because we don't use mode on Windows

CLI Example:

```
salt '*' file.set_mode /etc/passwd 0644
```

**salt.modules.win_file.stats**(path, hash_type='sha256', follow_symlinks=True)

Return a dict containing the stats for a given file

Under Windows, gid will equal uid and group will equal user.

While a file in Windows does have a `primary group`, this rarely used attribute generally has no bearing on permissions unless intentionally configured and is only used to support Unix compatibility features (e.g. Services For Unix, NFS services).

Salt, therefore, remaps these properties to keep some kind of compatibility with Unix behavior. If the `primary group` is required, it can be accessed in the pgroup and pgid properties.

CLI Example:

```
salt '*' file.stats /etc/passwd
```

**salt.modules.win_file.symlink**(src, link)

Create a symbolic link to a file

This is only supported with Windows Vista or later and must be executed by a user with the SeCreateSymbolicLink privilege.

The behavior of this function matches the Unix equivalent, with one exception - invalid symlinks cannot be created. The source path must exist. If it doesn’t, an error will be raised.
CLI Example:
```bash
salt '*' file.symlink /path/to/file /path/to/link
```

`salt.modules.win_file.uid_to_user(uid)`  
Convert a uid to a user name  
CLI Example:  
```bash
salt '*' file.uid_to_user S-1-5-21-626487655-2533044672-482107328-1010
```

`salt.modules.win_file.user_to_uid(user)`  
Convert user name to a uid  
CLI Example:  
```bash
salt '*' file.user_to_uid myusername
```

### 13.6.346 salt.modules.win_firewall

Module for configuring Windows Firewall

`salt.modules.win_firewall.add_rule(name, localport, protocol='tcp', action='allow', dir='in')`  
New in version 2015.5.0.  
Add a new firewall rule  
CLI Example:  
```bash
salt '*' firewall.add_rule 'test' '8080' 'tcp'
salt '*' firewall.add_rule 'test' '1' 'icmpv4'
```

`salt.modules.win_firewall.delete_rule(name, localport, protocol='tcp', dir='in')`  
New in version 2015.8.0.  
Delete an existing firewall rule  
CLI Example:  
```bash
salt '*' firewall.delete_rule 'test' '8080' 'tcp' 'in'
```

`salt.modules.win_firewall.disable(profile='allprofiles')`  
Disable firewall profile :param profile: (default: allprofiles)  
CLI Example:  
```bash
salt '*' firewall.disable
```

`salt.modules.win_firewall.enable(profile='allprofiles')`  
Enable firewall profile :param profile: (default: allprofiles)  
New in version 2015.5.0.  
CLI Example:  
```bash
salt '*' firewall.enable
```

`salt.modules.win_firewall.get_config()`  
Get the status of all the firewall profiles
CLI Example:

```
salt '*' firewall.get_config
```

```python
salt.modules.win_firewall.get_rule(name='all')
```

New in version 2015.5.0.

Get firewall rule(s) info

CLI Example:

```
salt '*' firewall.get_rule 'MyAppPort'
```

### 13.6.347 `salt.modules.win_groupadd`

Manage groups on Windows

**Important**: If you feel that Salt should be using this module to manage groups on a minion, and it is using a different module (or gives an error similar to 'group.info' is not available), see [here](#).

```python
salt.modules.win_groupadd.add(name, gid=None, system=False)
```

Add the specified group

CLI Example:

```
salt '*' group.add foo
```

```python
salt.modules.win_groupadd.adduser(name, username)
```

Add a user to a group

CLI Example:

```
salt '*' group.adduser foo username
```

```python
salt.modules.win_groupadd.delete(name)
```

Remove the named group

CLI Example:

```
salt '*' group.delete foo
```

```python
salt.modules.win_groupadd.deluser(name, username)
```

Remove a user from a group

CLI Example:

```
salt '*' group.deluser foo username
```

```python
salt.modules.win_groupadd.getent(refresh=False)
```

Return info on all groups

CLI Example:

```
salt '*' group.getent
```
salt.modules.win_groupadd.info(name)
Return information about a group

CLI Example:
```
salt '*' group.info foo
```

salt.modules.win_groupadd.members(name, members_list)
remove a user from a group

CLI Example:
```
salt '*' group.members foo 'user1,user2,user3'
```

### 13.6.348 salt.modules.win_iis module

Microsoft IIS site management via WebAdministration powershell module

**platform** Windows

New in version 2016.3.0.

salt.modules.win_iis.create_apppool(name)
Create IIS Application pools

CLI Example:
```
salt '*' win_iis.create_apppool name='MyTestPool'
```

salt.modules.win_iis.create_site(name, protocol, sourcepath, port, apppool='\', hostheader='\', ipaddress='\')
Create a basic website in IIS

CLI Example:
```
salt '*' win_iis.create_site name='My Test Site' protocol='http' sourcepath='c:\stage' port='80' apppool='TestPool'
```

salt.modules.win_iis.list_apppools()
List all configured IIS Application pools

CLI Example:
```
salt '*' win_iis.list_apppools
```

salt.modules.win_iis.list_sites()
List all the currently deployed websites

CLI Example:
```
salt '*' win_iis.list_sites
```

salt.modules.win_iis.remove_apppool(name)
Removes IIS Application pools

CLI Example:
```
salt '*' win_iis.remove_apppool name='MyTestPool'
```
salt.modules.win_iis.remove_site(name)
Delete website from IIS

CLI Example:

```
salt '*' win_iis.remove_site name='My Test Site'
```

13.6.349 salt.modules.win_ip

The networking module for Windows based systems

salt.modules.win_ip.disable(iface)
Disable an interface

CLI Example:

```
salt -G 'os_family:Windows' ip.disable 'Local Area Connection #2'
```

salt.modules.win_ip.enable(iface)
Enable an interface

CLI Example:

```
salt -G 'os_family:Windows' ip.enable 'Local Area Connection #2'
```

salt.modules.win_ip.get_all_interfaces()
Return configs for all interfaces

CLI Example:

```
salt -G 'os_family:Windows' ip.get_all_interfaces
```

salt.modules.win_ip.get_default_gateway()
Set DNS source to DHCP on Windows

CLI Example:

```
salt -G 'os_family:Windows' ip.get_default_gateway
```

salt.modules.win_ip.get_interface(iface)
Return the configuration of a network interface

CLI Example:

```
salt -G 'os_family:Windows' ip.get_interface 'Local Area Connection'
```

salt.modules.win_ip.get_subnet_length(mask)
Convenience function to convert the netmask to the CIDR subnet length

CLI Example:

```
salt -G 'os_family:Windows' ip.get_subnet_length 255.255.255.0
```

salt.modules.win_ip.is_disabled(iface)
Returns True if interface is disabled, otherwise False

CLI Example:
salt -G 'os_family:Windows' ip.is_disabled 'Local Area Connection #2'

salt.modules.win_ip.is_enabled(iface)
Returns True if interface is enabled, otherwise False

CLI Example:
salt -G 'os_family:Windows' ip.is_enabled 'Local Area Connection #2'

salt.modules.win_ip.raw_interface_configs()
Return raw configs for all interfaces

CLI Example:
salt -G 'os_family:Windows' ip.raw_interface_configs

salt.modules.win_ip.set_dhcp_all(iface)
Set both IP Address and DNS to DHCP

CLI Example:
salt -G 'os_family:Windows' ip.set_dhcp_all 'Local Area Connection'

salt.modules.win_ip.set_dhcp_dns(iface)
Set DNS source to DHCP on Windows

CLI Example:
salt -G 'os_family:Windows' ip.set_dhcp_dns 'Local Area Connection'

salt.modules.win_ip.set_dhcp_ip(iface)
Set Windows NIC to get IP from DHCP

CLI Example:
salt -G 'os_family:Windows' ip.set_dhcp_ip 'Local Area Connection'

salt.modules.win_ip.set_static_dns(iface, *addrs)
Set static DNS configuration on a Windows NIC

CLI Example:
salt -G 'os_family:Windows' ip.set_static_dns 'Local Area Connection' '192.168.1.1'
salt -G 'os_family:Windows' ip.set_static_dns 'Local Area Connection' '192.168.1.253'

salt.modules.win_ip.set_static_ip(iface, addr, gateway=None, append=False)
Set static IP configuration on a Windows NIC
iface The name of the interface to manage
addr IP address with subnet length (ex. 10.1.2.3/24). The ip.get_subnet_length function can be used to calculate the subnet length from a netmask.
gateway [None] If specified, the default gateway will be set to this value.
append [False] If True, this IP address will be added to the interface. Default is False, which overrides any existing configuration for the interface and sets addr as the only address on the interface.

CLI Example:
salt -G 'os_family:Windows' ip.set_static_ip 'Local Area Connection' 10.1.2.3/24
  --gateway=10.1.2.1
salt -G 'os_family:Windows' ip.set_static_ip 'Local Area Connection' 10.1.2.4/24
  --append=True
13.6.350 salt.modules.win_license module

This module allows you to manage windows licensing via slmgr.vbs

```python
salt '*' license.install XXXXX-XXXXX-XXXXX-XXXXX-XXXXX
```

```python
salt.modules.win_license.activate()
    Attempt to activate the current machine via Windows Activation
    CLI Example:
    
    ```
salt '*' license.activate
    ```
```

```python
salt.modules.win_license.info()
    Return information about the license, if the license is not correctly activated this will return None.
    CLI Example:
    
    ```
salt '*' license.info
    ```
```

```python
salt.modules.win_license.install(product_key)
    Install the given product key
    CLI Example:
    
    ```
salt '*' license.install XXXXX-XXXXX-XXXXX-XXXXX-XXXXX
    ```
```

```python
salt.modules.win_license.installed(product_key)
    Check to see if the product key is already installed.
    Note: This is not 100% accurate as we can only see the last 5 digits of the license.
    CLI Example:
    
    ```
salt '*' license.installed XXXXX-XXXXX-XXXXX-XXXXX-XXXXX
    ```
```

```python
salt.modules.win_license.licensed()
    Return true if the current machine is licensed correctly
    CLI Example:
    
    ```
salt '*' license.licensed
    ```
```

```python
salt.modules.win_license.uninstall()
    Uninstall the current product key
    CLI Example:
    
    ```
salt '*' license.uninstall
    ```
```

13.6.351 salt.modules.win_network

Module for gathering and managing network information

```python
salt.modules.win_network.connect(host, port=None, **kwargs)
    Test connectivity to a host using a particular port from the minion.
    ```
New in version 2016.3.0.

CLI Example:

```
salt '*' network.connect archlinux.org 80
salt '*' network.connect archlinux.org 80 timeout=3
salt '*' network.connect archlinux.org 80 timeout=3 family=ipv4
salt '*' network.connect google-public-dns-a.google.com port=53 proto=udp timeout=3
```

salt.modules.win_network.

**dig**(host)

Performs a DNS lookup with dig

Note: dig must be installed on the Windows minion

CLI Example:

```
salt '*' network.dig archlinux.org
```

salt.modules.win_network.

**hw_addr**(iface)

Return the hardware address (a.k.a. MAC address) for a given interface

CLI Example:

```
salt '*' network.hw_addr 'Wireless Connection #1'
```

salt.modules.win_network.

**hwaddr**(iface)

This function is an alias of hw_addr.

Return the hardware address (a.k.a. MAC address) for a given interface

CLI Example:

```
salt '*' network.hw_addr 'Wireless Connection #1'
```

salt.modules.win_network.

**in_subnet**(cidr)

Returns True if host is within specified subnet, otherwise False

CLI Example:

```
salt '*' network.in_subnet 10.0.0.0/16
```

salt.modules.win_network.

**interfaces()**

Return a dictionary of information about all the interfaces on the minion

CLI Example:

```
salt '*' network.interfaces
```

salt.modules.win_network.

**interfaces_names()**

Return a list of all the interfaces names

CLI Example:

```
salt '*' network.interfaces_names
```

salt.modules.win_network.

**ip_addrs**(interface=None, include_loopback=False)

Returns a list of IPv4 addresses assigned to the host. 127.0.0.1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned.
CLI Example:
```
salt '*' network.ip_addrs
```

```
salt.modules.win_network.ip_addrs6(interface=None, include_loopback=False)
Returns a list of IPv6 addresses assigned to the host. ::1 is ignored, unless `include_loopback=True' is indicated. If `interface' is provided, then only IP addresses from that interface will be returned.

CLI Example:
```
salt '*' network.ip_addrs6
```

```
salt.modules.win_network.ip_addrs(interface=None, include_loopback=False)
This function is an alias of ip_addrs.
Returns a list of IPv4 addresses assigned to the host. 127.0.0.1 is ignored, unless `include_loopback=True' is indicated. If `interface' is provided, then only IP addresses from that interface will be returned.

CLI Example:
```
salt '*' network.ip_addrs
```

```
salt.modules.win_network.ip_addrs6(interface=None, include_loopback=False)
This function is an alias of ip_addrs6.
Returns a list of IPv6 addresses assigned to the host. ::1 is ignored, unless `include_loopback=True' is indicated. If `interface' is provided, then only IP addresses from that interface will be returned.

CLI Example:
```
salt '*' network.ip_addrs6
```

```
salt.modules.win_network.netstat()
Return information on open ports and states

CLI Example:
```
salt '*' network.netstat
```

```
salt.modules.win_network.nslookup(host)
Query DNS for information about a domain or ip address

CLI Example:
```
salt '*' network.nslookup archlinux.org
```

```
salt.modules.win_network.ping(host)
Performs a ping to a host

CLI Example:
```
salt '*' network.ping archlinux.org
```

```
salt.modules.win_network.subnets()
Returns a list of subnets to which the host belongs

CLI Example:
```
salt '*' network.subnets
```
salt.modules.win_network.traceroute(host)
Performs a traceroute to a 3rd party host

CLI Example:

```shell
salt '*' network.traceroute archlinux.org
```

13.6.352 salt.modules.win_ntp

Management of NTP servers on Windows
New in version 2014.1.0.

salt.modules.win_ntp.get_servers()
Get list of configured NTP servers

CLI Example:

```shell
salt '*' ntp.get_servers
```

salt.modules.win_ntp.set_servers('servers')
Set Windows to use a list of NTP servers

CLI Example:

```shell
salt '*' ntp.set_servers 'pool.ntp.org' 'us.pool.ntp.org'
```

13.6.353 salt.modules.win_path

Manage the Windows System PATH
Note that not all Windows applications will rehash the PATH environment variable, Only the ones that listen to the
WM_SETTINGCHANGE message http://support.microsoft.com/kb/104011

salt.modules.win_path.add(path, index=0)
Add the directory to the SYSTEM path in the index location

Returns: boolean True if successful, False if unsuccessful

CLI Example:

```shell
# Will add to the beginning of the path
salt '*' win_path.add 'c:\python27' 0

# Will add to the end of the path
salt '*' win_path.add 'c:\python27' index='-1'
```

salt.modules.win_path.exists(path)
Check if the directory is configured in the SYSTEM path Case-insensitive and ignores trailing backslash

Returns: boolean True if path exists, False if not

CLI Example:

```shell
salt '*' win_path.exists 'c:\python27'
salt '*' win_path.exists 'c:\python27\'
salt '*' win_path.exists 'C:\pyThon27'
```

salt.modules.win_path.get_path()
Returns a list of items in the SYSTEM path
CLI Example:

```
salt '*' win_path.get_path
```

**salt.modules.win_path.rehash()**

Send a WM_SETTINGCHANGE Broadcast to Windows to refresh the Environment variables

CLI Example:

```
... code-block:: bash
    salt '*' win_path.rehash
```

**salt.modules.win_path.remove(path)**

Remove the directory from the SYSTEM path

**Returns:** boolean True if successful, False if unsuccessful

CLI Example:

```
# Will remove C:\Python27 from the path
salt '*' win_path.remove 'c:\\python27'
```

### 13.6.354 salt.modules.win_pkg

A module to manage software on Windows

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install` is not available), see [here](#).

**salt.modules.win_pkg.compare_versions**(*ver1='', oper='==', ver2='*)

Compare software package versions

**salt.modules.win_pkg.genrepo**(*saltenv='base')

Generate winrepo_cachefile based on sls files in the winrepo

CLI Example:

```
salt-run winrepo.genrepo
```

**salt.modules.win_pkg.get_name_map()**

**salt.modules.win_pkg.get_repo_data**(*saltenv='base')

Returns the cached winrepo data

CLI Example:

```
salt '*' pkg.get_repo_data
```

**salt.modules.win_pkg.install**(*name=None, refresh=False, pkgs=None, saltenv='base', **kwargs*)

Install the passed package(s) on the system using winrepo

**Parameters**

- **name** (*str, list, or None*) -- The name of a single package, or a comma-separated list of packages to install. (no spaces after the commas)
- **refresh** (*bool*) -- Boolean value representing whether or not to refresh the winrepo db
- **pkgs** (*list or None*) -- A list of packages to install from a software repository. All packages listed under pkgs will be installed via a single command.
Salt Documentation, Release 2016.3.6

• saltenv (str) -- e salt environment to use. Default is base.
Keyword Arguments (kwargs)
Parameters
• version (str) -- e speciﬁc version to install. If omied, the latest version will
be installed. If passed with multiple install, the version will apply to all packages.
Recommended for single installation only.
• cache_file (str) -- A single ﬁle to copy down for use with the installer. Copied
to the same location as the installer. Use this over cache_dir if there are many ﬁles
in the directory and you only need a speciﬁc ﬁle and don't want to cache additional
ﬁles that may reside in the installer directory. Only applies to ﬁles on salt://
• cache_dir (bool) -- True will copy the contents of the installer directory. is
is useful for installations that are not a single ﬁle. Only applies to directories on
salt://
Returns Return a dict containing the new package names and versions:
Return type
dict
If the package is installed by pkg.install:
{'<package>': {'old': '<old-version>',
'new': '<new-version>'}}

If the package is already installed:
{'<package>': {'current': '<current-version>'}}

e following example will refresh the winrepo and install a single package, 7zip.
CLI Example:
salt '*' pkg.install 7zip refresh=True

CLI Example:
salt '*' pkg.install 7zip
salt '*' pkg.install 7zip,filezilla
salt '*' pkg.install pkgs='["7zip","filezilla"]'

WinRepo Deﬁnition File Examples:
e following example demonstrates the use of cache_file. is would be used if you have multiple
installers in the same directory that use the same install.ini ﬁle and you don't want to download the
additional installers.
ntp:
4.2.8:
installer: 'salt://win/repo/ntp/ntp-4.2.8-win32-setup.exe'
full_name: Meinberg NTP Windows Client
locale: en_US
reboot: False
cache_file: 'salt://win/repo/ntp/install.ini'
install_flags: '/USEFILE=C:
,→\salt\var\cache\salt\minion\files\base\win\repo\ntp\install.ini'
uninstaller: 'NTP/uninst.exe'

e following example demonstrates the use of cache_dir. It assumes a ﬁle named install.ini resides
in the same directory as the installer.
1648

Chapter 13. Salt Module Reference


**ntp:**

4.2.8:
- installer: `salt://win/repo/ntp/ntp-4.2.8-win32-setup.exe`
- full_name: Meinberg NTP Windows Client
- locale: en_US
- reboot: False
- cache_dir: True
- install_flags: `/USEFILE=C:\salt\var\cache\salt\minion\files\base\win\repo\ntp\install.ini`
- uninstaller: `NTP/uninst.exe`

salt.modules.win_pkg.latest_version(*names, **kwargs*)

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

salt.modules.win_pkg.list_available(*names*)

Return a list of available versions of the specified package.

CLI Example:

```
salt '*' pkg.list_available <package name>
salt '*' pkg.list_available <package name01> <package name02>
```

salt.modules.win_pkg.list_pkgs(versions_as_list=False, **kwargs*)

List the packages currently installed in a dict:

```
{'<package_name>': '<version>'}
```

CLI Example:

```
salt '*' pkg.list_pkgs
salt '*' pkg.list_pkgs versions_as_list=True
```

salt.modules.win_pkg.list_upgrades(refresh=True, **kwargs*)

List all available package upgrades on this system.

CLI Example:

```
salt '*' pkg.list_upgrades
```

salt.modules.win_pkg.purge(name=None, pkg=None, version=None, **kwargs*)

Package purges are not supported, this function is identical to remove().

**name** The name of the package to be deleted.

**version** The version of the package to be deleted. If this option is used in combination with the *pkg* option below, then this version will be applied to all targeted packages.

Multiple Package Options:

**pkg** A list of packages to delete. Must be passed as a python list. The *name* parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.
CLI Example:

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'
```

```
salt.modules.win_pkg.refresh_db(saltenv='base')
```

Just recheck the repository and return a dict:

```
{'<database name>': Bool}
```

CLI Example:

```
salt '*' pkg.refresh_db
```

```
salt.modules.win_pkg.remove(name=None, pkgs=None, version=None, **kwargs)
```

Remove the passed package(s) from the system using winrepo

Parameters

- **name**(str, list, or None) -- The name of the package to be uninstalled.
- **version**(str) -- The version of the package to be uninstalled. If this option is used
to uninstall multiple packages, then this version will be applied to all targeted pack-
ages. Recommended using only when uninstalling a single package. If this parameter
is omitted, the latest version will be uninstalled.

Multiple Package Options:

Parameters **pkgs**(list or None) -- A list of packages to delete. Must be passed as a python
list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns Returns a dict containing the changes.

Return type
dict

If the package is removed by pkg.remove:

```
{'<package>': {'old': '<old-version>', 'new': '<new-version>'}}
```

If the package is already uninstalled:

```
{'<package>': {'current': 'not installed'}}
```

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

```
salt.modules.win_pkg.upgrade(refresh=True)
```

Run a full system upgrade

Return a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
              'new': '<new-version>'}}
```

CLI Example:

```
salt '*' pkg.upgrade
```
salt.modules.win_pkg.upgrade_available(name)
Check whether or not an upgrade is available for a given package

CLI Example:
salt '*' pkg.upgrade_available <package name>

salt.modules.win_pkg.version(*names, **kwargs)
Returns a version if the package is installed, else returns an empty string

CLI Example:
salt '*' pkg.version <package name>

13.6.355 salt.modules.win_powercfg
This module allows you to control the power settings of a windows minion via powercfg.
New in version 2015.8.0.

salt '*' powercfg.set_monitor_timeout 0 power=dc
salt '*' powercfg.set_disk_timeout 120 power=ac

salt.modules.win_powercfg.get_disk_timeout()
Get the current disk timeout of the current scheme

CLI Example:
salt '*' powercfg.get_disk_timeout

salt.modules.win_powercfg.get_hibernate_timeout()
Get the current hibernate timeout of the current scheme

CLI Example:
salt '*' powercfg.get_hibernate_timeout

salt.modules.win_powercfg.get_monitor_timeout()
Get the current monitor timeout of the current scheme

CLI Example:
salt '*' powercfg.get_monitor_timeout

salt.modules.win_powercfg.get_standby_timeout()
Get the current standby timeout of the current scheme

CLI Example:
salt '*' powercfg.get_standby_timeout

salt.modules.win_powercfg.set_disk_timeout(timeout, power='ac')
Set the disk timeout in minutes for the current power scheme

CLI Example:
salt '*' powercfg.set_disk_timeout 30 power=dc

timeout The amount of time in minutes before the disk will timeout
power Should we set the value for AC or DC (battery)? Valid options ac,dc.

```
salt.modules.win_powercfg.set_hibernate_timeout(timeout, power='ac')
```
Set the hibernate timeout in minutes for the current power scheme

CLI Example:
```
salt '*' powercfg.set_hibernate_timeout 30 power=pc
```

- **timeout**: The amount of time in minutes before the computer hibernates
- **power**: Should we set the value for AC or DC (battery)? Valid options ac,dc.

```
salt.modules.win_powercfg.set_monitor_timeout(timeout, power='ac')
```
Set the monitor timeout in minutes for the current power scheme

CLI Example:
```
salt '*' powercfg.set_monitor_timeout 30 power=ac
```

- **timeout**: The amount of time in minutes before the monitor will timeout
- **power**: Should we set the value for AC or DC (battery)? Valid options ac,dc.

```
salt.modules.win_powercfg.set_standby_timeout(timeout, power='ac')
```
Set the standby timeout in minutes for the current power scheme

CLI Example:
```
salt '*' powercfg.set_standby_timeout 30 power=dc
```

- **timeout**: The amount of time in minutes before the computer sleeps
- **power**: Should we set the value for AC or DC (battery)? Valid options ac,dc.

### 13.6.356 salt.modules.win_repo

Module to manage Windows software repo on a Standalone Minion

**file_client**: local must be set in the minion config file.

For documentation on Salt's Windows Repo feature, see here.

```
salt.modules.win_repo.genrepo()
```
Generate winrepo_cachefile based on sls files in the winrepo_dir

CLI Example:
```
salt-call winrepo.genrepo
```

```
salt.modules.win_repo.show_sls(name, saltenv='base')
```
New in version 2015.8.0.

Display the rendered software definition from a specific sls file in the local winrepo cache. This will parse all Jinja. Run pkg.refresh_db to pull the latest software definitions from the master.

**Note**: This function does not ask a master for an sls file to render. Instead it directly processes the file specified in name

**Args**: name str: The name/path of the package you want to view. This can be the full path to a file on the minion file system or a file on the local minion cache.
saltenv str: The default environment is base

Returns: dict: Returns a dictionary containing the rendered data structure

Note: To use a file from the minion cache start from the local winrepo root (C:\salt\var\cache\salt\minion\files\base\win\repo-ng). If you have .sls files organized in subdirectories you'll have to denote them with .. For example, if you have a test directory in the winrepo root with a gvim.sls file inside, would target that file like so: test.gvim. Directories can be targeted as well as long as they contain an init.sls inside. For example, if you have a node directory with an init.sls inside, target that like so: node.

CLI Example:

```
salt '*' winrepo.show_sls gvim
salt '*' winrepo.show_sls test.npp
salt '*' winrepo.show_sls C:\test\gvim.sls
```

salt.modules.win_repo.update_git_repos(clean=False)

Checkout git repos containing Windows Software Package Definitions.

Important: This function requires Git for Windows to be installed in order to work. When installing, make sure to select an installation option which permits the git executable to be run from the Command Prompt.

clean [False] Clean repo cachedirs which are not configured under winrepo_remotes.

Note: This option only applies if either pygit2 or GitPython is installed into Salt's bundled Python.

Warning: This argument should not be set to True if a mix of git and non-git repo definitions are being used, as it will result in the non-git repo definitions being removed.

New in version 2015.8.0.

CLI Example:

```
salt-call winrepo.update_git_repos
```

13.6.357 salt.modules.win_servermanager

Manage Windows features via the ServerManager powershell module

salt.modules.win_servermanager.install(feature, recurse=False, source=None, restart=False, exclude=None)

Install a feature

Note: Some features require reboot after un/installation, if so until the server is restarted other features can not be installed!

Note: Some features take a long time to complete un/installation, set -t with a long timeout
Parameters

- **feature (str)** -- The name of the feature to install
- **recurse (bool)** -- Install all sub-features. Default is False
- **source (str)** -- Path to the source files if missing from the target system. None means that the system will use windows update services to find the required files. Default is None
- **restart (bool)** -- Restarts the computer when installation is complete, if required by the role/feature installed. Default is False
- **exclude (str)** -- The name of the feature to exclude when installing the named feature.

Note: As there is no exclude option for the `Add-WindowsFeature` command, the feature will be installed with other sub-features and will then be removed.

Returns A dictionary containing the results of the install
Return type **dict**

CLI Example:

```bash
salt '*' win_servermanager.install Telnet-Client
salt '*' win_servermanager.install SNMP-Service True
salt '*' win_servermanager.install TFTP-Client source=d:\side-by-side
```

salt.modules.win_servermanager.list_available()
List available features to install
Returns A list of available features
Return type **list**

CLI Example:

```bash
salt '*' win_servermanager.list_available
```

salt.modules.win_servermanager.list_installed()
List installed features. Supported on Windows Server 2008 and Windows 8 and newer.
Returns A list of installed features
Return type **list**

CLI Example:

```bash
salt '*' win_servermanager.list_installed
```

salt.modules.win_servermanager.remove(feature, remove_payload=False, restart=False)
Remove an installed feature

Note: Some features require a reboot after installation/uninstallation. If one of these features are modified, then other features cannot be installed until the server is restarted. Additionally, some features take a while to complete installation/uninstallation, so it is a good idea to use the -t option to set a longer timeout.

Parameters

- **feature (str)** -- The name of the feature to remove
- **remove_payload (bool)** -- True will cause the feature to be removed from the side-by-side store (%SystemDrive%:\Windows\WinSxS). Default is False
• **restart**(bool) -- Restarts the computer when uninstall is complete, if required by
the role/feature removed. Default is False

**Returns** A dictionary containing the results of the uninstall

**Return type** dict

CLI Example:

```bash
salt -t 600 '*' win_servermanager.remove Telnet-Client
```

### 13.6.358 salt.modules.win_service

Windows Service module.

**salt.modules.win_service.available**(name)

Returns True if the specified service is available, otherwise returns False.

CLI Example:

```bash
salt '*' service.available <service name>
```

**salt.modules.win_service.config**(name, bin_path=None, display_name=None, svc_type=None,
start_type=None, error=None, group=None, tag=None, depend=None, obj=None, password=None, **kwargs)

Modify the named service.

**Required parameters:**

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>name</strong>(str)</td>
<td>Specifies the service name returned by the getkeyname operation</td>
</tr>
</tbody>
</table>

**Optional parameters:**

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>bin_path</strong>(str)</td>
<td>Specifies the path to the service binary file, backslashes must be escaped - eg: C:\path\to\binary.exe</td>
</tr>
<tr>
<td><strong>display_name</strong>(str)</td>
<td>the name to be displayed in the service manager</td>
</tr>
</tbody>
</table>

Specifies a more descriptive name for identifying the service in user interface programs.

**Parameters**

- **svc_type**(str) -- Specifies the service type. Acceptable values are:
  - own (default): Service runs in its own process
  - share: Service runs as a shared process
  - interact: Service can interact with the desktop
  - kernel: Service is a driver
  - filesys: Service is a system driver
  - rec: Service is a file system-recognized driver that identifies filesystems on the computer
  - adapt: Service is an adapter driver that identifies hardware such as keyboards, mice and disk drives

- **start_type**(str) -- Specifies the start type for the service.

Acceptable values are:

- boot: Device driver that is loaded by the boot loader
- system: Device driver that is started during kernel initialization
- auto: Service that automatically starts
- demand (default): Service must be started manually
- disabled: Service cannot be started
- delayed-auto: Service starts automatically after other auto-services start
Parameters **error (str)** -- Specifies the severity of the error if the service fails to start. Acceptable values are:

- normal (default): Error is logged and a message box is displayed
- severe: Error is logged and computer attempts a restart with last known good configuration
- critical: Error is logged, computer attempts to restart with last known good configuration, system halts on failure
- ignore: Error is logged and startup continues, no notification is given to the user

Parameters **group (str)** -- Specifies the name of the group of which this service is a member. The list of groups is stored in the registry, in the HKLMS\SystemCurrentControlSetControlService-GroupOrder subkey. The default is null.

Parameters **tag (str)** -- Specifies whether or not to obtain a TagID from the CreateService call. For boot-start and system-start drivers only. Acceptable values are:

- yes/no

Parameters **depend (str)** -- Specifies the names of services or groups that must start before this service. The names are separated by forward slashes.

Parameters **obj (str)** -- Specifies the name of an account in which a service will run or specifies a name of the Windows driver object in which the driver will run. Default is LocalSystem

Parameters **password (str)** -- Specifies a password. Required if other than LocalSystem account is used.

Returns True if successful, False if not

Return type bool

CLI Example:

```bash
salt '*' service.config <service name> <path to exe> display_name='<display name>'
```

salt.modules.win_service.create(name, binpath, DisplayName=None, type='own', start='demand', error='normal', group=None, tag='no', depend=None, obj=None, password=None, **kwargs)

Create the named service.

New in version 2015.8.0.

Required parameters:

Parameters

- **name** -- Specifies the service name returned by the getkeyname operation
- **binpath** -- Specifies the path to the service binary file, backslashes must be escaped - eg: C:\path\to\binary.exe

Optional parameters:

Parameters

- **DisplayName** -- the name to be displayed in the service manager
- **type** -- Specifies the service type, default is own - own (default): Service runs in its own process - share: Service runs as a shared process - interact: Service can interact with the desktop - kernel: Service is a driver - filesys: Service is a system driver - rec: Service is a file system-recognized driver that identifies filesystems on the computer
- **start** -- Specifies the start type for the service - boot: Device driver that is loaded by the boot loader - system: Device driver that is started during kernel initialization - auto: Service that automatically starts - demand (default): Service must be started manually - disabled: Service cannot be started - delayed-auto: Service starts automatically after other auto-services start
• **error** -- Specifies the severity of the error - normal (default): Error is logged and a message box is displayed - severe: Error is logged and computer attempts a restart with last known good configuration - critical: Error is logged, computer attempts to restart with last known good configuration, system halts on failure - ignore: Error is logged and startup continues, no notification is given to the user

• **group** -- Specifies the name of the group of which this service is a member

• **tag** -- Specifies whether or not to obtain a TagID from the CreateService call. For boot-start and system-start drivers - yes/no

• **depend** -- Specifies the names of services or groups that must start before this service. The names are separated by forward slashes.

• **obj** -- Specifies the name of an account in which a service will run. Default is LocalSystem

• **password** -- Specifies a password. Required if other than LocalSystem account is used.

CLI Example:

```
salt '*' service.create <service name> <path to exe> display_name='display name'
```

salt.modules.win_service.create_win_salt_restart_task()

Create a task in Windows task scheduler to enable restarting the salt-minion

CLI Example:

```
salt '*' service.create_win_salt_restart_task()
```

salt.modules.win_service.delete(name)

Delete the named service

CLI Example:

```
salt '*' service.delete <service name>
```

salt.modules.win_service.disable(name, **kwargs)

Disable the named service to start at boot

CLI Example:

```
salt '*' service.disable <service name>
```

salt.modules.win_service.disabled(name)

Check to see if the named service is disabled to start on boot

CLI Example:

```
salt '*' service.disabled <service name>
```

salt.modules.win_service.enable(name, **kwargs)

Enable the named service to start at boot

CLI Example:

```
salt '*' service.enable <service name>
```

salt.modules.win_service.enabled(name, **kwargs)

Check to see if the named service is enabled to start on boot
Salt Documentation, Release 2016.3.6

CLI Example:

```python
salt 'salt '*' service.enabled <service name>
```

```
salt.modules.win_service.execute_salt_restart_task()
```

Run the Windows Salt restart task

CLI Example:

```
salt 'salt '*' service.execute_salt_restart_task()
```

```
salt.modules.win_service.get_all()
```

Return all installed services

CLI Example:

```
salt 'salt '*' service.get_all
```

```
salt.modules.win_service.get_disabled()
```

Return the disabled services

CLI Example:

```
salt 'salt '*' service.get_disabled
```

```
salt.modules.win_service.get_enabled()
```

Return the enabled services

CLI Example:

```
salt 'salt '*' service.get_enabled
```

```
salt.modules.win_service.get_service_name("args")
```

The Display Name is what is displayed in Windows when services.msc is executed. Each Display Name has an associated Service Name which is the actual name of the service. This function allows you to discover the Service Name by returning a dictionary of Display Names and Service Names, or filter by adding arguments of Display Names.

If no args are passed, return a dict of all services where the keys are the service Display Names and the values are the Service Names.

If arguments are passed, create a dict of Display Names and Service Names

CLI Example:

```
salt 'salt '*' service.get_service_name
salt 'salt '*' service.get_service_name 'Google Update Service (gupdate)' 'DHCP Client'
```

```
salt.modules.win_service.getsid(name)
```

Return the sid for this windows service

CLI Example:

```
salt 'salt '*' service.getsid <service name>
```

```
salt.modules.win_service.missing(name)
```

The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:
salt '*' service.missing <service name>

salt.modules.win_service.restart(name)
    Restart the named service
    CLI Example:
    
salt '*' service.restart <service name>

salt.modules.win_service.start(name)
    Start the specified service.
    
    **Warning**: You cannot start a disabled service in Windows. If the service is disabled, it will be changed to Manual start.
    
    Args:
    name (str): The name of the service to start
    
    **Returns**: bool: True if successful, otherwise False
    
    CLI Example:
    
salt '*' service.start <service name>

salt.modules.win_service.status(name, sig=None)
    Return the status for a service, returns the PID or an empty string if the service is running or not, pass a signature to use to find the service via ps
    
    CLI Example:
    
salt '*' service.status <service name> [service signature]

salt.modules.win_service.stop(name)
    Stop the specified service
    
    CLI Example:
    
salt '*' service.stop <service name>

13.6.359 salt.modules.win_shadow

Manage the shadow file

**Important**: If you feel that Salt should be using this module to manage passwords on a minion, and it is using a different module (or gives an error similar to `shadow.info' is not available), see [here](#).

salt.modules.win_shadow.info(name)
    Return information for the specified user This is just returns dummy data so that salt states can work.
    
    **Parameters** name (str) -- The name of the user account to show.
    
    CLI Example:
    
salt '*' shadow.info root
salt.modules.win_shadow.require_password_change(name)
    Require the user to change their password the next time they log in.
    Parameters name -- The name of the user account to require a password change.
    Returns True if successful. False if unsuccessful.
    Return type bool

salt.modules.win_shadow.set_expire(name, expire)
    Set the expiration date for a user account.
    Parameters
        • name -- The name of the user account to edit.
        • expire -- The date the account will expire.
    Returns True if successful. False if unsuccessful.
    Return type bool

salt.modules.win_shadow.set_password(name, password)
    Set the password for a named user.
    Parameters
        • name (str) -- The name of the user account
        • password (str) -- The new password
    Returns True if successful. False if unsuccessful.
    Return type bool

    CLI Example:
    salt '*' shadow.set_password root mysecretpassword

salt.modules.win_shadow.unlock_account(name)
    Unlocks a user account.
    Parameters name -- The name of the user account to unlock.
    Returns True if successful. False if unsuccessful.
    Return type bool

13.6.360 salt.modules.win_status

Module for returning various status data about a minion. These data can be useful for compiling into stats later, or
for problem solving if your minion is having problems.

New in version 0.12.0.
    depends
        • pythoncom
        • wmi

salt.modules.win_status.cpuload()
    New in version 2015.8.0.
    Return the processor load as a percentage

    CLI Example:
    salt '*' status.cpuload

salt.modules.win_status.diskusage(human_readable=False, path=None)
    New in version 2015.8.0.
    Return the disk usage for this minion
**human_readable**  [False] If True, usage will be in KB/MB/GB etc.

CLI Example:
```
salt '*' status.diskusage path=c:/salt
```

**salt.modules.win_status.master** *(master=None, connected=True)*

New in version 2015.5.0.

Fire an event if the minion gets disconnected from its master. This function is meant to be run via a scheduled job from the minion. If master_ip is an FQDN/Hostname, is must be resolvable to a valid IPv4 address.

CLI Example:
```
salt '*' status.master
```

**salt.modules.win_status.procs**(count=False)

Return the process data

count  [False] If True, this function will simply return the number of processes.

New in version 2015.8.0.

CLI Example:
```
salt '*' status.procs
salt '*' status.procs count
```

**salt.modules.win_status.saltmem**(human_readable=False)

New in version 2015.8.0.

Returns the amount of memory that salt is using

human_readable  [False] return the value in a nicely formatted number

CLI Example:
```
salt '*' status.saltmem
salt '*' status.saltmem human_readable=True
```

**salt.modules.win_status.uptime**(human_readable=False)

New in version 2015.8.0.

Return the system uptime for this machine in seconds

human_readable  [False] If True, then return uptime in years, days, and seconds.

CLI Example:
```
salt '*' status.uptime
salt '*' status.uptime human_readable=True
```

### 13.6.361 salt.modules.win_system

Module for managing windows systems.

**depends**

- win32net

Support for reboot, shutdown, etc

**salt.modules.win_system.get_computer_desc()**

Get the Windows computer description

Returns  Returns the computer description if found. Otherwise returns False
CLI Example:

```
salt 'minion-id' system.get_computer_desc
```

```
salt.modules.win_system.get_computer_name()
Get the Windows computer name
  Returns  Returns the computer name if found. Otherwise returns False
```

CLI Example:

```
salt 'minion-id' system.get_computer_name
```

```
salt.modules.win_system.get_domain_workgroup()
Get the domain or workgroup the computer belongs to.
  New in version 2015.5.7.
  New in version 2015.8.2.
    Returns  The name of the domain or workgroup
    Return type  str
```

```
salt.modules.win_system.get_hostname()
New in version 2016.3.0.
    Get the hostname of the windows minion
    Returns  Returns the hostname of the windows minion
```

CLI Example:

```
salt 'minion-id' system.get_hostname
```

```
salt.modules.win_system.get_pending_computer_name()
Get a pending computer name. If the computer name has been changed, and the change is pending a system
reboot, this function will return the pending computer name. Otherwise, None will be returned. If there was
an error retrieving the pending computer name, False will be returned, and an error message will be logged
to the minion log.
    Returns  Returns the pending name if pending restart. Returns none if not pending restart.
```

CLI Example:

```
salt 'minion-id' system.get_pending_computer_name
```

```
salt.modules.win_system.get_system_date()
Get the Windows system date
    Returns  Returns the system date.
    Return type  str
```

CLI Example:

```
salt '* system.get_system_date
```

```
salt.modules.win_system.get_system_info()
Get system information.
    Returns  Returns a Dictionary containing information about the system to include name, descrip-
tion, version, etc...
    Return type  dict
```

```
salt.modules.win_system.get_system_time()
Get the system time.
    Returns  Returns the system time in HH:MM AM/PM format.
    Return type  str
```
salt.modules.win_system.halt(timeout=5, in_seconds=False)

Halt a running system.

Parameters
timeout (int) -- Number of seconds before halting the system. Default is 5 seconds.

Returns
True is successful.

Return type bool

timeout The wait time before the system will be shutdown.
in_seconds Whether to treat timeout as seconds or minutes.

New in version 2015.8.0.

CLI Example:
salt '*' system.halt 5

salt.modules.win_system.init(runlevel)

Change the system runlevel on sysV compatible systems

CLI Example:
salt '*' system.init 3

salt.modules.win_system.join_domain(domain, username=None, password=None, account_ou=None, account_exists=False, restart=False)

Join a computer to an Active Directory domain. Requires reboot.

Parameters

- domain (str) -- The domain to which the computer should be joined, e.g. example.com
- username (str) -- Username of an account which is authorized to join computers to the specified domain. Need to be either fully qualified like user@domain.tld or simply user
- password (str) -- Password of the specified user
- account_ou (str) -- The DN of the OU below which the account for this computer should be created when joining the domain, e.g. ou=computers,ou=department_432,dc=my-company,dc=com
- account_exists (bool) -- If set to True the computer will only join the domain if the account already exists. If set to False the computer account will be created if it does not exist, otherwise it will use the existing account. Default is False
- restart (bool) -- Restarts the computer after a successful join

New in version 2015.8.2/2015.5.7.

Returns
Returns a dictionary if successful. False if unsuccessful.

Return type dict, bool

CLI Example:
salt 'minion-id' system.join_domain domain='domain.tld' \ username='joinuser' password='joinpassword' \ account_ou='ou=clients,ou=org,dc=domain,dc=tld' \ account_exists=False, restart=True

salt.modules.win_system.lock()

Lock the workstation.

Returns
True if successful

Return type bool
salt.modules.win_system.poweroff(timeout=5, in_seconds=False)

Power off a running system.

Parameters
- **timeout** (*int*) -- Number of seconds before powering off the system. Default is 5 seconds.
- **Returns** True if successful
- **Return type** *bool*

- **timeout** The wait time before the system will be shutdown.
- **in_seconds** Whether to treat timeout as seconds or minutes.

New in version 2015.8.0.

CLI Example:
```
salt '*' system.poweroff 5
```

salt.modules.win_system.reboot(timeout=5, in_seconds=False, wait_for_reboot=False)

Reboot a running system.

Parameters
- **timeout** (*int*) -- Number of minutes/seconds before rebooting the system. Minutes vs seconds depends on the value of **in_seconds**. Default is 5 minutes.
- **in_seconds** (*bool*) -- Whether to treat timeout as seconds or minutes.

New in version 2015.8.0.

- **wait_for_reboot** (*bool*) -- Sleeps for timeout + 30 seconds after reboot has been initiated. This is useful for use in a highstate for example where you have many states that could be ran after this one. Which you don't want to start until after the restart i.e. You could end up with a half finished state.

New in version 2015.8.0.

- **Returns** True if successful
- **Return type** *bool*

CLI Example:
```
salt '*' system.reboot 5
salt '*' system.reboot 5 True
```

salt.modules.win_system.set_computer_desc(desc=None)

Set the Windows computer description

Parameters
- **desc** (*str*) -- The computer description
- **Returns** False if it fails. Description if successful.

CLI Example:
```
salt 'minion-id' system.set_computer_desc 'This computer belongs to Dave!'
```

salt.modules.win_system.set_computer_name(name)

Set the Windows computer name

Parameters
- **name** (*str*) -- The new name to give the computer. Requires a reboot to take effect.
- **Returns** Returns a dictionary containing the old and new names if successful. False if not.

CLI Example:
```
salt 'minion-id' system.set_computer_name 'DavesComputer'
```

salt.modules.win_system.set_hostname(hostname)

New in version 2016.3.0.

Set the hostname of the windows minion, requires a restart before this will be updated.
Parameters **hostname** *(str)* -- The hostname to set

CLI Example:

```bash
salt 'minion-id' system.set_hostname newhostname
```

**salt.modules.win_system.set_system_date**(newdate)

Set the Windows system date. Use `<mm-dd-yy>` format for the date.

**Parameters** **newdate** *(str)* -- The date to set. Can be any of the following formats - `YYYY-MM-DD` - `MM-DD-YYYY` - `MM/DD/YYYY` - `MM/DD/YY` - `YYYY/MM/DD`

CLI Example:

```bash
salt '*' system.set_system_date '03-28-13'
```

**salt.modules.win_system.set_system_date_time**(years=None, months=None, days=None, hours=None, minutes=None, seconds=None)

Set the system date and time. Each argument is an element of the date, but not required. If an element is not passed, the current system value for that element will be used. For example, if you don’t pass the year, the current system year will be used. (Used by `set_system_date` and `set_system_time`)

**Parameters**

- **years** *(int)* -- Years digit, ie: 2015
- **months** *(int)* -- Months digit: 1 - 12
- **days** *(int)* -- Days digit: 1 - 31
- **hours** *(int)* -- Hours digit: 0 - 23
- **minutes** *(int)* -- Minutes digit: 0 - 59
- **seconds** *(int)* -- Seconds digit: 0 - 59

**Returns** True if successful. Otherwise False.

**Return type** bool

CLI Example:

```bash
salt '*' system.set_system_date_time 2015 5 12 11 37 53
```

**salt.modules.win_system.set_system_time**(newtime)

Set the system time.

**Parameters** **newtime** *(str)* -- The time to set. Can be any of the following formats. - `HH:MM:SS AM/PM` - `HH:MM AM/PM` - `HH:MM:SS` (24 hour) - `HH:MM` (24 hour)

**Returns** Returns True if successful. Otherwise False.

**Return type** bool

**salt.modules.win_system.shutdown**(message=None, timeout=5, force_close=True, reboot=False, in_seconds=False)

Shutdown a running system.

**Parameters**

- **message** *(str)* -- A message to display to the user before shutting down.

- **timeout** *(int)* -- The length of time that the shutdown dialog box should be displayed, in seconds. While this dialog box is displayed, the shutdown can be stopped by the `shutdown_abort` function.

If timeout is not zero, `InitiateSystemShutdown` displays a dialog box on the specified computer. The dialog box displays the name of the user who called the function, displays the message specified by the lMessage parameter, and prompts the user to log off. The dialog box beeps when it is created and remains on top of other windows.
in the system. The dialog box can be moved but not closed. A timer counts down the remaining time before a forced shutdown.

If timeout is zero, the computer shuts down without displaying the dialog box, and the shutdown cannot be stopped by shutdown_abort.

Default is 5 minutes

- **in_seconds (bool)** -- Whether to treat timeout as seconds or minutes.
  
  New in version 2015.8.0.

- **force_close (bool)** -- True to force close all open applications. False displays a dialog box instructing the user to close the applications.

- **reboot (bool)** -- True restarts the computer immediately after shutdown. False caches to disk and safely powers down the system.

  Returns  True if successful
  Return type  bool

  CLI Example:
  ```
salt '*' system.shutdown 5
  ```

salt.modules.win_system.shutdown_abort()

Abort a shutdown. Only available while the dialog box is being displayed to the user. Once the shutdown has initiated, it cannot be aborted

  Returns  True if successful
  Return type  bool

salt.modules.win_system.shutdown_hard()

Shutdown a running system with no timeout or warning.

  Returns  True if successful
  Return type  bool

  CLI Example:
  ```
salt '*' system.shutdown_hard
  ```

salt.modules.win_system.start_time_service()

Start the Windows time service

  Returns  True if successful. Otherwise False
  Return type  bool

  CLI Example:
  ```
salt '*' system.start_time_service
  ```

salt.modules.win_system.stop_time_service()

Stop the Windows time service

  Returns  True if successful. Otherwise False
  Return type  bool

  CLI Example:
  ```
salt '*' system.stop_time_service
  ```

salt.modules.win_system.unjoin_domain(username=None, password=None, domain=None, workgroup='WORKGROUP', disable=False, restart=False)

Unjoin a computer from an Active Directory Domain. Requires restart.

Parameters
• **username** -- Username of an account which is authorized to manage computer accounts on the domain. Need to be fully qualified like `user@domain.tld` or `domain.tld\user`. If domain not specified, the passed domain will be used. If computer account doesn't need to be disabled, can be None.

• **password** *(str)* -- Password of the specified user

• **domain** *(str)* -- The domain from which to unjoin the computer. Can be None

• **workgroup** *(str)* -- The workgroup to join the computer to. Default is **WORKGROUP**

New in version 2015.8.2/2015.5.7.

**Parameters**

• **disable** *(bool)* -- Disable the computer account in Active Directory. True to disable. Default is False

• **restart** *(bool)* -- Restart the computer after successful unjoin

New in version 2015.8.2/2015.5.7.

**Returns**

Returns a dictionary if successful. False if unsuccessful.

**Return type**
dict, bool

**CLI Example:**

```
salt 'minion-id' system.unjoin_domain restart=True
salt 'minion-id' system.unjoin_domain username='unjoinuser' \password='unjoinpassword' disable=True \restart=True
```

### 13.6.362 salt.modules.win_task module

Windows Task Scheduler Module .. versionadded:: 2016.3.0

A module for working with the Windows Task Scheduler. You can add and edit existing tasks. You can add and clear triggers and actions. You can list all tasks, folders, triggers, and actions.

**salt.modules.win_task.add_action**(name=None, location='\', action_type='Execute', **kwargs)

Add an action to a task.

**Parameters**

• **name** *(str)* -- The name of the task to which to add the action.

• **location** *(str)* -- A string value representing the location of the task. Default is `\` which is the root for the task scheduler (C:\Windows\System32\tasks).

**Parameters**

**action_type** *(str)* -- The type of action to add. There are three action types. Each one requires its own set of Keyword Arguments (kwargs). Valid values are: - Execute - Email - Message  

**kwargs**

Required kwargs for each value:

**Execute** Execute a command or an executable.

**Parameters**

• **cmd** *(str)* -- (required) The command / executable to run.

• **arguments** *(str)* -- (optional) Arguments to be passed to the command /
executable. To launch a script the first command will need to be the interpreter for the script. For example, to run a vbscript you would pass `cscript.exe` in the `cmd` parameter and pass the script in the `arguments` parameter as follows:

```
cmd='cscript.exe' arguments='c:\scripts\myscript.vbs'
```
Batch files do not need an interpreter and may be passed to the `cmd` parameter directly.

**Parameters**

- `start_in (str)` -- (optional) The current working directory for the command.

**Email** Send and email. Requires `server`, `from`, and `to` or `cc`.

**Parameters**

- `from (str)` -- The sender
- `reply_to (str)` -- Who to reply to
- `to (str)` -- The recipient
- `cc (str)` -- The CC recipient
- `bcc (str)` -- The BCC recipient
- `subject (str)` -- The subject of the email
- `body (str)` -- The Message Body of the email
- `server (str)` -- The server used to send the email
- `attachments (list)` -- A list of attachments. These will be the paths to the files to attach. ie: `attachments=['C:\attachment1.txt', 'C:\attachment2.txt']`

**Message** Display a dialog box. The task must be set to "Run only when user is logged on" in order for the dialog box to display. Both parameters are required.

**Parameters**

- `title (str)` -- The dialog box title.
- `message (str)` -- The dialog box message body

**Returns** True if successful, False if unsuccessful

**Return type** `bool`

```python
salt.modules.win_task.add_trigger(name=None, location='\', trigger_type=None, trigger_enabled=True, start_date=None, start_time=None, end_date=None, end_time=None, random_delay=None, repeat_interval=None, repeat_duration=None, repeat_stop_at_duration_end=False, execution_time_limit=None, **kwargs)
```

**Parameters**

- `name (str)` -- The name of the task to which to add the trigger.
- `location (str)` -- A string value representing the location of the task. Default is `\` which is the root for the task scheduler (C:\Windows\System32\tasks).

**Parameters**

- `trigger_type (str)` -- The type of trigger to create. This is defined when the trigger is created and cannot be changed later. Options are as follows: - Event - Once - Daily - Weekly - Monthly - MonthlyDay - OnIdle - OnTaskCreation - OnBoot - OnLogon - OnSessionChange

- `trigger_enabled (bool)` -- Boolean value that indicates whether the trigger is enabled.

- `start_date (str)` -- The date when the trigger is activated. If no value is passed, the current date will be used. Can be one of the following formats: - %Y-%m-%d - %m-%d-%Y - %m-%d-%Y - %m/%d/%y - %m/%d/%Y - %Y/%m/%d

- `start_time (str)` -- The time when the trigger is activated. If no value
is passed, midnight will be used. Can be one of the following formats: - %I:%M:%S %p - %I:%M %p - %H:%M:%S
- %H:%M

Parameters **end_date** *(str)* -- The date when the trigger is deactivated. The trigger cannot start the task after it is deactivated. Can be one of the following formats: - %Y-%m-%d - %m-%d-%y - %m-%d-%Y - %m/%d/%y - %m/%d/%Y - %Y/%m/%d

Parameters **end_time** *(str)* -- The time when the trigger is deactivated. If the this is not passed with **end_date** it will be set to midnight. Can be one of the following formats: - %I:%M:%S %p - %I:%M %p - %H:%M:%S - %H:%M

Parameters **random_delay** *(str)* -- The delay time that is randomly added to the start time of the trigger. Valid values are: - 30 seconds = 1 minute - 30 minutes = 1 hour - 8 hours - 1 day

Parameters **repeat_interval** *(str)* -- The amount of time between each restart of the task. Valid values are: - 5 minutes - 10 minutes - 15 minutes - 30 minutes - 1 hour

Parameters **repeat_duration** *(str)* -- How long the pattern is repeated. Valid values are: - Indefinitely - 15 minutes - 30 minutes - 1 hour - 12 hours - 1 day

Parameters **repeat_stop_at_duration_end** *(bool)* -- Boolean value that indicates if a running instance of the task is stopped at the end of the repetition pattern duration.

Parameters **execution_time_limit** *(str)* -- The maximum amount of time that the task launched by the trigger is allowed to run. Valid values are: - 30 minutes - 1 hour - 2 hours - 4 hours - 8 hours - 12 hours - 1 day - 3 days (default)

**kwargs**

There are optional keyword arguments determined by the type of trigger being defined. They are as follows:

*Event* 
  :param str subscription: An event definition in xml format that fires the trigger. The easiest way to get this would is to create an event in windows task scheduler and then copy the xml text.

*Once* 
  No special parameters required.

*Daily* 
  :param int days_interval: The interval between days in the schedule. An interval of 1 produces a daily schedule. An interval of 2 produces an every-other day schedule. If no interval is specified, 1 is used. Valid entries are 1 - 999.

*Weekly* 
  :param int weeks_interval: The interval between weeks in the schedule. An interval of 1 produces a weekly schedule. An interval of 2 produces an every-other week schedule. If no interval is specified, 1 is used. Valid entries are 1 - 52.

  :param list days_of_week: Sets the days of the week on which the task runs. Should be a list. ie: ['Monday','Wednesday','Friday']. Valid entries are the names of the days of the week.

*Monthly* 
  :param list months_of_year: Sets the months of the year during which the task runs. Should be a list. ie: ['January','July']. Valid entries are the full names of all the months.

  Parameters **days_of_month** *(list)* -- Sets the days of the month during which the task runs. Should be a list. ie: [1, 15, 'Last']. Options are all days of the month 1 - 31 and the word `Last` to indicate the last day of the month.

  Parameters **last_day_of_month** *(bool)* -- Boolean value that indicates that the task runs on the last day of the month regardless of the actual date of that day.

You can set the task to run on the last day of the month by either including the word `Last` in the list of days, or setting the parameter `last_day_of_month` equal to True.

*MonthlyDay* 
  :param list months_of_year: Sets the months of the year during which the task runs. Should be a list. ie: ['January','July']. Valid entries are the full names of all the months.

  Parameters **weeks_of_month** *(list)* -- Sets the weeks of the month during which the task runs. Should be a list. ie: ['First','Third']. Valid options are: - First - Second - Third - Fourth

  Parameters **last_week_of_month** *(bool)* -- Boolean value that indicates that the task runs on the last week of the month.

  Parameters **days_of_week** *(list)* -- Sets the days of the week during which the
task runs. Should be a list. ie: ['Monday','Wednesday','Friday']. Valid entries are the names of the days of the week.

OnIdle No special parameters required.

OnTaskCreation No special parameters required.

OnBoot No special parameters required.

OnLogon No special parameters required.

OnSessionChange: param str session_user_name: Sets the user for the Terminal Server session. When a session state change is detected for this user, a task is started. To detect session status change for any user, do not pass this parameter.

Parameters state_change (str) -- Sets the kind of Terminal Server session change that would trigger a task launch. Valid options are: - ConsoleConnect: When you connect to a user session (switch users) - ConsoleDisconnect: When you disconnect a user session (switch users) - RemoteConnect: When a user connects via Remote Desktop - RemoteDisconnect: When a user disconnects via Remote Desktop - SessionLock: When the workstation is locked - SessionUnlock: When the workstation is unlocked

Returns True if successful, False if unsuccessful

Return type bool

salt.modules.win_task.create_folder(name, location='\')

Create a folder in which to create tasks.

Parameters

- name (str) -- The name of the folder. This will be displayed in the task scheduler.

- location (str) -- A string value representing the location in which to create the folder. Default is '\' which is the root for the task scheduler (C:WindowsSystem32tasks).

Returns True if successful, False if unsuccessful

Return type bool

salt.modules.win_task.create_task(name, location='\', user_name='System', password=None, force=False, **kwargs)

Create a new task in the designated location. This function has many keyword arguments that are not listed here. For additional arguments see:

- py:function::edit_task
- py:function::add_action
- py:function::add_trigger

Parameters

- name (str) -- The name of the task. This will be displayed in the task scheduler.

- location (str) -- A string value representing the location in which to create the task. Default is '\' which is the root for the task scheduler (C:WindowsSystem32tasks).

- user_name (str) -- The user account under which to run the task. To specify the 'System' account, use 'System'. The password will be ignored.

- password (str) -- The password to use for authentication. This should set the task to run whether the user is logged in or not, but is currently not working.

- force (bool) -- If the task exists, overwrite the existing task.
Returns True if successful, False if unsuccessful
Return type bool

salt.modules.win_task.create_task_from_xml(name, location='\\', xml_text=None, xml_path=None, user_name='System', password=None)

Create a task based on XML. Source can be a file or a string of XML.

Parameters

- **name** *(str)* -- The name of the task. This will be displayed in the task scheduler.
- **location** *(str)* -- A string value representing the location in which to create the task. Default is `\\` which is the root for the task scheduler (C:\Windows\System32\tasks).
- **xml_text** *(str)* -- A string of xml representing the task to be created. This will be overridden by **xml_path** if passed.
- **xml_path** *(str)* -- The path to an XML file on the local system containing the xml that defines the task. This will override **xml_text**
- **user_name** *(str)* -- The user account under which to run the task. To specify the `System` account, use `System`. The password will be ignored.
- **password** *(str)* -- The password to use for authentication. This should set the task to run whether the user is logged in or not, but is currently not working.

Returns True if successful, False if unsuccessful
Return type bool

salt.modules.win_task.delete_folder(name, location='\\')

Delete a folder from the task scheduler.

Parameters

- **name** *(str)* -- The name of the folder to delete.
- **location** *(str)* -- A string value representing the location of the folder. Default is `\\` which is the root for the task scheduler (C:\Windows\System32\tasks).

Returns True if successful, False if unsuccessful
Return type bool

salt.modules.win_task.delete_task(name, location='\\')

Delete a task from the task scheduler.

Parameters

- **name** *(str)* -- The name of the task to delete.
- **location** *(str)* -- A string value representing the location of the task. Default is `\\` which is the root for the task scheduler (C:\Windows\System32\tasks).

Returns True if successful, False if unsuccessful
Return type bool

salt.modules.win_task.edit_task(name=None, location='\\', user_name=None, password=None, description=None, enabled=None, hidden=None, run_if_idle=None, idle_duration=None, idle_wait_timeout=None, idle_stop_on_end=None, idle_restart=None, ac_only=None, stop_if_on_batteries=None, wake_to_run=None, run_if_network=None, network_id=None, network_name=None, allow_demand_start=None, start_when_available=None, restart_every=None, restart_count=3, execution_time_limit=None, force_stop=None, delete_after=None, multiple_instances=None, **kwargs)

Edit the parameters of a task. Triggers and Actions cannot be edited yet.

Parameters

- **name** *(str)* -- The name of the task. This will be displayed in the task scheduler.
- **location** *(str)* -- A string value representing the location in which to
create the task. Default is `\' which is the root for the task scheduler (C:WindowsSystem32tasks).

Parameters

- **user_name**(str) -- The user account under which to run the task. To specify the `System' account, use `System'. The password will be ignored.

- **password**(str) -- The password to use for authentication. This should set the task to run whether the user is logged in or not, but is currently not working.

**Note:** The combination of user_name and password determine how the task runs. For example, if a username is passed without at password the task will only run when the user is logged in. If a password is passed as well the task will run whether the user is logged on or not. If you pass `System' as the username the task will run as the system account (the password parameter is ignored.

- **description**(str) -- A string representing the text that will be displayed in the description field in the task scheduler.

- **enabled**(bool) -- A boolean value representing whether or not the task is enabled.

- **hidden**(bool) -- A boolean value representing whether or not the task is hidden.

- **run_if_idle**(bool) -- Boolean value that indicates that the Task Scheduler will run the task only if the computer is in an idle state.

- **idle_duration**(str) -- A value that indicates the amount of time that the computer must be in an idle state before the task is run. Valid values are: - 1 minute - 5 minutes - 10 minutes - 15 minutes - 30 minutes - 1 hour

- **idle_wait_timeout**(str) -- A value that indicates the amount of time that the Task Scheduler will wait for an idle condition to occur. Valid values are: - Do not wait - 1 minute - 5 minutes - 10 minutes - 15 minutes - 30 minutes - 1 hour - 2 hours

- **idle_stop_on_end**(bool) -- Boolean value that indicates that the Task Scheduler will terminate the task if the idle condition ends before the task is completed.

- **idle_restart**(bool) -- Boolean value that indicates whether the task is restarted when the computer cycles into an idle condition more than once.

- **ac_only**(bool) -- Boolean value that indicates that the Task Scheduler will launch the task only while on AC power.

- **stop_if_on_batteries**(bool) -- Boolean value that indicates that the task will be stopped if the computer begins to run on battery power.

- **wake_to_run**(bool) -- Boolean value that indicates that the Task Scheduler will wake the computer when it is time to run the task.

- **run_if_network**(bool) -- Boolean value that indicates that the Task Scheduler will run the task only when a network is available.

- **network_id**(guid) -- GUID value that identifies a network profile.

- **network_name**(str) -- Sets the name of a network profile. The name is used for display purposes.

- **allow_demand_start**(bool) -- Boolean value that indicates that the task can be started by using either the Run command or the Context menu.

- **start_when_available**(bool) -- Boolean value that indicates that the Task Scheduler can start the task at any time after its scheduled time has passed.

- **restart_every** -- A value that specifies the interval between task restart attempts. Valid values are: type: bool str - False (to disable) - 1 minute - 5 minutes - 10 minutes - 15 minutes - 30 minutes - 1 hour - 2 hours

- **restart_count**(int) -- The number of times the Task Scheduler will attempt to restart the task. Valid values are integers 1 - 999.

- **execution_time_limit** -- The amount of time allowed to complete the task. Valid values are: type: bool str - False (to disable) - 1 hour - 2 hours - 4 hours - 8 hours - 12 hours - 1
Parameters **force_stop** *(bool)* -- Boolean value that indicates that the task may be terminated by using TerminateProcess.

Parameters **delete_after** -- The amount of time that the Task Scheduler will wait before deleting the task after it expires. Requires a trigger with an expiration date. Valid values are: :type: bool str - False (to disable) - Immediately - 30 days - 90 days - 180 days - 365 days

Parameters **multiple_instances** *(str)* -- Sets the policy that defines how the Task Scheduler deals with multiple instances of the task. Valid values are: - Parallel - Queue - No New Instance - Stop Existing

Returns True if successful, False if unsuccessful
Return type *bool*

salt.modules.win_task.info(*name*, *location='\'*)
Get the details about a task in the task scheduler.

Parameters

- **name** *(str)* -- The name of the task for which to return the status
- **location** *(str)* -- A string value representing the location of the task.

Default is `\` which is the root for the task scheduler (C:\Windows\System32\tasks).

Returns
Return type *dict*

salt.modules.win_task.list_actions(*name*, *location='\'*)
List all actions that pertain to a task in the specified location.

Parameters

- **name** *(str)* -- The name of the task for which list actions.
- **location** *(str)* -- A string value representing the location of the task from which to list actions. Default is `\` which is the root for the task scheduler (C:\Windows\System32\tasks).

Returns Returns a list of actions.
Return type *list*

salt.modules.win_task.list_folders(*location='\'*)
List all folders located in a specific location in the task scheduler.

Parameters **location** *(str)* -- A string value representing the folder from which you want to list tasks. Default is `\` which is the root for the task scheduler (C:\Windows\System32\tasks).

Returns Returns a list of folders.
Return type *list*

salt.modules.win_task.list_tasks(*location='\'*)
List all tasks located in a specific location in the task scheduler.

Parameters **location** *(str)* -- A string value representing the folder from which you want to list tasks. Default is `\` which is the root for the task scheduler (C:\Windows\System32\tasks).

Returns Returns a list of tasks.
Return type *list*

salt.modules.win_task.list_triggers(*name*, *location='\'*)
List all triggers that pertain to a task in the specified location.

Parameters

- **name** *(str)* -- The name of the task for which list triggers.
- **location** *(str)* -- A string value representing the location of the task from which to list triggers. Default is `\` which is the root for the task scheduler (C:\Windows\System32\tasks).

Returns Returns a list of triggers.
Return type *list*
salt.modules.win_task.run(name, location='\')
    Run a scheduled task manually.
    Parameters
    • name (str) -- The name of the task to run.
    • location (str) -- A string value representing the location of the task.
      Default is `'\' which is the root for the task scheduler (C:WindowsSystem32tasks).
    Returns True if successful, False if unsuccessful
    Return type bool

salt.modules.win_task.run_wait(name, location='\')
    Run a scheduled task and return when the task finishes
    Parameters
    • name (str) -- The name of the task to run.
    • location (str) -- A string value representing the location of the task.
      Default is `'\' which is the root for the task scheduler (C:WindowsSystem32tasks).
    Returns True if successful, False if unsuccessful
    Return type bool

salt.modules.win_task.status(name, location='\')
    Determine the status of a task. Is it Running, Queued, Ready, etc.
    Parameters
    • name (str) -- The name of the task for which to return the status
    • location (str) -- A string value representing the location of the task.
      Default is `'\' which is the root for the task scheduler (C:WindowsSystem32tasks).
    Returns The current status of the task. Will be one of the following:
    • Unknown
    • Disabled
    • Queued
    • Ready
    • Running
    Return type string

salt.modules.win_task.stop(name, location='\')
    Stop a scheduled task.
    Parameters
    • name (str) -- The name of the task to stop.
    • location (str) -- A string value representing the location of the task.
      Default is `'\' which is the root for the task scheduler (C:WindowsSystem32tasks).
    Returns True if successful, False if unsuccessful
    Return type bool

13.6.363 salt.modules.win_timezone

Module for managing timezone on Windows systems.

salt.modules.win_timezone.get_hwclock()
    Get current hardware clock setting (UTC or localtime)
    CLI Example:
salt 'x' timezone.get_hwclock

salt.modules.win_timezone.get_offset()
    Get current numeric timezone offset from UCT (i.e. -0700)
    CLI Example:
    salt 'x' timezone.get_offset

salt.modules.win_timezone.get_zone()
    Get current timezone (i.e. America/Denver)
    CLI Example:
    salt 'x' timezone.get_zone

salt.modules.win_timezone.get_zonecode()
    Get current timezone (i.e. PST, MDT, etc)
    CLI Example:
    salt 'x' timezone.get_zonecode

salt.modules.win_timezone.set_hwclock(clock)
    Sets the hardware clock to be either UTC or localtime
    CLI Example:
    salt 'x' timezone.set_hwclock UTC

salt.modules.win_timezone.set_zone(timezone)
    Unlinks, then symlinks /etc/localtime to the set timezone.
    The timezone is crucial to several system processes, each of which SHOULD be restarted (for instance, whatever you system uses as its cron and syslog daemons). This will not be magically done for you!
    CLI Example:
    salt 'x' timezone.set_zone 'America/Denver'

salt.modules.win_timezone.zone_compare(timezone)
    Checks the md5sum between the given timezone, and the one set in /etc/localtime. Returns True if they match, and False if not. Mostly useful for running state checks.
    Example:
    salt 'x' timezone.zone_compare 'America/Denver'

13.6.364 salt.modules.win_update

Module for running windows updates.

    depends
        • win32com
        • win32con
        • win32api
• pywintypes

New in version 2014.7.0.

Set windows updates to run by category. Default behavior is to install all updates that do not require user interaction to complete. Optionally set categories to a category of your choice to only install certain updates. Default is to set to install all available but driver updates. The following example will install all Security and Critical Updates, and download but not install standard updates.

```python
salt '*' win_update.install_updates categories=[['Critical Updates', 'Security Updates']]
```

You can also specify a number of features about the update to have a fine grain approach to specific types of updates. These are the following features/states of updates available for configuring:

- `UI` - User interaction required, skipped by default
- `downloaded` - Already downloaded, included by default
- `present` - Present on computer, included by default
- `installed` - Already installed, skipped by default
- `reboot` - Reboot required, included by default
- `hidden` - Skip hidden updates, skipped by default
- `software` - Software updates, included by default
- `driver` - Driver updates, included by default

The following example installs all updates that don't require a reboot:

```bash
salt '*' win_update.install_updates skips=['reboot:True']
```

Once installed Salt will return a similar output:

```
2 : Windows Server 2012 Update (KB123456)
4 : Internet Explorer Security Update (KB098765)
2 : Malware Definition Update (KB321456)
...
```

The number at the beginning of the line is an OperationResultCode from the Windows Update Agent, it's enumeration is described here: https://msdn.microsoft.com/en-us/library/windows/desktop/aa387095(v=vs.85).aspx. The result code is then followed by the update name and its KB identifier.

class salt.modules.win_update.PyWinUpdater(categories=None, skipUI=True, skipDownloaded=False, skipInstalled=True, skipReboot=False, skipPresent=False, skipSoftwareUpdates=False, skipDriverUpdates=False, skipHidden=True):

  AutoSearch()
  Download()
  GetAvailableCategories()
  GetCategories()
  GetDownloadResults()
  GetInstallationResults()
  GetInstallationResultsPretty()
  GetSearchResults(fields=None)
  GetSearchResultsVerbose()
  Reduce full updates information to the most important information.
Install()

Search(searchString)

SetCategories(categories)

SetSkip(skip, state)

SetSkips(skips)

salt.modules.win_update.download_updates(skips=None, retries=5, categories=None)

Downloads all available updates, skipping those that require user interaction.

Various aspects of the updates can be included or excluded. This feature is still in development.

- retries: Number of retries to make before giving up. This is total, not per step.
- categories: Specify the categories to update. Must be passed as a list.

```
salt '*' win_update.download_updates categories="['Updates']"
```

Categories include the following:
- Updates
- Windows 7
- Critical Updates
- Security Updates
- Update Rollups

CLI Examples:
```
# Normal Usage
salt '*' win_update.download_updates

# Download critical updates only
salt '*' win_update.download_updates categories="['Critical Updates']"
```

salt.modules.win_update.install_updates(skips=None, retries=5, categories=None)

Downloads and installs all available updates, skipping those that require user interaction.

Add cached to only install those updates which have already been downloaded.

you can set the maximum number of retries to n in the search process by adding: retries=n

Various aspects of the updates can be included or excluded. This function is still under development.

- retries: Number of retries to make before giving up. This is total, not per step.
- categories: Specify the categories to install. Must be passed as a list.

```
salt '*' win_update.install_updates categories="['Updates']"
```

Categories include the following:
- Updates
- Windows 7
- Critical Updates
- Security Updates
- Update Rollups

CLI Examples:
```
# Normal Usage
salt '*' win_update.install_updates

# Install all critical updates
salt '*' win_update.install_updates categories="['Critical Updates']"
```
salt.modules.win_update.list_updates( verbose=False, fields=None, skips=None, retries=5, categories=None)

Returns a summary of available updates, grouped into their non-mutually exclusive categories.

- **verbose** Return full set of results, including several fields from the COM.
- **fields** Return a list of specific fields for each update. The optional values here are those at the root level of the verbose list. This is superseded by the verbose option.
- **retries** Number of retries to make before giving up. This is total, not per step.
- **categories** Specify the categories to list. Must be passed as a list.

```bash
salt '*' win_update.list_updates categories="['Updates']"
```

Categories include, but are not limited to, the following:
- Updates
- Windows 7
- Critical Updates
- Security Updates
- Update Rollups

CLI Examples:

```bash
# Normal Usage
salt '*' win_update.list_updates

# Specific Fields
salt '*' win_update.list_updates fields="['Title', 'Description']"

# List all critical updates list in verbose detail
salt '*' win_update.list_updates categories="['Critical Updates']" verbose=True
```

13.6.365 salt.modules.win_useradd

Module for managing Windows Users

**Important:** If you feel that Salt should be using this module to manage users on a minion, and it is using a different module (or gives an error similar to `user.info` is not available), see here.

**depends**
- pywintypes
- win32api
- win32net
- win32netcon
- win32profile
- win32security
- win32ts

**Note:** This currently only works with local user accounts, not domain accounts
salt.modules.win_useradd.add(name, password=None, fullname=False, description=None, groups=None, home=None, homedrive=None, profile=None, logonscript=None)

Add a user to the minion.

Parameters

- **name** *(str)* -- User name
- **password** *(str)* -- User's password in plain text.
- **fullname** *(str)* -- The user's full name.
- **description** *(str)* -- A brief description of the user account.
- **groups** *(list)* -- A list of groups to add the user to.
- **home** *(str)* -- The path to the user's home directory.
- **homedrive** *(str)* -- The drive letter to assign to the home directory. Must be the Drive Letter followed by a colon. ie: U:
- **profile** *(str)* -- An explicit path to a profile. Can be a UNC or a folder on the system. If left blank, windows uses it's default profile directory.
- **logonscript** *(str)* -- Path to a login script to run when the user logs on.

Returns  True if successful. False is unsuccessful.

Return type  bool

CLI Example:

```
salt '*' user.add name password
```

salt.modules.win_useradd.addgroup(name, group)

Add user to a group

Parameters

- **name** *(str)* -- user name to add to the group
- **group** *(str)* -- name of the group to which to add the user

Returns  True if successful. False is unsuccessful.

Return type  bool

CLI Example:

```
salt '*' user.addgroup jsnufff 'Power Users'
```

salt.modules.win_useradd.chfullname(name, fullname)

Change the full name of the user

Parameters

- **name** *(str)* -- user name for which to change the full name
- **fullname** *(str)* -- the new value for the full name

Returns  True if successful. False is unsuccessful.

Return type  bool

CLI Example:

```
salt '*' user.chfullname user 'First Last'
```

salt.modules.win_useradd.chgroups(name, groups, append=True)

Change the groups this user belongs to, add append=False to make the user a member of only the specified groups

Parameters

- **name** *(str)* -- user name
- **groups** *(list)* -- list of groups
- **append** *(bool, default=True)* -- append=False to make the user a member of only the specified groups

Returns  True if successful. False is unsuccessful.

Return type  bool

CLI Example:
• **name** (*str*) -- user name for which to change groups
• **groups** (*list, str*) -- a single group or a list of groups to assign to the user
• **append** (*bool*) -- True adds the passed groups to the user's current groups False sets the user's groups to the passed groups only

**Returns** True if successful. False is unsuccessful.
**Return type** bool

CLI Example:
```sh
salt '*' user.chgroups jsnuffy Administrators, Users True
```

salt.modules.win_useradd.chhome(*name, home, persist=False*)

Change the home directory of the user, pass True for persist to move files to the new home directory if the old home directory exist.

**Parameters**
• **name** (*str*) -- name of the user whose home directory you wish to change
• **home** (*str*) -- new location of the home directory
• **persist** (*bool*) -- True to move the contents of the existing home directory to the new location

**Returns** True if successful. False is unsuccessful.
**Return type** bool

CLI Example:
```sh
salt '*' user.chhome foo \fileserver\home\foo True
```

salt.modules.win_useradd.chprofile(*name, profile*)

Change the profile directory of the user

**Parameters**
• **name** (*str*) -- name of the user whose profile you wish to change
• **profile** (*str*) -- new location of the profile

**Returns** True if successful. False is unsuccessful.
**Return type** bool

CLI Example:
```sh
salt '*' user.chprofile foo \fileserver\profiles\foo
```

salt.modules.win_useradd.current(*sam=False*)

Get the username that salt-minion is running under. If salt-minion is running as a service it should return the Local System account. If salt is running from a command prompt it should return the username that started the command prompt.

New in version 2015.5.6.

**Parameters**
• **sam** (*bool*) -- False returns just the username without any domain notation. True returns the domain with the username in the SAM format. Ie: domain\username

**Returns** Returns False if the username cannot be returned. Otherwise returns the username.
**Return type** bool str

CLI Example:
```
salt '*' user.current
```

salt.modules.win_useradd.delete(*name, purge=False, force=False*)

Remove a user from the minion
Parameters

- **name (str)** -- The name of the user to delete
- **purge (bool)** -- Boolean value indicating that the user profile should also be removed when the user account is deleted. If set to True the profile will be removed.
- **force (bool)** -- Boolean value indicating that the user account should be deleted even if the user is logged in. True will log the user out and delete user.

**Returns** True if successful

**Return type** bool

**CLI Example:**
salt '*' user.delete name

salt.modules.win_useradd.getUsersId(username)
Get the Security ID for the user

**Parameters** username (str) -- user name for which to look up the SID

**Returns** Returns the user SID

**Return type** str

**CLI Example:**
salt '*' user.getUserId jsnuffy

salt.modules.win_useradd.getent(refresh=False)
Return the list of all info for all users

**Parameters** refresh (bool) -- Refresh the cached user information. Default is False. Useful when used from within a state function.

**Returns** A dictionary containing information about all users on the system

**Return type** dict

**CLI Example:**
salt '*' user.getent

salt.modules.win_useradd.info(name)
Return user information

**Parameters** name (str) -- Username for which to display information

**Returns**
A dictionary containing user information

- fullname
- username
- SID
- passwd (will always return None)
- comment (same as description, left here for backwards compatibility)
- description
- active
- logonscript
- profile
- home
- homedrive
- groups
- password_changed
- successful_logon_attempts
- failed_logon_attempts
- last_logon
- account_disabled
- account_locked
- password_neverExpires
- disallow_change_password
- gid

Return type: dict

CLI Example:
```
salt '*' user.info jsnuffy
```

salt.modules.win_useradd.list_groups(name)
Return a list of groups the named user belongs to
Parameters:
- name (str) -- user name for which to list groups
Returns:
- list of groups to which the user belongs
Return type: list

CLI Example:
```
salt '*' user.list_groups foo
```

salt.modules.win_useradd.list_users()
Return a list of users on Windows
Returns:
- list of users on the system
Return type: list

CLI Example:
```
salt '*' user.list_users
```

salt.modules.win_useradd.removegroup(name, group)
Remove user from a group
Parameters:
- name (str) -- user name to remove from the group
- group (str) -- name of the group from which to remove the user
Returns:
- True if successful. False is unsuccessful.
Return type: bool

CLI Example:
```
salt '*' user.removegroup jsnuffy 'Power Users'
```

salt.modules.win_useradd.rename(name, new_name)
Change the username for a named user
Parameters:
- name (str) -- user name to change
- new_name (str) -- the new name for the current user
Returns:
- True if successful. False is unsuccessful.
Return type: bool

CLI Example:
```
salt '*' user.rename jsnuffy jshmoe
```

```python
salt.modules.win_useradd.setpassword(name, password)
```
Set the user's password

Parameters
- name (str) -- user name for which to set the password
- password (str) -- the new password

Returns: True if successful. False is unsuccessful.

Return type: bool

CLI Example:
```
salt '*' user.setpassword jsnuffy sup3rs3cr3t
```

```python
salt.modules.win_useradd.update(name, password=None, fullname=None, description=None, home=None, homedrive=None, logonscript=None, profile=None, expiration_date=None, expired=None, account_disabled=None, unlock_account=None, password_neverExpires=None, disallow_change_password=None)
```
Updates settings for the windows user. Name is the only required parameter. Settings will only be changed if the parameter is passed a value.

New in version 2015.8.0.

Parameters
- name (str) -- The user name to update.
- password (str) -- New user password in plain text.
- fullname (str) -- The user's full name.
- description (str) -- A brief description of the user account.
- home (str) -- The path to the user's home directory.
- homedrive (str) -- The drive letter to assign to the home directory. Must be the Drive Letter followed by a colon. ie: U:
- logonscript (str) -- The path to the logon script.
- profile (str) -- The path to the user's profile directory.
- expiration_date (date) -- The date and time when the account expires. Can be a valid date/time string. To set to never expire pass the string 'Never'.
- expired (bool) -- Pass True to expire the account. The user will be prompted to change their password at the next logon. Pass False to mark the account as 'not expired'. You can't use this to negate the expiration if the expiration was caused by the account expiring. You'll have to change the `expiration_date` as well.
- account_disabled (bool) -- True disables the account. False enables the account.
- unlock_account (bool) -- True unlocks a locked user account. False is ignored.
- password_never_expires (bool) -- True sets the password to never expire. False allows the password to expire.
• **disallow_change_password** *(bool)* -- True blocks the user from changing the password. False allows the user to change the password.

**Returns** True if successful. False is unsuccessful.

**Return type** bool

CLI Example:

```bash
salt '*' user.update bob password=secret profile=C:\Users\Bob home=\\server\homeshare\bob homedrive=U:
```

### 13.6.366 **salt.modules.win_wua**

Module for managing Windows Updates using the Windows Update Agent.

New in version 2015.8.0.

**depends**

- win32com
- pythoncom

**salt.modules.win_wua.download_update**(guid=None)

Downloads a single update

**Parameters**

- **guid** -- str A GUID for the update to be downloaded

**Returns** A dictionary containing the status, a message, and a list of updates that were downloaded.

CLI Examples:

```bash
salt '*' win_wua.download_update 12345678-abcd-1234-abcd-1234567890ab
```

**salt.modules.win_wua.download_updates**(guid=None)

Downloads updates that match the list of passed GUIDs. It's easier to use this function by using list_updates and setting install=True.

**Parameters**

- **guid** -- A list of GUIDs to be downloaded

**Returns** A dictionary containing the status, a message, and a list of updates that were downloaded.

CLI Examples:

```bash
# Normal Usage
salt '*' win_wua.download_updates guid=['12345678-abcd-1234-abcd-1234567890ab', '87654321-dcba-4321-dcba-ba0987654321']
```

**salt.modules.win_wua.get_needs_reboot**()

Determines if the system needs to be rebooted.

**Returns** bool True if the system requires a reboot, False if not

CLI Examples:

```bash
salt '*' win_wua.get_needs_reboot
```

**salt.modules.win_wua.get_wu_settings**()

Get current Windows Update settings.

**Returns**

- **Featured Updates**: Boolean value that indicates whether to display notifications for featured updates.
- **Group Policy Required (Read-only)**: Boolean value that indicates whether Group Policy requires the Automatic Updates service.
**Microsoft Update**: Boolean value that indicates whether to turn on Microsoft Update for other Microsoft Products

**Needs Reboot**: Boolean value that indicates whether the machine is in a reboot pending state.

**Non Admins Elevated**: Boolean value that indicates whether non-administrators can perform some update-related actions without administrator approval.

**Notification Level**: Number 1 to 4 indicating the update level:

1. Never check for updates
2. Check for updates but let me choose whether to download and install them
3. Download updates but let me choose whether to install them
4. Install updates automatically

**Read Only (Read-only)**: Boolean value that indicates whether the Automatic Update settings are read-only.

**Recommended Updates**: Boolean value that indicates whether to include optional or recommended updates when a search for updates and installation of updates is performed.

**Scheduled Day**: Days of the week on which Automatic Updates installs or uninstalls updates.

**Scheduled Time**: Time at which Automatic Updates installs or uninstalls updates.

CLI Examples:

```bash
salt '*' win_wua.get_wu_settings
```

salt.modules.win_wua.install_update(guid=None)
Installs a single update

   Parameters guid -- str A GUID for the update to be installed

   Returns dict A dictionary containing the details about the installed update

CLI Examples:

```bash
guid=12345678-abcd-1234-abcd-1234567890ab
```

salt.modules.win_wua.install_updates(guid=None)
Installs updates that match the passed criteria. It may be easier to use the list_updates function and set install=True.

   Parameters guid -- list A list of GUIDs to be installed

   Returns dict A dictionary containing the details about the installed updates

CLI Examples:

```bash
# Normal Usage
salt '*' win_wua.install_updates
   guid=['12345678-abcd-1234-abcd-1234567890ab',
       '87654321-dcbe-4321-dcbe-ba987654321']
```

salt.modules.win_wua.list_update(name=None, download=False, install=False)
Returns details for all updates that match the search criteria

   Parameters
• **name** *(str)* -- The name of the update you're searching for. This can be the GUID (preferred), a KB number, or the full name of the update. Run `list_updates` to get the GUID for the update you're looking for.

• **download** *(bool)* -- Download the update returned by this function. Run this function first to see if the update exists, then set `download=True` to download the update.

• **install** *(bool)* -- Install the update returned by this function. Run this function first to see if the update exists, then set `install=True` to install the update. This will override `download=True`

**Returns**

Returns a dict containing a list of updates that match the name if `download` and `install` are both set to `False`. Should usually be a single update, but can return multiple if a partial name is given. If `download` or `install` is set to `true` it will return the results of `win_wua.download_updates`:

```plaintext
List of Updates:
{'<GUID>': {'Title': <title>,
'KB': <KB>,
'GUID': <the globally unique identifier for the update>,
'Description': <description>,
'Downloaded': <has the update been downloaded>,
'Installed': <has the update been installed>,
'Mandatory': <is the update mandatory>,
'UserInput': <is user input required>,
'EULAAccepted': <has the EULA been accepted>,
'Severity': <update severity>,
'NeedsReboot': <is the update installed and awaiting reboot>,
'RebootBehavior': <will the update require a reboot>,
'Categories': [ '<category 1>',
  '<category 2>',
  ...
  ]
}
```

**Return type** *dict*

**CLI Examples:**

```plaintext
# Recommended Usage using GUID without braces
# Use this to find the status of a specific update
salt '*' win_wua.list_update 12345678-abcd-1234-abcd-1234567890ab

# Use the following if you don't know the GUID:

# Using a KB number (could possibly return multiple results)
# Not all updates have an associated KB
salt '*' win_wua.list_update KB3030298

# Using part or all of the name of the update
# Could possibly return multiple results
# Not all updates have an associated KB
salt '*' win_wua.list_update 'Microsoft Camera Codec Pack'
```

```
import salt.modules.win_wua

salt.modules.win_wua.list_updates(software=True, drivers=False, summary=False, installed=False, categories=None, severities=None, download=False, install=False)
```

Returns a detailed list of available updates or a summary
Parameters

- `software (bool)` -- Include software updates in the results (default is True)
- `drivers (bool)` -- Include driver updates in the results (default is False)
- `summary (bool)` -- True: Return a summary of updates available for each category. False (default): Return a detailed list of available updates.
- `installed (bool)` -- Include installed updates in the results (default if False)
- `download (bool)` -- (Overrides reporting functionality) Download the list of updates returned by this function. Run this function first to see what will be installed, then set download=True to download the updates.
- `install (bool)` -- (Overides reporting functionality) Install the list of updates returned by this function. Run this function first to see what will be installed, then set install=True to install the updates. This will override download=True
- `categories (list)` -- Specify the categories to list. Must be passed as a list. All categories returned by default.

Categories include the following:
- Critical Updates
- Definition Updates
- Drivers (make sure you set drivers=True)
- Feature Packs
- Security Updates
- Update Rollups
- Updates
- Update Rollups
- Windows 7
- Windows 8.1
- Windows 8.1 drivers
- Windows 8.1 and later drivers
- Windows Defender

- `severities (list)` -- Specify the severities to include. Must be passed as a list. All severities returned by default.

Severities include the following:
- Critical
- Important

Returns

Returns a dict containing either a summary or a list of updates:

```
List of Updates:
{'GUID': {'Title': <title>,
'KB': <KB>,
'GUID': <the globally unique identifier for the update>
'Description': <description>,
```

13.6. execution modules
'Downloaded': <has the update been downloaded>,
'Installed': <has the update been installed>,
'Mandatory': <is the update mandatory>,
'UserInput': <is user input required>,
'EULAAccepted': <has the EULA been accepted>,
'Severity': <update severity>,
'NeedsReboot': <is the update installed and awaiting reboot>,
'RebootBehavior': <will the update require a reboot>,
'Categories': [ '<category 1>',
  '<category 2>',
  ...
]
}
}

Summary of Updates:
{'Total': <total number of updates returned>,
 'Available': <updates that are not downloaded or installed>,
 'Downloaded': <updates that are downloaded but not installed>,
 'Installed': <updates installed (usually 0 unless installed=True)>,
 'Categories': { <category 1>: <total for that category>,
                <category 2>: <total for category 2>,
                ...
          }
}

Return type dict

CLI Examples:

```python
# Normal Usage (list all software updates)
salt '*' win_wua.list_updates

# List all updates with categories of Critical Updates and Drivers
salt '*' win_wua.list_updates categories=['Critical Updates','Drivers']

# List all Critical Security Updates
salt '*' win_wua.list_updates categories=['Security Updates'] severities=['Critical']

# List all updates with a severity of Critical
salt '*' win_wua.list_updates severities=['Critical']

# A summary of all available updates
salt '*' win_wua.list_updates summary=True

# A summary of all Feature Packs and Windows 8.1 Updates
salt '*' win_wua.list_updates categories=['Feature Packs','Windows 8.1'] summary=True
```

salt.modules.win_wua.set_wu_settings(level=None, recommended=None, featured=None, elevated=None, msupdate=None, day=None, time=None)

Change Windows Update settings. If no parameters are passed, the current value will be returned.

Parameters

- **level**(int) --
  Number from 1 to 4 indicating the update level:

  1. Never check for updates
  2. Check for updates but let me choose whether to download and install them
3. Download updates but let me choose whether to install them

4. Install updates automatically

- **recommended (bool)** -- Boolean value that indicates whether to include optional or recommended updates when a search for updates and installation of updates is performed.

- **featured (bool)** -- Boolean value that indicates whether to display notifications for featured updates.

- **elevated (bool)** -- Boolean value that indicates whether non-administrators can perform some update-related actions without administrator approval.

- **msupdate (bool)** -- Boolean value that indicates whether to turn on Microsoft Update for other Microsoft products

- **day (str)** -- Days of the week on which Automatic Updates installs or uninstalls updates. Accepted values:
  - Everyday
  - Monday
  - Tuesday
  - Wednesday
  - Thursday
  - Friday
  - Saturday

- **time (str)** -- Time at which Automatic Updates installs or uninstalls updates. Must be in the ##:## 24hr format, eg. 3:00 PM would be 15:00

**Returns**

Returns a dictionary containing the results.

**CLI Examples:**

```
salt '*' win_wua.set_wu_settings level=4 recommended=True featured=False
```

### 13.6.367 salt.modules.x509

Manage X509 certificates

New in version 2015.8.0.

salt.modules.x509.create_certificate(path=None, text=False, ca_server=None, **kwargs)

Create an X509 certificate.

- **path**: Path to write the certificate to.
- **text**: If True, return the PEM text without writing to a file. Default False.
- **kwargs**: Any of the properties below can be included as additional keyword arguments.
- **ca_server**: Request a remotely signed certificate from ca_server. For this to work, a signing_policy must be specified, and that same policy must be configured on the ca_server. See signing_policy for details. Also the salt master must permit peers to call the sign_remote_certificate function.

Example:

```
/etc/salt/master.d/peer.conf
```
peer:
  .*:
    - x509.sign_remote_certificate

**subject properties:** Any of the values below can be included to set subject properties. Any other subject properties supported by OpenSSL should also work.
- C: 2 letter Country code
- CN: Certificate common name, typically the FQDN.
- Email: Email address
- GN: Given Name
- L: Locality
- O: Organization
- OU: Organization Unit
- SN: Surname
- ST: State or Province

**signing_private_key:** A path or string of the private key in PEM format that will be used to sign this certificate. If neither `signing_cert`, `public_key`, or `csr` are included, it will be assumed that this is a self-signed certificate, and the public key matching `signing_private_key` will be used to create the certificate.

**signing_cert:** A certificate matching the private key that will be used to sign this certificate. This is used to populate the issuer values in the resulting certificate. Do not include this value for self-signed certificates.

**public_key:** The public key to be included in this certificate. This can be sourced from a public key, certificate, csr or private key. If a private key is used, the matching public key from the private key will be generated before any processing is done. This means you can request a certificate from a remote CA using a private key file as your public_key and only the public key will be sent across the network to the CA. If neither public_key or csr are specified, it will be assumed that this is a self-signed certificate, and the public key derived from `signing_private_key` will be used. Specify either `public_key` or `csr`, not both. Because you can input a CSR as a public key or as a CSR, it is important to understand the difference. If you import a CSR as a public key, only the public key will be added to the certificate, subject or extension information in the CSR will be lost.

**csr:** A file or PEM string containing a certificate signing request. This will be used to supply the subject, extensions and public key of a certificate. Any subject or extensions specified explicitly will overwrite any in the CSR.

**basicConstraints:** X509v3 Basic Constraints extension.

**extensions:** The following arguments set X509v3 Extension values. If the value starts with `"critical "`, the extension will be marked as critical.

Some special extensions are `subjectKeyIdentifier` and `authorityKeyIdentifier`.

- subjectKeyIdentifier can be an explicit value or it can be the special string `hash`. `hash` will set the subjectKeyIdentifier equal to the SHA1 hash of the modulus of the public key in this certificate. Note that this is not the exact same hashing method used by OpenSSL when using the hash value.

- authorityKeyIdentifier Use values acceptable to the openssl CLI tools. This will automatically populate authorityKeyIdentifier with the subjectKeyIdentifier of signing_cert. If this is a self-signed cert these values will be the same.

**basicConstraints:** X509v3 Basic Constraints
**keyUsage:** X509v3 Key Usage
**extendedKeyUsage:** X509v3 Extended Key Usage
**subjectKeyIdentifier:** X509v3 Subject Key Identifier
**issuerAltName:** X509v3 Issuer Alternative Name
**subjectAltName:** X509v3 Subject Alternative Name
**crlDistributionPoints:** X509v3 CRL distribution points
**issuingDistributionPoint:** X509v3 Issuing Distribution Point
**certificatePolicies:** X509v3 Certificate Policies
Salt Documentation, Release 2016.3.6

policyConstraints: X509v3 Policy Constraints
inhibitAnyPolicy: X509v3 Inhibit Any Policy
nameConstraints: X509v3 Name Constraints
noCheck: X509v3 OCSP No Check
nsComment: Netscape Comment
nsCertType: Netscape Certificate Type
days_valid: The number of days this certificate should be valid. This sets the notAfter property of the certificate. Defaults to 365.
version: The version of the X509 certificate. Defaults to 3. This is automatically converted to the version value, so version=3 sets the certificate version field to 0x2.
serial_number: The serial number to assign to this certificate. If omitted a random serial number of size serial_bits is generated.
serial_bits: The number of bits to use when randomly generating a serial number. Defaults to 64.
algorithm: The hashing algorithm to be used for signing this certificate. Defaults to sha256.
copypath: An additional path to copy the resulting certificate to. Can be used to maintain a copy of all certificates issued for revocation purposes.
signing_policy: A signing policy that should be used to create this certificate. Signing policies should be defined in the minion configuration, or in a minion pillar. It should be a yaml formatted list of arguments which will override any arguments passed to this function. If the minions key is included in the signing policy, only minions matching that pattern will be permitted to remotely request certificates from that policy.

Example:

```yaml
x509_signing_policies:
www:
  - minions: 'www*'  
  - signing_private_key: /etc/pki/ca.key
  - signing_cert: /etc/pki/ca.crt
  - C: US
  - ST: Utah
  - L: Salt Lake City
  - basicConstraints: "critical CA:false"
  - keyUsage: "critical cRLSign, keyCertSign"
  - subjectKeyIdentifier: hash
  - authorityKeyIdentifier: keyid,issuer:always
  - days_valid: 90
  - copypath: /etc/pki/issued_certs/
```

The above signing policy can be invoked with signing_policy=www

CLI Example:

```bash
salt '*' x509.create_certificate path=/etc/pki/myca.crt 
signing_private_key='/etc/pki/myca.key' csr='/etc/pki/myca.csr'}
```

salt.modules.x509.create_crl(path=None, text=False, signing_private_key=None, signing_cert=None, revoked=None, include_expired=False, days_valid=100, digest='')

Create a CRL

Depends

- PyOpenSSL Python module

path: Path to write the crl to.
text: If True, return the PEM text without writing to a file. Default False.
signing_private_key: A path or string of the private key in PEM format that will be used to sign this crl. This is required.
signing_cert: A certificate matching the private key that will be used to sign this crl. This is required.

revoked: A list of dicts containing all the certificates to revoke. Each dict represents one certificate. A dict must contain either the key serial_number with the value of the serial number to revoke, or certificate with either the PEM encoded text of the certificate, or a path to the certificate to revoke.

The dict can optionally contain the revocation_date key. If this key is omitted the revocation date will be set to now. If should be a string in the format ``%Y-%m-%d %H:%M:%S``.

The dict can also optionally contain the not_after key. This is redundant if the certificate key is included. If the Certificate key is not included, this can be used for the logic behind the include_expired parameter. If should be a string in the format ``%Y-%m-%d %H:%M:%S``.

The dict can also optionally contain the reason key. This is the reason code for the revocation. Available choices are unspecified, keyCompromise, CACompromise, affiliationChanged, superseded, cessationOfOperation and certificateHold.

include_expired: Include expired certificates in the CRL. Default is False.

days_valid: The number of days that the CRL should be valid. This sets the Next Update field in the CRL.

digest: The digest to use for signing the CRL. This has no effect on versions of pyOpenSSL less than 0.14

CLI Example:

```bash
salt '*' x509.create_crl path=/etc/pki/mykey.key signing_private_key=/etc/pki/ca.key
  signing_cert=/etc/pki/ca.crt 
  revoked="{"compromized-web-key": {"certificate": "/etc/pki/certs/www1.crt", "revocation_date": "2015-03-01 00:00:00"}}"
```

salt.modules.x509.create_csr(path=None, text=False, **kwargs)
Create a certificate signing request.

path: Path to write the certificate to.

text: If True, return the PEM text without writing to a file. Default False.

algorithm: The hashing algorithm to be used for signing this request. Defaults to sha256.

kwargs: The subject, extension and version arguments from x509.create_certificate can be used.

CLI Example:

```bash
salt '*' x509.create_csr path=/etc/pki/myca.csr public_key="/etc/pki/myca.key" CN="My Cert"
```

salt.modules.x509.create_private_key(path=None, text=False, bits=2048)
Creates a private key in PEM format.

path: The path to write the file to, either path or text are required.

text: If True, return the PEM text without writing to a file. Default False.

bits: Length of the private key in bits. Default 2048

CLI Example:

```bash
salt '*' x509.create_private_key path=/etc/pki/mykey.key
```

salt.modules.x509.get_pem_entries(glob_path)
Returns a dict containing PEM entries in files matching a glob

glob_path: A path to certificates to be read and returned.

CLI Example:

```bash
salt '*' x509.read_pem_entries "/etc/pki/*
```

salt.modules.x509.get_pem_entry(text, pem_type=None)
Returns a properly formatted PEM string from the input text fixing any whitespace or line-break issues
text: Text containing the X509 PEM entry to be returned or path to a file containing the text.
pem_type: If specified, this function will only return a pem of a certain type, for example `CERTIFICATE' or `CERTIFICATE REQUEST'.

CLI Example:

```
salt '*' x509.get_pem_entry "-----BEGIN CERTIFICATE REQUEST-----MIICy...-----END CERTIFICATE REQUEST"
```

salt.modules.x509.get_private_key_size(private_key)

Returns the bit length of a private key in PEM format.

private_key: A path or PEM encoded string containing a private key.

CLI Example:

```
salt '*' x509.get_private_key_size /etc/pki/mycert.key
```

salt.modules.x509.get_public_key(key, asObj=False)

Returns a string containing the public key in PEM format.

key: A path or PEM encoded string containing a CSR, Certificate or Private Key from which a public key can be retrieved.

CLI Example:

```
salt '*' x509.get_public_key /etc/pki/mycert.cer
```

salt.modules.x509.get_signing_policy(signing_policy_name)

Returns the details of a names signing policy, including the text of the public key that will be used to sign it. Does not return the private key.

CLI Example:

```
salt '*' x509.get_signing_policy www
```

salt.modules.x509.read_certificate(certificate)

Returns a dict containing details of a certificate. Input can be a PEM string or file path.

certificate: The certificate to be read. Can be a path to a certificate file, or a string containing the PEM formatted text of the certificate.

CLI Example:

```
salt '*' x509.read_certificate /etc/pki/mycert.crt
```

salt.modules.x509.read_certificates(glob_path)

Returns a dict containing details of all certificates matching a glob

glob_path: A path to certificates to be read and returned.

CLI Example:

```
salt '*' x509.read_certificates "/etc/pki/*.*.crt"
```

salt.modules.x509.read_crl(crl)

Returns a dict containing details of a certificate revocation list. Input can be a PEM string or file path.

- OpenSSL command line tool
csl: A path or PEM encoded string containing the CSL to read.

CLI Example:

```
salt '*' x509.read_crl /etc/pki/mycrl.crl
```
salt.modules.x509.read_csr(csr)
    Returns a dict containing details of a certificate request.
    Depends
        • OpenSSL command line tool
csr: A path or PEM encoded string containing the CSR to read.
CLI Example:
salt '*' x509.read_csr /etc/pki/mycert.csr

salt.modules.x509.sign_remote_certificate(argdic, **kwargs)
    Request a certificate to be remotely signed according to a signing policy.
    argdic: A dict containing all the arguments to be passed into the create_certificate function. This will become kwargs when passed to create_certificate.
    kwargs: kwargs delivered from publish.publish
CLI Example:
salt '*' x509.sign_remote_certificate argdic={'public_key': '/etc/pki/www.key', 'signing_policy': 'www'} __pub_id='www1'

salt.modules.x509.verify_crl(crl, cert)
    Validate a CRL against a certificate. Parses openssl command line output, this is a workaround for M2Crypto's inability to get them from CSR objects.
crl: The CRL to verify
cert: The certificate to verify the CRL against
CLI Example:
salt '*' x509.verify_crl crl=/etc/pki/myca.crl cert=/etc/pki/myca.crt

salt.modules.x509.verify_private_key(private_key, public_key)
    Verify that 'private_key' matches 'public_key'
private_key: The private key to verify, can be a string or path to a private key in PEM format.
public_key: The public key to verify, can be a string or path to a PEM formatted certificate, csr, or another private key.
CLI Example:
salt '*' x509.verify_private_key private_key=/etc/pki/myca.key public_key=/etc/pki/myca.crt

salt.modules.x509.verify_signature(certificate, signing_pub_key=None)
    Verify that certificate has been signed by signing_pub_key
certificate: The certificate to verify. Can be a path or string containing a PEM formatted certificate.
signing_pub_key: The public key to verify, can be a string or path to a PEM formatted certificate, csr, or another private key.
CLI Example:
salt '*' x509.verify_private_key private_key=/etc/pki/myca.key public_key=/etc/pki/myca.crt

salt.modules.x509.write_pem(text, path, pem_type=None)
    Writes out a PEM string fixing any formatting or whitespace issues before writing.
text: PEM string input to be written out.
path: Path of the file to write the pem out to.
pem_type: The PEM type to be saved, for example CERTIFICATE or PUBLIC KEY. Adding this will allow the function to take input that may contain multiple pem types.
CLI Example:
```
salt '*' x509.write_pem "-----BEGIN CERTIFICATE-----MIIGMzCCBBugA..." path=/etc/pki/mycert.crt
```

### 13.6.368 salt.modules.xapi

This module (mostly) uses the XenAPI to manage Xen virtual machines.

Big fat warning: the XenAPI used in this file is the one bundled with Xen Source, NOT XenServer nor Xen Cloud Platform. As a matter of fact it will fail under those platforms. From what I've read, little work is needed to adapt this code to XS/XCP, mostly playing with XenAPI version, but as XCP is not taking precedence on Xen Source on many platforms, please keep compatibility in mind.

Useful documentation:

- http://docs.vmd.citrix.com/XenServer/6.0.0/1.0/en_gb/api/
- https://github.com/xapi-project/xen-api/tree/master/scripts/examples/python
- http://xenbits.xen.org/gitweb/?p=xen.git;a=tree;f=tools/python/xen/xm;hb=HEAD

salt.modules.xapi.create(`domain`)  
Deprecated since version 2016.3.0: Use start() instead.

Start a defined domain

CLI Example:
```
salt '*' virt.create <domain>
```

salt.modules.xapi.destroy(`domain`)  
Deprecated since version 2016.3.0: Use stop() instead.

Power off a defined domain

CLI Example:
```
salt '*' virt.destroy <domain>
```

salt.modules.xapi.freecpu()  
Return an int representing the number of unallocated cpus on this hypervisor

CLI Example:
```
salt '*' virt.freecpu
```

salt.modules.xapi.freemem()  
Return an int representing the amount of memory that has not been given to virtual machines on this node

CLI Example:
```
salt '*' virt.freemem
```

salt.modules.xapi.full_info()  
Return the node_info, vm_info and freemem

CLI Example:
```
salt '*' virt.full_info
```
salt.modules.xapi.get_disks(vm_)
    Return the disks of a named vm
    CLI Example:
    ```
salt '*' virt.get_disks <vm name>
    ```
	salt.modules.xapi.get_macs(vm_)
    Return a list off MAC addresses from the named vm
    CLI Example:
    ```
salt '*' virt.get_macs <vm name>
    ```
	salt.modules.xapi.get_nics(vm_)
    Return info about the network interfaces of a named vm
    CLI Example:
    ```
salt '*' virt.get_nics <vm name>
    ```
	salt.modules.xapi.is_hyper()
    Returns a bool whether or not this node is a hypervisor of any kind
    CLI Example:
    ```
salt '*' virt.is_hyper
    ```
	salt.modules.xapi.list_domains()
    Return a list of virtual machine names on the minion
    CLI Example:
    ```
salt '*' virt.list_domains
    ```
	salt.modules.xapi.list_vms()
    Deprecated since version 2016.3.0: Use list_domains() instead.
    List all virtual machines.
    CLI Example:
    ```
salt '*' virt.list_vms <domain>
    ```
	salt.modules.xapi.migrate(vm_, target,-live=1, port=0, node=-1, ssl=None, change_home_server=0)
    Migrates the virtual machine to another hypervisor
    CLI Example:
    ```
salt '*' virt.migrate <vm name> <target hypervisor> [live] [port] [node] [ssl] [change_home_server]
    ```
    Optional values:
    - live  Use live migration
    - port  Use a specified port
    - node  Use specified NUMA node on target
    - ssl  use ssl connection for migration
    - change_home_server  change home server for managed domains
salt.modules.xapi.node_info()  
Return a dict with information about this node  

CLI Example:

```
salt '*' virt.node_info
```

salt.modules.xapi.pause(vm_)
Pause the named vm

CLI Example:

```
salt '*' virt.pause <vm name>
```

salt.modules.xapi.reboot(vm_)
Reboot a domain via ACPI request

CLI Example:

```
salt '*' virt.reboot <vm name>
```

salt.modules.xapi.reset(vm_)
Reset a VM by emulating the reset button on a physical machine

CLI Example:

```
salt '*' virt.reset <vm name>
```

salt.modules.xapi.resume(vm_)
Resume the named vm

CLI Example:

```
salt '*' virt.resume <vm name>
```

salt.modules.xapi.setmem(vm_, memory)
Changes the amount of memory allocated to VM.  
Memory is to be specified in MB

CLI Example:

```
salt '*' virt.setmem myvm 768
```

salt.modules.xapi.setvcpus(vm_, vcpus)
Changes the amount of vcpus allocated to VM.  
vcpus is an int representing the number to be assigned

CLI Example:

```
salt '*' virt.setvcpus myvm 2
```

salt.modules.xapi.shutdown(vm_)
Send a soft shutdown signal to the named vm

CLI Example:

```
salt '*' virt.shutdown <vm name>
```
salt.modules.xapi.start(config_)
    Start a defined domain

    CLI Example:
    ```
salt '*' virt.start <path to Xen cfg file>
    ```

salt.modules.xapi.stop(vm_)
    Hard power down the virtual machine, this is equivalent to pulling the power

    CLI Example:
    ```
salt '*' virt.stop <vm name>
    ```

salt.modules.xapi.vcpu_pin(vm_, vcpu, cpus)
    Set which CPUs a VCPU can use.

    CLI Example:
    ```
salt 'foo' virt.vcpu_pin domU-id 2 1
salt 'foo' virt.vcpu_pin domU-id 2 2-6
    ```

salt.modules.xapi.vm_cputime(vm_=None)
    Return cputime used by the vms on this hyper in a list of dicts:

    ```
    [  
      'your-vm': {  
        'cputime' <int>  
        'cputime_percent' <int>  
      },  
      ...  
    ]
    ```

    If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

    CLI Example:
    ```
salt '*' virt.vm_cputime
    ```

salt.modules.xapi.vm_diskstats(vm_=None)
    Return disk usage counters used by the vms on this hyper in a list of dicts:

    ```
    [  
      'your-vm': {  
        'io_read_kbs' : 0, 
        'io_write_kbs' : 0  
      }, 
      ...  
    ]
    ```

    If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

    CLI Example:
    ```
salt '*' virt.vm_diskstats
    ```

salt.modules.xapi.vm_info(vm_=None)
    Return detailed information about the vms.
If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```shell
salt '*' virt.vm_info
```

```python
salt.modules.xapi.vm_netstats(vm_=None)
```

Return combined network counters used by the vms on this hyper in a list of dicts:

```
[
    {'your-vm': {
        'io_read_kbs': 0,
        'io_total_read_kbs': 0,
        'io_total_write_kbs': 0,
        'io_write_kbs': 0
    },
    ...
]
```

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```shell
salt '*' virt.vm_netstats
```

```python
salt.modules.xapi.vm_state(vm_=None)
```

Return list of all the vms and their state.

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```shell
salt '*' virt.vm_state <vm name>
```

### 13.6.369 salt.modules.xfs

Module for managing XFS file systems.

```python
salt.modules.xfs.defragment(device)
```

Defragment mounted XFS filesystem. In order to mount a filesystem, device should be properly mounted and writable.

CLI Example:

```shell
salt '*' xfs.defragment /dev/sda1
```

```python
salt.modules.xfs.devices()
```

Get known XFS formatted devices on the system.

CLI Example:

```shell
salt '*' xfs.devices
```

```python
salt.modules.xfs.dump(device, destination, level=0, label=None, noerase=None)
```

Dump filesystem device to the media (file, tape etc).
Required parameters:
- **device**: XFS device, content of which to be dumped.
- **destination**: Specifies a dump destination.

Valid options are:
- **label**: Label of the dump. Otherwise automatically generated label is used.
- **level**: Specifies a dump level of 0 to 9.
- **noerase**: Pre-erase media.

Other options are not used in order to let `xfsdump` use its default values, as they are most optimal. See the `xfsdump(8)` manpage for a more complete description of these options.

CLI Example:
```
salt '*' xfs.dump /dev/sda1 /destination/on/the/client
salt '*' xfs.dump /dev/sda1 /destination/on/the/client label='Company accountancy'
salt '*' xfs.dump /dev/sda1 /destination/on/the/client noerase=True
```

**salt.modules.xfs.estimate**(path)

Estimate the space that an XFS filesystem will take. For each directory estimate the space that directory would take if it were copied to an XFS filesystem. Estimation does not cross mount points.

CLI Example:
```
salt '*' xfs.estimate /path/to/file
salt '*' xfs.estimate /path/to/dir/*
```

**salt.modules.xfs.info**(device)

Get filesystem geometry information.

CLI Example:
```
salt '*' xfs.info /dev/sda1
```

**salt.modules.xfs.inventory**()

Display XFS dump inventory without restoration.

CLI Example:
```
salt '*' xfs.inventory
```

**salt.modules.xfs.mkfs**(device, label=None, ssize=None, noforce=None, bso=None, gmo=None, ino=None, lso=None, nmo=None, rso=None, dso=None)

Create a file system on the specified device. By default wipes out with force.

General options:
- **label**: Specify volume label.
- **ssize**: Specify the fundamental sector size of the filesystem.
- **noforce**: Do not force create filesystem, if disk is already formatted.

Filesystem geometry options:
- **bso**: Block size options.
- **gmo**: Global metadata options.
- **dso**: Data section options. These options specify the location, size, and other parameters of the data section of the filesystem.
- **ino**: Inode options to specify the inode size of the filesystem, and other inode allocation parameters.
- **lso**: Log section options.
- **nmo**: Naming options.
- **rso**: Realtime section options.

See the `mkfs.xfs(8)` manpage for a more complete description of corresponding options description.

CLI Example:
salt.modules.xfs.modify(device, label=None, lazy_counting=None, uuid=None)

Modify parameters of an XFS filesystem.

CLI Example:

```
salt '*' xfs.modify /dev/sda1 label='My backup' lazy_counting=False
salt '*' xfs.modify /dev/sda1 uuid=False
salt '*' xfs.modify /dev/sda1 uuid=True
```

salt.modules.xfs.prune_dump(sessionid)

Prunes the dump session identified by the given session id.

CLI Example:

```
salt '*' xfs.prune_dump b74a3586-e52e-4a4a-8775-c3334fa8ea2c
```

13.6.370 salt.modules.xmpp

Module for Sending Messages via XMPP (a.k.a. Jabber)

New in version 2014.1.0.

**depends**

- sleekxmpp>=1.3.1
- pyasn1
- pyasn1-modules
- dnspython

**configuration** This module can be used by either passing a jid and password directly to send_message, or by specifying the name of a configuration profile in the minion config, minion pillar, or master config.

For example:

```
my-xmpp-login:
  xmpp.jid: myuser@jabber.example.org/resourcename
  xmpp.password: verybadpass
```

The resourcename refers to the resource that is using this account. It is user-definable, and optional. The following configurations are both valid:

```
my-xmpp-login:
  xmpp.jid: myuser@jabber.example.org/salt
  xmpp.password: verybadpass

my-xmpp-login:
  xmpp.jid: myuser@jabber.example.org
  xmpp.password: verybadpass
```

class salt.modules.xmpp.SendMsgBot(jid, password, recipient, msg)
**classmethod create_multi** *(jid, password, msg, recipients=None, rooms=None, nick='SaltStack Bot')*
Alternate constructor that accept multiple recipients and rooms

**start**(event)

class salt.modules.xmpp.SleekXMPPMUC(name='')

**filter**(record)

salt.modules.xmpp.send_msg *(recipient, message, jid=None, password=None, profile=None)*
Send a message to an XMPP recipient. Designed for use in states.

**CLI Examples:**

```
xmpp.send_msg 'admins@xmpp.example.com' 'This is a salt module test'  # profile='my-xmpp-account'
xmpp.send_msg 'admins@xmpp.example.com' 'This is a salt module test'  # jid='myuser@xmpp.example.com/salt' password='verybadpass'
```

salt.modules.xmpp.send_msg_multi *(message, recipients=None, rooms=None, jid=None, password=None, nick='SaltStack Bot', profile=None)*
Send a message to an XMPP recipient, support send message to multiple recipients or chat room.

**CLI Examples:**

```
xmpp.send_msg recipients=['admins@xmpp.example.com'] rooms=['secret@conference.xmpp.example.com'] 'This is a salt module test'  # profile='my-xmpp-account'
xmpp.send_msg recipients=['admins@xmpp.example.com'] rooms=['secret@conference.xmpp.example.com'] 'This is a salt module test'  # jid='myuser@xmpp.example.com/salt' password='verybadpass'
```

## 13.6.371 salt.modules.yumpkg

Support for YUM/DNF

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to 'pkg.install' is not available), see [here](#).

**Note:** DNF is fully supported as of version 2015.5.10 and 2015.8.4 (partial support for DNF was initially added in 2015.8.0), and DNF is used automatically in place of YUM in Fedora 22 and newer.

salt.modules.yumpkg.clean_metadata (**kwargs)**
New in version 2014.1.0.

Cleans local yum metadata. Functionally identical to refresh_db().

**CLI Example:**

```
salt '*' pkg.clean_metadata
```

salt.modules.yumpkg.del_repo *(repo, basedir=None, **kwargs)*
Delete a repo from <basedir> (default basedir: all dirs in reposdir yum option).
If the .repo file in which the repo exists does not contain any other repo configuration, the file itself will be deleted.

CLI Examples:

```
salt '*' pkg.del_repo myrepo
salt '*' pkg.del_repo myrepo basedir=/path/to/dir
salt '*' pkg.del_repo myrepo basedir=/path/to/dir,/path/to/another/dir
```

**salt.modules.yumpkg.diff('paths')**

Return a formatted diff between current files and original in a package. NOTE: this function includes all files (configuration and not), but does not work on binary content.

- **Parameters**
  - `path` -- Full path to the installed file

- **Returns**
  Difference string or raises and exception if examined file is binary.

CLI example:

```
salt '*' pkg.diff /etc/apache2/httpd.conf /etc/sudoers
```

**salt.modules.yumpkg.download('packages')**

New in version 2015.5.0.

Download packages to the local disk. Requires yumdownloader from yum-utils package.

Note: yum-utils will already be installed on the minion if the package was installed from the Fedora / EPEL repositories.

CLI example:

```
salt '*' pkg.download httpd
salt '*' pkg.download httpd postfix
```

**salt.modules.yumpkg.file_dict('packages')**

New in version 2014.1.0.

List the files that belong to a package, grouped by package. Not specifying any packages will return a list of every file on the system’s rpm database (not generally recommended).

CLI Examples:

```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

**salt.modules.yumpkg.file_list('packages')**

New in version 2014.1.0.

List the files that belong to a package. Not specifying any packages will return a list of every file on the system’s rpm database (not generally recommended).

CLI Examples:

```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

**salt.modules.yumpkg.get_repo(name, basedir=None, **kwargs)**

Display a repo from <basedir> (default basedir: all dirs in reposdir yum option).
CLI Examples:

```
salt '*' pkg.get_repo myrepo
salt '*' pkg.get_repo myrepo basedir=/path/to/dir
salt '*' pkg.get_repo myrepo basedir=/path/to/dir,/path/to/another/dir
```

```
salt '*' pkg.group_diff 'Perl Support'
```

```
salt.modules.yumpkg.group_diff(name)
```

New in version 2014.1.0.

Changed in version 2016.3.0,2015.8.4,2015.5.10: Environment groups are now supported. The key names have been renamed, similar to the changes made in `pkg.group_info`.

Lists which of a group's packages are installed and which are not installed

CLI Example:

```
salt '*' pkg.group_diff 'Perl Support'
```

```
salt.modules.yumpkg.group_info(name, expand=False)
```

New in version 2014.1.0.

Changed in version 2016.3.0,2015.8.4,2015.5.10: The return data has changed. A new key type has been added to distinguish environment groups from package groups. Also, keys for the group name and group ID have been added. The mandatory packages, optional packages, and default packages keys have been renamed to mandatory, optional, and default for accuracy, as environment groups include other groups, and not packages. Finally, this function now properly identifies conditional packages.

Lists packages belonging to a certain group

`name` Name of the group to query

`expand` [False] If the specified group is an environment group, then the group will be expanded and the return data will include package names instead of group names.

New in version 2016.3.0.

CLI Example:

```
salt '*' pkg.group_info 'Perl Support'
```

```
salt.modules.yumpkg.group_install(name, skip=(), include=(), **kwargs)
```

New in version 2014.1.0.

Install the passed package group(s). This is basically a wrapper around `pkg.install`, which performs package group resolution for the user. This function is currently considered experimental, and should be expected to undergo changes.

`name` Package group to install. To install more than one group, either use a comma-separated list or pass the value as a python list.

CLI Examples:

```
salt '*' pkg.group_install 'Group 1'
salt '*' pkg.group_install 'Group 1,Group 2'
salt '*' pkg.group_install ['"Group 1", "Group 2"]'
```

`skip` Packages that would normally be installed by the package group (``default'' packages), which should not be installed. Can be passed either as a comma-separated list or a python list.

CLI Examples:

```
salt '*' pkg.group_install 'My Group' skip='foo,bar'
salt '*' pkg.group_install 'My Group' skip=['"foo", "bar"]'
```
include Packages which are included in a group, which would not normally be installed by a yum groupinstall ("optional" packages). Note that this will not enforce group membership; if you include packages which are not members of the specified groups, they will still be installed. Can be passed either as a comma-separated list or a python list.

CLI Examples:
```
salt '*' pkg.group_install 'My Group' include='foo,bar'
salt '*' pkg.group_install 'My Group' include='["foo", "bar"]'
```

Note: Because this is essentially a wrapper around pkg.install, any argument which can be passed to pkg.install may also be included here, and it will be passed along wholesale.

salt.modules.yumpkg.group_list() New in version 2014.1.0.
Lists all groups known by yum on this system

CLI Example:
```
salt '*' pkg.group_list
```

salt.modules.yumpkg.hold(name=None, pkgs=None, sources=None, normalize=True, **kwargs) New in version 2014.7.0.
Version-lock packages

Note: Requires the appropriate versionlock plugin package to be installed:
- On RHEL 5: yum-versionlock
- On RHEL 6 & 7: yum-plugin-versionlock
- On Fedora: python-dnf-plugins-extras-versionlock

name The name of the package to be held.

Multiple Package Options:
pkgs A list of packages to hold. Must be passed as a python list. The name parameter will be ignored if this option is passed.

Returns a dict containing the changes.

CLI Example:
```
salt '*' pkg.hold <package name>
salt '*' pkg.hold pkgs='["foo", "bar"]'
```

Return the information of the named package(s), installed on the system.

CLI example:
```
salt '*' pkg.info_installed <package1>
salt '*' pkg.info_installed <package1> <package2> <package3> ...
```

salt.modules.yumpkg.install(name=None, refresh=False, skip_verify=False, pkgs=None, sources=None, downloadonly=False, reinstall=False, normalize=True, **kwargs)

Changed in version 2015.8.12,2016.3.3,2016.11.0: On minions running systemd>=205, systemctl(1) is now

13.6. execution modules
used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any yum/dnf commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Install the passed package(s), add refresh=True to clean the yum database before package is installed.

**name** The name of the package to be installed. Note that this parameter is ignored if either `pkgs` or `sources` is passed. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the `sources` option.

32-bit packages can be installed on 64-bit systems by appending the architecture designation (.i686, .i586, etc.) to the end of the package name.

CLI Example:

```bash
salt '*' pkg.install <package name>
```

**refresh** Whether or not to update the yum database before executing.

**reinstall** Specifying reinstall=True will use yum reinstall rather than yum install for requested packages that are already installed.

If a version is specified with the requested package, then yum reinstall will only be used if the installed version matches the requested version.

Works with sources when the package header of the source can be matched to the name and version of an installed package.

New in version 2014.7.0.

**skip_verify** Skip the GPG verification check (e.g., --nogpgcheck)

**downloadonly** Only download the packages, do not install.

**version** Install a specific version of the package, e.g. 1.2.3-4.el6. Ignored if `pkgs` or `sources` is passed.

Repository Options:

**fromrepo** Specify a package repository (or repositories) from which to install. (e.g., yum --disablerepo='*' --enablerepo='somerepo')

**enablerepo (ignored if fromrepo is specified)** Specify a disabled package repository (or repositories) to enable. (e.g., yum --enablerepo='somerepo')

**disablerepo (ignored if fromrepo is specified)** Specify an enabled package repository (or repositories) to disable. (e.g., yum --disablerepo='somerepo')

**disableexcludes** Disable exclude from main, for a repo or for everything. (e.g., yum --disableexcludes='main')

New in version 2014.7.0.

Multiple Package Installation Options:

**pkgs** A list of packages to install from a software repository. Must be passed as a python list. A specific version number can be specified by using a single-element dict representing the package and its version.

CLI Examples:

```bash
salt '*' pkg.install pkgs='["foo", "bar"]'
salt '*' pkg.install pkgs='["foo", {"bar": "1.2.3-4.el5"}]'
```

**sources** A list of RPM packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

CLI Example:

```bash
salt '*' pkg.install sources='[{"foo": "salt://foo.rpm"}, {"bar": "salt://bar.rpm"}]'
```
normalize  [True] Normalize the package name by removing the architecture. This is useful for poorly created packages which might include the architecture as an actual part of the name such as kernel modules which match a specific kernel version.

New in version 2014.7.0.

salt.modules.yumpkg.latest_version(*names, **kwargs)

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

A specific repo can be requested using the fromrepo keyword argument, and the disableexcludes option is also supported.

New in version 2014.7.0: Support for the disableexcludes option

CLI Example:

salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package name> fromrepo=epel-testing
class '*' pkg.latest_version <package name> disableexcludes=main
class '*' pkg.latest_version <package1> <package2> <package3> ...

salt.modules.yumpkg.list_holds(pattern='\w+(?:[-.\[\]-]+)*', full=True)

List information on locked packages

Note: Requires the appropriate versionlock plugin package to be installed:
- On RHEL 5: yum-versionlock
- On RHEL 6 & 7: yum-plugin-versionlock
- On Fedora: python-dnf-plugins-extras-versionlock

pattern  [\w+(?:[-.\[\]-]+)*] Regular expression used to match the package name
full  [True] Show the full hold definition including version and epoch. Set to False to return just the name of the package(s) being held.

CLI Example:

salt '*' pkg.list_holds
salt '*' pkg.list_holds full=False

salt.modules.yumpkg.list_pkgs(versions_as_list=False, **kwargs)

List the packages currently installed in a dict:

[{'<package_name>': '<version>'}]

CLI Example:
salt '⋆' pkg.list_pkgs

salt.modules.yumpkg.list_repo_pkgs('args, **kwargs)
New in version 2014.1.0.

Changed in version 2014.7.0: All available versions of each package are now returned. This required a slight modification to the structure of the return dict. The return data shown below reflects the updated return dict structure. Note that packages which are version-locked using pkg.hold will only show the currently-installed version, as locking a package will make other versions appear unavailable to yum/dnf.

Returns all available packages. Optionally, package names (and name globs) can be passed and the results will be filtered to packages matching those names. This is recommended as it speeds up the function considerably.

**Warning:** Running this function on RHEL/CentOS 6 and earlier will be more resource-intensive, as the version of yum that ships with older RHEL/CentOS has no yum subcommand for listing packages from a repository. Thus, a `yum list installed` and `yum list available` are run, which generates a lot of output, which must then be analyzed to determine which package information to include in the return data.

This function can be helpful in discovering the version or repo to specify in a `pkg.installed` state.

The return data is a dictionary of repo names, with each repo containing a dictionary in which the keys are package names, and the values are a list of version numbers. Here is an example of the return data:

```python
{
    'base': {
        'bash': ['4.1.2-15.el6_4'],
        'kernel': ['2.6.32-431.el6']
    },
    'updates': {
        'bash': ['4.1.2-15.el6_5.2', '4.1.2-15.el6_5.1'],
        'kernel': ['2.6.32-431.29.2.el6',
                   '2.6.32-431.23.3.el6',
                   '2.6.32-431.28.5.el6',
                   '2.6.32-431.28.3.el6',
                   '2.6.32-431.17.1.el6',
                   '2.6.32-431.11.2.el6',
                   '2.6.32-431.5.1.el6',
                   '2.6.32-431.3.1.el6',
                   '2.6.32-431.1.2.0.1.el6']
    }
}
```

**fromrepo** [None] Only include results from the specified repo(s). Multiple repos can be specified, comma-separated.

CLI Example:

```bash
salt '⋆' pkg.list_repo_pkgs
salt '⋆' pkg.list_repo_pkgs foo bar baz
salt '⋆' pkg.list_repo_pkgs 'samba4★' fromrepo=base,updates
```

salt.modules.yumpkg.list_repos(basedir=None)
Lists all repos in <basedir> (default: all dirs in reposdir yum option).

CLI Example:
Salt Documentation, Release 2016.3.6

salt ' '*' pkg.list_repos
salt ' '*' pkg.list_repos basedir=/path/to/dir
salt ' '*' pkg.list_repos basedir=/path/to/dir,/path/to/another/dir

salt.modules.yumpkg.list_upgrades(refresh=True, **kwargs)
    Check whether or not an upgrade is available for all packages

    The fromrepo, enablerepo, and disablerepo arguments are supported, as used in pkg states, and the
disableexcludes option is also supported.

    New in version 2014.7.0: Support for the disableexcludes option

    CLI Example:
    
salt ' '*' pkg.list_upgrades

salt.modules.yumpkg.mod_repo(repo, basedir=None, **kwargs)
    Modify one or more values for a repo. If the repo does not exist, it will be created, so long as the following
    values are specified:
    
    repo  name by which the yum refers to the repo
    name  a human-readable name for the repo
    baseurl  the URL for yum to reference
    mirrorlist  the URL for yum to reference

    Key/Value pairs may also be removed from a repo's configuration by setting a key to a blank value. Bear in
    mind that a name cannot be deleted, and a baseurl can only be deleted if a mirrorlist is specified (or vice versa).

    CLI Examples:
    
salt ' '*' pkg.mod_repo reponame enabled=1 gpgcheck=1
salt ' '*' pkg.mod_repo reponame basedir=/path/to/dir enabled=1
salt ' '*' pkg.mod_repo reponame baseurl= mirrorlist=http://host.com/

salt.modules.yumpkg.modified(*packages, **flags)
    List the modified files that belong to a package. Not specifying any packages will return a list of _all_ modified
    files on the system's RPM database.

    New in version 2015.5.0.

    Filtering by flags (True or False):
    
    size  Include only files where size changed.
    mode  Include only files which file's mode has been changed.
    checksum  Include only files which MD5 checksum has been changed.
    device  Include only files which major and minor numbers has been changed.
    symlink  Include only files which are symbolic link contents.
    owner  Include only files where owner has been changed.
    group  Include only files where group has been changed.
    time  Include only files where modification time of the file has been changed.
    capabilities  Include only files where capabilities differ or not. Note: supported only on newer RPM versions.

    CLI Examples:
    
salt ' '*' pkg.modified
salt ' '*' pkg.modified httpd
salt ' '*' pkg.modified httpd postfix
salt ' '*' pkg.modified httpd owner=True group=False

salt.modules.yumpkg.normalize_name(name)
    Strips the architecture from the specified package name, if necessary. Circumstances where this would be
done include:

13.6. execution modules  1709
If the arch is 32 bit and the package name ends in a 32-bit arch.
If the arch matches the OS arch, or is noarch.

CLI Example:

```
salt '*' pkg.normalize_name zsh.x86_64
```

**salt.modules.yumpkg.owner('paths')**

New in version 2014.7.0.

Return the name of the package that owns the file. Multiple file paths can be passed. Like `pkg.version`
`<salt.modules.yumpkg.version`, if a single path is passed, a string will be returned, and if multiple
paths are passed, a dictionary of file/package name pairs will be returned.

If the file is not owned by a package, or is not present on the minion, then an empty string will be returned
for that path.

CLI Examples:

```
salt '*' pkg.owner /usr/bin/apachectl
salt '*' pkg.owner /usr/bin/apachectl /etc/httpd/conf/httpd.conf
```

**salt.modules.yumpkg.purge(name=None, pkgs=None, **kwargs)**

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, `systemd-run(1)`
is now used to isolate commands which modify installed packages from the `salt-minion` daemon's control group.
This is done to keep systemd from killing any yum/dnf commands spawned by Salt when the `salt-minion`
service is restarted. (see `KillMode` in the `systemd.kill(5)` manpage for more information). If desired, usage
of `systemd-run(1)` can be suppressed by setting a `config option` called `systemd.scope`, with a value of `False`
(no quotes).

Package purges are not supported by yum, this function is identical to `pkg.remove`.

**name** The name of the package to be purged

Multiple Package Options:

- **pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this
  option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'
```

**salt.modules.yumpkg.refresh_db(**kwargs)**

Check the yum repos for updated packages

Returns:

- **True**: Updates are available
- **False**: An error occurred
- **None**: No updates are available

**repo** Refresh just the specified repo

**disablerepo** Do not refresh the specified repo

**enablerepo** Refresh a disabled repo using this option

**branch** Add the specified branch when refreshing

**disableexcludes** Disable the excludes defined in your config files. Takes one of three options: `-all` - disable
all excludes - `main` - disable excludes defined in [main] in yum.conf - `repoid` - disable excludes defined
for that repo
CLI Example:

```
salt '*' pkg.refresh_db
```

```python
salt.modules.yumpkg.remove(name=None, pkgs=None, **kwargs)
```

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any yum/dnf commands spawned by Salt when the salt-minion service is restarted. (see `KillMode` in the `systemd.kill(5)` manpage for more information). If desired, usage of `systemd-run(1)` can be suppressed by setting a `config option` called `systemd.scope`, with a value of `False` (no quotes).

Remove packages

- **name**: The name of the package to be removed
- **Multiple Package Options:**
- **pkgs**: A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

```python
salt.modules.yumpkg.unhold(name=None, pkgs=None, sources=None, **kwargs)
```

New in version 2014.7.0.

Remove version locks

- **Note**: Requires the appropriate `versionlock plugin` package to be installed:
  - On RHEL 5: `yum-versionlock`
  - On RHEL 6 & 7: `yum-plugin-versionlock`
  - On Fedora: `python-dnf-plugins-extras-versionlock`

- **name**: The name of the package to be unheld
- **Multiple Package Options:**
- **pkgs**: A list of packages to unhold. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.unhold <package name>
salt '*' pkg.unhold pkgs='["foo", "bar"]'
```

```python
salt.modules.yumpkg.upgrade(name=None, pkgs=None, refresh=True, skip_verify=False, normalize=True, **kwargs)
```

Run a full system upgrade (a `yum upgrade` or `dnf upgrade`), or upgrade specified packages. If the packages aren't installed, they will not be installed.

Changed in version 2014.7.0.

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands which modify installed packages from the salt-minion daemon's control group.
This is done to keep systemd from killing any yum/dnf commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemctl-run() can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Run a full system upgrade, a yum upgrade

Return a dict containing the new package names and versions:

```
{"<package>": {"old": '<old-version>', 'new': '<new-version>'}}
```

CLI Example:

```
salt '*' pkg.upgrade
salt '*' pkg.upgrade name=openssl
```

Repository Options:

fromrepo Specify a package repository (or repositories) from which to install. (e.g., yum --disablerepo='*' --enablerepo='somerepo')

enablerepo (ignored if fromrepo is specified) Specify a disabled package repository (or repositories) to enable. (e.g., yum --enablerepo='somerepo')

disablerepo (ignored if fromrepo is specified) Specify an enabled package repository (or repositories) to disable. (e.g., yum --disablerepo='somerepo')

disableexcludes Disable exclude from main, for a repo or for everything. (e.g., yum --disableexcludes='main')

New in version 2014.7.

name The name of the package to be upgraded. Note that this parameter is ignored if ``pkgs'' is passed.

32-bit packages can be upgraded on 64-bit systems by appending the architecture designation (.i686, .i586, etc.) to the end of the package name.

Warning: if you forget `name=' and run pkg.upgrade openssl, ALL packages are upgraded. This will be addressed in next releases.

CLI Example:

```
salt '*' pkg.upgrade name=openssl
```

New in version 2016.3.0.

pkgs A list of packages to upgrade from a software repository. Must be passed as a python list. A specific version number can be specified by using a single-element dict representing the package and its version. If the package was not already installed on the system, it will not be installed.

CLI Examples:

```
salt '*' pkg.upgrade pkgs='["foo", "bar"]'
salt '*' pkg.upgrade pkgs='["foo", {"bar": "1.2.3-4.el5"}]'
```

New in version 2016.3.0.

normalize [True] Normalize the package name by removing the architecture. This is useful for poorly created packages which might include the architecture as an actual part of the name such as kernel modules which match a specific kernel version.

```
salt -G role:nsd pkg.upgrade gpfs.gplbin-2.6.32-279.31.1.el6.x86_64
   --normalize=False
```

New in version 2016.3.0.
salt.modules.yumpkg.upgrade_available(name)
Check whether or not an upgrade is available for a given package

CLI Example:
salt '*' pkg.upgrade_available <package name>

salt.modules.yumpkg.verify('names', **kwargs)
New in version 2014.1.0.
Runs an rpm -Va on a system, and returns the results in a dict
Files with an attribute of config, doc, ghost, license or readme in the package header can be ignored using the ignore_types keyword argument

CLI Example:
salt '*' pkg.verify
salt '*' pkg.verify httpd
salt '*' pkg.verify 'httpd postfix'
salt '*' pkg.verify 'httpd postfix' ignore_types=['config','doc']

salt.modules.yumpkg.version('names', **kwargs)
Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...

salt.modules.yumpkg.version_cmp(pkg1, pkg2, ignore_epoch=False)
New in version 2015.5.4.
Do a cmp-style comparison on two packages. Return -1 if pkg1 < pkg2, 0 if pkg1 == pkg2, and 1 if pkg1 > pkg2. Return None if there was a problem making the comparison.

ignore_epoch [False] Set to True to ignore the epoch when comparing versions

New in version 2015.8.10,2016.3.2.

CLI Example:
salt '*' pkg.version_cmp '0.2-001' '0.2.0.1-002'

13.6.372 salt.modules.zabbix module

Support for Zabbix

configuration This module is not usable until the zabbix user and zabbix password are specified either in a pillar or in the minion’s config file. Zabbix url should be also specified.

For example:

zabbix.user: Admin
zabbix.password: mypassword
zabbix.url: http://127.0.0.1/zabbix/api_jsonrpc.php

Connection arguments from the minion config file can be overridden on the CLI by using arguments with _connection_ prefix.

For example:
zabbix.apiinfo_version (**connection_args)**
Retrieve the version of the Zabbix API.

Args:
- **connection_args:**
  - _connection_user_: zabbix user (can also be set in opts or pillar, see module's docstring)
  - _connection_password_: zabbix password (can also be set in opts or pillar, see module's docstring)
  - _connection_url_: url of zabbix frontend (can also be set in opts or pillar, see module's docstring)

Returns:
- On success string with Zabbix API version, False on failure.

CLI Example:
```bash
salt '*' zabbix.apiinfo_version
```

salt.modules.zabbix.host_create (**host, groups, interfaces, **connection_args**)
Create new host.

Args:
- _host_: technical name of the host
- _groups_: groupids of host groups to add the host to
- _interfaces_: interfaces to be created for the host

Optional connection_args:
- _connection_user_: zabbix user (can also be set in opts or pillar, see module's docstring)
- _connection_password_: zabbix password (can also be set in opts or pillar, see module's docstring)
- _connection_url_: url of zabbix frontend (can also be set in opts or pillar, see module's docstring)

- **visible_name**: string with visible name of the host, use `visible_name` instead of `name` parameter to not mess with value supplied from Salt sls file.
- **all standard host properties**: keyword argument names differ depending on your zabbix version, see:
  - [https://www.zabbix.com/documentation/2.4/manual/api/reference/host/object#host](https://www.zabbix.com/documentation/2.4/manual/api/reference/host/object#host)

Returns:
- ID of the created host, False on failure.

CLI Example:
```bash
salt '*' zabbix.host_create technicalname 4 interfaces={["type": 1, "main": 1, "useip": 1, "ip": "192.168.3.1", "dns": "", "port": 10050], "visible_name": "Host Visible Name"}
```

salt.modules.zabbix.host_delete (hostids, **connection_args**)
Delete hosts.

Args:
- _hostids_: Hosts (hostids) to delete.

Optional connection_args:
- _connection_user_: zabbix user (can also be set in opts or pillar, see module's docstring)
- _connection_password_: zabbix password (can also be set in opts or pillar, see module's docstring)
- _connection_url_: url of zabbix frontend (can also be set in opts or pillar, see module's docstring)

Returns:
- IDs of the deleted hosts, False on failure.

CLI Example:
```bash
salt '*' zabbix.host_delete 10106
```

salt.modules.zabbix.host_exists (**host=None, hostid=None, name=None, node=None, nodeids=None, **connection_args**)
Checks if at least one host that matches the given filter criteria exists.

Args:
- _host_: technical name of the host
- _hostids_: Hosts (hostids) to delete.
- _name_: visible name of the host
- _node_: name of the node the hosts must belong to (zabbix API < 2.4)
- _nodeids_: IDs of the node the hosts must belong to (zabbix API < 2.4)

Optional connection_args:
- _connection_user_: zabbix user (can also be set in opts or pillar, see module's docstring)
- _connection_password_: zabbix password (can also be set in opts or pillar, see module's docstring)
- _connection_url_: url of zabbix frontend (can also be set in opts or pillar, see module's docstring)
Returns: IDs of the deleted hosts, False on failure.

CLI Example: .. code-block:: bash
    salt '*' zabbix.host_exists 'Zabbix server'

salt.modules.zabbix.host_get(host=None, name=None, hostids=None, **connection_args)
Retrieve hosts according to the given parameters.

Args:
    host: technical name of the host
    name: visible name of the host
    hostids: ids of the hosts

optional connection_args:
    _connection_user: zabbix user (can also be set in opts or pillar, see module's
docstring)
    _connection_password: zabbix password (can also be set in opts or pillar, see module's
docstring)
    _connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's
docstring)

all optional host.get parameters: keyword argument names differ depending on your zabbix version, see:
https://www.zabbix.com/documentation/2.4/manual/api/reference/host/get

Returns: Array with convenient hosts details, False if no host found or on failure.

CLI Example: .. code-block:: bash
    salt '*' zabbix.host_get 'Zabbix server'

salt.modules.zabbix.host_list(**connection_args)
Retrieve all hosts.

optional connection_args:
    _connection_user: zabbix user (can also be set in opts or pillar, see module's
docstring)
    _connection_password: zabbix password (can also be set in opts or pillar, see module's
docstring)
    _connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's
docstring)

Returns: Array with details about hosts, False on failure.

CLI Example: .. code-block:: bash
    salt '*' zabbix.host_list

salt.modules.zabbix.host_update(hostid, **connection_args)
Update existing hosts.

Args:
    hostid: ID of the host to update

optional connection_args:
    _connection_user: zabbix user (can also be set in opts or pillar, see module's
docstring)
    _connection_password: zabbix password (can also be set in opts or pillar, see module's
docstring)
    _connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's
docstring)

visible_name: string with visible name of the host, use `visible_name' instead of `name' parameter
to not mess with value supplied from Salt sls file.

all standard host and host.update properties: keyword argument names differ depending on your
zabbix version, see:
https://www.zabbix.com/documentation/2.4/manual/api/reference/host/object#host

Returns: ID of the updated host, False on failure.

CLI Example: .. code-block:: bash
    salt '*' zabbix.host_update 10084 name='Zabbix server2'

salt.modules.zabbix.hostgroup_create(name, **connection_args)
Create a host group.

Args:
    name: name of the host group

optional connection_args:
    _connection_user: zabbix user (can also be set in opts or pillar, see module's
docstring)
    _connection_password: zabbix password (can also be set in opts or pillar, see module's
docstring)
    _connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's
docstring)
all standard host group properties: keyword argument names differ depending on your zabbix version, see:

https://www.zabbix.com/documentation/2.2/manual/api/reference/hostgroup/object#host_group

Returns: ID of the created host group, False on failure.

CLI Example: .. code-block::

```
salt '*' zabbix.hostgroup_create MyNewGroup
```

salt.modules.zabbix.hostgroup_delete(hostgroupids, **connection_args)

Delete the host group.

Args:
hostgroupids: IDs of the host groups to delete

optional connection_args:
_connection_user: zabbix user (can also be set in opts or pillar, see module's docstring)
_connection_password: zabbix password (can also be set in opts or pillar, see module's docstring)
_connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's docstring)

Returns: ID of the deleted host groups, False on failure.

CLI Example: .. code-block::

```
salt '*' zabbix.hostgroup_delete 23
```

salt.modules.zabbix.hostgroup_exists(name=None, groupid=None, node=None, nodeids=None, **connection_args)

Checks if at least one host group that matches the given filter criteria exists.

Args:
name: names of the host groups groupid: host group IDs node: name of the node the host groups must belong to (zabbix API < 2.4) nodeids: IDs of the nodes the host groups must belong to (zabbix API < 2.4)

optional connection_args:
_connection_user: zabbix user (can also be set in opts or pillar, see module's docstring)
_connection_password: zabbix password (can also be set in opts or pillar, see module's docstring)
_connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's docstring)

Returns: True if at least one host group exists, False if not or on failure.

CLI Example: .. code-block::

```
salt '*' zabbix.hostgroup_exists MyNewGroup
```

salt.modules.zabbix.hostgroup_get(name=None, groupids=None, **connection_args)

Retrieve host groups according to the given parameters.

Args:
name: names of the host groups groupid: host group IDs node: name of the node the host groups must belong to nodeids: IDs of the nodes the host groups must belong to

optional connection_args:
_connection_user: zabbix user (can also be set in opts or pillar, see module's docstring)
_connection_password: zabbix password (can also be set in opts or pillar, see module's docstring)
_connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's docstring)

all standard hostgroup.get properties: keyword argument names differ depending on your zabbix version, see:

https://www.zabbix.com/documentation/2.2/manual/api/reference/hostgroup/get

Returns: Array with host groups details, False if no convenient host group found or on failure.

CLI Example: .. code-block::

```
salt '*' zabbix.hostgroup_get MyNewGroup
```

salt.modules.zabbix.hostgroup_list(**connection_args)

Retrieve all host groups.

Args:

optional connection_args:
_connection_user: zabbix user (can also be set in opts or pillar, see module's docstring)
_connection_password: zabbix password (can also be set in opts or pillar, see module's docstring)
_connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's docstring)

Returns: Array with details about host groups, False on failure.

CLI Example: .. code-block::

```
salt '*' zabbix.hostgroup_list
```
salt '*' zabbix.hostgroup_list

salt.modules.zabbix.hostgroup_update(groupid, name=None, **connection_args)
Update existing hosts group.
Args: groupid: ID of the host group to update name: name of the host group
optional connection_args: _connection_user: zabbix user (can also be set in opts or pillar, see module's
docstring)_connection_password: zabbix password (can also be set in opts or pillar, see module's
docstring)_connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's
docstring)
all standard host group properties: keyword argument names differ depending on your zabbix
version, see:
https://www.zabbix.com/documentation/2.4/manual/api/reference/hostgroup/object#host_group
Returns: IDs of updated host groups, False on failure.
CLI Example: .. code-block:: bash
salt '*' zabbix.hostgroup_update 24 name='Renamed Name'

salt.modules.zabbix.user_addmedia(users, medias, **connection_args)
Add new media to multiple users.
Args: users: Users (userid) to add the media too. madias: media to create for the given users
optional connection_args: _connection_user: zabbix user (can also be set in opts or pillar, see module's
docstring)_connection_password: zabbix password (can also be set in opts or pillar, see module's
docstring)_connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's
docstring)
Returns: IDs of the created media, False on failure.
CLI Example: .. code-block:: bash
salt '*' zabbix.user_addmedia 16 medias='{mediatypeid: 1, sendto: ''support@example.com'', active: 0, severity: 63, period: ''1-7,00:00-24:00''}''

salt.modules.zabbix.user_create(alias, passwd, usrgrps, **connection_args)
Create new zabbix user.
Args: alias: user alias passwd: user's password usrgrps: user groups to add the user to
optional connection_args: _connection_user: zabbix user (can also be set in opts or pillar, see module's
docstring)_connection_password: zabbix password (can also be set in opts or pillar, see module's
docstring)_connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's
docstring)
firstname: string with firstname of the user, use `firstname' instead of `name' parameter to not mess
with value supplied from Salt sls file.
all standard user properties: keyword argument names differ depending on your zabbix version,
see:
https://www.zabbix.com/documentation/2.0/manual/appendix/api/user/definitions#user
Returns: On success string with id of the created user, False on failure.
CLI Example: .. code-block:: bash
salt '*' zabbix.user_create james password007 [7, 12]' firstname='James Bond'

salt.modules.zabbix.user_delete(users, **connection_args)
Delete zabbix users.
Args: users: array of users (userids) to delete
optional connection_args: _connection_user: zabbix user (can also be set in opts or pillar, see module's
docstring)_connection_password: zabbix password (can also be set in opts or pillar, see module's
docstring)_connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's
docstring)
Returns: On success array with userids of deleted users, False on failure.
CLI Example: .. code-block:: bash

13.6. execution modules
salt '*' zabbix.user_delete 15

salt.modules.zabbix.user_deletemedia(mediaids, **connection_args)

Delete media by id.

Args: mediaids: IDs of the media to delete

optional connection_args: _connection_user: zabbix user (can also be set in opts or pillar, see module's
docstring) _connection_password: zabbix password (can also be set in opts or pillar, see module's
docstring) _connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's
docstring)

Returns: IDs of the deleted media, False on failure.

CLI Example: .. code-block:: bash
salt '*' zabbix.user_deletemedia 27

salt.modules.zabbix.user_exists(alias, **connection_args)

Checks if user with given alias exists.

Args: alias: user alias

optional connection_args: _connection_user: zabbix user (can also be set in opts or pillar, see module's
docstring) _connection_password: zabbix password (can also be set in opts or pillar, see module's
docstring) _connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's
docstring)

Returns: True if user exists, else False.

CLI Example: .. code-block:: bash
salt '*' zabbix.user_exists james

salt.modules.zabbix.user_get(alias=None, userids=None, **connection_args)

Retrieve users according to the given parameters.

Args: alias: user alias userids: return only users with the given IDs

optional connection_args: _connection_user: zabbix user (can also be set in opts or pillar, see module's
docstring) _connection_password: zabbix password (can also be set in opts or pillar, see module's
docstring) _connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's
docstring)

Returns: Array with details of convenient users, False on failure of if no user found.

CLI Example: .. code-block:: bash
salt '*' zabbix.user_get james

salt.modules.zabbix.user_list(**connection_args)

Retrieve all of the configured users.

Args: 

optional connection_args: _connection_user: zabbix user (can also be set in opts or pillar, see module's
docstring) _connection_password: zabbix password (can also be set in opts or pillar, see module's
docstring) _connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's
docstring)

Returns: Array with user details, False on failure.

CLI Example: .. code-block:: bash
salt '*' zabbix.user_list

salt.modules.zabbix.user_update(userid, **connection_args)

Update existing users.

Args: userid: id of the user to update

optional connection_args: _connection_user: zabbix user (can also be set in opts or pillar, see module's
docstring) _connection_password: zabbix password (can also be set in opts or pillar, see module's
docstring) _connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's
docstring)

all standard user properties: keyword argument names differ depending on your zabbix version, see:
Returns: Id of the updated user, False on failure.

CLI Example: .. code-block:: bash
    salt '*' zabbix.user_update 16 visible_name='James Brown'

salt.modules.zabbix.user_updatemedia(users, medias, **connection_args)
    Update media for multiple users.
    Args: users: Users (userid) to update. medias: Media to replace existing media. If a media has the mediaid property defined it will be updated, otherwise a new media will be created.
    optional connection_args: _connection_user: zabbix user (can also be set in opts or pillar, see module's docstring) _connection_password: zabbix password (can also be set in opts or pillar, see module's docstring) _connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's docstring)
    Returns: IDs of the updated users, False on failure.

CLI Example: .. code-block:: bash
    salt '*' zabbix.user_updatemedia 17 medias='{mediaid: 24, mediatypeid: 1, sendto: 'support_new@example.com', active: 0, severity: 63, period: '1-7,00:00-24:00'}'

salt.modules.zabbix.usergroup_create(name, **connection_args)
    Create new user group.
    Args: name: name of the user group.
    optional connection_args: _connection_user: zabbix user (can also be set in opts or pillar, see module's docstring) _connection_password: zabbix password (can also be set in opts or pillar, see module's docstring) _connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's docstring)
    all standard user group properties: keyword argument names differ depending on your zabbix version, see:
    https://www.zabbix.com/documentation/2.0/manual/appendix/api/usergroup/definitions#user_group
    Returns: IDs of the created user groups, False on failure.

CLI Example: .. code-block:: bash
    salt '*' zabbix.usergroup_create GroupName

salt.modules.zabbix.usergroup_delete(usergroupids, **connection_args)
    Delete user groups by id.
    Args: usergroupids: IDs of the user groups to delete.
    optional connection_args: _connection_user: zabbix user (can also be set in opts or pillar, see module's docstring) _connection_password: zabbix password (can also be set in opts or pillar, see module's docstring) _connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's docstring)
    Returns: IDs of the deleted user groups, False on failure.

CLI Example: .. code-block:: bash
    salt '*' zabbix.usergroup_delete 28

salt.modules.zabbix.usergroup_exists(name=None, node=None, nodeids=None, **connection_args)
    Checks if at least one user group that matches the given filter criteria exists.
    Args: name: names of the user groups. node: name of the node the user groups must belong to. (This will override the nodeids parameter.) nodeids: IDs of the nodes the user groups must belong to.
    optional connection_args: _connection_user: zabbix user (can also be set in opts or pillar, see module's docstring) _connection_password: zabbix password (can also be set in opts or pillar, see module's docstring) _connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's docstring)
    Returns: True if at least one user group that matches the given filter criteria exists, else False.
CLI Example: .. code-block:: bash
   salt '*' zabbix.usergroup_exists Guests

**salt.modules.zabbix.usergroup_get**(name=None, usrgrpids=None, **connection_args)

Retrieve user groups according to the given parameters.

**Args:**
- name: names of the user groups
- usrgrpids: return only user groups with the given IDs

**optional connection_args:**
- _connection_user: zabbix user (can also be set in opts or pillar, see module's
docstring)
- _connection_password: zabbix password (can also be set in opts or pillar, see module's
docstring)
- _connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's
docstring)

all usergroup_get properties: keyword argument names differ depending on your zabbix version, see:

https://www.zabbix.com/documentation/2.4/manual/api/reference/usergroup/get

**Returns:**
Array with convenient user groups details, False if no user group found or on failure.

CLI Example: .. code-block:: bash
   salt '*' zabbix.usergroup_get Guests

**salt.modules.zabbix.usergroup_list**(**connection_args)

Retrieve all enabled user groups.

**Args:**

**optional connection_args:**
- _connection_user: zabbix user (can also be set in opts or pillar, see module's
docstring)
- _connection_password: zabbix password (can also be set in opts or pillar, see module's
docstring)
- _connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's
docstring)

**Returns:**
Array with enabled user groups details, False on failure.

CLI Example: .. code-block:: bash
   salt '*' zabbix.usergroup_list

**salt.modules.zabbix.usergroup_update**(usrgrpid, **connection_args)

Update existing user group.

**Args:**
- usrgrpid: ID of the user group to update.

**optional connection_args:**
- _connection_user: zabbix user (can also be set in opts or pillar, see module's
docstring)
- _connection_password: zabbix password (can also be set in opts or pillar, see module's
docstring)
- _connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's
docstring)

all standard user group properties: keyword argument names differ depending on your zabbix version, see:

https://www.zabbix.com/documentation/2.4/manual/api/reference/usergroup/object#user_group

**Returns:**
IDs of the updated user group, False on failure.

CLI Example: .. code-block:: bash
   salt '*' zabbix.usergroup_update 8 name=guestsRenamed

13.6.373 **salt.modules.zcbuildout**

Management of zc.buildout

New in version 2014.1.0.

This module is inspired by minitage’s buildout maker

**Note:** The zc.buildout integration is still in beta; the API is subject to change
General notes

You have those following methods:

- `upgrade_bootstrap`
- `bootstrap`
- `run_buildout`
- `buildout`

```python
salt.modules.zcbuildout.bootstrap(*a, **kw)
```

Run the buildout bootstrap dance (python bootstrap.py).

- `directory` directory to execute in
- `config` alternative buildout configuration file to use
- `runas` User used to run buildout as
- `env` environment variables to set when running
- `buildout_ver` force a specific buildout version (1 | 2)
- `test_release` buildout accept test release
- `offline` are we executing buildout in offline mode
- `distribute` Forcing use of distribute
- `new_st` Forcing use of setuptools >= 0.7
- `python` path to a python executable to use in place of default (salt one)
- `onlyif` Only execute cmd if statement on the host return 0
- `unless` Do not execute cmd if statement on the host return 0
- `use_vt` Use the new salt VT to stream output [experimental]

CLI Example:

```
salt '*' buildout.bootstrap /srv/mybuildout
```

```python
salt.modules.zcbuildout.buildout(*a, **kw)
```

Run buildout in a directory.

- `directory` directory to execute in
- `config` buildout config to use
- `parts` specific buildout parts to run
- `runas` user used to run buildout as
- `env` environment variables to set when running
- `buildout_ver` force a specific buildout version (1 | 2)
- `test_release` buildout accept test release
- `new_st` Forcing use of setuptools >= 0.7
- `python` python to use
- `debug` run buildout with -D debug flag
- `onlyif` Only execute cmd if statement on the host return 0
- `unless` Do not execute cmd if statement on the host return 0
- `newest` run buildout in newest mode
- `verbose` run buildout in verbose mode (-vvvvv)
- `use_vt` Use the new salt VT to stream output [experimental]

CLI Example:

```
salt '*' buildout.buildout /srv/mybuildout
```

```python
salt.modules.zcbuildout.run_buildout(*a, **kw)
```

Run a buildout in a directory.

- `directory` directory to execute in
config alternative buildout configuration file to use
offline are we executing buildout in offline mode
runas user used to run buildout as
env environment variables to set when running
onlyif Only execute cmd if statement on the host return 0
unless Do not execute cmd if statement on the host return 0
newest run buildout in newest mode
force run buildout unconditionally
verbose run buildout in verbose mode (-vvvvv)
use_vt Use the new salt VT to stream output [experimental]

CLI Example:
```
salt '*' buildout.run_buildout /srv/mybuildout
```

salt.modules.zcbuildout.upgrade_bootstrap(a,**kw)
Upgrade current bootstrap.py with the last released one.

Indeed, when we first run a buildout, a common source of problem is to have a locally stale bootstrap, we just
try to grab a new copy
directory directory to execute in
offline are we executing buildout in offline mode
buildout_ver forcing to use a specific buildout version (1 | 2)
onlyif Only execute cmd if statement on the host return 0
unless Do not execute cmd if statement on the host return 0

CLI Example:
```
salt '*' buildout.upgrade_bootstrap /srv/mybuildout
```

13.6.374 salt.modules.zenoss

Module for working with the Zenoss API

New in version 2016.3.0.

depends requests
configuration This module requires a 'zenoss' entry in the master/minion config.

For example:
```
zenoss:
  hostname: https://zenoss.example.com
  username: admin
  password: admin123
```

salt.modules.zenoss.add_device(device=None, device_class=None, collector='localhost', prod_state=1000)
A function to connect to a zenoss server and add a new device entry.

Parameters: device: (Optional) Will use the grain 'fqdn' by default. device_class: (Optional) The device class
to use. If none, will determine based on kernel grain. collector: (Optional) The collector to use for this device. Defaults to 'localhost'. prod_state: (Optional) The prodState to set on the device. If none, defaults to 1000 ( production )

CLI Example: salt '*' zenoss.add_device

salt.modules.zenoss.device_exists(device=None)
Check to see if a device already exists in Zenoss.

Parameters: device: (Optional) Will use the grain 'fqdn' by default
CLI Example: `salt '*' zenoss.device_exists`

```python
salt.modules.zenoss.find_device(device=None)
```

Find a device in Zenoss. If device not found, returns None.

**Parameters:**
- `device`: (Optional) Will use the grain 'fqdn' by default

**CLI Example:** `salt '*' zenoss.find_device`

```python
salt.modules.zenoss.set_prod_state(prod_state, device=None)
```

A function to set the prod_state in zenoss.

**Parameters:**
- `prod_state`: (Required) Integer value of the state device: (Optional) Will use the grain 'fqdn' by default.

**CLI Example:** `salt zenoss.set_prod_state 1000 hostname`

---

### 13.6.3.75 salt.modules.zfs

Salt interface to ZFS commands

**Codeauthor:** Nitin Madhok &lt;nmadhok@clemson.edu&gt;

```python
salt.modules.zfs.bookmark(snapshot, bookmark)
```

New in version 2016.3.0.

Creates a bookmark of the given snapshot

**Note:** Bookmarks mark the point in time when the snapshot was created, and can be used as the incremental source for a zfs send command.

This feature must be enabled to be used. See zpool-features(5) for details on ZFS feature flags and the bookmarks feature.

**Parameters:**
- `snapshot`: [string] name of snapshot to bookmark
- `bookmark`: [string] name of bookmark

**CLI Example:**
```
salt '*' zfs.bookmark myzpool/mydataset@yesterday myzpool/mydataset#complete
```

```python
salt.modules.zfs.clone(name_a, name_b, **kwargs)
```

New in version 2016.3.0.

Creates a clone of the given snapshot.

**Parameters:**
- `name_a`: [string] name of snapshot
- `name_b`: [string] name of filesystem or volume
- `create_parent`: [boolean] creates all the non-existing parent datasets. any property specified on the command line using the -o option is ignored.
- `properties`: [dict] additional zfs properties (-o)

**Note:** ZFS properties can be specified at the time of creation of the filesystem by passing an additional argument called "properties" and specifying the properties with their respective values in the form of a python dictionary:

```
properties={"property1": 'value1', 'property2': 'value2'}
```

**CLI Example:**
salt 'zfs.clone myzpool/mydataset@yesterday myzpool/mydataset_yesterday

salt.modules.zfs.create(name, **kwargs)
New in version 2015.5.0.
Changed in version 2016.3.0.
Create a ZFS File System.
name [string] name of dataset or volume
volume_size [string] if specified, a zvol will be created instead of a dataset
sparse [boolean] create sparse volume
create_parent [boolean] creates all the non-existing parent datasets. any property specified on the command
type line using the -o option is ignored.
properties [dict] additional zfs properties (-o)

Note: ZFS properties can be specified at the time of creation of the filesystem by passing an additional
argument called `properties` and specifying the properties with their respective values in the form of a python
dictionary:

```
properties="{'property1': 'value1', 'property2': 'value2'}"
```

CLI Example:

salt 'zfs.create myzpool/mydataset [create_parent=True|False]
salt 'zfs.create myzpool/mydataset properties="{'mountpoint': '/export/zfs',
   'sharefns': 'on'}"
salt 'zfs.create myzpool/volume volume_size=1G [sparse=True|False]
salt 'zfs.create myzpool/volume volume_size=1G properties="{'volblocksize':
   '512'}" [sparse=True|False]

salt.modules.zfs.destroy(name, **kwargs)
New in version 2015.5.0.
Destroy a ZFS File System.
name [string] name of dataset, volume, or snapshot
force [boolean] force an unmount of any file systems using the unmount -f command.
recursive [boolean] recursively destroy all children. (-r)
recursive_all [boolean] recursively destroy all dependents, including cloned file systems outside the target
hierarchy. (-R)

**Warning:** watch out when using recursive and recursive_all

CLI Example:

salt 'zfs.destroy myzpool/mydataset [force=True|False]

salt.modules.zfs.diff(name_a, name_b, **kwargs)
New in version 2016.3.0.
Display the difference between a snapshot of a given filesystem and another snapshot of that filesystem from
a later time or the current contents of the filesystem.
name_a [string] name of snapshot
name_b [string] name of snapshot or filesystem
show_changetime [boolean] display the path's inode change time as the first column of output. (default = False)
**show_indication** [boolean] display an indication of the type of file. (default = True)

CLI Example:

```
salt '*' zfs.diff myzpool/mydataset@yesterday myzpool/mydataset
```

**salt.modules.zfs.exists**(name, **kwargs)

New in version 2015.5.0.

Check if a ZFS filesystem or volume or snapshot exists.

- **name** [string] name of dataset
- **type** [string] also check if dataset is of a certain type, valid choices are: filesystem, snapshot, volume, bookmark, or all.

CLI Example:

```
salt '*' zfs.exists myzpool/mydataset
salt '*' zfs.exists myzpool/myvolume type=volume
```

**salt.modules.zfs.get**( *dataset*, **kwargs**)

New in version 2016.3.0.

Displays properties for the given datasets.

- **dataset** [string] name of snapshot(s), filesystem(s), or volume(s)
- **properties** [string] comma-separated list of properties to list, defaults to all
- **recursive** [boolean] recursively list children
- **depth** [int] recursively list children to depth
- **fields** [string] comma-separated list of fields to include, the name and property field will always be added
- **type** [string] comma-separated list of types to display, where type is one of filesystem, snapshot, volume, bookmark, or all.
- **source** [string] comma-separated list of sources to display. Must be one of the following: local, default, inherited, temporary, and none. The default value is all sources.

**Note:** If no datasets are specified, then the command displays properties for all datasets on the system.

CLI Example:

```
salt '*' zfs.get
salt '*' zfs.get myzpool/mydataset [recursive=True|False]
salt '*' zfs.get myzpool/mydataset properties="sharefs,mountpoint"
--[recursive=True|False]
salt '*' zfs.get myzpool/mydataset myzpool/myotherdataset properties=available
--fields=value depth=1
```

**salt.modules.zfs.hold**(tag, *snapshot*, **kwargs**)

New in version 2016.3.0.

Adds a single reference, named with the tag argument, to the specified snapshot or snapshots.

**Note:** Each snapshot has its own tag namespace, and tags must be unique within that space.

If a hold exists on a snapshot, attempts to destroy that snapshot by using the zfs destroy command return EBUSY.

- **tag** [string] name of tag
- **snapshot** [string] name of snapshot(s)
- **recursive** [boolean] specifies that a hold with the given tag is applied recursively to the snapshots of all descendent file systems.
Note: A comma-separated list can be provided for the tag parameter to hold multiple tags.

CLI Example:

```bash
salt '*' zfs.hold mytag myzpool/mydataset@mysnapshot [recursive=True]
salt '*' zfs.hold mytag,myothertag myzpool/mydataset@mysnapshot
salt '*' zfs.hold mytag myzpool/mydataset@mysnapshot myzpool/
       ~mydataset@myothersnapshot
```

**salt.modules.zfs.holds(snapshot, **kwargs)**

New in version 2016.3.0.

Lists all existing user references for the given snapshot or snapshots.

- `snapshot` [string] name of snapshot
- `recursive` [boolean] lists the holds that are set on the named descendent snapshots also.

CLI Example:

```bash
salt '*' zfs.holds myzpool/mydataset@baseline
```

**salt.modules.zfs.inherit(prop, name, **kwargs)**

New in version 2016.3.0.

Clears the specified property

- `prop` [string] name of property
- `name` [string] name of the filesystem, volume, or snapshot
- `recursive` [boolean] recursively inherit the given property for all children.
- `revert` [boolean] revert the property to the received value if one exists; otherwise operate as if the -S option was not specified.

CLI Example:

```bash
salt '*' zfs.inherit canmount myzpool/mydataset [recursive=True|False]
```

**salt.modules.zfs.list(name=None, **kwargs)**

New in version 2015.5.0.

Changed in version 2016.3.0.

Return a list of all datasets or a specified dataset on the system and the values of their used, available, referenced, and mountpoint properties.

- `name` [string] name of dataset, volume, or snapshot
- `recursive` [boolean] recursively list children
- `depth` [int] limit recursion to depth
- `properties` [string] comma-separated list of properties to list, the name property will always be added
- `type` [string] comma-separated list of types to display, where type is one of filesystem, snapshot, volume, bookmark, or all.
- `sort` [string] property to sort on (default = name)
- `order` [string [ascending|descending]] sort order (default = ascending)

CLI Example:

```bash
salt '*' zfs.list
salt '*' zfs.list myzpool/mydataset [recursive=True|False]
salt '*' zfs.list myzpool/mydataset properties="sharenfs,mountpoint"
```

**salt.modules.zfs.mount(name='-a', **kwargs)**

New in version 2016.3.0.

Mounts ZFS file systems
**name** [string] name of the filesystem, you can use `-a` to mount all unmounted filesystems. (this is the default)

**overlay** [boolean] perform an overlay mount.

**options** [string] optional comma-separated list of mount options to use temporarily for the duration of the mount.

CLI Example:

```
salt '*' zfs.mount
salt '*' zfs.mount myzpool/mydataset
salt '*' zfs.mount myzpool/mydataset options=ro
```

salt.modules.zfs.promote(name)

New in version 2016.3.0.

Promotes a clone file system to no longer be dependent on its `origin` snapshot.

**Note:** This makes it possible to destroy the file system that the clone was created from. The clone parent-child dependency relationship is reversed, so that the origin file system becomes a clone of the specified file system.

The snapshot that was cloned, and any snapshots previous to this snapshot, are now owned by the promoted clone. The space they use moves from the origin file system to the promoted clone, so enough space must be available to accommodate these snapshots. No new space is consumed by this operation, but the space accounting is adjusted. The promoted clone must not have any conflicting snapshot names of its own. The rename subcommand can be used to rename any conflicting snapshots.

**name** [string] name of clone-filesystem

CLI Example:

```
salt '*' zfs.promote myzpool/myclone
```

salt.modules.zfs.release(tag, *snapshot, **kwargs)

New in version 2016.3.0.

Removes a single reference, named with the tag argument, from the specified snapshot or snapshots.

**Note:** The tag must already exist for each snapshot. If a hold exists on a snapshot, attempts to destroy that snapshot by using the zfs destroy command return EBUSY.

**tag** [string] name of tag

**snapshot** [string] name of snapshot(s)

**recursive** [boolean] recursively releases a hold with the given tag on the snapshots of all descendent file systems.

**Note:** A comma-separated list can be provided for the tag parameter to release multiple tags.

CLI Example:

```
salt '*' zfs.release mytag myzpool/mydataset@mysnapshot [recursive=True]
salt '*' zfs.release mytag myzpool/mydataset@mysnapshot myzpool/mydataset@myothersnapshot
```

salt.modules.zfs.rename(name, new_name, **kwargs)

New in version 2015.5.0.

Changed in version 2016.3.0.
Rename or Relocate a ZFS File System.

- **name** [string] name of dataset, volume, or snapshot
- **new_name** [string] new name of dataset, volume, or snapshot
- **force** [boolean] force unmount any filesystems that need to be unmounted in the process.
- **create_parent** [boolean] creates all the nonexistent parent datasets. Datasets created in this manner are automatically mounted according to the mountpoint property inherited from their parent.
- **recursive** [boolean] recursively rename the snapshots of all descendent datasets. Snapshots are the only dataset that can be renamed recursively.

CLI Example:

```
salt '*' zfs.rename myzpool/mydataset myzpool/renameddataset
```

`salt.modules.zfs.rollback(name, **kwargs)`

New in version 2016.3.0.

Roll back the given dataset to a previous snapshot.

**Warning:** When a dataset is rolled back, all data that has changed since the snapshot is discarded, and the dataset reverts to the state at the time of the snapshot. By default, the command refuses to roll back to a snapshot other than the most recent one.

In order to do so, all intermediate snapshots and bookmarks must be destroyed by specifying the `-r` option.

- **name** [string] name of snapshot
- **recursive** [boolean] destroy any snapshots and bookmarks more recent than the one specified.
- **recursive_all** [boolean] destroy any more recent snapshots and bookmarks, as well as any clones of those snapshots.
- **force** [boolean] used with the `-R` option to force an unmount of any clone file systems that are to be destroyed.

CLI Example:

```
salt '*' zfs.rollback myzpool/mydataset@yesterday
```

`salt.modules.zfs.set(*dataset, **kwargs)`

New in version 2016.3.0.

Sets the property or list of properties to the given value(s) for each dataset.

- **dataset** [string] name of snapshot(s), filesystem(s), or volume(s)
- **properties** [string] additional zfs properties pairs

**Note:** properties are passed as key-value pairs. e.g.

```
compression=off
```

**Note:** Only some properties can be edited.

See the Properties section for more information on what properties can be set and acceptable values.

Numeric values can be specified as exact values, or in a human-readable form with a suffix of B, K, M, G, T, P, E, Z (for bytes, kilobytes, megabytes, gigabytes, terabytes, petabytes, exabytes, or zettabytes, respectively).

CLI Example:

```
salt '*' zfs.set myzpool/mydataset compression=off
salt '*' zfs.set myzpool/mydataset myzpool/myotherdataset compression=off
salt '*' zfs.set myzpool/mydataset myzpool/myotherdataset compression=lz4
    canmount=off
```
salt.modules.zfs.snapshot(*snapshot, **kwargs)
    New in version 2016.3.0.
    Creates snapshots with the given names.
    * snapshot [string] name of snapshot(s)
    recursive [boolean] recursively create snapshots of all descendent datasets.
    properties [dict] additional zfs properties (-o)

    Note: ZFS properties can be specified at the time of creation of the filesystem by passing an additional
    argument called `properties` and specifying the properties with their respective values in the form of a python
    dictionary:

    ```
    properties = "{'property1': 'value1', 'property2': 'value2'}"
    ```

    CLI Example:

    ```
    salt '*' zfs.snapshot myzpool/mydataset@yesterday [recursive=True]
    salt '*' zfs.snapshot myzpool/mydataset@yesterday myzpool/
    !myotherdataset@yesterday [recursive=True]
    ```

salt.modules.zfs.unmount(name, **kwargs)
    New in version 2016.3.0.
    Unmounts ZFS file systems
    name [string] name of the filesystem, you can use `-a' to unmount all mounted filesystems.
    force [boolean] forcefully unmount the file system, even if it is currently in use.

    Warning: Using -a for the name parameter will probably break your system, unless your rootfs is not on
    zfs.

    CLI Example:

    ```
    salt '*' zfs.unmount myzpool/mydataset [force=True|False]
    ```

13.6.376 salt.modules.zk_concurrency

Concurreny controls in zookeeper

This module allows you to acquire and release a slot. This is primarily useful for ensuring that no more than N
hosts take a specific action at once. This can also be used to coordinate between masters.

salt.modules.zk_concurrency.lock(path, zk_hosts, identifier=None, max_concurrency=1, timeout=None, ephemeral_lease=False, force=False)

    Get lock (with optional timeout)
    path The path in zookeeper where the lock is
    zk_hosts zookeeper connect string
    identifier Name to identify this minion
    max_concurrency Maximum number of lock holders
    timeout timeout to wait for the lock. A None timeout will block forever
    ephemeral_lease Whether the locks in zookeeper should be ephemeral
    force Forcibly acquire the lock regardless of available slots
Example:

```bash
... code-block: bash
salt minion zk_concurrency.lock /lock/path host1:1234,host2:1234
```

```python
salt.modules.zk_concurrency.lock_holders(path, zk_hosts, max_concurrency=1, identifier=None, timeout=None, ephemeral_lease=False)
```

Return an un-ordered list of lock holders

- **path** The path in zookeeper where the lock is
- **zk_hosts** zookeeper connect string
- **identifier** Name to identify this minion
- **max_concurrency** Maximum number of lock holders
- **timeout** timeout to wait for the lock. A None timeout will block forever
- **ephemeral_lease** Whether the locks in zookeeper should be ephemeral

Example:

```bash
... code-block: bash
salt minion zk_concurrency.lock_holders /lock/path host1:1234,host2:1234
```

```python
salt.modules.zk_concurrency.party_members(path, zk_hosts)
```

Get the List of identifiers in a particular party

- **path** The path in zookeeper where the lock is
- **zk_hosts** zookeeper connect string

Example:

```bash
... code-block: bash
salt minion zk_concurrency.party_members /lock/path host1:1234,host2:1234
```

```python
salt.modules.zk_concurrency.unlock(path, zk_hosts=None, identifier=None, max_concurrency=1, ephemeral_lease=False)
```

Remove lease from semaphore

- **path** The path in zookeeper where the lock is
- **zk_hosts** zookeeper connect string
- **identifier** Name to identify this minion
- **max_concurrency** Maximum number of lock holders
- **timeout** timeout to wait for the lock. A None timeout will block forever
- **ephemeral_lease** Whether the locks in zookeeper should be ephemeral

Example:

```bash
... code-block: bash
salt minion zk_concurrency.unlock /lock/path host1:1234,host2:1234
```

### 13.6.377 salt.modules.znc

**znc** - An advanced IRC bouncer

New in version 2014.7.0.

Provides an interface to basic ZNC functionality

```python
salt.modules.znc.buildmod modules)
```

Build module using znc-buildmod

- **CLI Example:**

```bash
salt '*' znc.buildmod module.cpp [...]```
salt.modules.znc.dumpconf()
Write the active configuration state to config file
  CLI Example:
  
  salt '*' znc.dumpconf

salt.modules.znc.rehashconf()
Rehash the active configuration state from config file
  CLI Example:
  
  salt '*' znc.rehashconf

salt.modules.znc.version()
Return server version from znc --version
  CLI Example:
  
  salt '*' znc.version

13.6.378 salt.modules.zpool

Module for running ZFS zpool command

  codeauthor Nitin Madhok <nmadhok@clemson.edu>

salt.modules.zpool.add(zpool, *vdevs, **kwargs)
Changed in version 2016.3.0.
  Add the specified vdev's to the given storage pool
    zpool [string] name of storage pool
    *vdevs [string] one or more devices
    force [boolean] forces use of device
  CLI Example:
  
  salt '*' zpool.add myzpool /path/to/vdev1 /path/to/vdev2 [...]

salt.modules.zpool.attach(zpool, device, new_device, force=False)
Changed in version 2016.3.0.
  Attach specified device to zpool
    zpool [string] name of storage pool
    device [string] device to attach too
    new_device [string] device to attach
    force [boolean] forces use of device
  CLI Example:
  
  salt '*' zpool.attach myzpool /path/to/vdev1 /path/to/vdev2 [...]

salt.modules.zpool.create(zpool, *vdevs, **kwargs)
New in version 2015.5.0.
  Changed in version 2016.3.0.
  Create a simple zpool, a mirrored zpool, a zpool having nested VDEVs, a hybrid zpool with cache, spare and log drives or a zpool with RAIDZ-1, RAIDZ-2 or RAIDZ-3
    zpool [string] name of storage pool
vdevs [string] one or move devices
force [boolean] forces use of vdevs, even if they appear in use or specify a conflicting replication level.
mountpoint [string] sets the mount point for the root dataset
altroot [string] equivalent to `-o cachefile=none,altroot=root`
properties [dict] additional pool properties
filesystem_properties [dict] additional filesystem properties

CLI Example:

```
salt '*' zpool.create myzpool /path/to/vdev1 [...] [force=True|False]
salt '*' zpool.create myzpool mirror /path/to/vdev1 /path/to/vdev2 [...] [force=True|False]
salt '*' zpool.create myzpool raidz1 /path/to/vdev1 /path/to/vdev2 raidz2 /path/to/vdev3 /path/to/vdev4 /path/to/vdev5 [...] [force=True|False]
salt '*' zpool.create myzpool mirror /path/to/vdev1 [...] mirror /path/to/vdev2 / path/to/vdev3 [...] [force=True|False]
salt '*' zpool.create myhybridzpool mirror /tmp/file1 [...] log mirror /path/to/vdev1 [...] cache /path/to/vdev2 [...] spare /path/to/vdev3 [...] [force=True|False]
```

Note: Zpool properties can be specified at the time of creation of the pool by passing an additional argument called `''properties''` and specifying the properties with their respective values in the form of a python dictionary:

```
properties={''property1'': ''value1'', ''property2'': ''value2''}
```

Filesystem properties can be specified at the time of creation of the pool by passing an additional argument called `''filesystem_properties''` and specifying the properties with their respective values in the form of a python dictionary:

```
filesystem_properties={''property1'': ''value1'', ''property2'': ''value2''}
```

Example:

```
salt '*' zpool.create myzpool /path/to/vdev1 [...] properties={''property1'': ''value1'', ''property2'': ''value2''}
```

salt.modules.zpool.create_file_vdev(size, *vdevs)

Changed in version 2016.3.0.

Creates file based virtual devices for a zpool
*vdevs* is a list of full paths for mkfile to create

CLI Example:

```
salt '*' zpool.create_file_vdev 7g /path/to/vdev1 [...] [/path/to/vdev2] [...] [force=True|False]
```

Note: Depending on file size, the above command may take a while to return.

salt.modules.zpool.destroy(zpool, force=False)

Changed in version 2016.3.0.

Destroys a storage pool
zpool [string] name of storage pool
force [boolean] force destroy of pool
CLI Example:

```
salt '*' zpool.destroy myzpool
```

salt.modules.zpool.detach(zpool, device)
Changed in version 2016.3.0.
Detach specified device to zpool
zpool [string] name of storage pool
device [string] device to detach
CLI Example:

```
salt '*' zpool.detach myzpool /path/to/vdev1
```

salt.modules.zpool.exists(zpool)
Check if a ZFS storage pool is active
zpool [string] name of storage pool
CLI Example:

```
salt '*' zpool.exists myzpool
```

salt.modules.zpool.export('*pools', **kwargs)
New in version 2015.5.0.
Changed in version 2016.3.0.
Export storage pools
*pools [string] one or more storage pools to export
force [boolean] force export of storage pools
CLI Example:

```
salt '*' zpool.export myzpool ... [force=True|False]
salt '*' zpool.export myzpool2 myzpool2 ... [force=True|False]
```

salt.modules.zpool.get(zpool, prop=None, show_source=False)
New in version 2016.3.0.
Retrieves the given list of properties
zpool [string] name of storage pool
prop [string] optional name of property to retrieve
show_source [boolean] show source of property
CLI Example:

```
salt '*' zpool.get myzpool
```

salt.modules.zpool.healthy()
New in version 2016.3.0.
Check if all zpools are healthy
CLI Example:

```
salt '*' zpool.healthy
```

salt.modules.zpool.history(zpool=None, internal=False, verbose=False)
New in version 2016.3.0.
Displays the command history of the specified pools or all pools if no pool is specified
zpool [string] optional storage pool
internal [boolean] toggle display of internally logged ZFS events
verbose [boolean] toggle display of the user name, the hostname, and the zone in which the operation was performed

CLI Example:

```bash
salt '*' zpool.upgrade myzpool
```

salt.modules.zpool.import(zpool=None, new_name=None, **kwargs)

New in version 2015.5.0.

Changed in version 2016.3.0.

Import storage pools or list pools available for import
zpool [string] optional name of storage pool
new_name [string] optional new name for the storage pool
mntopts [string] comma-separated list of mount options to use when mounting datasets within the pool.
force [boolean] forces import, even if the pool appears to be potentially active.
altroot [string] equivalent to ``-o cachefile=none,altroot=root''
dir [string] searches for devices or files in dir, multiple dirs can be specified as follows:: dir="dir1,dir2"
no_mount [boolean] import the pool without mounting any file systems.
only_destroyed [boolean] imports destroyed pools only. this also sets force=True.
properties [dict] additional pool properties

Note: Zpool properties can be specified at the time of creation of the pool by passing an additional argument called `''properties'' and specifying the properties with their respective values in the form of a python dictionary:

```python
properties="{"property1": 'value1', 'property2': 'value2'}"
```

CLI Example:

```bash
salt '*' zpool.import [force=True|False]
salt '*' zpool.import myzpool [mynewzpool] [force=True|False]
salt '*' zpool.import myzpool dir='/tmp'
```

salt.modules.zpool.iostat(zpool=None, sample_time=0)

Changed in version 2016.3.0.

Display I/O statistics for the given pools
zpool [string] optional name of storage pool
sample_time [int] seconds to capture data before output

CLI Example:

```bash
salt '*' zpool.iostat myzpool
```

salt.modules.zpool.list(properties='size, alloc, free, cap, frag, health', zpool=None)

New in version 2015.5.0.

Changed in version 2016.3.0.

Return information about (all) storage pools
zpool [string] optional name of storage pool
properties [string] comma-separated list of properties to list

Note: the `name` property will always be included, the `frag` property will get removed if not available
zpool  [string] optional zpool

Note: multiple storage pool can be provided as a space separated list

CLI Example:

```bash
salt '*' zpool.list
```

**salt.modules.zpool.offline** *(zpool, *vdevs, **kwargs)*

New in version 2015.5.0.

Changed in version 2016.3.0.

Ensure that the specified devices are offline

**Warning:** By default, the OFFLINE state is persistent. The device remains offline when the system is rebooted. To temporarily take a device offline, use `temporary=True`.

```bash
zpool  [string] name of storage pool
*vdevs*  [string] one or more devices
temporary  [boolean] enable temporarily offline
```

CLI Example:

```bash
salt '*' zpool.offline myzpool /path/to/vdev1 [...] [temporary=True|False]
```

**salt.modules.zpool.online** *(zpool, *vdevs, **kwargs)*

New in version 2015.5.0.

Changed in version 2016.3.0.

Ensure that the specified devices are online

```bash
zpool  [string] name of storage pool
*vdevs*  [string] one or more devices
expand  [boolean] Expand the device to use all available space.
```

**Note:** If the device is part of a mirror or raidz then all devices must be expanded before the new space will become available to the pool.

CLI Example:

```bash
salt '*' zpool.online myzpool /path/to/vdev1 [...] 
```

**salt.modules.zpool.reguid** *(zpool)*

New in version 2016.3.0.

Generates a new unique identifier for the pool

**Warning:** You must ensure that all devices in this pool are online and healthy before performing this action.

```bash
zpool  [string] name of storage pool
```

CLI Example:
Salt Documentation, Release 2016.3.6

salt '*' zpool.reguid myzpool

salt.modules.zpool.reopen(zpool)
New in version 2016.3.0.

Reopen all the vdevs associated with the pool

zpool [string] name of storage pool

CLI Example:

salt '*' zpool.reopen myzpool

salt.modules.zpool.replace(zpool, old_device, new_device=None, force=False)
Changed in version 2016.3.0.

Replaces old_device with new_device.

Note: This is equivalent to attaching new_device, waiting for it to resilver, and then detaching old_device.
The size of new_device must be greater than or equal to the minimum size of all the devices in a mirror or raidz configuration.

zpool [string] name of storage pool
old_device [string] old device to replace
new_device [string] optional new device
force [boolean] Forces use of new_device, even if it appears to be in use.

CLI Example:

salt '*' zpool.replace myzpool /path/to/vdev1 /path/to/vdev2

salt.modules.zpool.scrub(zpool, stop=False)
Changed in version 2016.3.0.

Scrub a storage pool

zpool [string] name of storage pool
stop [boolean] if true, cancel ongoing scrub

CLI Example:

salt '*' zpool.scrub myzpool

salt.modules.zpool.set(zpool, prop, value)
New in version 2016.3.0.

Sets the given property on the specified pool

zpool [string] name of storage pool
prop [string] name of property
value [string] value to set property to

CLI Example:

salt '*' zpool.set myzpool readonly yes

salt.modules.zpool.status(zpool=None)
Changed in version 2016.3.0.

Return the status of the named zpool

zpool [string] optional name of storage pool

CLI Example:
salt ' '*' zpool.status myzpool

salt.modules.zpool.upgrade(zpool=None, version=None)
New in version 2016.3.0.
Enables all supported features on the given pool

**Warning:** Once this is done, the pool will no longer be accessible on systems that do not support feature flags. See zpool-features(5) for details on compatibility with systems that support feature flags, but do not support all features enabled on the pool.

zpool [string] optional storage pool, applies to all otherwise
version [int] version to upgrade to, if unspecified upgrade to the highest possible

CLI Example:
salt ' '*' zpool.upgrade myzpool

salt.modules.zpool.zpool_list()
Deprecated since version 2014.7.0: Use list() instead.
Return a list of all pools in the system with health status and space usage

CLI Example:
salt ' '*' zpool.zpool_list

## 13.6.379 salt.modules.zypper

Package support for openSUSE via the zypper package manager

depends
  • rpm Python module. Install with zypper install rpm-python

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to 'pkg.install' is not available), see [here](#).

salt.modules.zypper.add_lock(packages, **kwargs)
Add a package lock. Specify packages to lock by exact name.

CLI Example:
salt ' '*' pkg.add_lock <package name>
salt ' '*' pkg.add_lock <package1>,<package2>,<package3>
salt ' '*' pkg.add_lock pkgs='["foo", "bar"]'

salt.modules.zypper.clean_locks()
Remove unused locks that do not currently (with regard to repositories used) lock any package.

CLI Example:
salt ' '*' pkg.clean_locks

### 13.6. execution modules

1737
salt.modules.zypper.del_repo(repo)
Delete a repo.

CLI Examples:
```
salt '*' pkg.del_repo alias
```

salt.modules.zypper.diff(*paths)
Return a formatted diff between current files and original in a package. NOTE: this function includes all files (configuration and not), but does not work on binary content.

**Parameters**
- path -- Full path to the installed file

**Returns**
Difference string or raises and exception if examined file is binary.

CLI example:
```
salt '*' pkg.diff /etc/apache2/httpd.conf /etc/sudoers
```

salt.modules.zypper.download(*packages, **kwargs)
Download packages to the local disk.

**refresh** force a refresh if set to True. If set to False (default) it depends on zypper if a refresh is executed.

CLI example:
```
salt '*' pkg.download httpd
salt '*' pkg.download httpd postfix
```

salt.modules.zypper.file_dict(*packages)
List the files that belong to a package, grouped by package. Not specifying any packages will return a list of every file on the system’s rpm database (not generally recommended).

CLI Examples:
```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

salt.modules.zypper.file_list(*packages)
List the files that belong to a package. Not specifying any packages will return a list of every file on the system’s rpm database (not generally recommended).

CLI Examples:
```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

salt.modules.zypper.get_repo(repo, **kwargs)
Display a repo.

CLI Example:
```
salt '*' pkg.get_repo alias
```

salt.modules.zypper.info(*names, **kwargs)
Deprecated since version 2016.3.0: Use info_available() instead.

Return the information of the named package available for the system.

CLI example:
salt.modules.zypper.info_available(“names, **kwargs)
Return the information of the named package available for the system.
refresh force a refresh if set to True (default). If set to False it depends on zypper if a refresh is executed or not.
CLI example:

```
salt '*' pkg.info_available <package1>
salt '*' pkg.info_available <package1> <package2> <package3> ...
```

salt.modules.zypper.info_installed(“names, **kwargs)
Return the information of the named package(s), installed on the system.
Parameters
- **names** -- Names of the packages to get information about.
- **attr** -- Comma-separated package attributes. If no `attr` is specified, all available attributes returned.
  Valid attributes are: version, vendor, release, build_date, build_date_time_t, install_date, install_date_time_t, build_host, group, source_rpm, arch, epoch, size, license, signature, packager, url, summary, description.
- **errors** -- Handle RPM field errors (true|false). By default, various mistakes in the textual fields are simply ignored and omitted from the data. Otherwise a field with a mistake is not returned, instead a `N/A (bad UTF-8)' (not available, broken) text is returned.
  Valid attributes are: ignore, report

CLI example:

```
salt '*' pkg.info_installed <package1>
salt '*' pkg.info_installed <package1> <package2> <package3> ...
```

salt.modules.zypper.install(name=None, refresh=False, fromrepo=None, pkgs=None, sources=None, downloadonly=None, skip_verify=False, version=None, ignore_repo_failure=False, **kwargs)
Changed in version 2015.8.12,2016.3.3,2016.11.0: On minions running systemd>=205, systemd-run(1) is now used to isolate commands which modify installed packages from the salt-minion daemon’s control group. This is done to keep systemd from killing any zypper commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Install the passed package(s), add refresh=True to force a `zypper refresh' before package is installed.
name The name of the package to be installed. Note that this parameter is ignored if either pkgs or sources is passed. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the sources option.

CLI Example:
salt 'نتشر' pkg.install <package name>

refresh force a refresh if set to True. If set to False (default) it depends on zypper if a refresh is executed.
fromrepo Specify a package repository to install from.
downloadonly Only download the packages, do not install.
skip_verify Skip the GPG verification check (e.g., --no-gpg-checks)
version Can be either a version number, or the combination of a comparison operator (<, >, <=, >=, =) and a version number (ex. '>1.2.3-4'). This parameter is ignored if pkgs or sources is passed.

Multiple Package Installation Options:
pkgs A list of packages to install from a software repository. Must be passed as a python list. A specific version number can be specified by using a single-element dict representing the package and its version. As with the version parameter above, comparison operators can be used to target a specific version of a package.

CLI Examples:
salt 'نتشر' pkg.install pkgs='["foo", "bar"]'
salt 'نتشر' pkg.install pkgs='["foo", {"bar": "1.2.3-4"}]

sources A list of RPM packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

CLI Example:
salt 'نتشر' pkg.install sources='[{"foo": "salt://foo.rpm"},{"bar": "salt://bar.rpm"}]'

ignore_repo_failure Zypper returns error code 106 if one of the repositories are not available for various reasons. In case to set strict check, this parameter needs to be set to True. Default: False.

Returns a dict containing the new package names and versions:

```python
{'<package>': {'old': '<old-version>',
             'new': '<new-version>'}}
```

salt.modules.zypper.latest_version('names', **kwargs)
Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty dict will be returned for that package.

refresh force a refresh if set to True (default). If set to False it depends on zypper if a refresh is executed or not.

CLI example:
salt 'نتشر' pkg.latest_version <package name>
salt 'نتشر' pkg.latest_version <package1> <package2> <package3> ...

salt.modules.zypper.list_installed_patterns()
List installed patterns on the system.

CLI Examples:
salt 'نتشر' pkg.list_installed_patterns

salt.modules.zypper.list_locks()
List current package locks.

Return a dict containing the locked package with attributes:
{
    "<package>": {
        "case_sensitive": "<case_sensitive>",
        "match_type": "<match_type>",
        "type": "<type>"}
}

CLI Example:
salt '*' pkg.list_locks

salt.modules.zypper.list_patterns(refresh=False)
List all known patterns from available repos.
refresh force a refresh if set to True. If set to False (default) it depends on zypper if a refresh is executed.
CLI Examples:
salt '*' pkg.list_patterns

salt.modules.zypper.list_pkgs(versions_as_list=False, **kwargs)
List the packages currently installed as a dict with versions as a comma separated string:
{
    "<package_name>": ["<version>[,<version>...]"]
}

versions_as_list: If set to True, the versions are provided as a list
{
    "<package_name>": ["<version>[,<version>]"]
}
removed: not supported
purge_desired: not supported
CLI Example:
salt '*' pkg.list_pkgs

salt.modules.zypper.list_products(all=False, refresh=False)
List all available or installed SUSE products.
all List all products available or only installed. Default is False.
refresh force a refresh if set to True. If set to False (default) it depends on zypper if a refresh is executed. Includes handling for OEM products, which read the OEM productline file and overwrite the release value.
CLI Examples:
salt '*' pkg.list_products
salt '*' pkg.list_products all=True

salt.modules.zypper.list_repos()
Lists all repos.
CLI Example:
salt '*' pkg.list_repos

salt.modules.zypper.list_upgrades(refresh=True, **kwargs)
List all available package upgrades on this system
refresh force a refresh if set to True (default). If set to False it depends on zypper if a refresh is executed.
CLI Example:
salt '*' pkg.list_upgrades

salt.modules.zypper.mod_repo(repo, **kwargs)
Modify one or more values for a repo. If the repo does not exist, it will be created, so long as the following values are specified:

13.6. execution modules
repo or alias alias by which the zypper refers to the repo
url, mirrorlist or baseurl the URL for zypper to reference
enabled enable or disable (True or False) repository, but do not remove if disabled.
refresh enable or disable (True or False) auto-refresh of the repository.
cache Enable or disable (True or False) RPM files caching.
gpgcheck Enable or disable (True or False) GOG check for this repository.
gpgautoimport Automatically trust and import new repository.

Key/Value pairs may also be removed from a repo's configuration by setting a key to a blank value. Bear in mind that a name cannot be deleted, and a url can only be deleted if a mirrorlist is specified (or vice versa).

CLI Examples:

```
salt '*' pkg.mod_repo alias alias=new_alias
salt '*' pkg.mod_repo alias url= mirrorlist=http://host.com/
```

````
salt.modules.zypper.modified('packages', 'flags')  
````
List the modified files that belong to a package. Not specifying any packages will return a list of _all_ modified files on the system's RPM database.

New in version 2015.5.0.

Filtering by flags (True or False):
size Include only files where size changed.
mode Include only files which file's mode has been changed.
checksum Include only files which MD5 checksum has been changed.
device Include only files which major and minor numbers has been changed.
symlink Include only files which are symbolic link contents.
owner Include only files where owner has been changed.
group Include only files where group has been changed.
time Include only files where modification time of the file has been changed.
capabilities Include only files where capabilities differ or not. Note: supported only on newer RPM versions.

CLI Examples:

```
salt '*' pkg.modified
salt '*' pkg.modified httpd
salt '*' pkg.modified httpd postfix
salt '*' pkg.modified httpd owner=True group=False
```

````
salt.modules.zypper.owner('paths')
````
Return the name of the package that owns the file. Multiple file paths can be passed. If a single path is passed, a string will be returned, and if multiple paths are passed, a dictionary of file/package name pairs will be returned.

If the file is not owned by a package, or is not present on the minion, then an empty string will be returned for that path.

CLI Examples:

```
salt '*' pkg.owner /usr/bin/apachectl
salt '*' pkg.owner /usr/bin/apachectl /etc/httpd/conf/httpd.conf
```

````
salt.modules.zypper.purge(name=None, pkgs=None, **kwargs)
````
Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, systemctl(1) is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any zypper commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemctl(5) manpage for more information). If desired, usage of systemctl(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).
Recursively remove a package and all dependencies which were installed with it, this will call a `zypper -n remove -u`

**name**  The name of the package to be deleted.

Multiple Package Options:

**pkgs**  A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'
```

salt.modules.zypper.refresh_db()

Force a repository refresh by calling `zypper refresh --force`, return a dict:

```
{"<database name>": Bool}
```

CLI Example:

```
salt '*' pkg.refresh_db
```

salt.modules.zypper.remove(name=None, pkgs=None, **kwargs)

Changed in version 2015.8.12,2016.3.3,2016.11.0: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands which modify installed packages from the `salt-minion` daemon's control group. This is done to keep systemd from killing any zypper commands spawned by Salt when the `salt-minion` service is restarted. (see `KillMode` in the `systemd.kill(5)` manpage for more information). If desired, usage of `systemd-run(1)` can be suppressed by setting a config option called `systemd.scope`, with a value of False (no quotes).

Remove packages with `zypper -n remove`

**name**  The name of the package to be deleted.

Multiple Package Options:

**pkgs**  A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

salt.modules.zypper.remove_lock(packages, **kwargs)

Remove specified package lock.

CLI Example:

```
salt '*' pkg.remove_lock <package name>
salt '*' pkg.remove_lock <package1>,<package2>,<package3>
salt '*' pkg.remove_lock pkgs='["foo", "bar"]'
```

salt.modules.zypper.search(criteria, refresh=False)

List known packages, available to the system.
refresh  force a refresh if set to True. If set to False (default) it depends on zypper if a refresh is executed.

CLI Examples:

```
salt '*' pkg.search <criteria>
```

\[
\text{salt.modules.zypper.upgrade}(\text{refresh=True, dryrun=False, dist_upgrade=False, fromrepo=None,}
\text{novendorchange=False, skip_verify=False, **kwargs})
\]

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, \text{systemd-run(1)} is now
used to isolate commands which modify installed packages from the \text{salt-minion} daemon’s control group.
This is done to keep systemd from killing any \text{zypper} commands spawned by \text{Salt} when the \text{salt-minion}
service is restarted. (see \text{KillMode} in the \text{systemd.kill(5)} manpage for more information). If desired, usage
of \text{systemd-run(1)} can be suppressed by setting a \text{config option} called \text{systemd.scope}, with a value
of \text{False} (no quotes).

Run a full system upgrade, a \text{zypper upgrade}

\text{refresh}  force a refresh if set to True (default). If set to False it depends on zypper if a refresh is executed.

\text{dryrun}  If set to True, it creates a debug solver log file and then perform a dry-run upgrade (no changes are
made). Default: False

\text{dist_upgrade}  Perform a system dist-upgrade. Default: False

\text{fromrepo}  Specify a list of package repositories to upgrade from. Default: None

\text{novendorchange}  If set to True, no allow vendor changes. Default: False

\text{skip_verify}  Skip the GPG verification check (e.g., \text{--no-gpg-checks})

Return a dict containing the new package names and versions:

\[
\{\text{'<package>': \{'old': '<old-version>',}
\text{'new': '<new-version>'\}}\}
\]

CLI Example:

```
salt '*' pkg.upgrade
salt '*' pkg.upgrade dist-upgrade=True fromrepo=['"MyRepoName"']

salt '*' pkg.upgrade dist-upgrade=True dryrun=True
```

\text{salt.modules.zypper.upgrade_available}(\text{name, **kwargs})

Check whether or not an upgrade is available for a given package

\text{refresh}  force a refresh if set to True (default). If set to False it depends on zypper if a refresh is executed or
not.

CLI Example:

```
salt '*' pkg.upgrade_available <package name>
```

\text{salt.modules.zypper.verify}(\text{'names, **kwargs})

Runs an rpm -Va on a system, and returns the results in a dict

Files with an attribute of config, doc, ghost, license or readme in the package header can be ignored using the
\text{ignore_types} keyword argument

CLI Example:

```
salt '*' pkg.verify
salt '*' pkg.verify httpd
salt '*' pkg.verify 'httpd postfix'
salt '*' pkg.verify 'httpd postfix' ignore_types=['config','doc']
```

\text{salt.modules.zypper.version}(\text{'names, **kwargs})

Returns a string representing the package version or an empty dict if not installed. If more than one package
name is specified, a dict of name/version pairs is returned.
CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

```python
salt.modules.zypper.version_cmp(ver1, ver2, ignore_epoch=False)
```

New in version 2015.5.4.

Do a cmp-style comparison on two packages. Return -1 if ver1 < ver2, 0 if ver1 == ver2, and 1 if ver1 > ver2. Return None if there was a problem making the comparison.

**ignore_epoch** [False] Set to True to ignore the epoch when comparing versions

New in version 2015.8.10,2016.3.2.

CLI Example:

```
salt '*' pkg.version_cmp '0.2-001' '0.2.0.1-002'
```

### 13.7 netapi modules

#### 13.7.1 rest_cherrypy

A REST API for Salt

New in version 2014.7.0.

**depends**

- CherryPy Python module. Version 3.2.3 is currently recommended when SSL is enabled, since this version worked the best with SSL in internal testing. Versions 3.2.3 - 4.x can be used if SSL is not enabled. Be aware that there is a known SSL error introduced in version 3.2.5. The issue was reportedly resolved with CherryPy milestone 3.3, but the patch was committed for version 3.6.1.

**optdepends**

- ws4py Python module for websockets support.

**client_libraries**

- Java: https://github.com/SUSE/saltstack-netapi-client-java
- Python: https://github.com/saltstack/pepper

**setup** All steps below are performed on the machine running the Salt Master daemon. Configuration goes into the Master configuration file.

1. Install `salt-api`. (This step varies between OS and Linux distros. Some package systems have a split package, others include salt-api in the main Salt package. Ensure the `salt-api --version` output matches the `salt --version` output.)

2. Install CherryPy. (Read the version caveat in the section above.)

   Using a secure HTTPS connection is strongly recommended since Salt eauth authentication credentials will be sent over the wire.

   (a) Install the PyOpenSSL package.
(b) Generate a self-signed certificate using the `create_self_signed_cert()` execution function.

```
salt-call --local tls.create_self_signed_cert
```

4. Edit the master config to create at least one external auth user or group following the full external auth instructions.

5. Edit the master config with the following production-ready example to enable the `rest_cherrypy` module. (Adjust cert paths as needed, or disable SSL (not recommended!).)

```
rest_cherrypy:
  port: 8000
  ssl_crt: /etc/pki/tls/certs/localhost.crt
  ssl_key: /etc/pki/tls/certs/localhost.key
```

6. Restart the `salt-master` daemon.

7. Start the `salt-api` daemon.

**configuration** All available configuration options are detailed below. These settings configure the CherryPy HTTP server and do not apply when using an external server such as Apache or Nginx.

- **port** Required
  The port for the webserver to listen on.

- **host** `[0.0.0.0]` The socket interface for the HTTP server to listen on.

- **debug** `[False]` Starts the web server in development mode. It will reload itself when the underlying code is changed and will output more debugging info.

- **ssl_crt** The path to a SSL certificate. (See below)

- **ssl_key** The path to the private key for your SSL certificate. (See below)

- **disable_ssl** A flag to disable SSL. Warning: your Salt authentication credentials will be sent in the clear!

- **webhook_disable_auth** `[False]` The Webhook URL requires authentication by default but external services cannot always be configured to send authentication. See the Webhook documentation for suggestions on securing this interface.

- **webhook_url** `[/hook]` Configure the URL endpoint for the Webhook entry point.

- **thread_pool** `[100]` The number of worker threads to start up in the pool.

- **socket_queue_size** `[30]` Specify the maximum number of HTTP connections to queue.

- **expire_responses** `[True]` Whether to check for and kill HTTP responses that have exceeded the default timeout.

- **max_request_body_size** `[1048576]` Maximum size for the HTTP request body.

- **collect_stats** `[False]` Collect and report statistics about the CherryPy server

  Reports are available via the `Stats` URL.

- **static** A filesystem path to static HTML/JavaScript/CSS/image assets.

- **static_path** `[/static]` The URL prefix to use when serving static assets out of the directory specified in the static setting.
**app** A filesystem path to an HTML file that will be served as a static file. This is useful for bootstrapping a single-page JavaScript app.

**app_path** [/app] The URL prefix to use for serving the HTML file specified in the app setting. This should be a simple name containing no slashes.

Any path information after the specified path is ignored; this is useful for apps that utilize the HTML5 history API.

**root_prefix** [/] A URL path to the main entry point for the application. This is useful for serving multiple applications from the same URL.

### Authentication

Authentication is performed by passing a session token with each request. Tokens are generated via the Login URL.

The token may be sent in one of two ways: as a custom header or as a session cookie. The latter is far more convenient for clients that support cookies.

- Include a custom header named *X-Auth-Token*.

  For example, using curl:

  ```
curl -sSk https://localhost:8000/login
  -H 'Accept: application/x-yaml'
  -d username=saltdev
  -d password=saltdev
  -d eauth=auto
  ```

  Copy the token value from the output and include it in subsequent requests:

  ```
curl -sSk https://localhost:8000
  -H 'Accept: application/x-yaml'
  -H 'X-Auth-Token: 697adbdc8fe971d09ae4c2a3add7248859c87079'
  -d client=local
  -d tgt='*
  -d fun=test.ping
  ```

- Sent via a cookie. This option is a convenience for HTTP clients that automatically handle cookie support (such as browsers).

  For example, using curl:

  ```
  # Write the cookie file:
curl -sSk https://localhost:8000/login
  -c ~/cookies.txt
  -H 'Accept: application/x-yaml'
  -d username=saltdev
  -d password=saltdev
  -d eauth=auto

  # Read the cookie file:
curl -sSk https://localhost:8000
  -b ~/cookies.txt
  -H 'Accept: application/x-yaml'
  -d client=local
  -d tgt='*
  -d fun=test.ping
  ```
See also:

You can bypass the session handling via the Run URL.

Usage

This interface directly exposes Salt's Python API. Everything possible at the CLI is possible through the Python API. Commands are executed on the Salt Master.

The root URL (/) is RPC-like in that it accepts instructions in the request body for what Salt functions to execute, and the response contains the result of those function calls.

For example:

```
% curl -sSi https://localhost:8000 -H 'Content-type: application/json' -d '
  [ {
    "client": "local",
    "tgt": "*",
    "fun": "test.ping"
  }]
''
HTTP/1.1 200 OK
Content-Type: application/json
[...snip...]
{"return": [{"jerry": true}]}
```

The request body must be an array of commands. Use this workflow to build a command:

1. Choose a client interface.
2. Choose a function.
3. Fill out the remaining parameters needed for the chosen client.

The client field is a reference to the main Python classes used in Salt's Python API. Read the full client interfaces documentation, but in short:

- ``local`` uses `LocalClient` which sends commands to Minions. Equivalent to the `salt` CLI command.
- ``runner`` uses `RunnerClient` which invokes runner modules on the Master. Equivalent to the `salt-run` CLI command.
- ``wheel`` uses `WheelClient` which invokes wheel modules on the Master. Wheel modules do not have a direct CLI equivalent but they typically manage Master-side resources such as state files, pillar files, the Salt config files, and the key wheel module exposes similar functionality as the `salt-key` CLI command.

Most clients have variants like synchronous or asynchronous execution as well as others like batch execution. See the full list of client interfaces.

Each client requires different arguments and sometimes has different syntax. For example, `LocalClient` requires the `tgt` argument because it forwards the command to Minions and the other client interfaces do not. `LocalClient` also takes `arg` (array) and `karg` (dictionary) arguments because these values are sent to the Minions and used to execute the requested function there. `RunnerClient` and `WheelClient` are executed directly on the Master and thus do not need or accept those arguments.

Read the method signatures in the client documentation linked above, but hopefully an example will help illustrate the concept. This example causes Salt to execute two functions -- the `test.arg execution function` using `LocalClient` and the `test.arg runner function` using `RunnerClient`; note the different structure for each command. The results for both are combined and returned as one response.
One more example, this time with more commonly used functions:

```
curl -b /tmp/cookies.txt -ssI localhost:8000 -H 'Content-type: application/json' -d '```
```
[  
  {  
    "client": "local",  
    "tgt": "+",  
    "fun": "state.sls",  
    "args": [],  
    "kwargs": {
      "keyword arg two": "Runners do not support positional args",  
      "keyword arg one": "Hello from a master"
    }
  },
  {  
    "client": "runner",  
    "fun": "test.arg",  
    "keyword arg one": "Hello from a master",  
    "keyword arg two": "Runners do not support positional args"
  }
]
HTTP/1.1 200 OK
 [...]snip...]
```
```
{  
  "return": [
    {  
      "jerry": {  
        "args": [
          "positional arg one",  
          "positional arg two"
        ],  
        "kwargs": {
          "keyword arg one": "Hello from a minion",  
          "keyword arg two": "Hello again from a minion",
          [...]snip...
        }
      },
      [...]snip; other minion returns here...]
    },
    {  
      "args": [],
      "kwargs": {
        "keyword arg two": "Runners do not support positional args",
        "keyword arg one": "Hello from a master"
      }
    }
  ]
}
```
"kwarg": {
    "mods": "apache",
    "pillar": {
        "lookup": {
            "wwwdir": "/srv/httpd/htdocs"
        }
    }
},
{
    "client": "runner",
    "fun": "cloud.create",
    "provider": "my-ec2-provider",
    "instances": "my-centos-6",
    "image": "ami-1624987f",
    "delvol_on_destroy": true
}
]
HTTP/1.1 200 OK
[...snip...]
{
    "return": [
        {
            "jerry": {
                "pkg_|-install_apache_|-httpd_|-installed": {
                    [...snip full state return here...]
                }
            }
        },
        [...snip other minion returns here...]
    }
}

Content negotiation

This REST interface is flexible in what data formats it will accept as well as what formats it will return (e.g., JSON, YAML, urlencoded).

- Specify the format of data in the request body by including the Content-Type header.
- Specify the desired data format for the response body with the Accept header.

We recommend the JSON format for most HTTP requests. urlencoded data is simple and cannot express complex data structures -- and that is often required for some Salt commands, such as starting a state run that uses Pillar data. Salt's CLI tool can reformat strings passed in at the CLI into complex data structures, and that behavior also works via salt-api, but that can be brittle and since salt-api can accept JSON it is best just to send JSON.

Here is an example of sending urlencoded data:

```
curl -sSik https://localhost:8000 \
    -b ~/cookies.txt \
    -d client=runner \
```

---

Salt Documentation, Release 2016.3.6

1750 Chapter 13. Salt Module Reference
-d fun='jobs.lookup_jid' \
-d jid='20150129182456704682'

urlencode data caveats

- Only a single command may be sent per HTTP request.
- Repeating the arg parameter multiple times will cause those parameters to be combined into a single list.

Note, some popular frameworks and languages (notably jQuery, PHP, and Ruby on Rails) will automatically append empty brackets onto repeated query string parameters. E.g., ?foo[]=fooone&foo[]=footwo. This is not supported; send ?foo=fooone&foo=footwo instead, or send JSON or YAML.

A note about curl

The -d flag to curl does not automatically urlencode data which can affect passwords and other data that contains characters that must be encoded. Use the --data-urlencode flag instead. E.g.:

```bash
curl -ksi http://localhost:8000/login \
-H "Accept: application/json" \
-d username='myapiuser' \
--data-urlencode password='1234+' \
-d eauth='pam'
```

Deployment

The rest_cherrypy netapi module is a standard Python WSGI app. It can be deployed one of two ways.

salt-api using the CherryPy server

The default configuration is to run this module using salt-api to start the Python-based CherryPy server. This server is lightweight, multi-threaded, encrypted with SSL, and should be considered production-ready.

Using a WSGI-compliant web server

This module may be deployed on any WSGI-compliant server such as Apache with mod_wsgi or Nginx with FastCGI, to name just two (there are many).

Note, external WSGI servers handle URLs, paths, and SSL certs directly. The rest_cherrypy configuration options are ignored and the salt-api daemon does not need to be running at all. Remember Salt authentication credentials are sent in the clear unless SSL is being enforced!

An example Apache virtual host configuration:

```xml
<VirtualHost *:80>
    ServerName example.com
    ServerAlias *.example.com

    ServerAdmin webmaster@example.com

    LogLevel warn
    ErrorLog /var/www/example.com/logs/error.log
    CustomLog /var/www/example.com/logs/access.log combined
</VirtualHost>
```
DocumentRoot /var/www/example.com/htdocs

WSGIScriptAlias / /path/to/salt/netapi/rest_cherrypy/wsgi.py
</VirtualHost>

**REST URI Reference**

- `/`
- `/login`
- `/logout`
- `/minions`
- `/jobs`
- `/run`
- `/events`
- `/hook`
- `/keys`
- `/ws`
- `/stats`

/  

class salt.netapi.rest_cherrypy.app.**LowDataAdapter**

The primary entry point to Salt's REST API

**GET()**  
An explanation of the API with links of where to go next

**GET /**

Request Headers

- **Accept** -- the desired response format.

Status Codes

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

Example request:

curl -i localhost:8000

**GET / HTTP/1.1**
Host: localhost:8000
Accept: application/json
Example response:

```
HTTP/1.1 200 OK
Content-Type: application/json
```

**POST**

Mock out specified imports.

This allows autodoc to do its thing without having oodles of req’d installed libs. This doesn’t work with `import *` imports.

This Mock class can be configured to return a specific values at specific names, if required.

http://read-the-docs.readthedocs.org/en/latest/faq.html#i-get-import-errors-on-libraries-that-depend-on-c-modules

### /login

class salt.netapi.rest_cherrypy.app.Login(args, **kwargs)

Log in to receive a session token

*Authentication information.*

**GET()**

Present the login interface

**GET /login**

An explanation of how to log in.

**Status Codes**

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

Example request:

```
curl -i localhost:8000/login
```

```
GET /login HTTP/1.1
Host: localhost:8000
Accept: text/html
```

Example response:

```
HTTP/1.1 200 OK
Content-Type: text/html
```

**POST(** **kwargs)**

*Authenticate* against Salt’s eauth system

**POST /login**

Request Headers

- **X-Auth-Token** -- a session token from *Login*.
- **Accept** -- the desired response format.
- **Content-Type** -- the format of the request body.
Form Parameters

- **eauth** -- the eauth backend configured for the user
- **username** -- username
- **password** -- password

Status Codes

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

Example request:

```
curl -si localhost:8000/login \
  -c ~/cookies.txt \
  -H "Accept: application/json" \
  -H "Content-type: application/json" \
  -d '{
      "username": "saltuser",
      "password": "saltuser",
      "eauth": "auto"
  }'
```

Example response:

```
POST / HTTP/1.1
Host: localhost:8000
Content-Length: 42
Content-Type: application/json
Accept: application/json

{
    "username": "saltuser",
    "password": "saltuser",
    "eauth": "auto"
}

HTTP/1.1 200 OK
Content-Type: application/json
Content-Length: 206
X-Auth-Token: 6d1b722e
Set-Cookie: session_id=6d1b722e; expires=Sat, 17 Nov 2012 03:23:52 GMT; Path=/

{"return": {
    "token": "6d1b722e",
    "start": 1363805943.776223,
    "expire": 1363849143.776224,
    "user": "saltuser",
    "eauth": "pam",
    "perms": [
        "grains.*",
        "status.*",
        "sys.*",
        "test.*"
    ]
}}
```
/logout

class salt.netapi.rest_cherrypy.app.Logout

Class to remove or invalidate sessions

**POST()**

Destroy the currently active session and expire the session cookie

/minions

class salt.netapi.rest_cherrypy.app.Minions

Convenience URLs for working with minions

**GET**(mid=None)

A convenience URL for getting lists of minions or getting minion details

**GET /minions/**(mid)

Request Headers

• **X-Auth-Token** -- a session token from Login.
• **Accept** -- the desired response format.

Status Codes

• **200** -- success
• **401** -- authentication required
• **406** -- requested Content-Type not available

Example request:

curl -i localhost:8000/minions/ms-3

Example response:

```
HTTP/1.1 200 OK
Content-Length: 129005
Content-Type: application/x-yaml

return:
- ms-3:
  grains.items:
  ...
```

**POST(****kwargs**)

Start an execution command and immediately return the job id

**POST /minions**

Request Headers

• **X-Auth-Token** -- a session token from Login.
• **Accept** -- the desired response format.
- **Content-Type** -- the format of the request body.

**Response Headers**

- **Content-Type** -- the format of the response body; depends on the `Accept` request header.

**Status Codes**

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

Lowstate data describing Salt commands must be sent in the request body. The `client` option will be set to `local_async()`.

**Example request:**

```bash
curl -sSi localhost:8000/minions \
  -b ~/cookies.txt \
  -H "Accept: application/x-yaml" \
  -d '[["tgt": ",", "fun": "status.diskusage"]]'
```

**POST /minions HTTP/1.1**

- **Host:** localhost:8000
- **Accept:** application/x-yaml
- **Content-Type:** application/json

  tgt=*&fun=status.diskusage

**Example response:**

```
HTTP/1.1 202 Accepted
Content-Length: 86
Content-Type: application/x-yaml

return:
- jid: '20130603122505459265'
  minions: [ms-4, ms-3, ms-2, ms-1, ms-0]
  _links:
    jobs:
      - href: /jobs/20130603122505459265
```

/jobs

class salt.netapi.rest_cherrypy.app.Jobs

**GET**(jid=None, timeout="")

A convenience URL for getting lists of previously run jobs or getting the return from a single job

**GET** /jobs/(jid)

List jobs or show a single job from the job cache.

**Request Headers**

- **X-Auth-Token** -- a session token from Login.
- **Accept** -- the desired response format.
Status Codes

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

Example request:
```
curl -i localhost:8000/jobs
```

**GET /jobs**
```text
HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml
```

Example response:
```
HTTP/1.1 200 OK
Content-Length: 165
Content-Type: application/x-yaml

return:
- '20121130104633606931':
  - Arguments:
    - '3'
  Function: test.fib
  Target: jerry
  Target-type: glob
```

Example request:
```
curl -i localhost:8000/jobs/20121130104633606931
```

**GET /jobs/20121130104633606931**
```text
HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml
```

Example response:
```
HTTP/1.1 200 OK
Content-Length: 73
Content-Type: application/x-yaml

info:
- Arguments:
  - '3'
  Function: test.fib
  Minions:
  - jerry
  Target: '*'
  Target-type: glob
  User: saltdev
  jid: '20121130104633606931'
return:
- jerry:
  - 0
class salt.netapi.rest_cherrypy.app.Run

Class to run commands without normal session handling

POST(**kwargs)

Run commands bypassing the normal session handling

POST /run

This entry point is primarily for `one-off` commands. Each request must pass full Salt authentication credentials. Otherwise this URL is identical to the root URL (/).

lowstate data describing Salt commands must be sent in the request body.

Status Codes

- 200 -- success
- 401 -- authentication required
- 406 -- requested Content-Type not available

Example request:

curl -sS localhost:8000/run \
   -H 'Accept: application/x-yaml' \
   -H 'Content-type: application/json' \
   -d '[["client": "local", "tgt": ",", "fun": "test.ping", "username": "saltdev", "password": "saltdev", "eauth": "auto"]]

Example response:

```
HTTP/1.1 200 OK
Content-Length: 73
Content-Type: application/x-yaml

return:
- ms-0: true
```
The `/run` endpoint can also be used to issue commands using the salt-ssh subsystem.

When using salt-ssh, eauth credentials should not be supplied. Instead, authentication should be handled by the SSH layer itself. The use of the salt-ssh client does not require a salt master to be running. Instead, only a roster file must be present in the salt configuration directory.

All SSH client requests are synchronous.

Example SSH client request:

```
curl -sS localhost:8000/run \
   -H 'Accept: application/x-yaml' \
   -d client='ssh' \
   -d tgt='*' \
   -d fun='test.ping'
```

Example SSH response:

```
return:
 - silver:
   fun: test.ping
   fun_args: []
   id: silver

   return: true
   success: true
```

/events

class salt.netapi.rest_cherrypy.app.Events

Expose the Salt event bus

The event bus on the Salt master exposes a large variety of things, notably when executions are started on the master and also when minions ultimately return their results. This URL provides a real-time window into a running Salt infrastructure.

See also:

Events & Reactor

GET(:token=`None`, salt_token=`None`)  
An HTTP stream of the Salt master event bus

This stream is formatted per the Server Sent Events (SSE) spec. Each event is formatted as JSON.
GET /events

Status Codes

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

Query Parameters

- **token** -- optional parameter containing the token ordinarily supplied via the X-Auth-Token header in order to allow cross-domain requests in browsers that do not include CORS support in the EventSource API. E.g.,
curl -NsS localhost:8000/events?token=308650d

- **salt_token** -- optional parameter containing a raw Salt eauth token (not to be confused with the token returned from the /login URL). E.g.,
curl -NsS localhost:8000/events?salt_token=30742765

Example request:
curl -NsS localhost:8000/events

Example response:

Note, the tag field is not part of the spec. SSE compliant clients should ignore unknown fields. This addition allows non-compliant clients to only watch for certain tags without having to deserialize the JSON object each time.

The event stream can be easily consumed via JavaScript:

```javascript
var source = new EventSource('/events');
source.onopen = function() { console.info('Listening ...'); };
source.onerror = function(err) { console.error(err); };
source.onmessage = function(message) {
  var saltEvent = JSON.parse(message.data);
  console.info(saltEvent.tag);
  console.debug(saltEvent.data);
};
```
Or using CORS:

```javascript
var source = new EventSource('/events?token=ecd589e4e01912cf3c4835afad73426db8dba75', {withCredentials: true});
```

It is also possible to consume the stream via the shell.

Records are separated by blank lines; the `data:` and `tag:` prefixes will need to be removed manually before attempting to unserialize the JSON.

curl's `-N` flag turns off input buffering which is required to process the stream incrementally.

Here is a basic example of printing each event as it comes in:

```bash
curl -Ns localhost:8000/events |
  while IFS= read -r line ; do
echo $line
  done
```

Here is an example of using awk to filter events based on tag:

```bash
curl -NsS localhost:8000/events |
  awk 'BEGIN { RS=""; FS="\n" } $1 ~ /^tag: salt/job/[0-9]+/new$/ { print $0 }',
```

/hook

class salt.netapi.rest_cherrypy.app.Webhook
A generic web hook entry point that fires an event on Salt's event bus

External services can POST data to this URL to trigger an event in Salt. For example, Amazon SNS, Jenkins-CI or Travis-CI, or GitHub web hooks.

**Note:** Be mindful of security

Salt’s Reactor can run any code. A Reactor SLS that responds to a hook event is responsible for validating that the event came from a trusted source and contains valid data.

This is a generic interface and securing it is up to you!

This URL requires authentication however not all external services can be configured to authenticate. For this reason authentication can be selectively disabled for this URL. Follow best practices -- always use SSL, pass a secret key, configure the firewall to only allow traffic from a known source, etc.

The event data is taken from the request body. The `Content-Type` header is respected for the payload.
The event tag is prefixed with `salt/netapi/hook` and the URL path is appended to the end. For example, a POST request sent to `/hook/mycompany/myapp/mydata` will produce a Salt event with the tag `salt/netapi/hook/mycompany/myapp/mydata`.

The following is an example `.travis.yml` file to send notifications to Salt of successful test runs:

```
language: python
script: python -m unittest tests
after_success:
  - |

See also:

* Events & Reactor, reactor

**POST** (*args, **kwargs*)

Fire an event in Salt with a custom event tag and data

**POST /hook**

Status Codes

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available
- **413** -- request body is too large

Example request:

```
curl -sS localhost:8000/hook \
   -H 'Content-type: application/json' \
   -d '{"foo": "Foo!", "bar": "Bar!"}'
```

Example response:

```
HTTP/1.1 200 OK
Content-Length: 14
Content-Type: application/json

{"success": true}
```

As a practical example, an internal continuous-integration build server could send an HTTP POST request to the URL `https://localhost:8000/hook/mycompany/build/success` which contains the result of a build and the SHA of the version that was built as JSON. That would then produce the following event in Salt that could be used to kick off a deployment via Salt’s Reactor:

```
Event fired at Fri Feb 14 17:40:11 2014
```

Salt's Reactor could listen for the event:

```yaml
reactor:
  - 'salt/netapi/hook/mycompany/build/*':
    - /srv/reactor/react_ci_builds.sls
```

And finally deploy the new build:

```python
{% set secret_key = data.get('headers', {}).get('X-My-Secret-Key') %}
{% set build = data.get('post', {}) %}
{% if secret_key == 'F0fAgoQjIT@W' and build.result == True %}
deploy_my_app:
  cmd.state.sls:
    - tgt: 'application*'
    - arg:
      - myapp.deploy
    - kwarg:
      pillar:
        revision: {{ revision }}
{% endif %}
```

### /keys

class `salt.netapi.rest_cherrypy.app.Keys`

Convenience URLs for working with minion keys

New in version 2014.7.0.

These URLs wrap the functionality provided by the `key wheel module` functions.

- **GET** *(mid=None)*
  
  Show the list of minion keys or detail on a specific key

  New in version 2014.7.0.

- **GET /keys/** *(mid)*
  
  List all keys or show a specific key

  **Status Codes**

  - `200` -- success
  - `401` -- authentication required
  - `406` -- requested Content-Type not available

  **Example request:**
curl -i localhost:8000/keys

GET /keys HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml

Example response:

HTTP/1.1 200 OK
Content-Length: 165
Content-Type: application/x-yaml

return:
- local:
  - master.pem
  - master.pub
- minions:
  - jerry
- minions_pre: []
- minions_rejected: []

Example request:

curl -i localhost:8000/keys/jerry

GET /keys/jerry HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml

Example response:

HTTP/1.1 200 OK
Content-Length: 73
Content-Type: application/x-yaml

return:
- minions:

POST (**kwargs)
Easily generate keys for a minion and auto-accept the new key
Accepts all the same parameters as the key.gen_accept.

Example partial kickstart script to bootstrap a new minion:

```
%post
mkdir -p /etc/salt/pki/minion
curl -sSk https://localhost:8000/keys \
  -d mid=jerry \ 
  -d username=kickstart \ 
  -d password=kickstart \ 
  -d eauth=pam \ 
  | tar -C /etc/salt/pki/minion -xf -

mkdir -p /etc/salt/minion.d
printf 'master: 10.0.0.5\nid: jerry' > /etc/salt/minion.d/id.conf
%end
```
**POST /keys**
Generate a public and private key and return both as a tarball
Authentication credentials must be passed in the request.

**Status Codes**
- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

**Example request:**
```
curl -sSk https://localhost:8000/keys
    -d mid=jerry
    -d username=kickstart
    -d password=kickstart
    -d eauth=pam
    -o jerry-salt-keys.tar
```

**Example response:**
```
HTTP/1.1 200 OK
Content-Length: 10240
Content-Disposition: attachment; filename="saltkeys-jerry.tar"
Content-Type: application/x-tar

jerry.pub:00064000000000000000000000000703000000000000000010730 ustarg
```

**/ws**

class `salt.netapi.rest_cherrypy.app.WebsocketEndpoint`
Open a WebSocket connection to Salt's event bus

The event bus on the Salt master exposes a large variety of things, notably when executions are started on the master and also when minions ultimately return their results. This URL provides a real-time window into a running Salt infrastructure. Uses websocket as the transport mechanism.

See also:

* Events & Reactor

**GET**(token=None, **kwargs)**
Return a websocket connection of Salt's event stream

**GET** /ws/**(token)**

Query **format_events** The event stream will undergo server-side formatting if the `format_events` URL parameter is included in the request. This can be useful to avoid formatting on the client-side:
```
curl -NsS <...snip...> localhost:8000/ws?format_events
```

Reqheader **X-Auth-Token** an authentication token from `Login`
Status 101  switching to the websockets protocol  
Status 401  authentication required  
Status 406  requested Content-Type not available

Example request:

```bash
curl -NsSk \
-H 'X-Auth-Token: ffedf49d' \
-H 'Host: localhost:8000' \
-H 'Connection: Upgrade' \
-H 'Upgrade: websocket' \
-H 'Origin: https://localhost:8000' \
-H 'Sec-WebSocket-Version: 13' \
-H 'Sec-WebSocket-Key: "$(echo -n $RANDOM | base64)"' \
localhost:8000/ws
```

Example response:

```
GET /ws HTTP/1.1
Connection: Upgrade  
Upgrade: websocket  
Host: localhost:8000  
Origin: https://localhost:8000  
Sec-WebSocket-Version: 13  
Sec-WebSocket-Key: s65VsgHigh7v/Jcf4nXHnA==  
X-Auth-Token: ffedf49d
```

An authentication token may optionally be passed as part of the URL for browsers that cannot be configured to send the authentication header or cookie:

```bash
curl -Ns <...snip...> localhost:8000/ws/ffedf49d
```

The event stream can be easily consumed via JavaScript:

```javascript
// Note, you must be authenticated!
var source = new WebSocket('ws://localhost:8000/ws/d0ce6c1a');
source.onerror = function(e) { console.debug('error!', e); };
source.onmessage = function(e) { console.debug(e.data); };
source.send('websocket client ready')
source.close();
```

Or via Python, using the Python module websocket-client for example.

```python
# Note, you must be authenticated!
from websocket import create_connection
ws = create_connection('ws://localhost:8000/ws/d0ce6c1a')
ws.send('websocket client ready')
```
Above examples show how to establish a websocket connection to Salt and activating real time updates from Salt's event stream by signaling `websocket client ready`.

### /stats

class salt.netapi.rest_cherrypy.app.Stats

Expose statistics on the running CherryPy server

**GET()**

Return a dump of statistics collected from the CherryPy server

#### GET /stats

**Request Headers**

- **X-Auth-Token** -- a session token from `Login`.
- **Accept** -- the desired response format.

**Response Headers**

- **Content-Type** -- the format of the response body; depends on the `Accept` request header.

**Status Codes**

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

#### 13.7.2 rest_tornado

A Websockets add-on to saltnado

```python
rest_tornado:
    # can be any port
    port: 8000
    ssl_crt: /etc/pki/api/certs/server.crt
    # no need to specify ssl_key if cert and key
    # are in one single file
    ssl_key: /etc/pki/api/certs/server.key
    debug: False
```

In order to enable saltnado_websockets you must add websockets: True to your saltnado config block.
disable_ssl: False
websockets: True

All Events

Exposes all `"real-time"` events from Salt's event bus on a websocket connection. It should be noted that `"Real-
time"` here means these events are made available to the server as soon as any salt related action (changes to minions,
new jobs etc) happens. Clients are however assumed to be able to tolerate any network transport related latencies.
Functionality provided by this endpoint is similar to the `/events` end point.

The event bus on the Salt master exposes a large variety of things, notably when executions are started on the master
and also when minions ultimately return their results. This URL provides a real-time window into a running Salt
infrastructure. Uses websocket as the transport mechanism.

Exposes GET method to return websocket connections. All requests should include an auth token. A way to obtain
obtain authentication tokens is shown below.

```bash
% curl -si localhost:8000/login \
   -H "Accept: application/json" \n   -d username='salt' \n   -d password='salt' \n   -d eauth='pam'
```

Which results in the response

```json
{
   "return": [
       "perms": [".*", "@runner", "@wheel"],
       "start": 1400556492.277421,
       "token": "d0ce6c1a37e99dcc0374392f272fe19c0090cca7",
       "expire": 1400599692.277422,
       "user": "salt",
       "eauth": "pam"
    ]
}
```

In this example the token returned is `d0ce6c1a37e99dcc0374392f272fe19c0090cca7` and can be in-
cluded in subsequent websocket requests (as part of the URL).

The event stream can be easily consumed via JavaScript:

```javascript
// Note, you must be authenticated!

// Get the Websocket connection to Salt
var source = new WebSocket('wss://localhost:8000/all_events/
d0ce6c1a37e99dcc0374392f272fe19c0090cca7');

// Get Salt's "real time" event stream.
source.onopen = function() { source.send('websocket client ready'); };

// Other handlers
source.onerror = function(e) { console.debug('error!', e); };

// e.data represents Salt's "real time" event data as serialized JSON.
source.onmessage = function(e) { console.debug(e.data); };
```

1768 Chapter 13. Salt Module Reference
Or via Python, using the Python module websocket-client for example. Or the tornado client.

```python
# Note, you must be authenticated!

from websocket import create_connection

# Get the Websocket connection to Salt
ws = create_connection('wss://localhost:8000/all_events/
\-d0ce6c1a37e99dce0374392f272fe19c0098ccae7')

# Get Salt's "real time" event stream.
w.send('websocket client ready')

# Simple listener to print results of Salt's "real time" event stream.
# Look at https://pypi.python.org/pypi/websocket-client/ for more examples.
while listening_to_events:
    print ws.recv()  # Salt's "real time" event data as serialized JSON.

# Terminates websocket connection and Salt's "real time" event stream on the server.
ws.close()

# Please refer to https://github.com/liris/websocket-client/issues/81 when using a
\-self signed cert
```

Above examples show how to establish a websocket connection to Salt and activating real time updates from Salt’s event stream by signaling websocket client ready.

**Formatted Events**

Exposes formatted `"real-time"` events from Salt’s event bus on a websocket connection. It should be noted that `"Real-time"` here means these events are made available to the server as soon as any salt related action (changes to minions, new jobs etc) happens. Clients are however assumed to be able to tolerate any network transport related latencies. Functionality provided by this endpoint is similar to the /events end point.

The event bus on the Salt master exposes a large variety of things, notably when executions are started on the master and also when minions ultimately return their results. This URL provides a real-time window into a running Salt infrastructure. Uses websocket as the transport mechanism.

Formatted events parses the raw `"real time"` event stream and maintains a current view of the following:

- minions
- jobs

A change to the minions (such as addition, removal of keys or connection drops) or jobs is processed and clients are updated. Since we use salt's presence events to track minions, please enable presence_events and set a small value for the loop_interval in the salt master config file.

Exposes GET method to return websocket connections. All requests should include an auth token. A way to obtain authentication tokens is shown below.

```bash
% curl -si localhost:8000/login \
-H "Accept: application/json" \
-d username='salt'
```
Which results in the response

```json
{
"return": [{
   "perms": [".*", "@runner", "@wheel"],
   "start": 1400556492.277421,
   "token": "d0ce6c1a37e99dcc0374392f272fe19c0090cca7",
   "expire": 1400599692.277422,
   "user": "salt",
   "eauth": "pam"
}]
}
```

In this example the token returned is d0ce6c1a37e99dcc0374392f272fe19c0090cca7 and can be included in subsequent websocket requests (as part of the URL).

The event stream can be easily consumed via JavaScript:

```javascript
// Note, you must be authenticated!

// Get the Websocket connection to Salt
var source = new WebSocket('wss://localhost:8000/formatted_events/' + 'd0ce6c1a37e99dcc0374392f272fe19c0090cca7');

// Get Salt's "real time" event stream.
source.onopen = function() { source.send('websocket client ready'); };

// Other handlers
source.onerror = function(e) { console.debug('error!', e); };

// e.data represents Salt's "real time" event data as serialized JSON.
source.onmessage = function(e) { console.debug(e.data); };

// Terminates websocket connection and Salt's "real time" event stream on the server.
source.close();
```

Or via Python, using the Python module websocket-client for example. Or the tornado client.

```python
# Note, you must be authenticated!

from websocket import create_connection

# Get the Websocket connection to Salt
ws = create_connection('wss://localhost:8000/formatted_events/' + 'd0ce6c1a37e99dcc0374392f272fe19c0090cca7')

# Get Salt's "real time" event stream.
ws.send('websocket client ready')

# Simple listener to print results of Salt's "real time" event stream.
# Look at https://pypi.python.org/pypi/websocket-client/ for more examples.
while listening_to_events:
    print ws.recv()   # Salt's "real time" event data as serialized JSON.
```
Above examples show how to establish a websocket connection to Salt and activating real time updates from Salt's event stream by signaling websocket client ready.

Example responses

Minion information is a dictionary keyed by each connected minion's id (mid), grains information for each minion is also included.

Minion information is sent in response to the following minion events:

- connection drops
  - requires running manage.present periodically every loop_interval seconds
- minion addition
- minion removal

```python
# Not all grains are shown
data: {
  "minions": {
    "minion1": {
      "id": "minion1",
      "grains": {
        "kernel": "Darwin",
        "domain": "local",
        "zmqversion": "4.0.3",
        "kernelrelease": "13.2.0"
      }
    }
  }
}
```

Job information is also tracked and delivered.

Job information is also a dictionary in which each job's information is keyed by salt's jid.

```python
data: {
  "jobs": {
    "20140609153646699137": {
      "tgt_type": "glob",
      "jid": "20140609153646699137",
      "tgt": "*",
      "start_time": "2014-06-09T15:36:46.700315",
      "state": "complete",
      "fun": "test.ping",
      "minions": {
        "minion1": {
          "return": true,
          "retcode": 0,
          "success": true
        }
      }
    }
  }
}
```

13.7.3 rest_wsgi

A minimalist REST API for Salt

This rest_wsgi module provides a no-frills REST interface for sending commands to the Salt master. There are no dependencies.

Extra care must be taken when deploying this module into production. Please read this documentation in entirety. All authentication is done through Salt's external auth system.

Usage

- All requests must be sent to the root URL (/).
- All requests must be sent as a POST request with JSON content in the request body.
- All responses are in JSON.

See also:

rest_cherrypy

The rest_cherrypy module is more full-featured, production-ready, and has builtin security features.

Deployment

The rest_wsgi netapi module is a standard Python WSGI app. It can be deployed one of two ways.

Using a WSGI-compliant web server

This module may be run via any WSGI-compliant production server such as Apache with mod_wsgi or Nginx with FastCGI.

It is strongly recommended that this app be used with a server that supports HTTPS encryption since raw Salt authentication credentials must be sent with every request. Any apps that access Salt through this interface will need to manually manage authentication credentials (either username and password or a Salt token). Tread carefully.
**salt-api using a development-only server**

If run directly via the salt-api daemon it uses the `wsgiref.simple_server()` that ships in the Python standard library. This is a single-threaded server that is intended for testing and development. **This server does not use encryption; please note that raw Salt authentication credentials must be sent with every HTTP request.**

Running this module via salt-api is not recommended!

In order to start this module via the salt-api daemon the following must be put into the Salt master config:

```
rest_wsgi:
  port: 8001
```

**Usage examples**

**POST /**

Example request for a basic `test.ping`:

```
% curl -sS -i \
  -H 'Content-Type: application/json' \
  -d '[{"eauth":"pam","username":"saltdev","password":"saltdev","client":\n    "local","tgt":"*","fun":"test.ping"}]
```

Example response:

```
HTTP/1.0 200 OK
Content-Length: 89
Content-Type: application/json

{"return": [{"ms--4": true, "ms--3": true, "ms--2": true, "ms--1": true, "ms--0": true}]} }
```

Example request for an asynchronous `test.ping`:

```
% curl -sS -i \
  -H 'Content-Type: application/json' \
  -d '[{"eauth":"pam","username":"saltdev","password":"saltdev","client":\n    "local_async","tgt":"*","fun":"test.ping"}]
```

Example response:

```
HTTP/1.0 200 OK
Content-Length: 103
Content-Type: application/json

{"return": [{"jid": "20130412192112593739", "minions": [{"ms--4": "ms--3", "ms--2": ", "ms--1": ", "ms--0": "true"}]}} }
```

Example request for looking up a job ID:

```
% curl -sS -i \
  -H 'Content-Type: application/json' \
  -d '[{"eauth":"pam","username":"saltdev","password":"saltdev","client":\n    "runner","fun":"jobs.lookup_jid","jid":"20130412192112593739"}]
```

Example response:
HTTP/1.0 200 OK
Content-Length: 89
Content-Type: application/json

{"return": [{"ms--4": true, "ms--3": true, "ms--2": true, "ms--1": true, "ms--0": false}]}

form lowstate  A list of lowstate data appropriate for the client interface you are calling.

status 200  success
status 401  authentication required

13.8.1 salt.output.compact

Display compact output data structure

Example output: `saltdev': {'test_|-always-passes_|-foo_|-succeed_without_changes': {'comment': 'Success!', 'name': 'foo', 'start_time': '05:16:26.118141', 'result': True, 'duration': 1, '__run_num__': 0, 'changes': {}}, 'test_|-my-custom-combo_|-foo_|-configurable_test_state': {'comment': 'bar.baz', 'name': 'foo', 'start_time': '05:16:26.117177', 'result': False, 'duration': 1, '__run_num__': 4, 'changes': {'testing': {'new': 'Something pretended to change', 'old': 'Unchanged'}}}, 'test_|-always-fails_|-foo_|-fail_without_changes': {'comment': 'Failure!', 'name': 'foo', 'start_time': '05:16:26.113244', 'result': False, 'duration': 1, '__run_num__': 1, 'changes': {}}, 'test_|-always-changes-and-succeeds_|-foo_|-succeed_with_changes': {'comment': 'Success!', 'name': 'foo', 'start_time': '05:16:26.114570', 'result': True, 'duration': 0, '__run_num__': 2, 'changes': {'testing': {'new': 'Something pretended to change', 'old': 'Unchanged'}}}, 'test_|-always-changes-and-fails_|-foo_|-fail_with_changes': {'comment': 'Failure!', 'name': 'foo', 'start_time': '05:16:26.115561', 'result': False, 'duration': 1, '__run_num__': 3, 'changes': {'testing': {'new': 'Something pretended to change', 'old': 'Unchanged'}}}},{myminion: {'foo': {'list': ['Hello', 'World'], 'bar': 'baz', 'dictionary': {'abc': 123, 'def': 456}}}}

salt.output.compact.output(data)
   Rather basic....
13.8.2 salt.output.highstate

Outputter for displaying results of state runs

The return data from the Highstate command is a standard data structure which is parsed by the highstate outputter to deliver a clean and readable set of information about the HighState run on minions.

Two configurations can be set to modify the highstate outputter. These values can be set in the master config to change the output of the salt command or set in the minion config to change the output of the salt-call command.

state_verbose: By default state_verbose is set to True, setting this to False will instruct the highstate outputter to omit displaying anything in green, this means that nothing with a result of True and no changes will not be printed

state_output: The highstate outputter has five output modes, full, terse, mixed, changes and filter.

- The default is set to full, which will display many lines of detailed information for each executed chunk.
- If terse is used, then the output is greatly simplified and shown in only one line.
- If mixed is used, then terse output will be used unless a state failed, in which case full output will be used.
- If changes is used, then terse output will be used if there was no error and no changes, otherwise full output will be used.
- If filter is used, then either or both of two different filters can be used: exclude or terse. * for exclude, state.highstate expects a list of states to be excluded
  (or None) followed by True for terse output or False for regular output. Because of parsing nuances, if only one of these is used, it must still contain a comma. For instance:
  exclude=True,
  - for terse, state.highstate expects simply True or False.

  These can be set as such from the command line, or in the Salt config as state_output_exclude or state_output_terse, respectively.

state_tabular: If state_output uses the terse output, set this to True for an aligned output format. If you wish to use a custom format, this can be set to a string.

Example usage:

If state_output: filter is set in the configuration file:

```
salt '*' state.highstate exclude=None,True
```

means to exclude no states from the highstate and turn on terse output.

```
salt twd state.highstate exclude=problemstate1,problemstate2,False
```

means to exclude states problemstate1 and problemstate2 from the highstate, and use regular output.

Example output for the above highstate call when top.sls defines only one other state to apply to minion twd:

```
twd:
Summary for twd
----------
Succeeded: 1 (changed=1)
```
Failed: 0
------------
Total states run: 1

Example output with no special settings in configuration files:

```plaintext
myminion:
----------
  ID: test.ping
  Function: module.run
  Result: True
  Comment: Module function test.ping executed
  Changes:
  ----------
  ret:
    True

Summary for myminion
----------
Succeeded: 1
Failed: 0
------------
Total: 0
```

`salt.output.highstate.output(data)`

The HighState Outputer is only meant to be used with the state.highstate function, or a function that returns highstate return data.

### 13.8.3 salt.output.json_out

Display return data in JSON format

**configuration** The output format can be configured in two ways: Using the `--out-indent` CLI flag and specifying a positive integer or a negative integer to group JSON from each minion to a single line.

Or setting the `output_indent` setting in the Master or Minion configuration file with one of the following values:

- Null: put each minion return on a single line.
- Pretty: use four-space indents and sort the keys.
- An integer: specify the indentation level.

Salt's outputters operate on a per-minion basis. Each minion return will be output as a single JSON object once it comes in to the master.

Some JSON parsers can guess when an object ends and a new one begins but many can not. A good way to differentiate between each minion return is to use the single-line output format and to parse each line individually. Example output (truncated):

```json
{"dave": {"en0": {"hwaddr": "02:b0:26:32:4c:69", ...}}}
{"jerry": {"en0": {"hwaddr": "02:26:ab:0d:b9:0d", ...}}}
{"kevin": {"en0": {"hwaddr": "02:6d:7f:ce:9f:ee", ...}}}
{"mike": {"en0": {"hwaddr": "02:48:a2:4b:70:a0", ...}}}
{"phill": {"en0": {"hwaddr": "02:1d:cc:a2:33:55", ...}}}
{"stuart": {"en0": {"hwaddr": "02:9a:e0:ea:9e:3c", ...}}}
```
salt.output.json_out.output(data)
    Print the output data in JSON

13.8.4 salt.output.key

Display salt-key output

The salt-key command makes use of this outpuer to format its output.

salt.output.key.output(data)
    Read in the dict structure generated by the salt key API methods and print the structure.

13.8.5 salt.output.nested

Recursively display nested data

This is the default outpuer for most execution functions.

Example output:

```plaintext
myminion:
    foo:
        bar:
            baz
dictionary:
    abc: 123
def: 456
list:
    - Hello
    - World
```

class salt.output.nested: :NestDisplay
    Manage the nested display contents

    display(ret, indent, prefix, out)
        Recursively iterate down through data structures to determine output

    ustring(indent, color, msg, prefix='', suffix='', endc=None)

salt.output.nested.output(ret)
    Display ret data

13.8.6 salt.output.newline_values_only

Display values only, separated by newlines

New in version 2015.5.0.

This outpuer is designed for Salt CLI return data. It will do the following to the return dict:
1. Get just the values (ignoring the minion IDs).
2. Each value, if it is iterable, is split a separate line.
3. Each minion's values are separated by newlines.

This results in a single string of return data containing all the values from the various minions.

**Warning:** As noted above, this outputter will discard the minion ID. If the minion ID is important, then an outputter that returns the full return dictionary in a parsable format (such as json, pprint, or yaml) may be more suitable.

**Example 1**

**Input**

```python
{
    'myminion': ['127.0.0.1', '10.0.0.1'],
    'second-minion': ['127.0.0.1', '10.0.0.2']
}
```

**Output**

```
127.0.0.1
10.0.0.1
127.0.0.1
10.0.0.2
```

**Example 2**

**Input**

```python
{
    'myminion': 8,
    'second-minion': 10
}
```

**Output**

```
8
10
```

```python
salt.output.newline_values_only(output(data)
    Display modified ret data
```
13.8.7 salt.output.no_out

Display no output

No output is produced when this outputter is selected

```python
salt.output.no_out.output(ret)
```

Don't display data. Used when you only are interested in the return.

13.8.8 salt.output.no_return

Display output for minions that did not return

This outputter is used to display notices about which minions failed to return when a salt function is run with \-v or \--verbose. It should not be called directly from the CLI.

Example output:

```python
virtucentos:
    Minion did not return
```

```python
class salt.output.no_return.NestDisplay
    Create generator for nested output
    display(ret, indent, prefix, out)
        Recursively iterate down through data structures to determine output
salt.output.no_return.output(ret)
    Display ret data
```

13.8.9 salt.output.overstatestage

Display clean output of an overstate stage

This outputter is used to display OverState stages, and should not be called directly.

```python
salt.output.overstatestage.output(data)
    Format the data for printing stage information from the overstate system
```

13.8.10 salt.output.pprint_out

Python pretty-print (pprint)

The python pretty-print system was once the default outputter. It simply passes the return data through to `pprint.pformat` and prints the results.

Example output:

```python
{'saltmine': {'foo': {'bar': 'baz',
                      'dictionary': {'abc': 123, 'def': 456},
                      'list': ['Hello', 'World']}}}
```

```python
salt.output.pprint_out.output(data)
    Print out via pretty print
```
13.8.11 salt.output.progress

Display return data as a progress bar

salt.output.progress.output(ret, bar)
  Update the progress bar

salt.output.progress.progress_iter(progress)
  Initialize and return a progress bar iter

13.8.12 salt.output.raw

Display raw output data structure

This outputter simply displays the output as a python data structure, by printing a string representation of it. It is similar to the pprint outputter, only the data is not nicely formatted/indented.

This was the original outputter used by Salt before the outputter system was developed.

Example output:

```
{
'myminion': {
'foo': {'list': ['Hello', 'World'], 'bar': 'baz', 'dictionary': {'abc': 123, 'def': 456}}}
}
```

salt.output.raw.output(data)
  Rather basic....

13.8.13 salt.output.txt

Simple text outputter

The txt outputter has been developed to make the output from shell commands on minions appear as they do when the command is executed on the minion.

salt.output.txt.output(data)
  Output the data in lines, very nice for running commands

13.8.14 salt.output.virt_query

virt.query outputter

Used to display the output from the virt.query runner.

salt.output.virt_query.output(data)
  Display output for the salt-run virt.query function

13.8.15 salt.output.yaml_out

Display return data in YAML format

This outputter defaults to printing in YAML block mode for better readability.

Example output:
saltmine:
  foo:
    bar: baz
dictionary:
  abc: 123
def: 456
list:
  - Hello
  - World

`salt.output.yaml_out.output(data)`
Print out YAML using the block mode

13.9 pillar modules

- **cmd_json**
  Execute a command and read the output as JSON.
- **cmd_yaml**
  Execute a command and read the output as YAML.
- **cmd_yamlex**
  Execute a command and read the output as YAMLEX.
- **cobbler**
  A module to pull data from Cobbler via its API into the Pillar dictionary.
- **consul_pillar**
  Use consul data as a Pillar source.
- **django ORM**
  Generate Pillar data from Django models through the Django ORM.
- **ec2_pillar**
  Retrieve EC2 instance data for minions.
- **etcd_pillar**
  Use etcd data as a Pillar source.
- **file_tree**
  `file_tree` is an external pillar that allows
- **foreman**
  A module to pull data from Foreman via its API into the Pillar dictionary.
- **git_pillar**
  Use a git repository as a Pillar source.
- **hg_pillar**
  Use remote Mercurial repository as a Pillar source.
- **hiera**
  Use hiera data as a Pillar source.
- **http_yaml**
  A module that adds data to the Pillar structure retrieved by an http request.
- **libvirt**
  Load up the libvirt keys into Pillar for a given minion if said keys have been
- **mongo**
  Read Pillar data from a mongodb collection.
- **mysql**
  Retrieve Pillar data by doing a MySQL query.
- **neutron**
  Use Openstack Neutron data as a Pillar source.
- **pepa**
  Pepa
- **pillar_ldap**
  Use LDAP data as a Pillar source.
- **puppet**
  Execute an unmodified puppet_node_classifier and read the output as YAML.
- **reclass_adapter**
  Use the `reclass` database as a Pillar source.
- **redismod**
  Read pillar data from a Redis backend.
- **s3**
  Copy pillar data from a bucket in Amazon S3.
- **sql_base**
  Retrieve Pillar data by doing a SQL query.
- **sqlcipher**
  Retrieve Pillar data by running a SQLCipher query.
- **sqlite3**
  Retrieve Pillar data by doing a SQLite3 query.
- **stack**
  Simple and flexible YAML ext_pillar which can read pillar from within pillar.
Table 13.9 -- continued from previous page

<table>
<thead>
<tr>
<th>Pillar</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>svn_pillar</strong></td>
<td>Clone a remote SVN repository and use the filesystem as a Pillar source</td>
</tr>
<tr>
<td><strong>varstack_pillar</strong></td>
<td>Use Varstack data as a Pillar source</td>
</tr>
<tr>
<td><strong>virtkey</strong></td>
<td>Accept a key from a hypervisor if the virt runner has already submitted an authorization request</td>
</tr>
</tbody>
</table>

13.9.1 salt.pillar.cmd_json

Execute a command and read the output as JSON. The JSON data is then directly overlaid onto the minion's Pillar data.

```python
salt.pillar.cmd_json.ext_pillar(minion_id, pillar, command)
```

Execute a command and read the output as JSON

13.9.2 salt.pillar.cmd_yaml

Execute a command and read the output as YAML. The YAML data is then directly overlaid onto the minion's Pillar data

```python
salt.pillar.cmd_yaml.ext_pillar(minion_id, pillar, command)
```

Execute a command and read the output as YAML

13.9.3 salt.pillar.cmd_yamlex

Execute a command and read the output as YAMLEX. The YAMLEX data is then directly overlaid onto the minion's Pillar data

```python
salt.pillar.cmd_yamlex.ext_pillar(minion_id, pillar, command)
```

Execute a command and read the output as YAMLEX

13.9.4 salt.pillar.cobbler

A module to pull data from Cobbler via its API into the Pillar dictionary

Configuring the Cobbler ext_pillar

The same cobbler.* parameters are used for both the Cobbler tops and Cobbler pillar modules.

```
ext_pillar:
  - cobbler:
      key: cobbler # Nest results within this key. By default, values are not nested.
      only: [parameters] # Add only these keys to pillar.

cobbler.url: https://example.com/cobbler_api #default is http://localhost/cobbler_api
cobbler.user: username # default is no username
cobbler.password: password # default is no password
```

13.9. pillar modules
Module Documentation

salt.pillar.cobbler.ext_pillar(minion_id, pillar, key=None, only=())

Read pillar data from Cobbler via its API.

13.9.5 salt.pillar.consul_pillar module

Use consul data as a Pillar source

depends

  • python-consul

In order to use an consul server, a profile must be created in the master configuration file:

```yaml
my_consul_config:
  consul.host: 127.0.0.1
  consul.port: 8500
  consul.token: my_consul_acl_token
```

The consul.token is optional and requires python-consul >= 0.4.7.

After the profile is created, configure the external pillar system to use it. Optionally, a root may be specified.

```yaml
ext_pillar:
  - consul: my_consul_config
ext_pillar:
  - consul: my_consul_config root=/salt
```

Using these configuration profiles, multiple consul sources may also be used:

```yaml
ext_pillar:
  - consul: my_consul_config
  - consul: my_other_consul_config
```

The minion_id may be used in the root path to expose minion-specific information stored in consul.

```yaml
ext_pillar:
  - consul: my_consul_config root=/salt/%(minion_id)s
```

Minion-specific values may override shared values when the minion-specific root appears after the shared root:

```yaml
ext_pillar:
  - consul: my_consul_config root=/salt-shared
  - consul: my_other_consul_config root=/salt-private/%(minion_id)s
```

salt.pillar.consul_pillar.consul_fetch(client, path)

Query consul for all keys/values within base path

salt.pillar.consul_pillar.ext_pillar(minion_id, pillar, conf)

Check consul for all data

salt.pillar.consul_pillar.fetch_tree(client, path)

Grab data from consul, trim base path and remove any keys which are folders. Take the remaining data and send it to be formatted in such a way as to be used as pillar data.

salt.pillar.consul_pillar.get_conn(opts, profile)

Return a client object for accessing consul
salt.pillar.consul_pillar.pillar_format(ret, keys, value)
Perform data formatting to be used as pillar data and merge it with the current pillar data

13.9.6 salt.pillar.django_orm

Generate Pillar data from Django models through the Django ORM

maintainer Micah Hausler <micah.hausler@gmail.com>
maturity new

Configuring the django_orm ext_pillar

To use this module, your Django project must be on the salt master server with database access. This assumes you are using virtualenv with all the project’s requirements installed.

```yaml
ext_pillar:
  - django_orm:
      pillar_name: my_application
      project_path: /path/to/project/
      settings_module: my_application.settings
      env_file: /path/to/env/file.sh
      # Optional: If your project is not using the system python, # add your virtualenv path below.
      env: /path/to/virtualenv/
  
  django_app:
    # Required: the app that is included in INSTALLED_APPS
    my_application.clients:
      # Required: the model name
      Client:
        # Required: model field to use as the key in the rendered
        # Pillar. Must be unique; must also be included in the
        # `fields` list below.
        name: shortname
        # Optional:
        # See Django’s QuerySet documentation for how to use .filter()
        filter: {'kw': 'args'}
        # Required: a list of field names
        # List items will be used as arguments to the .values() method.
        # See Django’s QuerySet documentation for how to use .values()
        fields:
          - field_1
          - field_2
```

This would return pillar data that would look like

```yaml
my_application:
  my_application.clients:
    Client:
      client_1:
        field_1: data_from_field_1
```

13.9. pillar modules
As another example, data from multiple database tables can be fetched using Django's regular lookup syntax. Note, using ManyToManyFields will not currently work since the return from values() changes if a ManyToMany is present.

```
field_2: data_from_field_2
client_2:
  field_1: data_from_field_1
  field_2: data_from_field_2
```

Module Documentation

```python
salt.pillar.django_orm.ext_pillar(minion_id, pillar, pillar_name, project_path, settings_module, django_app, env=None, env_file=None, *args, **kwargs)
```

Connect to a Django database through the ORM and retrieve model fields

**Parameters**

- `pillar_name (str)` -- The name of the pillar to be returned
- `project_path (str)` -- The full path to your Django project (the directory manage.py is in)
- `settings_module (str)` -- The settings module for your project. This can be found in your manage.py file
- `django_app (str)` -- A dictionary containing your apps, models, and fields
- `env (str)` -- The full path to the virtualenv for your Django project
- `env_file (str)` -- An optional bash file that sets up your environment. The file is run in a subprocess and the changed variables are then added

### 13.9.7 salt.pillar.ec2_pillar

Retrieve EC2 instance data for minions.

The minion id must be the instance-id retrieved from AWS. As an option, use_grain can be set to True. This allows the use of an instance-id grain instead of the minion-id. Since this is a potential security risk, the configuration can be further expanded to include a list of minions that are trusted to only allow the alternate id of the instances to specific hosts. There is no glob matching at this time.
ext_pillar:
  - ec2_pillar:
    use_grain: True
    minion_ids:
    - trusted-minion-1
    - trusted-minion-2
    - trusted-minion-3

This is a very simple pillar that simply retrieves the instance data from AWS. Currently the only portion implemented are EC2 tags, which returns a list of key/value pairs for all of the EC2 tags assigned to the instance.

salt.pillar.ec2_pillar.ext_pillar(minion_id, pillar, use_grain=False, minion_ids=None)
  Execute a command and read the output as YAML

13.9.8 salt.pillar.etcd_pillar

Use etcd data as a Pillar source

New in version 2014.7.0.

depends
  • python-etcd

In order to use an etcd server, a profile must be created in the master configuration file:

```
my_etcd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001
```

After the profile is created, configure the external pillar system to use it. Optionally, a root may be specified.

```
ext_pillar:
  - etcd: my_etcd_config

ext_pillar:
  - etcd: my_etcd_config root=/salt
```

Using these configuration profiles, multiple etcd sources may also be used:

```
ext_pillar:
  - etcd: my_etcd_config
  - etcd: my_other_etcd_config
```

The minion_id may be used in the root path to expose minion-specific information stored in etcd.

```
ext_pillar:
  - etcd: my_etcd_config root=/salt/%(minion_id)s
```

Minion-specific values may override shared values when the minion-specific root appears after the shared root:

```
ext_pillar:
  - etcd: my_etcd_config root=/salt-shared
  - etcd: my_other_etcd_config root=/salt-private/%(minion_id)s
```

Using the configuration above, the following commands could be used to share a key with all minions but override its value for a specific minion:
etcdctl set /salt-shared/mykey my_value
etcdctl set /salt-private/special_minion_id/mykey my_other_value

cancel.pillar.etcd_pillar.ext_pillar(minion_id, pillar, conf)
    Check etcd for all data

13.9.9 salt.pillar.file_tree

File_tree is an external pillar that allows values from all files in a directory tree to be imported as Pillar data.

Note this is an external pillar, and is subject to the rules and constraints governing external pillars detailed here: External Pillars.

New in version 2015.5.0.

Example Configuration

```
ext_pillar:
    - file_tree:
        root_dir: /path/to/root/directory
        follow_dir_links: False
        keep_newline: True
```

The root_dir parameter is required and points to the directory where files for each host are stored. The follow_dir_links parameter is optional and defaults to False. If follow_dir_links is set to True, this external pillar will follow symbolic links to other directories.

**Warning:** Be careful when using follow_dir_links, as a recursive symlink chain will result in unexpected results.

If keep_newline is set to True, then the pillar values for files ending in newlines will keep that newline. The default behavior is to remove the end-of-file newline. keep_newline should be turned on if the pillar data is intended to be used to deploy a file using contents_pillar with a file.managed state.

Changed in version 2015.8.4: The raw_data parameter has been renamed to keep_newline. In earlier releases, raw_data must be used. Also, this parameter can now be a list of globs, allowing for more granular control over which pillar values keep their end-of-file newline. The globs match paths relative to the directories named for minion IDs and nodegroups underneath the root_dir (see the layout examples in the below sections).

```
ext_pillar:
    - file_tree:
        root_dir: /path/to/root/directory
        keep_newline:
            - files/testdir/*
```

**Note:** In earlier releases, this documentation incorrectly stated that binary files would not affect the keep_newline configuration. However, this module does not actually distinguish between binary and text files.
Assigning Pillar Data to Individual Hosts

To configure pillar data for each host, this external pillar will recursively iterate over `root_dir/hosts/id` (where `id` is a minion ID), and compile pillar data with each subdirectory as a dictionary key and each file as a value.

For example, the following `root_dir` tree:

```
./hosts/
./hosts/test-host/
./hosts/test-host/files/
./hosts/test-host/files/testdir/
./hosts/test-host/files/testdir/file1.txt
./hosts/test-host/files/testdir/file2.txt
./hosts/test-host/files/another-testdir/
./hosts/test-host/files/another-testdir/symlink-to-file1.txt
```

will result in the following pillar tree for minion with ID `test-host`:

```
test-host:
    ---------
    files:
        ---------
        another-testdir:
            ---------
            symlink-to-file1.txt:
                Contents of file #1.
        testdir:
            ---------
            file1.txt:
                Contents of file #1.
            file2.txt:
                Contents of file #2.
```

Note: Subdirectories underneath `root_dir/hosts/id` become nested dictionaries, as shown above.

Assigning Pillar Data to Entire Nodegroups

To assign Pillar data to all minions in a given nodegroup, this external pillar recursively iterates over `root_dir/nodegroups/nodegroup` (where `nodegroup` is the name of a nodegroup), and like for individual hosts, compiles pillar data with each subdirectory as a dictionary key and each file as a value.

Important: If the same Pillar key is set for a minion both by nodegroup and by individual host, then the value set for the individual host will take precedence.

For example, the following `root_dir` tree:

```
./nodegroups/
./nodegroups/test-group/
./nodegroups/test-group/files/
./nodegroups/test-group/files/testdir/
./nodegroups/test-group/files/testdir/file1.txt
./nodegroups/test-group/files/testdir/file2.txt
```
will result in the following pillar data for minions in the node group test-group:

```yaml
test-host:
    files:
      another-testdir:
        symlink-to-file1.txt:
          Contents of file #1.

      testdir:
        file1.txt:
          Contents of file #1.
        file2.txt:
          Contents of file #2.
```

salt.pillar.file_tree.ext_pillar(minion_id, pillar, root_dir=None, follow_dir_links=False, debug=False, raw_data=None, keep_newline=False)

Compile pillar data for the specified minion ID

### 13.9.10 salt.pillar.foreman

A module to pull data from Foreman via its API into the Pillar dictionary

**Configuring the Foreman ext_pillar**

Set the following Salt config to setup Foreman as external pillar source:

```yaml
ext_pillar:
  - foreman:
      key: foreman # Nest results within this key
      only: ['hostgroup_name', 'parameters'] # Add only these keys to pillar

foreman.url: https://example.com/foreman_api
foreman.user: username # default is admin
foreman.password: password # default is changeme
```

The following options are optional:

```yaml
foreman.api: apiversion # default is 2 (1 is not supported yet)
foreman.verifyssl: False # default is True
foreman.certfile: /etc/ssl/certs/mycert.pem # default is None
foreman.keyfile: /etc/ssl/private/mykey.pem # default is None
foreman.cafile: /etc/ssl/certs/mycert.ca.pem # default is None
foreman.lookup_parameters: True # default is True
```

An alternative would be to use the Foreman modules integrating Salt features in the Smart Proxy and the webinterface.

Further information can be found on GitHub.
Module Documentation

salt.pillar.foreman.ext_pillar(minion_id, pillar, key=None, only=())
Read pillar data from Foreman via its API.

13.9.11 salt.pillar.git_pillar

Use a git repository as a Pillar source

Note: This external pillar has been rewritten for the 2015.8.0 release. The old method of configuring this external pillar will be maintained for a couple releases, allowing time for configurations to be updated to reflect the new usage.

This external pillar allows for a Pillar top file and Pillar SLS files to be sourced from a git repository. However, since git_pillar does not have an equivalent to the pillar_roots parameter, configuration is slightly different. A Pillar top file is required to be in the git repository and must still contain the relevant environment, like so:

```
base:
  '*':
    - foo
```

The branch/tag which maps to that environment must then be specified along with the repo's URL. Configuration details can be found below.

Important: Each branch/tag used for git_pillar must have its own top file. This is different from how the top file works when configuring States. The reason for this is that each git_pillar branch/tag is processed separately from the rest. Therefore, if the qa branch is to be used for git_pillar, it would need to have its own top file, with the qa environment defined within it, like this:

```
qa:
  'dev-*':
    - bar
```

Additionally, while git_pillar allows for the branch/tag to be overridden (see here, or here for Salt releases before 2015.8.0), keep in mind that the top file must reference the actual environment name. It is common practice to make the environment in a git_pillar top file match the branch/tag name, but when remapping, the environment of course no longer matches the branch/tag, and the top file needs to be adjusted accordingly. When expected Pillar values configured in git_pillar are missing, this is a common misconfiguration that may be to blame, and is a good first step in troubleshooting.

Configuring git_pillar for Salt releases before 2015.8.0

For Salt releases earlier than 2015.8.0, GitPython is the only supported provider for git_pillar. Individual repositories can be configured under the ext_pillar configuration parameter like so:

```
ext_pillar:
  - git: master https://gitserver/git-pillar.git root=subdirectory
```
The repository is specified in the format `<branch> <repo_url>`, with an optional root parameter (added in the 2014.7.0 release) which allows the pillar SLS files to be served up from a subdirectory (similar to `gitfs_root` in `gitfs`).

To use more than one branch from the same repo, multiple lines must be specified under `ext_pillar`:

```
ext_pillar:
  - git: master https://gitserver/git-pillar.git
  - git: dev https://gitserver/git-pillar.git
```

To remap a specific branch to a specific Pillar environment, use the format `<branch>:<env>`:

```
ext_pillar:
  - git: develop:dev https://gitserver/git-pillar.git
  - git: master:prod https://gitserver/git-pillar.git
```

In this case, the develop branch would need its own `top.sls` with a dev section in it, like this:

```
dev:
  '*':
    - bar
```

The master branch would need its own `top.sls` with a prod section in it:

```
prod:
  '*':
    - bar
```

If `__env__` is specified as the branch name, then `git_pillar` will first look at the minion's `environment` option. If unset, it will fall back to using the branch specified by the master's `gitfs_base`:

```
ext_pillar:
  - git: __env__ https://gitserver/git-pillar.git root=pillar
```

The corresponding Pillar top file would look like this:

```
{{env}}:
  '*':
    - bar
```

**Note:** This feature was unintentionally omitted when `git_pillar` was rewritten for the 2015.8.0 release. It was added again in the 2016.3.4 release, but it has changed slightly in that release. On Salt masters running 2015.8.0 through 2016.3.3, this feature can only be accessed using the legacy config described above. For 2016.3.4 and later, refer to explanation of the `__env__` parameter in the below section.

Versions 2016.3.0 through 2016.3.4 incorrectly check the master's `environment` config option (instead of the minion's) before falling back to `gitfs_base`. This has been fixed in the 2016.3.5 and 2016.11.1 releases (2016.11.0 contains the incorrect behavior).

**Configuring git_pillar for Salt releases 2015.8.0 and later**

**Note:** In version 2015.8.0, the method of configuring git external pillars has changed, and now more closely resembles that of the `Git Fileserver Backend`. If Salt detects the old configuration schema, it will use the pre-2015.8.0 code.
to compile the external pillar. A warning will also be logged.

Beginning with Salt version 2015.8.0, pygit2 is now supported in addition to GitPython (Dulwich will not be supported for the foreseeable future). The requirements for GitPython and pygit2 are the same as for gitfs, as described here.

Important: git_pillar has its own set of global configuration parameters. While it may seem intuitive to use the global gitfs configuration parameters (gitfs_base, etc.) to manage git_pillar, this will not work. The main difference for this is the fact that the different components which use Salt's git backend code do not all function identically. For instance, in git_pillar it is necessary to specify which branch/tag to be used for git_pillar remotes. This is the reverse behavior from gitfs, where branches/tags make up your environments.

See here for documentation on the git_pillar configuration options and their usage.

Here is an example git_pillar configuration:

```
ext_pillar:
  - git:
      # Use 'prod' instead of the branch name 'production' as the environment
      # Use 'dev' instead of the branch name 'develop' as the environment
      # No per-remote config parameters (and no trailing colon), 'qa' will be used as the environment
      # SSH key authentication
      - master git@other-git-server:pillardata-ssh.git:
        # Pillar SLS files will be read from the 'pillar' subdirectory in this repository
        - root: pillar
        - privkey: /path/to/key
        - pubkey: /path/to/key.pub
        - passphrase: CorrectHorseBatteryStaple
      # HTTPS authentication
      - master https://other-git-server/pillardata-https.git:
        - user: git
        - password: CorrectHorseBatteryStaple
```

The main difference between this and the old way of configuring git_pillar is that multiple remotes can be configured under one git section under ext_pillar. More than one git section can be used, but it is not necessary. Remotes will be evaluated sequentially.

Per-remote configuration parameters are supported (similar to gitfs), and global versions of the git_pillar configuration parameters can also be set. To remap a specific branch to a specific Pillar environment, use the env per-remote parameter:

```
ext_pillar:
  - git:
      - production https://gitserver/git-pillar.git:
        - env: prod
```

If __env__ is specified as the branch name, then git_pillar will use the branch specified by git_pillar_base:
ext_pillar:
  - git:
    - __env__ https://gitserver/git-pillar.git:
    - root: pillar

The corresponding Pillar top file would look like this:

```yaml
{{env}}:
  '*':
    - bar
```

Note: This feature was unintentionally omitted when git_pillar was rewritten for the 2015.8.0 release. It was added again in the 2016.3.4 release, but it has changed slightly in that release. The fallback value replaced by {{env}} is :conf_master: is git_pillar_base, while the legacy config's version of this feature replaces {{env}} with gitfs_base.

On Salt masters running 2015.8.0 through 2016.3.3, this feature can only be accessed using the legacy config in the previous section of this page.

The same issue which affected the behavior of the minion's environment config value using the legacy configuration syntax (see the documentation in the pre-2015.8.0 section above for the legacy support of this feature) also affects the new-style git_pillar syntax in version 2016.3.4. This has been corrected in version 2016.3.5 and 2016.11.1 (2016.11.0 contains the incorrect behavior).

2016.3.4 incorrectly checks the master's environment config option (instead of the minion's) before falling back to the master's git_pillar_base.

With the addition of pygit2 support, git_pillar can now interact with authenticated remotes. Authentication works just like in gitfs (as outlined in the Git Fileserver Backend Walkthrough), only with the global authentication parameter names prefixed with git_pillar instead of gitfs (e.g. git_pillar_pubkey, git_pillar_privkey, git_pillar_passphrase, etc.).

Note: The name parameter can be used to further differentiate between two remotes with the same URL and branch. When using two remotes with the same URL, the name option is required.

salt.pillar.git_pillar.ext_pillar(minion_id, repo, pillar_dirs)

Checkout the ext_pillar sources and compile the resulting pillar SLS

13.9.12 salt.pillar.hg_piller

Use remote Mercurial repository as a Pillar source.

New in version 2015.8.0.

The module depends on the hglib python module being available. This is the same requirement as for hgfs_ so should not pose any extra hurdles.

This external Pillar source can be configured in the master config file as such:

```python
ext_pillar:
  - hg: ssh://hg@example.co/user/repo
```

class salt.pillar.hg_pillar.Repo(repo_uri)

Deal with remote hg (mercurial) repository for Pillar
**close()**

Cleanup mercurial command server

**pull()**

**update(branch='default')**

Ensure we are using the latest revision in the hg repository

```python
salt.pillar.hg_pillar.ext_pillar(minion_id, pillar, repo, branch='default', root=None)
```

Extract pillar from an hg repository

```python
salt.pillar.hg_pillar.update(repo_uri)
```

Execute an hg pull on all the repos

### 13.9.13 salt.pillar.hiera

Use hiera data as a Pillar source

```python
salt.pillar.hiera.ext_pillar(minion_id, pillar, conf)
```

Execute hiera and return the data

### 13.9.14 salt.pillar.http_yaml module

A module that adds data to the Pillar structure retrieved by an http request

**Configuring the HTTP_YAML ext_pillar**

Set the following Salt config to setup Foreman as external pillar source:

```yaml
ext_pillar:
  - http_yaml:
      url: http://example.com/api/minion_id
      username: username
      password: password
```

**Module Documentation**

```python
salt.pillar.http_yaml.ext_pillar(minion_id, pillar, url=None)
```

Read pillar data from HTTP response.

:param url String to make request :returns dict with pillar data to add :returns empty if error

### 13.9.15 salt.pillar.libvirt

Load up the libvirt keys into Pillar for a given minion if said keys have been generated using the libvirt key runner

**depends** certtool

```python
salt.pillar.libvirt.ext_pillar(minion_id, pillar, command)
```

Read in the generated libvirt keys
salt.pillar.libvirt.gen_hyper_keys(minion_id, country='US', state='Utah', locality='Salt Lake City', organization='Salted')

Generate the keys to be used by libvirt hypervisors, this routine gens the keys and applies them to the pillar for the hypervisor minions

13.9.16 salt.pillar.mongo

Read Pillar data from a mongodb collection

depends pymongo (for salt-master)

This module will load a node-specific pillar dictionary from a mongo collection. It uses the node's id for lookups and can load either the whole document, or just a specific field from that document as the pillar dictionary.

Salt Master Mongo Configuration

The module shares the same base mongo connection variables as salt.returners.mongo_return. These variables go in your master config file.

- mongo.db - The mongo database to connect to. Defaults to 'salt'.
- mongo.host - The mongo host to connect to. Supports replica sets by specifying all hosts in the set, comma-delimited. Defaults to 'salt'.
- mongo.port - The port that the mongo database is running on. Defaults to 27017.
- mongo.user - The username for connecting to mongo. Only required if you are using mongo authentication. Defaults to ''.
- mongo.password - The password for connecting to mongo. Only required if you are using mongo authentication. Defaults to ''.

Configuring the Mongo ext_pillar

The Mongo ext_pillar takes advantage of the fact that the Salt Master configuration file is yaml. It uses a sub-dictionary of values to adjust specific features of the pillar. This is the explicit single-line dictionary notation for yaml. One may be able to get the easier-to-read multi-line dict to work correctly with some experimentation.

```
ext_pillar:
  - mongo: {collection: vm, id_field: name, re_pattern: \.example\..com, fields: [customer_id, software, apache_vhosts]}
```

In the example above, we've decided to use the vm collection in the database to store the data. Minion ids are stored in the name field on documents in that collection. And, since minion ids are FQDNs in most cases, we'll need to trim the domain name in order to find the minion by hostname in the collection. When we find a minion, return only the customer_id, software, and apache_vhosts fields, as that will contain the data we want for a given node. They will be available directly inside the pillar dict in your SLS templates.

Module Documentation

salt.pillar.mongo.ext_pillar(minion_id, pillar, collection='pillar', id_field='id', re_pattern=None, re_replace=':', fields=None)

Connect to a mongo database and read per-node pillar information.

Parameters:
- collection: The mongodb collection to read data from. Defaults to 'pillar'.
• **id_field**: The field in the collection that represents an individual minion id. Defaults to '._id'.

• **re_pattern**: If your naming convention in the collection is shorter than the minion id, you can use this to trim the name. *re_pattern* will be used to match the name, and *re_replace* will be used to replace it. Backrefs are supported as they are in the Python standard library. If *None*, no mangling of the name will be performed - the collection will be searched with the entire minion id. Defaults to *None*.

• **re_replace**: Use as the replacement value in node ids matched with *re_pattern*. Defaults to `''. Feel free to use backreferences here.

• **fields**: The specific fields in the document to use for the pillar data. If *None*, will use the entire document. If using the entire document, the _id field will be converted to string. Be careful with other fields in the document as they must be string serializable. Defaults to *None*.

### 13.9.17 salt.pillar.mysql

Retrieve Pillar data by doing a MySQL query

MariaDB provides Python support through the MySQL Python package. Therefore, you may use this module with both MySQL or MariaDB.

This module is a concrete implementation of the sql_base ext_pillar for MySQL.

```
maturity  new
depends  python-mysqldb
platform  all
```

#### Configuring the mysql ext_pillar

Use the 'mysql' key under ext_pillar for configuration of queries.

MySQL configuration of the MySQL returner is being used (mysql.db, mysql.user, mysql.pass, mysql.port, mysql.host) for database connection info.

Required python modules: MySQLdb

#### Complete example

```python
mysql:
  user: 'salt'
  pass: 'super_secret_password'
  db: 'salt_db'

ext_pillar:
  - mysql:
      fromdb:
        query: '
          SELECT col1,col2,col3,col4,col5,col6,col7
          FROM some_random_table
          WHERE minion_pattern LIKE %s'
        depth: 5
        as_list: True
        with_lists: [1,3]
```

class salt.pillar.mysql.MySQLExtPillar

This class receives and processes the database rows from MySQL.
**extract_queries**(args, kwargs)

This function normalizes the config block into a set of queries we can use. The return is a list of consistently laid out dicts.

salt.pillar.mysql.ext_pillar(minion_id, pillar, *args, **kwargs)

Execute queries against MySQL, merge and return as a dict

### 13.9.18 salt.pillar.neutron module

Use Openstack Neutron data as a Pillar source. Will list all networks listed inside of Neutron, to all minions.

New in version 2015.5.1.

**depends**

- `python-neutronclient`

A keystone profile must be used for the pillar to work (no generic keystone configuration here). For example:

```yaml
my_openstack_config:
  keystone.user: 'admin'
  keystone.password: 'password'
  keystone.tenant: 'admin'
  keystone.auth_url: 'http://127.0.0.1:5000/v2.0/
  keystone.region_name: 'RegionOne'
  keystone.service_type: 'network'
```

After the profile is created, configure the external pillar system to use it.

```yaml
ext_pillar:
  - neutron: my_openstack_config
```

Using these configuration profiles, multiple neutron sources may also be used:

```yaml
ext_pillar:
  - neutron: my_openstack_config
  - neutron: my_other_openstack_config
```

By default, these networks will be returned as a pillar item called `networks`. In order to have them returned under a different name, add the name after the Keystone profile name:

```yaml
ext_pillar:
  - neutron: my_openstack_config neutron_networks
```

salt.pillar.neutron.ext_pillar(minion_id, pillar, conf)

Check neutron for all data

### 13.9.19 salt.pillar.pepa

Pepa

Configuration templating for SaltStack using Hierarchical substitution and Jinja.
Configuring Pepa

```yaml
extension_modules: /srv/salt/ext

ext_pillar:
  - pepa:
      resource: host
      sequence:
        - hostname:
            name: input
            base_only: True
      staging:
        - default:
          - environment:
            - location..region:
                name: region
            - location..country:
                name: country
            - location..datacenter:
                name: datacenter
            - roles:
              - osfinger:
                  name: os
              - hostname:
                  name: override
                  base_only: True
      subkey: True
      subkey_only: True
      resource in this case [host]
      untouched

pepa_roots:
  base: /srv/pepa/base
  dev: /srv/pepa/base
  qa: /srv/pepa/qa
  prod: /srv/pepa/prod

# Use a different delimiter for nested dictionaries, defaults to '..' since some keys may use '
#pepa_delimiter: ..

# Supply Grains for Pepa, this should **ONLY** be used for testing or validation
#pepa_grains:
#  environment: dev

# Supply Pillar for Pepa, this should **ONLY** be used for testing or validation
#pepa_pillars:
#  saltversion: 0.17.4

# Enable debug for Pepa, and keep Salt on warning
#log_level: debug

#log_granular_levels:
#  salt: warning
#  salt.loaded.ext.pillar.pepa: debug
```

Pepa can also be used in Master-less SaltStack setup.
Command line

positional arguments:
  hostname              Hostname

optional arguments:
  -h, --help             show this help message and exit
  -c CONFIG, --config CONFIG   Configuration file
  -d, --debug             Print debug info
  -g GRAINS, --grains GRAINS  Input Grains as YAML
  -p PILLAR, --pillar PILLAR  Input Pillar as YAML
  -n, --no-color          No color output
  -v, --validate          Validate output

Templates

Templates is configuration for a host or software, that can use information from Grains or Pillars. These can then be used for hierarchically substitution.

Example File: host/input/test_example_com.yaml

```yaml
location..region: emea
location..country: nl
location..datacenter: foobar
environment: dev
roles:
  - salt.master
network..gateway: 10.0.0.254
network..interfaces..eth0..hwaddr: 00:20:26:a1:12:12
network..interfaces..eth0..dhcp: False
network..interfaces..eth0..ipv4: 10.0.0.3
network..interfaces..eth0..netmask: 255.255.255.0
network..interfaces..eth0..fqdn: {{ hostname }}
cobbler..profile: fedora-19-x86_64
```

As you see in this example you can use Jinja directly inside the template.

Example File: host/region/amer.yaml

```yaml
network..dns..servers:
  - 10.0.0.1
  - 10.0.0.2
time..ntp..servers:
  - ntp1.amer.example.com
  - ntp2.amer.example.com
  - ntp3.amer.example.com
time..timezone: America/Chihuahua
yum..mirror: yum.amer.example.com
```

Each template is named after the value of the key using lowercase and all extended characters are replaced with underscore.
Example:

omfinger: Fedora-19

Would become:

fedora_19.yaml

**Nested dictionaries**

In order to create nested dictionaries as output you can use double dot `"."` as a delimiter. You can change this using `"pepa_delimiter"` we choose double dot since single dot is already used by key names in some modules, and using `";"` requires quoting in the YAML.

Example:

```yaml
network..dns..servers:
  - 10.0.0.1
  - 10.0.0.2

network..dns..options:
  - timeout:2
  - attempts:1
  - ndots:1

network..dns..search:
  - example.com
```

Would become:

```yaml
network:
  dns:
    servers:
      - 10.0.0.1
      - 10.0.0.2
    options:
      - timeout:2
      - attempts:1
      - ndots:1
    search:
      - example.com
```

**Operators**

Operators can be used to merge/unset a list/hash or set the key as immutable, so it can’t be changed.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>merge()</td>
<td>Merge list or hash</td>
</tr>
<tr>
<td>unset()</td>
<td>Unset key</td>
</tr>
<tr>
<td>immutable()</td>
<td>Set the key as immutable, so it can’t be changed</td>
</tr>
<tr>
<td>imerge()</td>
<td>Set immutable and merge</td>
</tr>
<tr>
<td>iunset()</td>
<td>Set immutable and unset</td>
</tr>
</tbody>
</table>

Example:

```yaml
network..dns..search..merge():
  - foobar.com
  - dummy.nl
```
Validation

Since it’s very hard to test Jinja as is, the best approach is to run all the permutations of input and validate the output, i.e. Unit Testing.

To facilitate this in Pepa we use YAML, Jinja and Cerberus <https://github.com/nicolaiarocci/cerberus>.

Schema

So this is a validation schema for network configuration, as you see it can be customized with Jinja just as Pepa templates.

This was designed to be run as a build job in Jenkins or similar tool. You can provide Grains/Pillar input using either the config file or command line arguments.

File Example: host/validation/network.yaml

```yaml
network..dns..search:
  type: list
  allowed:
    - example.com

network..dns..options:
  type: list
  allowed: ['timeout:2', 'attempts:1', 'ndots:1']

network..dns..servers:
  type: list
  schema:
    regex: ^([0-9]{1,3}\.)\{3\}[0-9]{1,3}$

network..gateway:
  type: string
  regex: ^([0-9]{1,3}\.)\{3\}[0-9]{1,3}$

{% if network.interfaces is defined %}
{% for interface in network.interfaces %}

network..interfaces..{{ interface }}..dhcp:
  type: boolean

network..interfaces..{{ interface }}..fqdn:
  type: string
  regex: ^([a-z0-9]([a-z0-9-]{0,61}[a-z0-9])?\.)+[a-zA-Z]{2,6}$

network..interfaces..{{ interface }}..hwaddr:
  type: string
  regex: ^([0-9a-f]{1,2}:){5}[0-9a-f]{1,2}$

network..interfaces..{{ interface }}..ipv4:
  type: string
  regex: ^([0-9]{1,3}\.)\{3\}[0-9]{1,3}$

{% endfor %}
{% endif %}
```
network..interfaces..{{ interface }}..netmask:
  type: string
  regex: ^([0-9]{1,3}.){3}[0-9]{1,3}$

{% endfor %}
{% endif %}

**Links**

For more examples and information see <https://github.com/mickep76/pepa>.

**salt.pillar.pepa.ext_pillar**(minion_id, pillar, resource, sequence, subkey=False, subkey_only=False)

Evaluate Pepa templates

**salt.pillar.pepa.key_value_to_tree**(data)

Convert key/value to tree

**salt.pillar.pepa.validate**(output, resource)

Validate Pepa templates

### 13.9.20 salt.pillar.pillar_ldap

Use LDAP data as a Pillar source

This pillar module executes a series of LDAP searches. Data returned by these searches are aggregated, whereby data returned by later searches override data by previous searches with the same key.

The final result is merged with existing pillar data.

The configuration of this external pillar module is done via an external file which provides the actual configuration for the LDAP searches.

**Configuring the LDAP ext_pillar**

The basic configuration is part of the master configuration.

```
ext_pillar:
  - pillar_ldap: /etc/salt/master.d/pillar_ldap.yaml
```

**Note:** When placing the file in the master.d directory, make sure its name doesn't end in .conf, otherwise the salt-master process will attempt to parse its content.

**Warning:** Make sure this file has very restrictive permissions, as it will contain possibly sensitive LDAP credentials!

The only required key in the master configuration is pillar_ldap pointing to a file containing the actual configuration.
Configuring the LDAP searches

The file is processed using Salt’s Renderers `<renderers>` which makes it possible to reference grains within the configuration.

**Warning:** When using Jinja in this file, make sure to do it in a way which prevents leaking sensitive information. A rogue minion could send arbitrary grains to trick the master into returning secret data. Use only the `id` grain which is verified through the minion’s key/cert.

**Map Mode**

The `it-admins` configuration below returns the Pillar `it-admins` by:

- filtering for:
  - members of the group `it-admins`
  - objects with `objectclass=user`
- returning the data of users (mode: map), where each user is a dictionary containing the configured string or list attributes.

**Configuration:**

```
salt-users:
  server: ldap.company.tld
  port: 389
  tls: true
  dn: 'dc=company,dc=tld'
  binddn: 'cn=salt-pillars,ou=users,dc=company,dc=tld'
  bindpw: bi7ieBai5Ano
  referrals: false
  anonymous: false
  mode: map
  dn: 'ou=users,dc=company,dc=tld'
  filter: '(&(memberof=cn=it-admins,ou=groups,dc=company,dc=tld)(objectclass=user))'
  attrs:
    - cn
    - displayName
    - givenName
    - sn
  lists:
    - memberOf

**Result:**

```
- cn: cn=johndoe,ou=users,dc=company,dc=tld
displayName: John Doe
givenName: John
sn: Doe
memberOf:
  - cn=it-admins,ou=groups,dc=company,dc=tld
  - cn=team01,ou=groups,dc=company
- cn: cn=janedoe,ou=users,dc=company,dc=tld
```
List Mode

TODO: see also _result_to_dict() documentation

salt.pillar.pillar_ldap.ext_pillar(minion_id, pillar, config_file)
   Execute LDAP searches and return the aggregated data

13.9.21 salt.pillar.puppet

Execute an unmodified puppet_node_classifier and read the output as YAML. The YAML data is then directly overlaid onto the minion's Pillar data.

salt.pillar.puppet.ext_pillar(minion_id, pillar, command)
   Execute an unmodified puppet_node_classifier and read the output as YAML

13.9.22 salt.pillar.reclass_adapter

Use the `reclass` database as a Pillar source

This ext_pillar plugin provides access to the reclass database, such that Pillar data for a specific minion are fetched using reclass.

You can find more information about reclass at http://reclass.pantsfullofunix.net.

To use the plugin, add it to the ext_pillar list in the Salt master config and tell reclass by way of a few options how and where to find the inventory:

```yaml
ext_pillar:
  - reclass:
      storage_type: yaml_fs
      inventory_base_uri: /srv/salt
```

This would cause reclass to read the inventory from YAML files in /srv/salt/nodes and /srv/salt/classes.

If you are also using reclass as master_tops plugin, and you want to avoid having to specify the same information for both, use YAML anchors (take note of the differing data types for ext_pillar and master_tops):

```yaml
reclass: &reclass
  storage_type: yaml_fs
  inventory_base_uri: /srv/salt
  reclass_source_path: ~/code/reclass

ext_pillar:
  - reclass: !reclass

master_tops:
  reclass: !reclass
```

13.9. pillar modules
If you want to run reclass from source, rather than installing it, you can either let the master know via the PYTHON-PATH environment variable, or by setting the configuration option, like in the example above.

```python
salt.pillar.reclass_adapter.ext_pillar(minion_id, pillar, **kwargs)
```

Obtain the Pillar data from reclass for the given minion_id.

### 13.9.23 salt.pillar.redismod

**Read pillar data from a Redis backend**

New in version 2014.7.0.

```text
    depends
        • redis Python module (on master)
```

**Salt Master Redis Configuration**

The module shares the same base Redis connection variables as `salt.returners.redis_return`. These variables go in your master config file.

- **redis.db** - The Redis database to use. Defaults to 0.
- **redis.host** - The Redis host to connect to. Defaults to 'salt'.
- **redis.port** - The port that the Redis database is listening on. Defaults to 6379.
- **redis.password** - The password for authenticating with Redis. Only required if you are using master auth. Defaults to None.

**Configuring the Redis ext_pillar**

```python
def ext_pillar:
    - redis: {function: key_value}
```

```python
salt.pillar.redismod.ext_pillar(minion_id, pillar, **kwargs)
```

Grabs external pillar data based on configured function

```python
salt.pillar.redismod.key_json(minion_id, pillar, pillar_key=None)
```

Pulls a string from redis and deserializes it from json. Deserialized dictionary data loaded directly into top level if pillar_key is not set.

- **pillar_key** - Pillar key to return data into

```python
salt.pillar.redismod.key_value(minion_id, pillar, pillar_key='redis_pillar')
```

Looks for key in redis matching minion_id, returns a structure based on the data type of the redis key. String for string type, dict for hash type and lists for lists, sets and sorted sets.

- **pillar_key** - Pillar key to return data into

### 13.9.24 salt.pillar.s3

**Copy pillar data from a bucket in Amazon S3**

The S3 pillar can be configured in the master config file with the following options
The `bucket` parameter specifies the target S3 bucket. It is required.

The `keyid` parameter specifies the key id to use when access the S3 bucket. If it is not provided, an attempt to fetch it from EC2 instance meta-data will be made.

The `key` parameter specifies the key to use when access the S3 bucket. If it is not provided, an attempt to fetch it from EC2 instance meta-data will be made.

The `multiple_env` defaults to False. It specifies whether the pillar should interpret top level folders as pillar environments (see mode section below).

The `environment` defaults to `base`. It specifies which environment the bucket represents when in single environments mode (see mode section below). It is ignored if multiple_env is True.

The `prefix` defaults to `. It specifies a key prefix to use when searching for data in the bucket for the pillar. It works when multiple_env is True or False. Essentially it tells ext_pillar to look for your pillar data in a `subdirectory` of your S3 bucket

The `verify_ssl` parameter defaults to True. It specifies whether to check for valid S3 SSL certificates. NOTE If you use bucket names with periods, this must be set to False else an invalid certificate error will be thrown (issue #12200).

The `service_url` parameter defaults to `s3.amazonaws.com`. It specifies the base url to use for accessing S3.

The `kms_keyid` parameter is optional. It specifies the ID of the Key Management Service (KMS) master key that was used to encrypt the object.

The `s3_cache_expire` parameter defaults to 30s. It specifies expiration time of S3 metadata cache file.

The `s3_sync_on_update` parameter defaults to True. It specifies if cache is synced on update rather than jit.

This pillar can operate in two modes, single environment per bucket or multiple environments per bucket.

Single environment mode must have this bucket structure:

```
s3://<bucket name>/<prefix>/<files>
```

Multiple environment mode must have this bucket structure:

```
s3://<bucket name>/<prefix>/<environment>/<files>
```

If you wish to define your pillar data entirely within S3 it’s recommended that you use the `prefix=` parameter and specify one entry in ext_pillar for each environment rather than specifying multiple_env. This is due to issue #22471 (https://github.com/saltstack/salt/issues/22471)

```
class salt.pillar.s3.S3Credentials(key, keyid, bucket, service_url, verify_ssl=True, kms_keyid=None, location=None)
```

13.9. pillar modules
salt.pillar.s3.ext_pillar(minion_id, pillar, bucket, key=None, keyid=None, verify_ssl=True, location=None, multiple_env=False, environment='base', prefix='`, service_url=None, kms_keyid=None, s3_cache_expire=30, s3_sync_on_update=True)

Execute a command and read the output as YAML

## 13.9.25 salt.pillar.sql_base module

Retrieve Pillar data by doing a SQL query

This module is not meant to be used directly as an ext_pillar. It is a place to put code common to PEP 249 compliant SQL database adapters. It exposes a python ABC that can be subclassed for new database providers.

- **maturity**: new
- **platform**: all

### Theory of sql_base ext_pillar

Ok, here's the theory for how this works...

- First, any non-keyword args are processed in order.
- Then, remaining keywords are processed.

We do this so that it's backward compatible with older configs. Keyword arguments are sorted before being appended, so that they're predictable, but they will always be applied last so overall it's moot.

For each of those items we process, it depends on the object type:

- Strings are executed as is and the pillar depth is determined by the number of fields returned.
- A list has the first entry used as the query, the second as the pillar depth.
- A mapping uses the keys `query` and `depth` as the tuple

You can retrieve as many fields as you like, how they get used depends on the exact settings.

### Configuring a sql_base ext_pillar

The sql_base ext_pillar cannot be used directly, but shares query configuration with its implementations. These examples use a fake `sql_base` adapter, which should be replaced with the name of the adapter you are using.

A list of queries can be passed in

```yaml
ext_pillar:
  - sql_base:
    - SELECT pillar, value FROM pillars WHERE minion_id = %s
    - SELECT pillar, value FROM more_pillars WHERE minion_id = %s
```

Or you can pass in a mapping

```yaml
ext_pillar:
  - sql_base:
    main: "SELECT pillar, value FROM pillars WHERE minion_id = %s"
    extras: "SELECT pillar, value FROM more_pillars WHERE minion_id = %s"
```

The query can be provided as a string as we have just shown, but they can be provided as lists.
Or as a mapping

```yaml
ext_pillar:
  - sql_base:
    - query: "SELECT pillar,value FROM pillars WHERE minion_id = %s"
    depth: 2
```

The depth defines how the dicts are constructed. Essentially if you query for fields `a,b,c,d` for each row you’ll get:

- With depth 1: `{a: {`b': b, `c': c, `d': d}}
- With depth 2: `{a: {`c': c, `d': d}}
- With depth 3: `{a: `{c: c, `d': d}}}

Depth greater than 3 wouldn’t be different from 3 itself. Depth of 0 translates to the largest depth needed, so 3 in this case. (max depth == key count - 1)

Then they are merged in a similar way to plain pillar data, in the order returned by the SQL database.

Thus subsequent results overwrite previous ones when they collide.

The ignore_null option can be used to change the overwrite behavior so that only non-NULL values in subsequent results will overwrite. This can be used to selectively overwrite default values.

```yaml
ext_pillar:
  - sql_base:
    - query: "SELECT pillar,value FROM pillars WHERE minion_id = 'default' and minion_id != %s"
    depth: 2
    - query: "SELECT pillar,value FROM pillars WHERE minion_id = %s"
    depth: 2
    ignore_null: True
```

If you specify `as_list: True` in the mapping expression it will convert collisions to lists.

If you specify `with_lists: `...` in the mapping expression it will convert the specified depths to list. The string provided is a sequence numbers that are comma separated. The string `1,3` will result in:

```yaml
a,b,c,d,e,1 # field 1 same, field 3 differs
a,b,c,f,g,2 # ^^^^  
a,z,h,y,j,3 # field 1 same, field 3 same
a,z,h,y,k,4 # ^^^^ ^
```

These columns define list grouping

```python
{a: [
    {c: [
        {e: 1},
        {g: 2}
    ],
    {h: [
        {j: 3, k: 4 }
    ]
```
The range for with_lists is 1 to number_of_fields, inclusive. Numbers outside this range are ignored.

Finally, if you pass the queries in via a mapping, the key will be the first level name where as passing them in as a list will place them in the root. This isolates the query results into their own subtrees. This may be a help or hindrance to your aims and can be used as such.

You can basically use any SELECT query that gets you the information, you could even do joins or subqueries in case your minion_id is stored elsewhere. It is capable of handling single rows or multiple rows per minion.

Configuration of the connection depends on the adapter in use.

**More complete example for MySQL (to also show configuration)**

```
mysql:
  user: 'salt'
  pass: 'super_secret_password'
  db: 'salt_db'

ext_pillar:
  - mysql:
      fromdb:
        query: 'SELECT col1,col2,col3,col4,col5,col6,col7
                  FROM some_random_table
                  WHERE minion_pattern LIKE %s'
        depth: 5
        as_list: True
        with_lists: [1,3]
```

class salt.pillar.sql_base.SqlBaseExtPillar

This class receives and processes the database rows in a database agnostic way.

**as_list** = False

**depth** = 0

**enter_root**(root)
Set self.focus for kwarg queries

**extract_queries**(args, kwargs)
This function normalizes the config block into a set of queries we can use. The return is a list of consistently laid out dicts.

**fetch**(minion_id, pillar, *args, **kwargs)
Execute queries, merge and return as a dict.

**field_names** = None

**focus** = None

**ignore_null** = False

**num_fields** = 0

**process_fields**(field_names, depth)
The primary purpose of this function is to store the sql field list and the depth to which we process.
**process_results**(*rows*)

This function takes a list of database results and iterates over, merging them into a dict form.

```python
result = None
with_lists = None
```

## 13.9.26 salt.pillar.sqlcipher module

Retrieve Pillar data by running a SQLCipher query

New in version 2016.3.0.

Python SQLCipher support is provided by the pysqlcipher Python package. You need this module installed to query Pillar data from a SQLCipher database.

This module is a concrete implementation of the sql_base ext_pillar for SQLCipher.

```ini
maturity = new
depends = pysqlcipher
platform = all
```

### Configuring the sqlcipher ext_pillar

Use the `sqlcipher` key under ext_pillar for configuration of queries.

SQLCipher database connection configuration requires the following values configured in the master config:

- `sqlcipher.database` - The SQLCipher database to connect to. Defaults to `'/var/lib/salt/pillar-sqlcipher.db'`.
- `sqlcipher.pass` - The SQLCipher database decryption password.
- `sqlcipher.timeout` - The connection timeout in seconds.

Example configuration

```
salt:
  database: /var/lib/salt/pillar-sqlcipher.db
  pass: strong_pass_phrase
  timeout: 5.0
```

### Complete example

```
salt:
  database: '/var/lib/salt/pillar-sqlcipher.db'
  pass: strong_pass_phrase
  timeout: 5.0

ext_pillar:
  - sqlcipher:
    fromdb:
      query: '
SELECT col1, col2, col3, col4, col5, col6, col7
FROM some_random_table
WHERE minion_pattern LIKE ?'
      depth: 5
```
class salt.pillar.sqlcipher.SQLCipherExtPillar
    This class receives and processes the database rows from SQLCipher.
salt.pillar.sqlcipher.ext_pillar(minion_id, pillar, *args, **kwargs)
    Execute queries against SQLCipher, merge and return as a dict

### 13.9.27 salt.pillar.sqlite3 module
Retrieve Pillar data by doing a SQLite3 query
New in version 2015.8.0.
sqlite3 is included in the stdlib since Python 2.5.
This module is a concrete implementation of the sql_base ext_pillar for SQLite3.

```python
    platform  all
```

#### Configuring the sqlite3 ext_pillar
Use the `sqlite3` key under ext_pillar for configuration of queries.
SQLite3 database connection configuration requires the following values configured in the master config:
Note, timeout is in seconds.

```python
    sqlite3.database: /var/lib/salt/pillar.db
    sqlite3.timeout: 5.0
```

#### Legacy Compatibility
SQLite3 database connection configuration previously had keys under pillar.

```python
    pillar.sqlite3.database: /var/lib/salt/pillar.db
    pillar.sqlite3.timeout: 5.0
```

This has been deprecated in 2016.3.0 and will be removed in Salt Nitrogen.

#### Complete Example

```python
    sqlite3:
        database: '/var/lib/salt/pillar.db'
        timeout: 5.0
    ext_pillar:
        - sqlite3:
            fromdb: 
                query: 'SELECT col1,col2,col3,col4,col5,col6,col7
                       FROM some_random_table
                       WHERE minion_pattern LIKE ?'
            depth: 5
```
class salt.pillar.sqlite3.SQLite3ExtPillar
    This class receives and processes the database rows from SQLite3.

salt.pillar.sqlite3.ext_pillar(minion_id, pillar, *args, **kwargs)
    Execute queries against SQLite3, merge and return as a dict

13.9.28 salt.pillar.stack

Simple and flexible YAML ext_pillar which can read pillar from within pillar.

New in version 2016.3.0.

PillarStack is a custom saltstack ext_pillar which was inspired by varstack but is heavily based on Jinja2 for maximum flexibility.

Any issue should be reported to the upstream project at: https://github.com/bbinet/pillarstack/issues

It supports the following features:

- multiple config files that are jinja2 templates with support for pillar, __grains__, __salt__, __opts__ objects
- a config file renders as an ordered list of files (paths of these files are relative to the current config file)
- this list of files are read in ordered as jinja2 templates with support for stack, pillar, __grains__, __salt__, __opts__ objects
- all these rendered files are then parsed as yaml
- then all yaml dicts are merged in order with support for the following merging strategies: merge-first, merge-last, remove, and overwrite
- stack config files can be matched based on pillar, grains, or opts values, which make it possible to support kind of self-contained environments

Installation

PillarStack is already bundled with Salt since 2016.3.0 version so there is nothing to install from version 2016.3.0.

If you use an older Salt version or you want to override PillarStack with a more recent one, follow the installation procedure below.

Installing the PillarStack ext_pillar is as simple as dropping the stack.py file in the <extension_modules>/pillar directory (no external python module required), given that extension_modules is set in your salt-master configuration, see: http://docs.saltstack.com/en/latest/ref/configuration/master.html#extension-modules

Configuration in Salt

Like any other external pillar, its configuration takes place through the ext_pillar key in the master config file. However, you can configure PillarStack in 3 different ways:
Single config file

This is the simplest option, you just need to set the path to your single PillarStack config file like below:

```
ext_pillar:
  - stack: /path/to/stack.cfg
```

List of config files

You can also provide a list of config files:

```
ext_pillar:
  - stack:
    - /path/to/stack1.cfg
    - /path/to/stack2.cfg
```

Select config files through grains|pillar|opts matching

You can also opt for a much more flexible configuration: PillarStack allows one to select the config files for the current minion based on matching values from either grains, or pillar, or opts objects.

Here is an example of such a configuration, which should speak by itself:

```
ext_pillar:
  - stack:
    pillar:environment:
      dev: /path/to/dev/stack.cfg
      prod: /path/to/prod/stack.cfg
    grains:custom:grain:
      value:
        - /path/to/stack1.cfg
        - /path/to/stack2.cfg
    opts:custom:opt:
      value: /path/to/stack0.cfg
```

PillarStack configuration files

The config files that are referenced in the above ext_pillar configuration are jinja2 templates which must render as a simple ordered list of yaml files that will then be merged to build pillar data.

The path of these yaml files must be relative to the directory of the PillarStack config file.

The following variables are available in jinja2 templating of PillarStack configuration files:

- `pillar`: the pillar data (as passed by Salt to our ext_pillar function)
- `minion_id`: the minion id ;-)
- `__opts__`: a dictionary of mostly Salt configuration options
- `__grains__`: a dictionary of the grains of the minion making this pillar call
- `__salt__`: a dictionary of Salt module functions, useful so you don’t have to duplicate functions that already exist (note: runs on the master)
So you can use all the power of jinja2 to build your list of yaml files that will be merged in pillar data.

For example, you could have a PillarStack config file which looks like:

```bash
$ cat /path/to/stack/config.cfg
core.yml
osarchs/{{ __grains__['osarch'] }}.yml
oscodenames/{{ __grains__['oscodename'] }}.yml
{% for role in pillar.get('roles', []) %}
roles/{{ role }}.yml
{% endfor %}
minions/{{ minion_id }}.yml
```

And the whole directory structure could look like:

```bash
$ tree /path/to/stack/
/path/to/stack/
    ├── config.cfg
    ├── core.yml
    │    └── osarchs/
    │        ├── amd64.yml
    │        └── armhf.yml
    │    └── oscodenames/
    │        ├── wheezy.yml
    │        └── jessie.yml
    │    └── roles/
    │        ├── web.yml
    │        └── db.yml
    └── minions/
        ├── test-1-dev.yml
        └── test-2-dev.yml
```

**Overall process**

In the above PillarStack configuration, given that test-1-dev minion is an amd64 platform running Debian Jessie, and which pillar roles is ["db"], the following yaml files would be merged in order:

- `core.yml`
- `osarchs/amd64.yml`
- `oscodenames/jessie.yml`
- `roles/db.yml`
- `minions/test-1-dev.yml`

Before merging, every files above will be preprocessed as Jinja2 templates. The following variables are available in Jinja2 templating of yaml files:

- `stack`: the PillarStack pillar data object that has currently been merged (data from previous yaml files in PillarStack configuration)
- `pillar`: the pillar data (as passed by Salt to our `ext_pillar` function)
- `minion_id`: the minion id ;-)  
- `__opts__`: a dictionary of mostly Salt configuration options
• __grains__: a dictionary of the grains of the minion making this pillar call
• __salt__: a dictionary of Salt module functions, useful so you don’t have to duplicate functions that already exist (note: runs on the master)

So you can use all the power of jinja2 to build your pillar data, and even use other pillar values that has already been merged by PillarStack (from previous yaml files in PillarStack configuration) through the stack variable.

Once a yaml file has been preprocessed by Jinja2, we obtain a Python dict - let's call it yaml_data - then, PillarStack will merge this yaml_data dict in the main stack dict (which contains already merged PillarStack pillar data). By default, PillarStack will deeply merge yaml_data in stack (similarly to the recurse salt pillar_source_merging_strategy), but 3 merging strategies are currently available for you to choose (see next section).

Once every yaml files have been processed, the stack dict will contain your whole own pillar data, merged in order by PillarStack. So PillarStack ext_pillar returns the stack dict, the contents of which Salt takes care to merge in with all of the other pillars and finally return the whole pillar to the minion.

### Merging strategies

The way the data from a new yaml_data dict is merged with the existing stack data can be controlled by specifying a merging strategy. Right now this strategy can either be merge-last (the default), merge-first, remove, or overwrite.

Note that scalar values like strings, integers, booleans, etc. are always evaluated using the overwrite strategy (other strategies don't make sense in that case).

The merging strategy can be set by including a dict in the form of:

```
__: <merging strategy>
```

as the first item of the dict or list. This allows fine grained control over the merging process.

**merge-last (default) strategy**

If the merge-last strategy is selected (the default), then content of dict or list variables is merged recursively with previous definitions of this variable (similarly to the recurse salt pillar_source_merging_strategy). This allows for extending previously defined data.

**merge-first strategy**

If the merge-first strategy is selected, then the content of dict or list variables are swapped between the yaml_data and stack objects before being merged recursively with the merge-last previous strategy.

**remove strategy**

If the remove strategy is selected, then content of dict or list variables in stack are removed only if the corresponding item is present in the yaml_data dict. This allows for removing items from previously defined data.

**overwrite strategy**

If the overwrite strategy is selected, then the content of dict or list variables in stack is overwritten by the content of yaml_data dict. So this allows one to overwrite variables from previous definitions.
Merging examples

Let's go through small examples that should clarify what's going on when a `yaml_data` dict is merged in the `stack` dict.

When you don't specify any strategy, the default `merge-last` strategy is selected:

<table>
<thead>
<tr>
<th>stack</th>
<th>yaml_data</th>
<th>stack (after merge)</th>
</tr>
</thead>
<tbody>
<tr>

<td>uid: 0</td>
<td></td>
</tr>
</tbody>
</table>

Then you can select a custom merging strategy using the `__` key in a dict:
You can also select a custom merging strategy using a `__` object in a list:
### 13.9.29 `salt.pillar.svn_pillar`

Clone a remote SVN repository and use the filesystem as a Pillar source.

This external Pillar source can be configured in the master config file like so:

```yaml
ext_pillar:
  - svn: trunk svn://svnserver/repo root=subdirectory
```

The `root=` parameter is optional and used to set the subdirectory from where to look for Pillar files (such as `top.sls`).

Changed in version 2014.7.0: The optional `root` parameter will be added.

Note that this is not the same thing as configuring pillar data using the `pillar_roots` parameter. The branch referenced in the `ext_pillar` entry above (`master`), would evaluate to the `base` environment, so this branch needs to contain a `top.sls` with a `base` section in it, like this:

```yaml
base:
  '*':
    - foo
```

To use other environments from the same SVN repo as `svn_pillar` sources, just add additional lines, like so:

```yaml
ext_pillar:
  - svn: trunk svn://svnserver/repo
  - svn: dev svn://svnserver/repo
```

In this case, the `dev` branch would need its own `top.sls` with a `dev` section in it, like this:

```yaml
dev:
  '*':
    - bar
```
class `salt.pillar.svn_pillar.SvnPillar(branch, repo_location, root, opts)`
Deal with the remote SVN repository for Pillar

    pillar_dir()
    Returns the directory of the pillars (repo cache + branch + root)

    update()

`salt.pillar.svn_pillar.ext_pillar(minion_id, pillar, repo_string)`
Execute a command and read the output as YAML

### 13.9.30 `salt.pillar.varstack_pillar`

Use Varstack data as a Pillar source

#### Configuring Varstack

Using varstack in Salt is fairly simple. Just put the following into the config file of your master:

```
ext_pillar:
  - varstack: /etc/varstack.yaml
```

Varstack will then use `/etc/varstack.yaml` to determine which configuration data to return as pillar information. From there you can take a look at the README of varstack on how this file is evaluated.

`salt.pillar.varstack_pillar.ext_pillar(minion_id, pillar, conf)`
Parse varstack data and return the result

### 13.9.31 `salt.pillar.virtkey`

Accept a key from a hypervisor if the virt runner has already submitted an authorization request

`salt.pillar.virtkey.ext_pillar(hyper_id, pillar, name, key)`
Accept the key for the VM on the hyper, if authorized.

### 13.10 Proxy Modules

1820 Chapter 13. Salt Module Reference
13.10.1 salt.proxy.chronos module

Chronos

Proxy minion for managing a Chronos cluster.

Dependencies

- chronos execution module (salt.modules.chronos)

Pillar

The chronos proxy configuration requires a `base_url' property that points to the chronos endpoint:

```
proxy:
  proxysend: chronos
  base_url: http://my-chronos-master.mydomain.com:4400
```

New in version 2015.8.2.

salt.proxy.chronos.init(opts)

Perform any needed setup.

salt.proxy.chronos.ping()

Is the chronos api responding?

salt.proxy.chronos.shutdown(opts)

For this proxy shutdown is a no-op

13.10.2 salt.proxy.esxi

Proxy Minion interface module for managing VMWare ESXi hosts.

New in version 2015.8.4.

Special Note: SaltStack thanks Adobe Corporation for their support in creating this Proxy Minion integration.

This proxy minion enables VMware ESXi (hereafter referred to as simply 'ESXi') hosts to be treated individually like a Salt Minion.

Since the ESXi host may not necessarily run on an OS capable of hosting a Python stack, the ESXi host can't run a Salt Minion directly. Salt's "Proxy Minion" functionality enables you to designate another machine to host a minion process that "proxies" communication from the Salt Master. The master does not know nor care that the target is not a "real" Salt Minion.

More in-depth conceptual reading on Proxy Minions can be found in the Proxy Minion section of Salt's documentation.

Dependencies

- pyVmomi Python Module
- ESXCLI
**pyVmomi**

PyVmomi can be installed via pip:

```
pip install pyVmomi
```

**Note:** Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, Python 2.6, Python 2.7.9, or newer must be present. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the following:

```
pip install pyVmomi==5.5.0.2014.1.1
```

The 5.5.0.2014.1.1 is a known stable version that this original ESXi State Module was developed against.

**ESXCLI**

Currently, about a third of the functions used in the vSphere Execution Module require the ESXCLI package be installed on the machine running the Proxy Minion process.

The ESXCLI package is also referred to as the VMware vSphere CLI, or vCLI. VMware provides vCLI package installation instructions for vSphere 5.5 and vSphere 6.0.

Once all of the required dependencies are in place and the vCLI package is installed, you can check to see if you can connect to your ESXi host or vCenter server by running the following command:

```
esxcli -s <host-location> -u <username> -p <password> system syslog config get
```

If the connection was successful, ESXCLI was successfully installed on your system. You should see output related to the ESXi host's syslog configuration.

**Configuration**

To use this integration proxy module, please configure the following:

**Pillar**

Proxy minions get their configuration from Salt’s Pillar. Every proxy must have a stanza in Pillar and a reference in the Pillar top-file that matches the ID. At a minimum for communication with the ESXi host, the pillar should look like this:

```
proxy:
  proxitype: esxi
  host: <ip or dns name of esxi host>
  username: <ESXi username>
  passwords:
    - first_password
    - second_password
    - third_password
```
**proxytype**

The **proxytype** key and value pair is critical, as it tells Salt which interface to load from the **proxy** directory in Salt’s install hierarchy, or from `/srv/salt/_proxy` on the Salt Master (if you have created your own proxy module, for example). To use this ESXi Proxy Module, set this to `esxi`.

**host**

The location, or ip/dns, of the ESXi host. Required.

**username**

The username used to login to the ESXi host, such as `root`. Required.

**passwords**

A list of passwords to be used to try and login to the ESXi host. At least one password in this list is required.

The proxy integration will try the passwords listed in order. It is configured this way so you can have a regular password and the password you may be updating for an ESXi host either via the `vsphere.update_host_password` execution module function or via the `esxi.password_present` state function. This way, after the password is changed, you should not need to restart the proxy minion—it should just pick up the the new password provided in the list. You can then change pillar at will to move that password to the front and retire the unused ones.

This also allows you to use any number of potential fallback passwords.

**Note:** When a password is changed on the host to one in the list of possible passwords, the further down on the list the password is, the longer individual commands will take to return. This is due to the nature of pyVmomi’s login system. We have to wait for the first attempt to fail before trying the next password on the list.

This scenario is especially true, and even slower, when the proxy minion first starts. If the correct password is not the first password on the list, it may take up to a minute for `test.ping` to respond with a `True` result. Once the initial authorization is complete, the responses for commands will be a little faster.

To avoid these longer waiting periods, SaltStack recommends moving the correct password to the top of the list and restarting the proxy minion at your earliest convenience.

**protocol**

If the ESXi host is not using the default protocol, set this value to an alternate protocol. Default is `https`.

**port**

If the ESXi host is not using the default port, set this value to an alternate port. Default is `443`.
Salt Proxy

After your pillar is in place, you can test the proxy. The proxy can run on any machine that has network connectivity to your Salt Master and to the ESXi host in question. SaltStack recommends that the machine running the salt-proxy process also run a regular minion, though it is not strictly necessary.

On the machine that will run the proxy, make sure there is an /etc/salt/proxy file with at least the following in it:

```
master: <ip or hostname of salt-master>
```

You can then start the salt-proxy process with:

```
salt-proxy --proxyid <id you want to give the host>
```

You may want to add `-l debug` to run the above in the foreground in debug mode just to make sure everything is OK.

Next, accept the key for the proxy on your salt-master, just like you would for a regular minion:

```
salt-key -a <id you gave the esxi host>
```

You can confirm that the pillar data is in place for the proxy:

```
salt <id> pillar.items
```

And now you should be able to ping the ESXi host to make sure it is responding:

```
salt <id> test.ping
```

At this point you can execute one-off commands against the host. For example, you can get the ESXi host’s system information:

```
salt <id> esxi.cmd system_info
```

Note that you don’t need to provide credentials or an ip/hostname. Salt knows to use the credentials you stored in Pillar.

It’s important to understand how this particular proxy works. `Salt.modules.vsphere` is a standard Salt execution module. If you pull up the docs for it you’ll see that almost every function in the module takes credentials and a target host. When credentials and a host aren’t passed, Salt runs commands through `pyVmomi` against the local machine. If you wanted, you could run functions from this module on any host where an appropriate version of `pyVmomi` is installed, and that host would reach out over the network and communicate with the ESXi host.

`esxi.cmd` acts as a ‘shim’ between the execution module and the proxy. Its first parameter is always the function from `salt.modules.vsphere`. If the function takes more positional or keyword arguments you can append them to the call. It’s this shim that speaks to the ESXi host through the proxy, arranging for the credentials and hostname to be pulled from the Pillar section for this Proxy Minion.

Because of the presence of the shim, to lookup documentation for what functions you can use to interface with the ESXi host, you’ll want to look in `salt.modules.vsphere` instead of `salt.modules.esxi`.

States

Associated states are thoroughly documented in `salt.states.esxi`. Look there to find an example structure for Pillar as well as an example `.sls` file for standing up an ESXi host from scratch.
salt.proxy.esxi.ch_config(cmd, *args, **kwargs)
This function is called by the salt.modules.esxi.cmd shim. It then calls whatever is passed in cmd inside the salt.modules.vsphere module. Passes the return through from the vsphere module.

- **cmd** The command to call inside salt.modules.vsphere
- **args** Arguments that need to be passed to that command.
- **kwargs** Keyword arguments that need to be passed to that command.

salt.proxy.esxi.find_credentials(host)
Cycle through all the possible credentials and return the first one that works.

salt.proxy.esxi.grains()
Get the grains from the proxy device.

salt.proxy.esxi.grains_refresh()
Refresh the grains from the proxy device.

salt.proxy.esxi.init(opts)
This function gets called when the proxy starts up. For ESXi devices, the host, login credentials, and, if configured, the protocol and port are cached.

salt.proxy.esxi.ping()
Check to see if the host is responding. Returns False if the host didn't respond, True otherwise.

    CLI Example:
    salt esxi-host test.ping

salt.proxy.esxi.shutdown()
Shutdown the connection to the proxy device. For this proxy, shutdown is a no-op.

13.10.3 salt.proxy.fx2

Dell FX2 chassis

New in version 2015.8.2.

Proxy minion interface module for managing Dell FX2 chassis (Dell Chassis Management Controller version 1.2 and above, iDRAC8 version 2.00 and above)

Dependencies

- iDRAC Remote execution module (salt.modules.dracr)
- Chassis command shim (salt.modules.chassis)
- Dell Chassis States (salt.states.dellchassis)
- Dell's racadm command line interface to CMC and iDRAC devices.

Special Note: SaltStack thanks Adobe Corporation for their support in creating this proxy minion integration.

This proxy minion enables Dell FX2 and FX2s (hereafter referred to as simply "chassis", "CMC", or "FX2") chassis to be treated individually like a salt-minion.

Since the CMC embedded in the chassis does not run an OS capable of hosting a Python stack, the chassis can't run a minion directly. Salt's "Proxy Minion" functionality enables you to designate another machine to host a minion process that "proxies" communication from the salt-master. The master does not know nor care that the target is not a real minion.
More in-depth conceptual reading on Proxy Minions can be found in the Proxy Minion section of Salt's documentation.

To configure this integration, follow these steps:

**Pillar**

Proxy minions get their configuration from Salt's Pillar. Every proxy must have a stanza in Pillar, and a reference in the Pillar topfile that matches the ID. At a minimum for communication with the chassis the pillar should look like this:

```yaml
proxy:
  host: <ip or dns name of chassis controller>
  admin_username: <iDRAC username for the CMC, usually 'root'>
  fallback_admin_username: <username to try if the first fails>
  passwords:
    - first_password
    - second_password
    - third_password
  proxytype: fx2
```

The `proxytype` line above is critical, it tells Salt which interface to load from the `proxy` directory in Salt's install hierarchy, or from `/srv/salt/_proxy` on the salt-master (if you have created your own proxy module, for example).

The proxy integration will try the passwords listed in order. It is configured this way so you can have a regular password, a potential fallback password, and the third password can be the one you intend to change the chassis to use. This way, after it is changed, you should not need to restart the proxy minion--it should just pick up the third password in the list. You can then change pillar at will to move that password to the front and retire the unused ones.

Beware, many Dell CMC and iDRAC units are configured to lockout IP addresses or users after too many failed password attempts. This can generate user panic in the form of "I no longer know what the password is!!". To mitigate panic try the web interface from a different IP, or setup a emergency administrator user in the CMC before doing a wholesale password rotation.

The automatic lockout can be disabled via Salt with the following:

```bash
salt <cmc> chassis.cmd set_general cfgRacTuning cfgRacTuneIpBlkEnable 0
```

and then verified with

```bash
salt <cmc> chassis.cmd get_general cfgRacTuning cfgRacTuneIpBlkEnable
```

**salt-proxy**

After your pillar is in place, you can test the proxy. The proxy can run on any machine that has network connectivity to your salt-master and to the chassis in question. SaltStack recommends that this machine also run a regular minion, though it is not strictly necessary.

On the machine that will run the proxy, make sure there is an `/etc/salt/proxy` file with at least the following in it:

```plaintext
master: <ip or hostname of salt-master>
```

You can start the proxy with
You may want to add `-l debug` to run the above in the foreground in debug mode just to make sure everything is OK.

Next, accept the key for the proxy on your salt-master, just like you would for a regular minion:

```bash
salt-key -a <id you want to give the chassis>
```

You can confirm that the pillar data is in place for the proxy:

```bash
salt <id> pillar.items
```

And now you should be able to ping the chassis to make sure it is responding:

```bash
salt <id> test.ping
```

At this point you can execute one-off commands against the chassis. For example, you can get the chassis inventory:

```bash
salt <id> chassis.cmd inventory
```

Note that you don't need to provide credentials or an ip/hostname. Salt knows to use the credentials you stored in Pillar.

It's important to understand how this particular proxy works. `Salt.modules.dracr` is a standard Salt execution module. If you pull up the docs for it you'll see that almost every function in the module takes credentials and a target host. When credentials and a host aren't passed, Salt runs `racadm` against the local machine. If you wanted you could run functions from this module on any host where an appropriate version of `racadm` is installed, and that host would reach out over the network and communicate with the chassis.

`Chassis.cmd` acts as a ``` shim`` between the execution module and the proxy. It's first parameter is always the function from `salt.modules.dracr` to execute. If the function takes more positional or keyword arguments you can append them to the call. It's this shim that speaks to the chassis through the proxy, arranging for the credentials and hostname to be pulled from the pillar section for this proxy minion.

Because of the presence of the shim, to lookup documentation for what functions you can use to interface with the chassis, you'll want to look in `salt.modules.dracr` instead of `salt.modules.chassis`.

**States**

Associated states are thoroughly documented in `salt.states.dellchassis`. Look there to find an example structure for pillar as well as an example .sls file for standing up a Dell Chassis from scratch.

`salt.proxy.fx2.admin_password()`

Return the admin_password in the DETAILS dictionary, or `calvin` (the Dell default) if there is none present

`salt.proxy.fx2.admin_username()`

Return the admin_username in the DETAILS dictionary, or root if there is none present

`salt.proxy.fx2.chconfig(cmd, *args, **kwargs)`

This function is called by the `salt.modules.chassis.cmd` shim. It then calls whatever is passed in `cmd` inside the `salt.modules.dracr` module.

**Parameters**

- `cmd` -- The command to call inside `salt.modules.dracr`
- `args` -- Arguments that need to be passed to that command
- `kwargs` -- Keyword arguments that need to be passed to that command
Returns Passthrough the return from the dracr module.

`salt.proxy.fx2.find_credentials()`  
Cycle through all the possible credentials and return the first one that works

`salt.proxy.fx2.grains()`  
Get the grains from the proxied device

`salt.proxy.fx2.grains_refresh()`  
Refresh the grains from the proxied device

`salt.proxy.fx2.host()`

`salt.proxy.fx2.init(opts)`  
This function gets called when the proxy starts up. We check opts to see if a fallback user and password are supplied. If they are present, and the primary credentials don't work, then we try the backup before failing.

Whichever set of credentials works is placed in the persistent DETAILS dictionary and will be used for further communication with the chassis.

`salt.proxy.fx2.ping()`  
Is the chassis responding?  
Returns Returns False if the chassis didn't respond, True otherwise.

`salt.proxy.fx2.shutdown(opts)`  
Shutdown the connection to the proxied device. For this proxy shutdown is a no-op.

### 13.10.4 `salt.proxy.junos`

Interface with a Junos device via proxy-minion.

`salt.proxy.junos.conn()`

`salt.proxy.junos.facts()`

`salt.proxy.junos.id(opts)`  
Returns a unique ID for this proxy minion

`salt.proxy.junos.init(opts)`  
Open the connection to the Junos device, login, and bind to the Resource class

`salt.proxy.junos.ping()`  
Ping? Pong!

`salt.proxy.junos.proxytype()`  
Returns the name of this proxy

`salt.proxy.junos.refresh()`

`salt.proxy.junos.rpc()`

`salt.proxy.junos.shutdown(opts)`  
This is called when the proxy-minion is exiting to make sure the connection to the device is closed cleanly.

### 13.10.5 `salt.proxy.marathon module`

Marathon

Proxy minion for managing a Marathon cluster.
Dependencies

- marathon execution module (salt.modules.marathon)

Pillar

The marathon proxy configuration requires a `base_url' property that points to the marathon endpoint:

```
proxy:
    proxytype: marathon
    base_url: http://my-marathon-master.mydomain.com:8080
```

New in version 2015.8.2.

```
salt.proxy.marathon.init(opts)
    Perform any needed setup.
	salt.proxy.marathon.ping()
    Is the marathon api responding?
	salt.proxy.marathon.shutdown(opts)
    For this proxy shutdown is a no-op
```

13.10.6 salt.proxy.philips_hue module

Philips HUE lamps module for proxy.

New in version 2015.8.3.

```
class salt.proxy.philips_hue.Const
    Constants for the lamp operations.
        COLOR_BLUE = {'hue': 46920, 'sat': 254}
        COLOR_DAYLIGHT = {'xy': [0.3806, 0.3576]}
        COLOR_GREEN = {'hue': 25500, 'sat': 254}
        COLOR_ORANGE = {'hue': 12000, 'sat': 254}
        COLOR_PINK = {'xy': [0.3688, 0.2095]}
        COLOR_PURPLE = {'xy': [0.3787, 0.1724]}
        COLOR_RED = {'hue': 0, 'sat': 254}
        COLOR_WHITE = {'xy': [0.3227, 0.329]}
        COLOR_YELLOW = {'xy': [0.4432, 0.5154]}
        LAMP_OFF = {'transitiontime': 0, 'on': False}
        LAMP_ON = {'transitiontime': 0, 'on': True}
	salt.proxy.philips_hue.call_alert(*args, **kwargs)
    Lamp alert
        Options:
            • id: Specifies a device ID. Can be a comma-separated values. All, if omitted.
            • on: Turns on or off an alert. Default is True.

CLI Example:
```

13.10. proxy modules
```python
salt '*' hue.alert
salt '*' hue.alert id=1
salt '*' hue.alert id=1,2,3 on=false
```

```
salt.proxy.philsips_hue.call_blink(*args, **kwargs)
Blink a lamp. If lamp is ON, then blink ON-OFF-ON, otherwise OFF-ON-OFF.

Options:
- **id**: Specifies a device ID. Can be a comma-separated values. All, if omitted.
- **pause**: Time in seconds. Can be less than 1, i.e. 0.7, 0.5 sec.

CLI Example:
```python
salt '*' hue.blink id=1
salt '*' hue.blink id=1,2,3
```

```
salt.proxy.philsips_hue.call_brightness(*args, **kwargs)
Set an effect to the lamp.

Arguments:
- **value**: 0~255 brightness of the lamp.

Options:
- **id**: Specifies a device ID. Can be a comma-separated values. All, if omitted.
- **transition**: Transition 0~200. Default 0.

CLI Example:
```python
salt '*' hue.brightness value=100
salt '*' hue.brightness id=1 value=150
salt '*' hue.brightness id=1,2,3 value=255
```

```
salt.proxy.philsips_hue.call_color(*args, **kwargs)
Set a color to the lamp.

Options:
- **id**: Specifies a device ID. Can be a comma-separated values. All, if omitted.
- **color**: Fixed color. Values are: red, green, blue, orange, pink, white, yellow, daylight, purple. Default white.
- **transition**: Transition 0~200.

Advanced:
- **gamut**: XY coordinates. Use gamut according to the Philips HUE devices documentation. More: http://www.developers.meethue.com/documentation/hue-xy-values

CLI Example:
```python
salt '*' hue.color
salt '*' hue.color id=1
salt '*' hue.color id=1,2,3 color=red transition=30
salt '*' hue.color id=1 gamut=0.3,0.5
```

```
salt.proxy.philsips_hue.call_effect(*args, **kwargs)
Set an effect to the lamp.

Options:
- **id**: Specifies a device ID. Can be a comma-separated values. All, if omitted.
- **type**: Type of the effect. Possible values are ```"none"``` or ```"colorloop"```. Default ```"none"```.

CLI Example:
```
Salt Documentation, Release 2016.3.6

```python
salt '*' hue.effect
salt '*' hue.effect id=1
salt '*' hue.effect id=1,2,3 type=colorloop
```

```
salt.proxy.philips_hue.call_lights(*args, **kwargs)
Get info about all available lamps.

Options:
• id: Specifies a device ID. Can be a comma-separated values. All, if omitted.

CLI Example:
```
salt '*' hue.lights
salt '*' hue.lights id=1
salt '*' hue.lights id=1,2,3
```

```
salt.proxy.philips_hue.call_ping(*args, **kwargs)
Ping the lamps by issuing a short inversion blink to all available devices.

CLI Example:
```
salt '*' hue.ping
```

```
salt.proxy.philips_hue.call_rename(*args, **kwargs)
Rename a device.

Options:
• id: Specifies a device ID. Only one device at a time.
  • title: Title of the device.

CLI Example:
```
salt '*' hue.rename id=1 title='WC for cats'
```

```
salt.proxy.philips_hue.call_status(*args, **kwargs)
Return the status of the lamps.

Options:
• id: Specifies a device ID. Can be a comma-separated values. All, if omitted.

CLI Example:
```
salt '*' hue.status
salt '*' hue.status id=1
salt '*' hue.status id=1,2,3
```

```
salt.proxy.philips_hue.call_switch(*args, **kwargs)
Switch lamp ON/OFF. If no particular state is passed, then lamp will be switched to the opposite state.

Options:
• id: Specifies a device ID. Can be a comma-separated values. All, if omitted.
  • on: True or False. Inverted current, if omitted

CLI Example:
```
salt '*' hue.switch
salt '*' hue.switch id=1
salt '*' hue.switch id=1,2,3 on=True
```

```
salt.proxy.philips_hue.call_temperature(*args, **kwargs)
Set the mired color temperature. More: http://en.wikipedia.org/wiki/Mired
```
Arguments:
• value: 150–500.
Options:
• id: Specifies a device ID. Can be a comma-separated values. All, if omitted.
CLI Example:

```
salt '*' hue.temperature value=150
salt '*' hue.temperature value=150 id=1
salt '*' hue.temperature value=150 id=1,2,3
```

salt.proxy.philips_hue.init(cnf)
Initialize the module.
salt.proxy.philips_hue.ping(*args, **kw)
Ping the lamps.
salt.proxy.philips_hue.shutdown(opts, *args, **kw)
Shuts down the service.

13.10.7 salt.proxy.rest_sample

This is a simple proxy-minion designed to connect to and communicate with the bottle-based web service contained in https://github.com/saltstack/salt-contrib/tree/master/proxyminion_rest_example

salt.proxy.rest_sample.fix_outage()
salt.proxy.rest_sample.fns()
salt.proxy.rest_sample.grains()
Get the grains from the proxied device
salt.proxy.rest_sample.grains_refresh()
Refresh the grains from the proxied device
salt.proxy.rest_sample.id(opts)
Return a unique ID for this proxy minion. This ID MUST NOT CHANGE. If it changes while the proxy is running the salt-master will get really confused and may stop talking to this minion
salt.proxy.rest_sample.init(opts)
salt.proxy.rest_sample.initialized()
Since grains are loaded in many different places and some of those places occur before the proxy can be initialized, return whether our init() function has been called
salt.proxy.rest_sample.package_install(name, **kwargs)
Install a `package` on the REST server
salt.proxy.rest_sample.package_list()
List `packages` installed on the REST server
salt.proxy.rest_sample.package_remove(name)
Remove a `package` on the REST server
salt.proxy.rest_sample.package_status(name)
Check the installation status of a package on the REST server
salt.proxy.rest_sample.ping()
Is the REST server up?
salt.proxy.rest_sample.service_list()
List `services` on the REST server
salt.proxy.rest_sample.service_restart(name)
    Restart a "service" on the REST server

salt.proxy.rest_sample.service_start(name)
    Start a "service" on the REST server

salt.proxy.rest_sample.service_status(name)
    Check if a service is running on the REST server

salt.proxy.rest_sample.service_stop(name)
    Stop a "service" on the REST server

salt.proxy.rest_sample.shutdown(opts)
    For this proxy shutdown is a no-op

salt.proxy.rest_sample.test_from_state()
    Test function so we have something to call from a state :return:

salt.proxy.rest_sample.uptodate(name)
    Call the REST endpoint to see if the packages on the "server" are up to date.

13.10.8 salt.proxy.ssh_sample

This is a simple proxy-minion designed to connect to and communicate with a server that exposes functionality via SSH. This can be used as an option when the device does not provide an api over HTTP and doesn't have the python stack to run a minion.

salt.proxy.ssh_sample.fns()

salt.proxy.ssh_sample.grains()
    Get the grains from the proxied device

salt.proxy.ssh_sample.grains_refresh()
    Refresh the grains from the proxied device

salt.proxy.ssh_sample.init(opts)
    Required. Can be used to initialize the server connection.

salt.proxy.ssh_sample.initialized()
    Since grains are loaded in many different places and some of those places occur before the proxy can be initialized, return whether our init() function has been called

salt.proxy.ssh_sample.package_install(name, **kwargs)
    Install a "package" on the ssh server

salt.proxy.ssh_sample.package_list()
    List "packages" by executing a command via ssh This function is called in response to the salt command ..code-block::bash salt target_minion pkg.list_pkgs

salt.proxy.ssh_sample.package_remove(name)
    Remove a "package" on the ssh server

salt.proxy.ssh_sample.parse(out)
    Extract json from out.
    Parameter out: Type string. The data returned by the ssh command.

salt.proxy.ssh_sample.ping()
    Required. Ping the device on the other end of the connection

salt.proxy.ssh_sample.service_list()
    Start a "service" on the ssh server

13.10. proxy modules
New in version 2015.8.2.

```
salt.proxy.ssh_sample.service_restart(name)
```
Restart a "service" on the ssh server

New in version 2015.8.2.

```
salt.proxy.ssh_sample.service_start(name)
```
Start a "service" on the ssh server

New in version 2015.8.2.

```
salt.proxy.ssh_sample.service_stop(name)
```
Stop a "service" on the ssh server

New in version 2015.8.2.

```
salt.proxy.ssh_sample.shutdown(opts)
```
Disconnect

### 13.11 queue modules

#### pgjsonb_queue

New in version 2016.3.0.

#### sqlite_queue

New in version 2014.7.0.

#### 13.11.1 salt.queues.pgjsonb_queue module

New in version 2016.3.0.

This is a queue with postgres as the backend. It uses the jsonb store to store information for queues.

```
depends  python-psycopg2
```

To enable this queue, the following needs to be configured in your master config. These are the defaults:

```
queue.pgjsonb.host: 'salt'
queue.pgjsonb.user: 'salt'
queue.pgjsonb.pass: 'salt'
queue.pgjsonb.db: 'salt'
queue.pgjsonb.port: 5432
```

Use the following Pg database schema:

```
CREATE DATABASE  salt WITH ENCODING  'utf-8';

-- 
-- Table structure for table `salt`
--

DROP TABLE IF EXISTS salt;
CREATE OR REPLACE TABLE salt( 
    id SERIAL PRIMARY KEY, 
    data jsonb NOT NULL 
);
```
```
salt-run queue.insert test '{"name": "redis", "host": "172.16.0.8", "port": 6379}'}
   ...backend=pgjsonb
salt-run queue.process_queue test all backend=pgjsonb
```

```
salt.queues.pgjsonb_queue.delete(queue, items)
   Delete an item or items from a queue

salt.queues.pgjsonb_queue.handle_queue_creation(queue)

salt.queues.pgjsonb_queue.insert(queue, items)
   Add an item or items to a queue

salt.queues.pgjsonb_queue.list_items(queue)
   List contents of a queue

salt.queues.pgjsonb_queue.list_length(queue)
   Provide the number of items in a queue

salt.queues.pgjsonb_queue.list_queues()
   Return a list of Salt Queues on the Salt Master

salt.queues.pgjsonb_queue.pop(queue, quantity=1)
   Pop one or more or all items from the queue return them.
```

### 13.11.2 salt.queues.sqlite_queue module

New in version 2014.7.0.

This is the default local master event queue built on sqlite. By default, an sqlite3 database file is created in the `sqlite_queue_dir` which is found at:

```
/var/cache/salt/master/queues
```

It's possible to store the sqlite3 database files by setting `sqlite_queue_dir` to another location:

```
sqlite_queue_dir: /home/myuser/salt/master/queues
```

```
salt.queues.sqlite_queue.delete(queue, items)
   Delete an item or items from a queue

salt.queues.sqlite_queue.insert(queue, items)
   Add an item or items to a queue

salt.queues.sqlite_queue.list_items(queue)
   List contents of a queue

salt.queues.sqlite_queue.list_length(queue)
   Provide the number of items in a queue

salt.queues.sqlite_queue.list_queues()
   Return a list of Salt Queues on the Salt Master

salt.queues.sqlite_queue.pop(queue, quantity=1)
   Pop one or more or all items from the queue return them.
```

### 13.12 roster modules
| **ansible** | Read in an Ansible inventory file or script |
| **cache** | Use the minion cache on the master to derive IP addresses based on minion ID. |
| **cloud** | Use the cloud cache on the master to derive IPv4 addresses based on minion ID. |
| **clustershell** | This roster resolves hostname in a pdsh/clustershell style. |
| **flat** | Read in the roster from a flat file using the renderer system |
| **range** | This roster resolves targets from a range server. |
| **scan** | Scan a netmask or ipaddr for open ssh ports |

### 13.12.1 salt.roster.ansible

Read in an Ansible inventory file or script

Flat inventory files should be in the regular ansible inventory format.

```bash
[servers]
salt.gtmanfred.com ansible_ssh_user=gtmanfred ansible_ssh_host=127.0.0.1 ansible_ssh_port=22 ansible_ssh_pass='password'

[desktop]
home ansible_ssh_user=gtmanfred ansible_ssh_host=12.34.56.78 ansible_ssh_port=23 ansible_ssh_pass='password'

[computers:children]
desktop
servers

[names:vars]
http_port=80
```

then salt-ssh can be used to hit any of them

```bash
[~]# salt-ssh all test.ping
salt.gtmanfred.com: True
home: True
[~]# salt-ssh desktop test.ping
home: True
[~]# salt-ssh computers test.ping
salt.gtmanfred.com: True
home: True
[~]# salt-ssh salt.gtmanfred.com test.ping
salt.gtmanfred.com: True
```

There is also the option of specifying a dynamic inventory, and generating it on the fly

```bash
#!/bin/bash
echo '{
    "servers": {
        "hosts": [
```
This is the format that an inventory script needs to output to work with ansible, and thus here.

```
[~]# salt-ssh --roster-file /etc/salt/hosts salt.gtmanfred.com test.ping
salt.gtmanfred.com:
   True
```

Any of the [groups] or direct hostnames will return. The `all' is special, and returns everything.

class salt.roster.ansible.Inventory(tgt, tgt_type='glob', inventory_file='/etc/salt/roster')
   Matcher for static inventory files

class salt.roster.ansible.Script(tgt, tgt_type='glob', inventory_file='/etc/salt/roster')
   Matcher for Inventory scripts

class salt.roster.ansible.Target

   get_glob()
      Return minions that match via glob

   targets()
      Execute the correct tgt_type routine and return

salt.roster.ansible.targets(tgt, tgt_type='glob', **kwargs)
   Return the targets from the ansible inventory_file Default: /etc/salt/roster
13.12.2 salt.roster.cache

Use the minion cache on the master to derive IP addresses based on minion ID.
Currently only contains logic to return an IPv4 address; does not handle IPv6, or authentication (passwords, keys, etc).
It is possible to configure this roster to prefer a particular type of IP over another. To configure the order, set the roster_order in the master config file. The default for this is:

```
roster_order:
  - public
  - private
  - local
```

```
salt.roster.cache.extract_ipv4(roster_order, ipv4)
  Extract the preferred IP address from the ipv4 grain

salt.roster.cache.targets(tgt, tgt_type='glob', **kwargs)
  Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster
```

13.12.3 salt.roster.cloud

Use the cloud cache on the master to derive IPv4 addresses based on minion ID.
This roster requires that the minion in question was created using at least the 2015.5.0 version of Salt Cloud. Starting with the 2015.5.0 release, Salt Cloud maintains an index of minions that it creates and deletes. This index tracks the provider and profile configuration used to provision the minion, including authentication information. So long as this configuration remains current, it can be used by Salt SSH to log into any minion in the index.
To connect as a user other than root, modify the cloud configuration file usually located at /etc/salt/cloud. For example, add the following:

```
ssh_username: my_user
sudo: True
```

```
salt.roster.cloud.extract_ipv4(roster_order, ipv4)
  Extract the preferred IP address from the ipv4 grain

salt.roster.cloud.targets(tgt, tgt_type='glob', **kwargs)
  Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster
```

13.12.4 salt.roster.clustershell

This roster resolves hostname in a pdsh/clustershell style.

```
depends clustershell, https://github.com/cea-hpc/clustershell
```

When you want to use host globs for target matching, use `--roster clustershell`. For example:

```
salt-ssh --roster clustershell 'server_[1-10,21-30],test_server[5,7,9]' test.ping
```

```
salt.roster.clustershell.targets(tgt, tgt_type='glob', **kwargs)
  Return the targets
```
13.12.5 salt.roster.flat

Read in the roster from a flat file using the renderer system

class salt.roster.flat.RosterMatcher (raw, tgt, tgt_type, ipv='ipv4')
Matcher for the roster data structure

    get_data (minion)
    Return the configured ip

    ret_glob_minions ()
    Return minions that match via glob

    ret_list_minions ()
    Return minions that match via list

    ret_nodegroup_minions ()
    Return minions which match the special list-only groups defined by ssh_list_nodegroups

    ret_pcre_minions ()
    Return minions that match via pcre

    ret_range_minions ()
    Return minions that are returned by a range query

    targets ()
    Execute the correct tgt_type routine and return

salt.roster.flat.targets (tgt, tgt_type='glob', **kwargs)
Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster

13.12.6 salt.roster.range module

This roster resolves targets from a range server.

    depends seco.range, https://github.com/ytoolshed/range

When you want to use a range query for target matching, use --roster range. For example:

    salt-ssh --roster range '%%%example.range.cluster' test.ping

    salt.roster.range.target_glob (tgt, hosts)

    salt.roster.range.target_range (tgt, hosts)

    salt.roster.range.targets (tgt, tgt_type='range', **kwargs)
    Return the targets from a range query

13.12.7 salt.roster.scan

Scan a netmask or ipaddr for open ssh ports

class salt.roster.scan.RosterMatcher (tgt, tgt_type)
Matcher for the roster data structure

    targets ()
    Return ip addrs based on netmask, sitting in the ``glob'' spot because it is the default

salt.roster.scan.targets (tgt, tgt_type='glob', **kwargs)
Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster
### 13.13 runner modules

<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>

13.13.1 salt.runners.asam

Novell ASAM Runner

New in version Beryllium.

Runner to interact with Novell ASAM Fan-Out Driver

**codeauthor** Nitin Madhok <nmadhok@clemson.edu>

To use this runner, set up the Novell Fan-Out Driver URL, username and password in the master configuration at `/etc/salt/master` or `/etc/salt/master.d/asam.conf`:

```yaml
asam:
  prov1.domain.com
  username: "testuser"
  password: "verybadpass"
  prov2.domain.com
  username: "testuser"
  password: "verybadpass"
```

**Note:** Optionally, `protocol` and `port` can be specified if the Fan-Out Driver server is not using the defaults. Default is `protocol: https` and `port: 3451`.

- **salt.runners.asam.add_platform**(name, platform_set, server_url)
  
  To add an ASAM platform using the specified ASAM platform set on the Novell Fan-Out Driver

  CLI Example:

  ```bash
  salt-run asam.add_platform my-test-vm test-platform-set prov1.domain.com
  ```

- **salt.runners.asam.list_platform_sets**(server_url)
  
  To list all ASAM platform sets present on the Novell Fan-Out Driver

  CLI Example:

  ```bash
  salt-run asam.list_platform_sets prov1.domain.com
  ```

- **salt.runners.asam.list_platforms**(server_url)
  
  To list all ASAM platforms present on the Novell Fan-Out Driver

  CLI Example:

  ```bash
  salt-run asam.list_platforms prov1.domain.com
  ```

- **salt.runners.asam.remove_platform**(name, server_url)
  
  To remove specified ASAM platform from the Novell Fan-Out Driver

  CLI Example:

  ```bash
  salt-run asam.remove_platform my-test-vm prov1.domain.com
  ```

13.13.2 salt.runners.cache

Return cached data from minions
salt.runners.cache.clear_all(tgt=None, expr_form='glob')
Clear the cached pillar, grains, and mine data of the targeted minions

CLI Example:
```
salt-run_cache.clear_all
```

salt.runners.cache.clear_git_lock(role, remote=None, **kwargs)
New in version 2015.8.2.
Remove the update locks for Salt components (gitfs, git_pillar, winrepo) which use gitfs backend code from salt.utils.gitfs.

**Note:** Running `cache.clear_all` will not include this function as it does for pillar, grains, and mine. Additionally, executing this function with a `role` of `gitfs` is equivalent to running `salt-run file-server.clear_lock backend=git`.

**role** Which type of lock to remove (gitfs, git_pillar, or winrepo)
**remote** If specified, then any remotes which contain the passed string will have their lock cleared. For example, a `remote` value of `github` will remove the lock from all github.com remotes.
**type** [update, checkout] The types of lock to clear. Can be update, checkout, or both of et (either comma-separated or as a Python list).

CLI Example:
```
salt-run_cache.clear_git_lock git_pillar
```

salt.runners.cache.clear_grains(tgt=None, expr_form='glob')
Clear the cached grains data of the targeted minions

CLI Example:
```
salt-run_cache.clear_grains
```

salt.runners.cache.clear_mine(tgt=None, expr_form='glob')
Clear the cached mine data of the targeted minions

CLI Example:
```
salt-run_cache.clear_mine
```

salt.runners.cache.clear_mine_func(tgt=None, expr_form='glob', clear_mine_func_flag=None)
Clear the cached mine function data of the targeted minions

CLI Example:
```
salt-run_cache.clear_mine_func tgt='*' clear_mine_func_flag='network.interfaces'
```

salt.runners.cache.clear_pillar(tgt=None, expr_form='glob')
Clear the cached pillar data of the targeted minions

CLI Example:
```
salt-run_cache.clear_pillar
```

salt.runners.cache.grains(tgt=None, expr_form='glob', outputter=None, **kwargs)
Return cached grains of the targeted minions
CLI Example:
```
salt-run cache.grains
```

`salt.runners.cache.mine(tgt=None, expr_form='glob', outputter=None, **kwargs)`
Return cached mine data of the targeted minions

CLI Example:
```
salt-run cache.mine
```

`salt.runners.cache.pillar(tgt=None, expr_form='glob', outputter=None, **kwargs)`
Return cached pillars of the targeted minions

CLI Example:
```
salt-run cache.pillar
```

### 13.13.3 salt.runners.cloud

The Salt Cloud Runner

This runner wraps the functionality of salt cloud making salt cloud routines available to all internal apis via the runner system

`salt.runners.cloud.action(func=None, cloudmap=None, instances=None, provider=None, instance=None, **kwargs)`
Execute a single action on the given map/provider-instance

CLI Example:
```
salt-run cloud.actions start my-salt-vm
```

`salt.runners.cloud.create(provider, instances, **kwargs)`
Create an instance using Salt Cloud

CLI Example:
```
salt-run cloud.create my-ec2-config myinstance image=ami-1624987f size=t1.micro ssh_username=ec2-user securitygroup=default delvol_on_destroy=True
```

`salt.runners.cloud.destroy(instances)`
Destroy the named vm(s)

`salt.runners.cloud.full_query(query_type='list_nodes_full')`
List all available cloud provider data

`salt.runners.cloud.list_images(provider='all')`
List cloud provider images for the given providers

`salt.runners.cloud.list_locations(provider='all')`
List cloud provider sizes for the given providers

`salt.runners.cloud.list_sizes(provider='all')`
List cloud provider sizes for the given providers

`salt.runners.cloud.map_run(path, **kwargs)`
Execute a salt cloud map file
salt.runners.cloud.profile(prof=None, instances=None, **kwargs)
Create a cloud vm with the given profile and instances, instances can be a list or comma-delimited string

CLI Example:
```
salt-run cloud.profile prof=my-ec2 instances=node1,node2,node3
```

class runners.cloud.query(query_type='list_nodes')
List cloud provider data for all providers

class runners.cloud.select_query(query_type='list_nodes_select')
List selected nodes

### 13.13.4 salt.runners.ddns

Dynamic DNS Runner

New in version Beryllium.

Runner to interact with DNS server and create/delete/update DNS records

**codeauthor** Nitin Madhok <nmadhok@clemson.edu>

salt.runners.ddns.add_host(zone, name, ttl, ip, keyname, keyfile, nameserver)
Create both A and PTR (reverse) records for a host.

CLI Example:
```
salt-run ddns.add_host domain.com my-test-vm 3600 10.20.30.40 my-tsig-key /etc/salt/tsig.keyring 10.0.0.1
```

class runners.ddns.create(zone, name, ttl, rdtype, data, keyname, keyfile, nameserver)
Create a DNS record. The nameserver must be an IP address and the master running this runner must have create privileges on that server.

CLI Example:
```
salt-run ddns.create domain.com my-test-vm 3600 A 10.20.30.40 my-tsig-key /etc/salt/tsig.keyring 10.0.0.1
```

salt.runners.ddns.delete(zone, name, keyname, keyfile, nameserver, rdtype=None, data=None)
Delete a DNS record.

CLI Example:
```
salt-run ddns.delete domain.com my-test-vm my-tsig-key /etc/salt/tsig.keyring 10.0.0.1 A
```

class runners.ddns.delete_host(zone, name, keyname, keyfile, nameserver)
Delete both forward (A) and reverse (PTR) records for a host only if the forward (A) record exists.

CLI Example:
```
salt-run ddns.delete_host domain.com my-test-vm my-tsig-key /etc/salt/tsig.keyring 10.0.0.1
```

class runners.ddns.update(zone, name, ttl, rdtype, data, keyname, keyfile, nameserver, replace=False)
Replace, or update a DNS record. The nameserver must be an IP address and the master running this runner must have update privileges on that server.
Note: If `replace` is set to True, all records for this name and type will first be deleted and then recreated. Default is `replace=False`.

CLI Example:

```
salt-run ddns.update domain.com my-test-vm 3600 A 10.20.30.40 my-tsig-key /etc/salt/tsig.keyring 10.0.0.1
```

### 13.13.5 `salt.runners.doc`

A runner module to collect and display the inline documentation from the various module types

#### `salt.runners.doc.execution`

Collect all the `sys.doc` output from each minion and return the aggregate

CLI Example:

```
salt-run doc.execution
```

#### `salt.runners.doc.runner`

Return all inline documentation for runner modules

CLI Example:

```
salt-run doc.runner
```

#### `salt.runners.doc.wheel`

Return all inline documentation for wheel modules

CLI Example:

```
salt-run doc.wheel
```

### 13.13.6 `salt.runners.drac`

Manage Dell DRAC from the Master

The login credentials need to be configured in the Salt master configuration file.

#### `salt.runners.drac.poweroff`

Power server off

CLI Example:

```
salt-run drac.poweroff example.com
```

#### `salt.runners.drac.poweron`

Power server on

CLI Example:

```
salt-run drac.poweron example.com
```

#### `salt.runners.drac.pxe`

Connect to the Dell DRAC and have the boot order set to PXE and power cycle the system to PXE boot
CLI Example:

```
salt-run drac.pxe example.com
```

```
salt.runners.drac.reboot(hostname, timeout=20, username=None, password=None)
```
Reboot a server using the Dell DRAC

CLI Example:

```
salt-run drac.reboot example.com
```

```
salt.runners.drac.version(hostname, timeout=20, username=None, password=None)
```
Display the version of DRAC

CLI Example:

```
salt-run drac.version example.com
```

### 13.13.7 salt.runners.error

Error generator to enable integration testing of salt runner error handling

```
salt.runners.error.error(name=None, message='')
```
If name is None Then return empty dict

Otherwise raise an exception with `__name__` from name, message from message

CLI Example:

```
salt-run error
salt-run error.error name="Exception" message="This is an error."
```

### 13.13.8 salt.runners.f5

Runner to provide F5 Load Balancer functionality

**depends**

- pycontrol Python module

**configuration** In order to connect to a F5 Load Balancer, you must specify in the Salt master configuration the currently available load balancers

```
load_balancers:
    bigip1.example.com
    username: admin
    password: secret
    bigip2.example.com:
    username: admin
    password: secret
```

```
class salt.runners.f5.F5Mgmt(lb, username, password)
```

**add_pool_member** *(name, port, pool_name)*

Add a node to a pool
check_member_pool\( (member, pool_name) \)
Check a pool member exists in a specific pool

check_pool\( (name) \)
Check to see if a pool exists

check_virtualserver\( (name) \)
Check to see if a virtual server exists

create_pool\( (name, method='ROUND_ROBIN') \)
Create a pool on the F5 load balancer

create_vs\( (name, ip, port, protocol, profile, pool_name) \)
Create a virtual server

lbmethods() \nList all the load balancer methods

salt.runners.f5.add_pool_member\( (lb, name, port, pool_name) \)
Add a node to a pool

CLI Examples:

```
salt-run f5.add_pool_member load_balancer 10.0.0.1 80 my_pool
```

salt.runners.f5.check_member_pool\( (lb, member, pool_name) \)
Check a pool member exists in a specific pool

CLI Examples:

```
salt-run f5.check_member_pool load_balancer 10.0.0.1 my_pool
```

salt.runners.f5.check_pool\( (lb, name) \)
Check to see if a pool exists

CLI Examples:

```
salt-run f5.check_pool load_balancer pool_name
```

salt.runners.f5.check_virtualserver\( (lb, name) \)
Check to see if a virtual server exists

CLI Examples:

```
salt-run f5.check_virtualserver load_balancer virtual_server
```

salt.runners.f5.create_pool\( (lb, name, method='ROUND_ROBIN') \)
Create a pool on the F5 load balancer

CLI Examples:

```
salt-run f5.create_pool load_balancer pool_name loadbalance_method
salt-run f5.create_pool load_balancer my_pool ROUND_ROBIN
```

salt.runners.f5.create_vs\( (lb, name, ip, port, protocol, profile, pool_name) \)
Create a virtual server

CLI Examples:

```
salt-run f5.create_vs lbalancer vs_name 10.0.0.1 80 tcp http poolname
```
13.13.9 salt.runners.fileserver

Directly manage the Salt fileserver plugins

salt.runners.fileserver.clear_cache(backend=None)

New in version 2015.5.0.

Clear the fileserver cache from VCS fileserver backends (git, hg, svn). Executing this runner with no arguments will clear the cache for all enabled VCS fileserver backends, but this can be narrowed using the backend argument.

backend Only clear the update lock for the specified backend(s). If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.

CLI Example:

```
salt-run fileserver.clear_cache
salt-run fileserver.clear_cache backend=git,hg
salt-run fileserver.clear_cache hg
salt-run fileserver.clear_cache -roots
```

salt.runners.fileserver.clear_lock(backend=None, remote=None)

New in version 2015.5.0.

Clear the fileserver update lock from VCS fileserver backends (git, hg, svn). This should only need to be done if a fileserver update was interrupted and a remote is not updating (generating a warning in the Master’s log file). Executing this runner with no arguments will remove all update locks from all enabled VCS fileserver backends, but this can be narrowed by using the following arguments:

backend Only clear the update lock for the specified backend(s).

remote If specified, then any remotes which contain the passed string will have their lock cleared. For example, a remote value of github will remove the lock from all github.com remotes.

CLI Example:

```
salt-run fileserver.clear_lock
salt-run fileserver.clear_lock backend=git,hg
salt-run fileserver.clear_lock backend=git remote=github
salt-run fileserver.clear_lock remote=bitbucket
```

salt.runners.fileserver.dir_list(saltenv='base', backend=None, outputter=None)

Return a list of directories in the given environment

saltenv [base] The salt fileserver environment to be listed

backend Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.

New in version 2015.5.0.

CLI Example:

```
salt-run fileserver.dir_list
salt-run fileserver.dir_list saltenv=prod
salt-run fileserver.dir_list saltenv=dev backend=git
salt-run fileserver.dir_list base hg,roots
salt-run fileserver.dir_list -git
```

salt.runners.fileserver.empty_dir_list(saltenv='base', backend=None, outputter=None)

New in version 2015.5.0.
Return a list of empty directories in the given environment

**saltenv** [base] The salt fileserver environment to be listed

**backend** Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.

**Note:** Some backends (such as git and hg) do not support empty directories. So, passing backend=git or backend=hg will result in an empty list being returned.

**CLI Example:**

```
salt-run fileserver.empty_dir_list
salt-run fileserver.empty_dir_list saltenv=prod
salt-run fileserver.empty_dir_list backend=roots
```

salt.runners.fileserver.envs(backend=None, sources=False, outputter=None)

Return the available fileserver environments. If no backend is provided, then the environments for all configured backends will be returned.

**backend** Narrow fileserver backends to a subset of the enabled ones.

Changed in version 2015.5.0: If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.

Additionally, fileserver backends can now be passed as a comma-separated list. In earlier versions, they needed to be passed as a python list (ex: backend="['roots','git']")

**CLI Example:**

```
salt-run fileserver.envs
salt-run fileserver.envs backend=roots,git
salt-run fileserver.envs git
```

salt.runners.fileserver.file_list(saltenv='base', backend=None, outputter=None)

Return a list of files from the salt fileserver

**saltenv** [base] The salt fileserver environment to be listed

**backend** Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.

New in version 2015.5.0.

**CLI Examples:**

```
salt-run fileserver.file_list
salt-run fileserver.file_list saltenv=prod
salt-run fileserver.file_list saltenv=dev backend=git
salt-run fileserver.file_list base hg,roots
salt-run fileserver.file_list -git
```

salt.runners.fileserver.lock(backend=None, remote=None)

New in version 2015.5.0.

Set a fileserver update lock for VCS fileserver backends (git, hg, svn).

**Note:** This will only operate on enabled backends (those configured in fileserver_backend).
**backend** Only set the update lock for the specified backend(s).

**remote** If not None, then any remotes which contain the passed string will have their lock cleared. For example, a remote value of `*github.com*` will remove the lock from all github.com remotes.

CLI Example:

```bash
salt-run fileserver.lock
salt-run fileserver.lock backend=git,hg
salt-run fileserver.lock backend=git remote='*github.com*'
```

**salt.runners.fileserver.symlink_list**(saltenv=`base`, backend=None, outputer=None)

Return a list of symlinked files and dirs

**saltenv** [base] The salt fileserver environment to be listed

**backend** Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (`-`), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: `backend=-roots,git`) then the ones starting with a minus sign will be disregarded.

New in version 2015.5.0.

CLI Example:

```bash
salt-run fileserver.symlink_list
salt-run fileserver.symlink_list saltenv=prod
salt-run fileserver.symlink_list saltenv=dev backend=git
salt-run fileserver.symlink_list base hg,roots
salt-run fileserver.symlink_list -git
```

**salt.runners.fileserver.update**(backend=None)

Update the fileserver cache. If no backend is provided, then the cache for all configured backends will be updated.

**backend** Narrow fileserver backends to a subset of the enabled ones.

Changed in version 2015.5.0: If all passed backends start with a minus sign (`-`), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: `backend=-roots,git`) then the ones starting with a minus sign will be disregarded.

Additionally, fileserver backends can now be passed as a comma-separated list. In earlier versions, they needed to be passed as a python list (ex: `backend=['roots','git']`).

CLI Example:

```bash
salt-run fileserver.update
salt-run fileserver.update backend=roots,git
```

### 13.13.10 salt.runners.git_pillar

Runner module to directly manage the git external pillar

**salt.runners.git_pillar.update**(branch=None, repo=None)

New in version 2014.1.0.

Changed in version 2015.8.4: This runner function now supports the new git_pillar configuration schema introduced in 2015.8.0. Additionally, the branch and repo can now be omitted to update all git_pillar remotes. The return data has also changed. For releases 2015.8.3 and earlier, there is no value returned. Starting with 2015.8.4, the return data is a dictionary. If using the old git_pillar configuration schema, then the dictionary values will be True if the update completed without error, and False if an error occurred. If using the new
**git_pillar configuration schema**, the values will be `True` only if new commits were fetched, and `False` if there were errors or no new commits were fetched.

Fetch one or all configured `git_pillar` remotes.

**Note:** This will not fast-forward the `git_pillar` cachedir on the master. All it does is perform a `git fetch`. If this runner is executed with `-l debug`, you may see a log message that says that the repo is up-to-date. Keep in mind that Salt automatically fetches `git_pillar` repos roughly every 60 seconds (or whatever `loop_interval` is set to). So, it is possible that the repo was fetched automatically in the time between when changes were pushed to the repo, and when this runner was executed. When in doubt, simply refresh pillar data using `saltutil.refresh_pillar` and then use `pillar.item` to check if the pillar data has changed as expected.

CLI Example:

```bash
salt-run git_pillar.update branch='branch' repo='https://foo.com/bar.git'
salt-run git_pillar.update
salt-run git_pillar.update -l debug
```

## 13.13.11 `salt.runners.http`

Module for making various web calls. Primarily designed for webhooks and the like, but also useful for basic `http` testing.

New in version 2015.5.0.

```
salt.runners.http.query(url, output=True, **kwargs)
```

Query a resource, and decode the return data

New in version 2015.5.0.

CLI Example:

```bash
salt-run http.query http://somelink.com/
salt-run http.query http://somelink.com/ method=POST params='key1=val1&key2=val2'
salt-run http.query http://somelink.com/ method=POST data='<xml>
somecontent</xml>'
```

```
salt.runners.http.update_ca_bundle(target=None, source=None, merge_files=None)
```

Update the local CA bundle file from a URL

New in version 2015.5.0.

CLI Example:

```bash
salt-run http.update_ca_bundle
target=/path/to/cacerts.pem
salt-run http.update_ca_bundle target=/path/to/cacerts.pem source=//example.com/cacerts.pem
```

If the `target` is not specified, it will be pulled from the `ca_cert` configuration variable available to the master. If it cannot be found there, it will be placed at `<<<FILE_ROOTS>>>/cacerts.pem`. 

13.13. runner modules
If the `source` is not specified, it will be pulled from the `ca_cert_url` configuration variable available to the master. If it cannot be found, it will be downloaded from the cURL website, using an http (not https) URL. USING THE DEFAULT URL SHOULD BE AVOIDED!

`merge_files` may also be specified, which includes a string or list of strings representing a file or files to be appended to the end of the CA bundle, once it is downloaded.

CLI Example:

```bash
salt-run http.update_ca_bundle merge_files=/path/to/mycert.pem
```

### 13.13.12 `salt.runners.jobs`

A convenience system to manage jobs, both active and already run

#### `salt.runners.jobs.active` *(outputter=``None``, display_progress=``False``)*

Return a report on all actively running jobs from a job id centric perspective

CLI Example:

```bash
salt-run jobs.active
```

#### `salt.runners.jobs.exit_success`(jid, ext_source=``None``)

Check if a job has been executed and exit successfully

- **jid** The jid to look up.
- **ext_source** The external job cache to use. Default: `None`.

CLI Example:

```bash
salt-run jobs.exit_success 20160520145827701627
```

#### `salt.runners.jobs.last_run`(ext_source=``None``, outputter=``None``, metadata=``None``, function=``None``, target=``None``, display_progress=``False``)

New in version 2015.8.0.

List all detectable jobs and associated functions

CLI Example:

```bash
salt-run jobs.last_run
salt-run jobs.last_run target=nodename
salt-run jobs.last_run function='cmd.run'
salt-run jobs.last_run metadata="{'foo': 'bar'}"
```

#### `salt.runners.jobs.list_job`(jid, ext_source=``None``, outputter=``None``, display_progress=``False``)

List a specific job given by its jid

- **ext_source** If provided, specifies which external job cache to use.
- **display_progress** [False] If True, fire progress events.

CLI Example:

```bash
salt-run jobs.list_job 20130916125524463507
salt-run jobs.list_job 20130916125524463507 --out=pprint
```

#### `salt.runners.jobs.list_jobs`(ext_source=``None``, outputter=``None``, search_metadata=``None``, search_function=``None``, search_target=``None``, start_time=``None``, end_time=``None``, display_progress=``False``)

List all detectable jobs and associated functions

- **ext_source** If provided, specifies which external job cache to use.
FILTER OPTIONS

**Note:** If more than one of the below options are used, only jobs which match all of the filters will be returned.

**search_metadata** Specify a dictionary to match to the job's metadata. If any of the key-value pairs in this dictionary match, the job will be returned. Example:

```
salt-run jobs.list_jobs search_metadata='{"foo": "bar", "baz": "qux"}'
```

**search_function** Can be passed as a string or a list. Returns jobs which match the specified function. Globbing is allowed. Example:

```
salt-run jobs.list_jobs search_function='test.*'
salt-run jobs.list_jobs search_function='["test.*", "pkg.install"]'
```

Changed in version 2015.8.8: Multiple targets can now also be passed as a comma-separated list. For example:

```
salt-run jobs.list_jobs search_function='test.*,pkg.install'
```

**search_target** Can be passed as a string or a list. Returns jobs which match the specified minion name. Globbing is allowed. Example:

```
salt-run jobs.list_jobs search_target='*.mydomain.tld'
salt-run jobs.list_jobs search_target='["db", "myminion"]'
```

Changed in version 2015.8.8: Multiple targets can now also be passed as a comma-separated list. For example:

```
salt-run jobs.list_jobs search_target='db*,myminion'
```

**start_time** Accepts any timestamp supported by the **dateutil** Python module (if this module is not installed, this argument will be ignored). Returns jobs which started after this timestamp.

**end_time** Accepts any timestamp supported by the **dateutil** Python module (if this module is not installed, this argument will be ignored). Returns jobs which started before this timestamp.

CLI Example:

```
salt-run jobs.list_jobs
salt-run jobs.list_jobs search_function='test.*' search_target='localhost' search_metadata='{"bar": "foo"}'
salt-run jobs.list_jobs start_time='2015, Mar 16 19:00' end_time='2015, Mar 18 22:00'
```

salt.runners.jobs.list_jobs_filter(count, filter_find_job=True, ext_source=None, outputter=None, display_progress=False)

List all detectable jobs and associated functions

**ext_source** The external job cache to use. Default: None.

CLI Example:

```
salt-run jobs.list_jobs_filter 50
salt-run jobs.list_jobs_filter 100 filter_find_job=False
```

salt.runners.jobs.lookup_jid(jid, ext_source=None, returned=True, missing=False, outputter=None, display_progress=False)

Return the printout from a previously executed job

**jid** The jid to look up.

**ext_source** The external job cache to use. Default: None.
returned  [True] If True, include the minions that did return from the command.

    New in version 2015.8.0.
missing  [False] If True, include the minions that did not return from the command.
display_progress  [False] If True, fire progress events.

    New in version 2015.5.0.

CLI Example:

```sh
salt-run jobs.lookup_jid 20130916125524463507
salt-run jobs.lookup_jid 20130916125524463507 --out=highstate
```

```
salt.runners.jobs.print_job(jid, ext_source=None, outpuer=None)
```

Print a specific job's detail given by it's jid, including the return data.

CLI Example:

```
salt-run jobs.print_job 20130916125524463507
```

**13.13.13 salt.runners.launchd**

Manage launchd plist files

```
salt.runners.launchd.write_launchd_plist(program)
```

Write a launchd plist for managing salt-master or salt-minion

CLI Example:

```
salt-run launchd.write_launchd_plist salt-master
```

**13.13.14 salt.runners.lxc**

Control Linux Containers via Salt

depends lxc execution module

```
salt.runners.lxc.cloud_init(names, host=None, quiet=False, **kwargs)
```

Wrapper for using lxc.init in saltcloud compatibility mode

names  Name of the containers, supports a single name or a comma delimited list of names.
host  Minion to start the container on. Required.
path  path to the container parent default: /var/lib/lxc (system default)

    New in version 2015.8.0.
saltcloud_mode  init the container with the saltcloud opts format instead

```
salt.runners.lxc.find_guest(name, quiet=False, path=None)
```

Returns the host for a container.

path  path to the container parent default: /var/lib/lxc (system default)

    New in version 2015.8.0.

```
salt-run lxc.find_guest name
```

```
salt.runners.lxc.find_guests(names, path=None)
```

Return a dict of hosts and named guests.

path  path to the container parent default: /var/lib/lxc (system default)

    New in version 2015.8.0.
salt.runners.lxc.freeze(name, quiet=False, path=None)

Freeze the named container

path  path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

salt-run lxc.freeze name

salt.runners.lxc.info(name, quiet=False, path=None)

Returns information about a container.

path  path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

salt-run lxc.info name

salt.runners.lxc.init(names, host=None, saltcloud_mode=False, quiet=False, **kwargs)

Initialize a new container

salt-run lxc.init name host=minion_id [cpuset=cgroups_cpuset] \ 
    [cpushare=cgroups_cpushare] [memory=cgroups_memory] \ 
    [template=lxc_template_name] [clone=original name] \ 
    [profile=lxc_profile] [network_profile=network_profile] \ 
    [nic=network_profile] [nic_opts=nic_opts] \ 
    [start=(true|false)] [seed=(true|false)] \ 
    [install=(true|false)] [config=minion_config] \ 
    [snapshot=(true|false)]

names  Name of the containers, supports a single name or a comma delimited list of names.
host  Minion on which to initialize the container (required)
path  path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

saltcloud_mode  init the container with the saltcloud opts format instead See lxc.init_interface module documentation

cpuset  cgroups cpuset.
cpushare  cgroups cpu shares.
memory  cgroups memory limit, in MB

Changed in version 2015.5.0: If no value is passed, no limit is set. In earlier Salt versions, not passing this value causes a 1024MB memory limit to be set, and it was necessary to pass memory=0 to set no limit.
template  Name of LXC template on which to base this container
cloned  Clone this container from an existing container
profile  A LXC profile (defined in config or pillar).
network_profile  Network profile to use for the container

New in version 2015.5.2.
nic  Deprecated since version 2015.5.0: Use network_profile instead
nic_opts  Extra options for network interfaces. E.g.:

    "{"eth0": {"mac": "aa:bb:cc:dd:ee:ff","ipv4": "10.1.1.1","ipv6": "2001:db8::ff00:42:8329"}}"

start  Start the newly created container.
seed  Seed the container with the minion config and autosign its key. Default: true
install  If salt-minion is not already installed, install it. Default: true
config  Optional config parameters. By default, the id is set to the name of the container.
salt.runners.lxc.list(*host=None, quiet=False, path=None*)
List defined containers (running, stopped, and frozen) for the named (or all) host(s).

path  path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```
salt-run lxc.list [host=minion_id]
```

salt.runners.lxc.purge(*name, delete_key=True, quiet=False, path=None*)
Purge the named container and delete its minion key if present. WARNING: Destroys all data associated with the container.

path  path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```
salt-run lxc.purge name
```

salt.runners.lxc.start(*name, quiet=False, path=None*)
Start the named container.

path  path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```
salt-run lxc.start name
```

salt.runners.lxc.stop(*name, quiet=False, path=None*)
Stop the named container.

path  path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```
salt-run lxc.stop name
```

salt.runners.lxc.unfreeze(*name, quiet=False, path=None*)
Unfreeze the named container

path  path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```
salt-run lxc.unfreeze name
```

### 13.13.15  salt.runners.manage

General management functions for salt, tools like seeing what hosts are up and what hosts are down

salt.runners.manage.alived(*subset=None, show_ipv4=False*)
Print a list of all minions that are up according to Salt's presence detection (no commands will be sent to minions)

subset  [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4  [False] Also show the IP address each minion is connecting from.

CLI Example:

```
salt-run manage.alived
```

salt.runners.manage.allowed(*subset=None, show_ipv4=False*)
New in version 2015.8.0.
Print a list of all minions that are up according to Salt’s presence detection (no commands will be sent to minions)

subset [None] Pass in a CIDR range to filter minions by IP address.

show_ipv4 [False] Also show the IP address each minion is connecting from.

CLI Example:

```
salt-run manage.allowed
```

salt.runners.manage.bootstrap(**version**='develop', **script**=None, **hosts**='-', **root_user**=True)

Bootstrap minions with salt-bootstrap

- **version** [develop] Git tag of version to install
- **script** [https://bootstrap.saltstack.com] Script to execute
- **hosts** Comma-separated hosts [example: hosts='host1.local,host2.local']
- **root_user** [True] Prepend root@ to each host.

CLI Example:

```
salt-run manage.bootstrap
hosts='host1,host2'
salt-run manage.bootstrap
hosts='host1,host2' version='v0.17'
salt-run manage.bootstrap
hosts='host1,host2' version='v0.17' script=https://bootstrap.saltstack.com/develop
salt-run manage.bootstrap
hosts='ec2-user@host1,ec2-user@host2' root_user=False
```

salt.runners.manage.bootstrap_psexec(**hosts**='-', **master**=None, **version**=None, **arch**='win32', **installer_url**=None, **username**=None, **password**=None)

Bootstrap Windows minions via PsExec.

- **hosts** Comma separated list of hosts to deploy the Windows Salt minion.
- **master** Address of the Salt master passed as an argument to the installer.
- **version** Point release of installer to download. Defaults to the most recent.
- **arch** Architecture of installer to download. Defaults to win32.
- **installer_url** URL of minion installer executable. Defaults to the latest version from https://repo.saltstack.com/windows/
- **username** Optional user name for login on remote computer.
- **password** Password for optional username. If omitted, PsExec will prompt for one to be entered for each host.

CLI Example:

```
salt-run manage.bootstrap_psexec
hosts='host1,host2'
salt-run manage.bootstrap_psexec
hosts='host1,host2' version='0.17'
salt-run manage.bootstrap_psexec
hosts='host1,host2' version='0.17' username=\"DOMAIN\Administrator\"
salt-run manage.bootstrap_psexec
hosts='host1,host2' installer_url='http://\"exampledomain/salt-installer.exe'\"
```

salt.runners.manage.down(**removekeys**=False)

Print a list of all the down or unresponsive salt minions Optionally remove keys of down minions

CLI Example:

```
salt-run manage.down
salt-run manage.down removekeys=True
```

salt.runners.manage.get_stats(**estate**=None, **stack**='road')

Print the stack stats

- **estate** [None] The name of the target estate. Master stats would be requested by default
- **stack** ['road'] Show stats on either road or lane stack Allowed values are `road` or `lane`.

CLI Example:

```
salt-run manage.get_stats [estate=alpha_minion] [stack=lane]
```
salt.runners.manage.joined(subset=None, show_ipv4=False)

New in version 2015.8.0.

Print a list of all minions that are up according to Salt’s presence detection (no commands will be sent to minions)
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.
CLI Example:

```
salt-run manage.joined
```

salt.runners.manage.key_regen()

This routine is used to regenerate all keys in an environment. This is invasive! ALL KEYS IN THE SALT ENVIRONMENT WILL BE REGENERATED‼

The key_regen routine sends a command out to minions to revoke the master key and remove all minion keys, it then removes all keys from the master and prompts the user to restart the master. The minions will all reconnect and keys will be placed in pending.

After the master is restarted and minion keys are in the pending directory execute a salt-key -A command to accept the regenerated minion keys.

The master must be restarted within 60 seconds of running this command or the minions will think there is something wrong with the keys and abort.

Only Execute this runner after upgrading minions and master to 0.15.1 or higher!

CLI Example:

```
salt-run manage.key_regen
```

salt.runners.manage.lane_stats(estate=None)

Print the estate manor lane stack stats
estate [None] The name of the target estate. Master stats would be requested by default
CLI Example:

```
salt-run manage.lane_stats [estate=alpha_minion]
```

salt.runners.manage.list_not_state(subset=None, show_ipv4=False, state=None)

New in version 2015.8.0.

Print a list of all minions that are NOT up according to Salt’s presence detection (no commands will be sent to minions)
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.
state [‘available’] Show minions being in specific state that is one of ‘available’, ‘joined’, ‘allowed’, ‘alived’ or ‘reaped’.
CLI Example:

```
salt-run manage.list_not_state
```

salt.runners.manage.list_state(subset=None, show_ipv4=False, state=None)

New in version 2015.8.0.

Print a list of all minions that are up according to Salt’s presence detection (no commands will be sent to minions)
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.
state  ['available'] Show minions being in specific state that is one of 'available', 'joined', 'allowed', 'alived' or 'reaped'.
CLI Example:

```
salt-run manage.list_state
```

salt.runners.manage.not_alived(subset=None, show_ipv4=False)
New in version 2015.8.0.
Print a list of all minions that are NOT up according to Salt's presence detection (no commands will be sent)
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.
CLI Example:

```
salt-run manage.not_alived
```

salt.runners.manage.not_allowed(subset=None, show_ipv4=False)
New in version 2015.8.0.
Print a list of all minions that are NOT up according to Salt's presence detection (no commands will be sent)
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.
CLI Example:

```
salt-run manage.not_allowed
```

salt.runners.manage.not_joined(subset=None, show_ipv4=False)
New in version 2015.8.0.
Print a list of all minions that are NOT up according to Salt's presence detection (no commands will be sent)
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.
CLI Example:

```
salt-run manage.not_joined
```

salt.runners.manage.not_present(subset=None, show_ipv4=False)
New in version 2015.5.0.
Print a list of all minions that are NOT up according to Salt's presence detection (no commands will be sent)
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.
CLI Example:

```
salt-run manage.not_present
```

salt.runners.manage.not_reaped(subset=None, show_ipv4=False)
New in version 2015.8.0.
Print a list of all minions that are NOT up according to Salt's presence detection (no commands will be sent)
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.
CLI Example:

```
salt-run manage.not_reaped
```

salt.runners.manage.present(subset=None, show_ipv4=False)
Print a list of all minions that are up according to Salt's presence detection (no commands will be sent to
minions)
```
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.
```
CLI Example:
```
salt-run manage.present
```

**salt.runners.manage.reaped**(subset=None, show_ipv4=False)
New in version 2015.8.0.
Print a list of all minions that are up according to Salt’s presence detection (no commands will be sent to minions)
```
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.
```
CLI Example:
```
salt-run manage.reaped
```

**salt.runners.manage.road_stats**(estate=None)
Print the estate road stack stats
```
estate [None] The name of the target estate. Master stats would be requested by default
```
CLI Example:
```
salt-run manage.road_stats [estate=alpha_minion]
```

**salt.runners.manage.safe_accept**(target, expr_form='glob')
Accept a minion’s public key after checking the fingerprint over salt-ssh
CLI Example:
```
salt-run manage.safe_accept my_minion
salt-run manage.safe_accept minion1,minion2 expr_form=list
```

**salt.runners.manage.status**(output=True, timeout=None, gather_job_timeout=None)
Print the status of all known salt minions
CLI Example:
```
salt-run manage.status
```

**salt.runners.manage.up**(timeout=None, gather_job_timeout=None)
Print a list of all of the minions that are up
CLI Example:
```
salt-run manage.up
salt-run manage.up timeout=5 gather_job_timeout=5
```

**salt.runners.manage.versions**()
Check the version of active minions
CLI Example:
```
salt-run manage.versions
```

13.13.16 salt.runners.mine

A runner to access data from the salt mine
salt.runner.get(tgt, fun, tgt_type=’glob’)
Gathers the data from the specified minions’ mine, pass in the target, function to look up and the target type

CLI Example:
salt-run mine.get ‘*’ network.interfaces

13.13.17 salt.runners.nacl

This runner helps create encrypted passwords that can be included in pillars.

depends libnacl, https://github.com/saltstack/libnacl

This is often useful if you wish to store your pillars in source control or share your pillar data with others that you trust. I don’t advise making your pillars public regardless if they are encrypted or not.

The following configurations can be defined in the master config so your users can create encrypted passwords using the runner nacl:

```bash
cat /etc/salt/master.d/nacl.conf
nacl.config:
  key: ‘cKEzd4kXsbeCE7/nLTIqXwnUiD1ulg4NoeeYcCFpd9k=’
  keyfile: /root/.nacl
```

Now with the config in the master you can use the runner nacl like:

```
salt-run nacl.enc ‘data’
```

salt.runners.nacl.dec(data, **kwargs)
Takes a key generated from nacl.keygen and decrypt some data.

CLI Examples:

```
salt-run nacl.dec pEXHQM6cuaF7A= salt-run nacl.dec data=’pEXHQM6cuaF7A=’ keyfile=/root/.nacl
salt-run nacl.dec data='pEXHQM6cuaF7A=’ key=cKEzd4kXsbeCE7/nLTIqXwnUiD1ulg4NoeeYcCFpd9k=
```

salt.runners.nacl.enc(data, **kwargs)
Takes a key generated from nacl.keygen and encrypt some data.

CLI Examples:

```
salt-run nacl.enc datatoenc
salt-run nacl.enc datatoenc keyfile=/root/.nacl
salt-run nacl.enc datatoenc key=cKEzd4kXsbeCE7/nLTIqXwnUiD1ulg4NoeeYcCFpd9k=
```

salt.runners.nacl.keygen(keyfile=None)
Use libnacl to generate a private key

CLI Examples:

```
salt-run nacl.keygen
salt-run nacl.keygen keyfile=/root/.nacl
salt-run --out=newline_values_only nacl.keygen > /root/.nacl
```
13.13.18 salt.runners.network

Network tools to run from the Master

salt.runners.network.wol(mac, bcast=`255.255.255.255', destport=9)

Send a "Magic Packet" to wake up a Minion

CLI Example:

```
salt-run network.wol 08-00-27-13-69-77
salt-run network.wol 080027136977 255.255.255.255 7
salt-run network.wol 08:00:27:13:69:77 255.255.255.255 7
```

salt.runners.network.wollist(maclist, bcast=`255.255.255.255', destport=9)

Send a "Magic Packet" to wake up a list of Minions. This list must contain one MAC hardware address per line

CLI Example:

```
salt-run network.wollist '/path/to/maclist'
salt-run network.wollist '/path/to/maclist' 255.255.255.255 7
salt-run network.wollist '/path/to/maclist' 255.255.255.255 7
```

13.13.19 salt.runners.pagerduty

Runner Module for Firing Events via PagerDuty

New in version 2014.1.0.

configuration This module can be used by specifying the name of a configuration profile in the master config.

For example:

```
my-pagerduty-account:
pagerduty.api_key: F3Rbyjbve43rfWf2214
pagerduty.subdomain: mysubdomain
```

salt.runners.pagerduty.create_event(service_key=None, description=None, details=None, incident_key=None, profile=None)

Create an event in PagerDuty. Designed for use in states.

CLI Example:

```
salt-run pagerduty.create_event <service_key> <description> <details> !
  profile=my-pagerduty-account
```

The following parameters are required:

- **service_key** This key can be found by using pagerduty.list_services.
- **description** This is a short description of the event.
- **details** This can be a more detailed description of the event.
- **profile** This refers to the configuration profile to use to connect to the PagerDuty service.

salt.runners.pagerduty.list_escalation_policies(profile=None, api_key=None)

This function is an alias of list_policies.

List escalation policies belonging to this account

CLI Example:
salt.runs.pagerduty.list_policies my-pagerduty-account

salt.runs.pagerduty.list_incidents

  CLI Example:
  salt-run pagerduty.list_incidents my-pagerduty-account

salt.runs.pagerduty.list_escalation_policies my-pagerduty-account

salt.runs.pagerduty.list_incidences

  CLI Example:
  salt-run pagerduty.list_incidents my-pagerduty-account

salt.runs.pagerduty.list_policies

  CLI Example:
  salt-run pagerduty.list_policies my-pagerduty-account

salt.runs.pagerduty.list_escalation_policies

salt.runs.pagerduty.list_schedules

  CLI Example:
  salt-run pagerduty.list_schedules my-pagerduty-account

salt.runs.pagerduty.list_services

  CLI Example:
  salt-run pagerduty.list_services my-pagerduty-account

salt.runs.pagerduty.list_users

  CLI Example:
  salt-run pagerduty.list_users my-pagerduty-account

salt.runs.pagerduty.list_windows

  CLI Example:
  salt-run pagerduty.list_windows my-pagerduty-account

13.13.20 salt.runners.pillar

Functions to interact with the pillar compiler on the master

salt.runners.pillar.show_pillar

  CLI Example:
  show_pillar

  returns compiled pillar either of a specific minion or just the global available pillars. This function assumes
  that no minion has the id *.

  CLI Example:
  shows minion specific pillar:
salt-run pillar.show_pillar 'www.example.com'

shows global pillar:
salt-run pillar.show_pillar

shows global pillar for `dev' pillar environment:
salt-run pillar.show_pillar 'saltenv=dev'

API Example:

```python
import salt.config
import salt.runner

opts = salt.config.master_config('/etc/salt/master')
runner = salt.runner.RunnerClient(opts)
pillar = runner.cmd('pillar.show_pillar', [])

print(pillar)
```

salt.runners.pillar.show_top(minion=None, saltenv='base')

Returns the compiled top data for pillar for a specific minion. If no minion is specified, we use the first minion we find.

CLI Example:
salt-run pillar.show_top

### 13.13.21 salt.runners.pkg

Package helper functions using salt.modules.pkg

New in version 2015.8.0.

salt.runners.pkg.list_upgrades(jid, style='group', outputter='nested', ext_source=None)

Show list of available pkg upgrades using a specified format style

CLI Example:

```
salt-run pkg.list_upgrades jid=20141120114141719 style=group
```

### 13.13.22 salt.runners.queue

General management and processing of queues.

This runner facilitates interacting with various queue backends such as the included sqlite3 queue or the planned AWS SQS and Redis queues.

The queue functions such as `insert`, `delete`, and `pop` can be used for typical management of the queue.

The `process_queue` function pops the requested number of items from the queue and creates a Salt Event that can then be processed by a Reactor. The `process_queue` function can be called manually, or can be configured to run on a schedule with the Salt Scheduler or regular system cron. It is also possible to use the peer system to allow a minion to call the runner.

This runner, as well as the Queues system, is not api stable at this time.
There are many things that could potentially be done with queues within Salt. For the time being the focus will be on queueing infrastructure actions on specific minions. The queues generally will be populated with minion IDs. When the `process_queue` runner function is called events are created on the Salt Event bus that indicate the queue and a list of one or more minion IDs. The reactor is set up to match on event tags for a specific queue and then take infrastructure actions on those minion IDs. These actions might be to delete the minion’s key from the master, use salt-cloud to destroy the vm, or some other custom action.

```
salt.runners.queue.delete(queue, items, backend='sqlite')
Delete an item or items from a queue

CLI Example:
salt-run queue.delete myqueue myitem
salt-run queue.delete myqueue myitem backend=sqlite
salt-run queue.delete myqueue "["item1", "item2", "item3"]"
```

```
salt.runners.queue.insert(queue, items, backend='sqlite')
Add an item or items to a queue

CLI Example:
salt-run queue.insert myqueue myitem
salt-run queue.insert myqueue "["item1", "item2", "item3"]"
```

```
salt.runners.queue.list_items(queue, backend='sqlite')
List contents of a queue

CLI Example:
salt-run queue.list_items myqueue
```

```
salt.runners.queue.list_length(queue, backend='sqlite')
Provide the number of items in a queue

CLI Example:
salt-run queue.list_length myqueue
```

```
salt.runners.queue.list_queues(backend='sqlite')
Return a list of Salt Queues on the backend

CLI Example:
salt-run queue.list_queues
```

```
salt.runners.queue.pop(queue, quantity=1, backend='sqlite')
Pop one or more or all items from a queue

CLI Example:
salt-run queue.pop myqueue
salt-run queue.pop myqueue 6
salt-run queue.pop myqueue all
salt-run queue.pop myqueue 6 backend=sqlite
salt-run queue.pop myqueue all backend=sqlite
```
salt.runners.queue.**process_queue**(queue, quantity=1, backend='sqlite')
Pop items off a queue and create an event on the Salt event bus to be processed by a Reactor.

CLI Example:
```
salt-run queue.process_queue myqueue
salt-run queue.process_queue myqueue 6
salt-run queue.process_queue myqueue all backend=sqlite
```

13.13.23 salt.runners.reactor

A convenience system to manage reactors

salt.runners.reactor.**add**(event, reactors, saltenv='base', test=None)
Add a new reactor

CLI Example:
```
salt-run reactor.add 'salt/cloud/*/destroyed' reactors='/srv/reactor/destroy/*.sls'
```

salt.runners.reactor.**delete**(event, saltenv='base', test=None)
Delete a reactor

CLI Example:
```
salt-run reactor.delete 'salt/cloud/*/destroyed'
```

salt.runners.reactor.**list**(saltenv='base', test=None)
List currently configured reactors

CLI Example:
```
salt-run reactor.list
```

13.13.24 salt.runners.saltutil

Sync custom types to the Master

New in version 2016.3.0.

salt.runners.saltutil.**sync_all**(saltenv='base')
Sync all custom types

```
saltenv [base]  The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
```

CLI Example:
```
salt '*' saltutil.sync_all
```

salt.runners.saltutil.**sync_engines**(saltenv='base')
Sync engines from salt://_engines to the master

```
saltenv [base]  The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
```

CLI Example:
salt-run saltutil.sync_engines

salt.runners.saltutil.sync_grains(saltenv='base')
Sync grains modules from salt://_grains to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
CLI Example:
salt-run saltutil.sync_grains

salt.runners.saltutil.sync_modules(saltenv='base')
Sync execution modules from salt://_modules to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
CLI Example:
salt-run saltutil.sync_modules

salt.runners.saltutil.sync_output(saltenv='base')
Sync output modules from salt://_output to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
CLI Example:
salt-run saltutil.sync_output

salt.runners.saltutil.sync_pillar(saltenv='base')
Sync pillar modules from salt://_pillar to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
CLI Example:
salt-run saltutil.sync_pillar

salt.runners.saltutil.sync_proxymodules(saltenv='base')
Sync proxy modules from salt://_proxy to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
CLI Example:
salt-run saltutil.sync_proxy

salt.runners.saltutil.sync_queues(saltenv='base')
Sync queue modules from salt://_queues to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
CLI Example:
salt-run saltutil.sync_queues

salt.runners.saltutil.sync_renderers(saltenv='base')
Sync renderer modules from salt://_renderers to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
CLI Example:
salt-run saltutil.sync_renderers

salt.runners.saltutil.sync_returners(saltenv='base')
Sync returner modules from salt://_returners to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
CLI Example:
salt-run saltutil.sync_returners

salt.runners.saltutil.sync_runners(saltenv='base')
Sync runners from salt://_runners to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
CLI Example:
salt-run saltutil.sync_runners

salt.runners.saltutil.sync_states(saltenv='base')
Sync state modules from salt://_states to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
CLI Example:
salt-run saltutil.sync_states

salt.runners.saltutil.sync_tops(salenv='base')
New in version 2016.3.7,2016.11.4,Nitrogen.
Sync master_tops modules from salt://_tops to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
CLI Example:
salt-run saltutil.sync_tops

salt.runners.saltutil.sync_wheel(saltenv='base')
Sync wheel modules from salt://_wheel to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
CLI Example:
salt-run saltutil.sync_wheel

13.13.25 salt.runners.sdb

Runner for setting and querying data via the sdb API on the master
salt.runners.sdb.get(uri)
Get a value from a db, using a uri in the form of sdb://<profile>/<key>. If the uri provided does not start with sdb://, then it will be returned as-is.
CLI Example:
salt 'sdb.get sdb://mymemcached/foo

salt.runners.sdb.set(uri, value)
Set a value in a db, using a uri in the form of sdb://<profile>/<key>. If the uri provided does not start with sdb:// or the value is not successfully set, return False.

CLI Example:
salt 'sdb.set sdb://mymemcached/foo bar

13.13.26 salt.runners.search

Runner frontend to search system

salt.runners.search.query(term)
Query the search system

CLI Example:
salt-run search.query foo

13.13.27 salt.runners.spacewalk

Spacewalk Runner

New in version 2016.3.0.

Runner to interact with Spacewalk using Spacewalk API

codeauthor Nitin Madhok <nmadhok@clemson.edu>

To use this runner, set up the Spacewalk URL, username and password in the master configuration at /etc/salt/master or /etc/salt/master.d/spacewalk.conf:

```yaml
spacewalk:
  spacewalk01.domain.com
  username: "testuser"
  password: "verybadpass"
  spacewalk02.domain.com
  username: "testuser"
  password: "verybadpass"
```

Note: Optionally, protocol can be specified if the spacewalk server is not using the defaults. Default is protocol: https.

salt.runners.spacewalk.unregister(name, server_url)
To unregister specified server from Spacewalk

CLI Example:
salt-run spacewalk.unregister my-test-vm spacewalk01.domain.com
13.13.28  salt.runners.ssh

A Runner module interface on top of the salt-ssh Python API.

This allows for programmatic use from salt-api, the Reactor, Orchestrate, etc.

salt.runners.ssh.cmd(tgt, fun, arg=(), timeout=None, expr_form='glob', kwarg=None)

Execute a single command via the salt-ssh subsystem and return all routines at once

New in version 2015.5.0.

A wrapper around the SSHClient.cmd method.

13.13.29  salt.runners.state

Execute orchestration functions

salt.runners.state.event(tagmatch='*', count=-1, quiet=False, sock_dir=None, pretty=False, node='master')

Watch Salt's event bus and block until the given tag is matched

New in version 2014.7.0.

This is useful for utilizing Salt’s event bus from shell scripts or for taking simple actions directly from the CLI.

Enable debug logging to see ignored events.

Parameters

- **tagmatch** -- the event is written to stdout for each tag that matches this pattern; uses the same matching semantics as Salt’s Reactor.
- **count** -- this number is decremented for each event that matches the tagmatch parameter; pass -1 to listen forever.
- **quiet** -- do not print to stdout; just block
- **sock_dir** -- path to the Salt master’s event socket file.
- **pretty** -- Output the JSON all on a single line if False (useful for shell tools); pretty-print the JSON output if True.
- **node** -- Watch the minion-side or master-side event bus. .. versionadded:: 2016.3.0

CLI Examples:

```bash
# Reboot a minion and run highstate when it comes back online
salt 'jerry' system.reboot &
salt-run state.event 'salt/minion/jerry/start' count=1 quiet=True &
salt 'jerry' state.highstate

# Reboot multiple minions and run highstate when all are back online
salt -L 'kevin,stewart,dave' system.reboot &
salt-run state.event 'salt/minion/*/start' count=3 quiet=True &
salt -L 'kevin,stewart,dave' state.highstate

# Watch the event bus forever in a shell while-loop.
salt-run state.event | while read -r tag data; do
echo $tag
echo $data | jq -colour-output .
done
```
See also:

See https://github.com/saltstack/salt/blob/develop/tests/eventlisten.sh for an example of usage within a shell script.

```python
salt.runners.state.orchestrate(mods, saltenv='base', test=None, exclude=None, pillar=None)
```

New in version 0.17.0.

Execute a state run from the master, used as a powerful orchestration system.

See also:

More Orchestrate documentation
  • [Full Orchestrate Tutorial](https://docs.saltstack.com/en/latest/ref/module/salt.runners.state.html#salt.runners.state.orchestrate)
  • [Docs for the master-side state module](https://docs.saltstack.com/en/latest/ref/module/salt.runners.state.html#salt.runners.state.orchestrate)

CLI Examples:

```bash
salt-run state.orchestrate webserver
salt-run state.orchestrate webserver saltenv=dev test=True
```

Changed in version 2014.1.1: Runner renamed from state.sls to state.orchestrate

Changed in version 2014.7.0: Runner uses the pillar variable

```python
salt.runners.state.orchestrate_high(data, test=None, queue=False, pillar=None, **kwars)
```

Execute a single state orchestration routine

New in version 2015.5.0.

CLI Example:

```bash
salt-run state.orchestrate_high '{
    stage_one:
        {salt.state: [{tgt: "db*"}, {sls: postgres_setup}]},
    stage_two:
        {salt.state: [{tgt: "web*"}, {sls: apache_setup}, {
            require: [[salt: stage_one]],
        }],
    }
}'
```

```python
salt.runners.state.orchestrate_single(fun, name, test=None, queue=False, pillar=None, **kwars)
```

Execute a single state orchestration routine

New in version 2015.5.0.

CLI Example:

```bash
salt-run state.orchestrate_single fun=salt.wheel name=key.list_all
```

**13.13.30 salt.runners.survey**

A general map/reduce style salt runner for aggregating results returned by several different minions.

New in version 2014.7.0.

Aggregated results are sorted by the size of the minion pools which returned matching results.

Useful for playing the game: "some of these things are not like the others..." when identifying discrepancies in a large infrastructure managed by salt.
salt.runners.survey.diff(*args, **kwargs)
Return the DIFFERENCE of the result sets returned by each matching minion pool
New in version 2014.7.0.
These pools are determined from the aggregated and sorted results of a salt command.
This command displays the ```diffs``` as a series of 2-way differences -- namely the difference between the FIRST displayed minion pool (according to sort order) and EACH SUBSEQUENT minion pool result set.
Differences are displayed according to the Python `difflib.unified_diff()` as in the case of the salt execution module `file.get_diff`.
This command is submitted via a salt runner using the general form:
```
salt-run survey.diff [survey_sort=up/down] <target> <salt-execution-module> <salt-execution-module parameters>
```
Optionally accept a `survey_sort` parameter. Default: `survey_sort=down`
CLI Example #1: (Example to display the ```differences of files```)  
```
salt-run survey.diff survey_sort=up "*" cp.get_file_str file:///etc/hosts
```

salt.runners.survey.hash(*args, **kwargs)
Return the MATCHING minion pools from the aggregated and sorted results of a salt command
New in version 2014.7.0.
This command is submitted via a salt runner using the general form:
```
salt-run survey.hash [survey_sort=up/down] <target> <salt-execution-module> <salt-execution-module parameters>
```
Optionally accept a `survey_sort` parameter. Default: `survey_sort=down`
CLI Example #1: (functionally equivalent to `salt-run manage.up`)  
```
salt-run survey.hash "*" test.ping
```
CLI Example #2: (find an ```outlier``` minion config file)  
```
salt-run survey.hash "*" file.get_hash /etc/salt/minion survey_sort=up
```

13.13.31 salt.runners.test

This runner is used only for test purposes and servers no production purpose
salt.runners.test.arg(*args, **kwargs)
Output the given args and kwargs
Kwargs will be filtered for `private' keynames.
salt.runners.test.raw_arg(*args, **kwargs)
Output the given args and kwargs
salt.runners.test.sleep(s_time=10)
Sleep t seconds, then return True
salt.runners.test.stdout_print()  
Print `foo' and return `bar'
13.13.32 salt.runners.thin

The thin runner is used to manage the salt thin systems.

Salt Thin is a transport-less version of Salt that can be used to run routines in a standalone way. This runner has tools which generate the standalone salt system for easy consumption.

**salt.runners.thin.generate**

```python
salt.runners.thin.generate(extra_mods='', overwrite=False, so_mods='',
                           python2_bin='python2',
                           python3_bin='python3')
```

Generate the salt-thin tarball and print the location of the tarball Optional additional mods to include (e.g. mako) can be supplied as a comma delimited string. Permits forcing an overwrite of the output file as well.

CLI Example:

```
salt-run thin.generate
salt-run thin.generate mako
salt-run thin.generate mako,wempy 1
salt-run thin.generate overwrite=1
```

**salt.runners.thin.generate_min**

```python
salt.runners.thin.generate_min(extra_mods='', overwrite=False, so_mods='',
                               python2_bin='python2',
                               python3_bin='python3')
```

Generate the salt-thin tarball and print the location of the tarball. Optional additional mods to include (e.g. mako) can be supplied as a comma delimited string. Permits forcing an overwrite of the output file as well.

CLI Example:

```
salt-run thin.generate_min
```

13.13.33 salt.runners.virt

Control virtual machines via Salt

**salt.runners.virt.force_off**(name)

Force power down the named virtual machine

**salt.runners.virt.host_info**(host=None)

Return information about the host connected to this master

**salt.runners.virt.hyper_info**(hyper=None)

Return information about the host connected to this master

**salt.runners.virt.init**(name, cpu, mem, image, hyper=None, hypervisor='kvm', host=None, seed=True, nic='default', install=True, start=True, disk='default', saltenv='base', enable_vnc=False)

This routine is used to create a new virtual machine. This routines takes a number of options to determine what the newly created virtual machine will look like.

- **name** The mandatory name of the new virtual machine. The name option is also the minion id, all minions must have an id.
- **cpu** The number of cpus to allocate to this new virtual machine.
- **mem** The amount of memory to allocate to his virtual machine. The number is interpreted in megabytes.
- **image** The network location of the virtual machine image, commonly a location on the salt fileserver, but http, https and ftp can also be used.
- **hypervisor** The hypervisor to use for the new virtual machine. Default is `kvm`. 

---

13.13. runner modules
**host** The host to use for the new virtual machine, if this is omitted Salt will automatically detect what host to use.

**seed** Set to False to prevent Salt from seeding the new virtual machine.

**nic** The nic profile to use, defaults to the ``default`` nic profile which assumes a single network interface per VM associated with the ``br0`` bridge on the master.

**install** Set to False to prevent Salt from installing a minion on the new VM before it spins up.

**disk** The disk profile to use

**saltenv** The Salt environment to use

salt.runners.virt.list(*host=None, quiet=False, hyper=None*)

List the virtual machines on each host, this is a simplified query, showing only the virtual machine names belonging to each host. A single host can be passed in to specify an individual host to list.

salt.runners.virt.migrate(*name, target='')*

Migrate a VM from one host to another. This routine will just start the migration and display information on how to look up the progress.

salt.runners.virt.next_host()

Return the host to use for the next autodeployed VM. This queries the available host and executes some math to determine the most "available" next host.

salt.runners.virt.next_hyper()

Return the host to use for the next autodeployed VM. This queries the available host and executes some math to determine the most "available" next host.

salt.runners.virt.pause(*name*)

Pause the named VM

salt.runners.virt.purge(*name, delete_key=True*)

Destroy the named VM

salt.runners.virt.query(*host=None, quiet=False, hyper=None*)

Query the virtual machines. When called without options all hosts are detected and a full query is returned. A single host can be passed in to specify an individual host to query.

salt.runners.virt.reset(*name*)

Force power down and restart an existing VM

salt.runners.virt.resume(*name*)

Resume a paused VM

salt.runners.virt.start(*name*)

Start a named virtual machine

salt.runners.virt.vm_info(*name, quiet=False*)

Return the information on the named VM

---

**13.13.34 salt.runners.winrepo**

Runner to manage Windows software repo

salt.runners.winrepo.genrepo(*opts=None, fire_event=True*)

Generate winrepo_cachefile based on sls files in the winrepo_dir

- **opts** Specify an alternate opts dict. Should not be used unless this function is imported into an execution module.
- **fire_event** [True] Fire an event on failure. Only supported on the master.

CLI Example:
salt-run winrepo.genrepo

salt.runners.winrepo.update_git_repos(opts=None, clean=False, masterless=False)

Checkout git repos containing Windows Software Package Definitions

opts Specify an alternate opts dict. Should not be used unless this function is imported into an execution module.

clean [False] Clean repo cachedirs which are not configured under winrepo_remotes.

Warning: This argument should not be set to True if a mix of git and non-git repo definitions are being used, as it will result in the non-git repo definitions being removed.

New in version 2015.8.0.

CLI Examples:

```bash
salt-run winrepo.update_git_repos
salt-run winrepo.update_git_repos clean=True
```

### 13.14 sdb modules

<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>couchdb</td>

</tr>
<tr>
<td>rest</td>
<td>Generic REST API SDB Module</td>
</tr>
<tr>
<td>sqlite3</td>
<td>SQLite sdb Module</td>
</tr>
</tbody>
</table>

#### 13.14.1 salt.sdb.couchdb

CouchDB sdb Module

- **maintainer** SaltStack
- **maturity** New
- **depends** python2-couch
- **platform** all

This allow interaction between Salt and a CouchDB [couchdb.apache.org] database. It uses salt's sdb system to allow for inserts and retrievals using the sdb:// prefix in salt configuration files.

To use the couchbase sdb module, it must first be configured in the salt master or minion config. The following arguments are required:

```yaml
couchdb_sdb:
  driver: couchdb
  host: localhost
  port: 5984
  database: salt_sdb
```

One could then query the CouchDB instance via an sdb:// URI such as the following:
password: sdb://couchdb_sdb/mykey

To use this interface, you must track IDs on your own or have another source to do the map-reduce logic necessary to calculate the ID you wish to fetch.

Additional contributions to build true map-reduce functionality into this module would be welcome.

salt.sdb.couchdb.get(key, profile=None)
Get a value from couchdb by id

salt.sdb.couchdb.set(key, value, profile=None)
Set a key/value pair in couchdb

13.14.2 salt.sdb.etcd_db

etcd Database Module

maintainer SaltStack
maturity New
depends python-etcd
platform all

New in version 2015.5.0.

This module allows access to the etcd database using an sdb:// URI. This package is located at https://pypi.python.org/pypi/python-etcd.

Like all sdb modules, the etcd module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

myetcd:
driver: etcd
etcd.host: 127.0.0.1
etcd.port: 4001

The driver refers to the etcd module, etcd.host refers to the host that is hosting the etcd database and etcd.port refers to the port on that host.

password: sdb://myetcd/mypassword

salt.sdb.etcd_db.get(key, service=None, profile=None)
Get a value from the etcd service

salt.sdb.etcd_db.set(key, value, service=None, profile=None)
Set a key/value pair in the etcd service

13.14.3 salt.sdb.keyring_db

Keyring Database Module

maintainer SaltStack
maturity New
depends keyring
platform all
This module allows access to the keyring package using an sdb:// URI. This package is located at https://pypi.python.org/pypi/keyring.

Care must be taken when using keyring. Not all keyend backends are supported on all operating systems. Also, many backends require an agent to be running in order to work. For instance, the "Secret Service" backend requires a compatible agent such as gnome-keyring-daemon or kwallet to be running. The keyczar backend does not seem to enjoy the benefits of an agent, and so using it will require either that the password is typed in manually (which is unreasonable for the salt-minion and salt-master daemons, especially in production) or an agent is written for it.

Like all sdb modules, the keyring module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```
mykeyring:
  driver: keyring
  service: system
```

The driver refers to the keyring module, service refers to the service that will be used inside of keyring (which may be likened unto a database table) and mykeyring refers to the name that will appear in the URI:

```
password: sdb://mykeyring/mypassword
```

The underlying backend configuration must be configured via keyring itself. For examples and documentation, see keyring:

https://pypi.python.org/pypi/keyring

New in version 2014.1.4.

```
salt.sdb.keyring_db.get(key, service=None, profile=None)
  Get a value from a keyring service
```
```
salt.sdb.keyring_db.set(key, value, service=None, profile=None)
  Set a key/value pair in a keyring service
```

### 13.14.4 salt.sdb.memcached

Memcached sdb Module

- maintainer SaltStack
- maturity New
- depends python-memcached
- platform all

This module allows access to memcached using an sdb:// URI. This package is located at https://pypi.python.org/pypi/python-memcached.

Like all sdb modules, the memcached module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```
mymemcache:
  driver: memcached
  host: localhost
  port: 11211
```

The driver refers to the memcached module, host and port the memcached server to connect to (defaults to localhost and 11211, and mymemcached refers to the name that will appear in the URI:
password: sdb://mymemcached/mykey

```python
salt.sdb.memcached.get(key, profile=None)
Get a value from memcached
```

```python
class.sdb.memcached.set(key, value, profile=None)
Set a key/value pair in memcached
```

### 13.14.5 salt.sdb.rest module

Generic REST API SDB Module

- **maintainer**: SaltStack
- **maturity**: New
- **platform**: all

New in version 2015.8.0.

This module allows access to a REST interface using an `sdb://` URI.

Like all REST modules, the REST module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```yaml
my-rest-api:
  driver: rest
  urls:
    url: https://api.github.com/
  keys:
    url: https://api.github.com/users/{{user}}/keys
    requests_lib: True
```

The `driver` refers to the REST module, and must be set to `rest` in order to use this driver. Each of the other items inside this block refers to a separate set of HTTP items, including a URL and any options associated with it. The options used here should match the options available in `salt.utils.http.query()`.

In order to call the `urls` item in the example, the following reference can be made inside a configuration file:

```yaml
github_urls: sdb://my-rest-api/urls
```

Key/Value pairs may also be used with this driver, and merged into the URL using the configured renderer (jinja, by default). For instance, in order to use the keys item in the example, the following reference can be made:

```yaml
github_urls: sdb://my-rest-api/keys?user=myuser
```

This will cause the following URL to actually be called:

```yaml
https://api.github.com/users/myuser/keys
```

Key/Value pairs will NOT be passed through as GET data. If GET data needs to be sent to the URL, then it should be configured in the SDB configuration block. For instance:

```yaml
another-rest-api:
  driver: rest
  url: https://api.example.com/users/
  params:
    user: myuser
```
salt.sdb.rest.get(key, service=None, profile=None)
    Get a value from the REST interface

salt.sdb.rest.query(key, value=None, service=None, profile=None)
    Get a value from the REST interface

salt.sdb.rest.set(key, value, service=None, profile=None)
    Set a key/value pair in the REST interface

13.14.6 salt.sdb.sqlite3

SQLite sdb Module

    maintainer    SaltStack
    maturity      New
    platform      all

This module allows access to sqlite3 using an sdb:// URI

Like all sdb modules, the sqlite3 module requires a configuration profile to be configured in either the minion or
master configuration file. This profile requires very little. For example:

```yaml
mysqlite:
    driver: sqlite3
    database: /tmp/sdb.sqlite
    table: sdb
    create_table: True
```

The driver refers to the sqlite3 module, database refers to the sqlite3 database file. table is the table within
the db that will hold keys and values (defaults to sdb). The database and table will be created if they do not exist.

**Advanced Usage:**

Instead of a table name, it is possible to provide custom SQL statements to create the table(s) and get and set values.

salt.sdb.sqlite3.get(key, profile=None)
    Get a value from sqlite3

salt.sdb.sqlite3.set(key, value, profile=None)
    Set a key/value pair in sqlite3

13.15 serializer modules

<table>
<thead>
<tr>

</tr>
<tr>
<td>yaml</td>
<td>salt.serializers.yaml</td>
</tr>
<tr>
<td>yamlex</td>
<td>salt.serializers.yamlex</td>
</tr>
</tbody>
</table>
13.15.1 salt.serializers.configparser module

**salt.serializers.configparser**

New in version 2016.3.0.

Implements a configparser serializer.

```python
salt.serializers.configparser.deserialize(stream_or_string, **options)
```

Deserializes any string or stream like object into a Python data structure.

**Parameters**

- `stream_or_string` -- stream or string to deserialize.
- `options` -- options given to lower configparser module.

```python
salt.serializers.configparser.serialize(obj, **options)
```

Serializes Python data to a configparser formatted string or file.

**Parameters**

- `obj` -- the data structure to serialize
- `options` -- options given to lower configparser module.

13.15.2 salt.serializers.json

**salt.serializers.json**

Implements JSON serializer.

It's just a wrapper around json (or simplejson if available).

```python
salt.serializers.json.deserialize(stream_or_string, **options)
```

Deserializes any string or stream like object into a Python data structure.

**Parameters**

- `stream_or_string` -- stream or string to deserialize.
- `options` -- options given to lower json/simplejson module.

```python
salt.serializers.json.serialize(obj, **options)
```

Serializes Python data to JSON.

**Parameters**

- `obj` -- the data structure to serialize
- `options` -- options given to lower json/simplejson module.

13.15.3 salt.serializers.msgpack

**salt.serializers.msgpack**

Implements MsgPack serializer.

```python
salt.serializers.msgpack.deserialize(stream_or_string, **options)
```

Deserializes any string of stream like object into a Python data structure.

**Parameters**

- `stream_or_string` -- stream or string to deserialize.
- **options** -- options given to lower msgpack module.

    ```python
    salt.serializers.msgpack.serialize(obj, **options)
    # Serialize Python data to MsgPack.
    ``

    Parameters
    - **obj** -- the data structure to serialize
    - **options** -- options given to lower msgpack module.

13.15.4 salt.serializers.python module

    ```python
    salt.serializers.python
    # New in version 2016.3.0.
    # Implements a Python serializer (via pprint.format)
    ```

    ```python
    salt.serializers.python.serialize(obj, **options)
    # Serialize Python data to a Python string representation (via pprint.format)
    ``

    Parameters
    - **obj** -- the data structure to serialize
    - **options** -- options given to pprint.format

13.15.5 salt.serializers.yaml

    ```python
    salt.serializers.yaml
    # Implements YAML serializer.
    ```

    Underneath, it is based on pyyaml and use the safe dumper and loader. It also use C bindings if they are available.

    ```python
    salt.serializers.yamldeserialize(stream_or_string, **options)
    # Deserialize any string of stream like object into a Python data structure.
    ``

    Parameters
    - **stream_or_string** -- stream or string to deserialize.
    - **options** -- options given to lower yaml module.

    ```python
    salt.serializers.yaml.serialize(obj, **options)
    # Serialize Python data to YAML.
    ``

    Parameters
    - **obj** -- the data structure to serialize
    - **options** -- options given to lower yaml module.

13.15.6 salt.serializers.yamlex

    ```python
    salt.serializers.yamlex
    # YAMLEX is a format that allows for things like sls files to be more intuitive.
    # It's an extension of YAML that implements all the salt magic:
    # - it implies omap for any dict like.
    # - it implies that string like data are str, not unicode.
    # ...
For example, the file `states.sls` has this contents:

```plaintext
foo:
  bar: 42
  baz: [1, 2, 3]
```

The file can be parsed into Python like this

```python
from salt.serializers import yamlex
with open('state.sls', 'r') as stream:
    obj = yamlex.deserialize(stream)
```

Check that `obj` is an OrderedDict

```python
from salt.utils.odict import OrderedDict
assert isinstance(obj, dict)
assert isinstance(obj, OrderedDict)
```

yamlex `__repr__` and `__str__` objects’ methods render YAML understandable string. It means that they are template friendly.

```python
print '{0}'.format(obj)
```

returns:

```plaintext
{foo: {bar: 42, baz: [1, 2, 3]}}
```

and they are still valid YAML:

```python
from salt.serializers import yaml
yml_obj = yaml.deserialize(str(obj))
assert yml_obj == obj
```

yamlex implements also custom tags:

`!aggregate`

this tag allows structures aggregation.

For example:

```plaintext
placeholder: !aggregate foo
placeholder: !aggregate bar
placeholder: !aggregate baz
```

is rendered as

```plaintext
placeholder: [foo, bar, baz]
```

`!reset`

this tag flushes the computing value.

```plaintext
placeholder: {!aggregate foo: {foo: 42}}
placeholder: {!aggregate foo: {bar: null}}
!reset placeholder: {!aggregate foo: {baz: ina}}
```
is roughly equivalent to

```python
placeholder: {!aggregate foo: {baz: inga}}
```

Document is defacto an aggregate mapping.

```python
salt.serializers.yamlex.deserialize(stream_or_string, **options)
```
Deserialise any string of stream like object into a Python data structure.

**Parameters**

- `stream_or_string` -- stream or string to deserialise.
- `options` -- options given to lower yaml module.

```python
salt.serializers.yamlex.serialize(obj, **options)
```
Serialize Python data to YAML.

**Parameters**

- `obj` -- the data structure to serialize
- `options` -- options given to lower yaml module.

</table>

### 13.16.1 salt.states.alias

Configuration of email aliases

The mail aliases file can be managed to contain definitions for specific email aliases:

```yaml
username:
  alias.present:
    - target: user@example.com

thomas:
  alias.present:
    - target: thomas@example.com
```

The default alias file is set to /etc/aliases, as defined in Salt’s config execution module. To change the alias file from the default location, set the following in your minion config:

```yaml
aliases.file: /my/alias/file
```

**salt.states.alias.absent(name)**

Ensure that the named alias is absent

*name* The alias to remove

**salt.states.alias.present(name, target)**

Ensures that the named alias is present with the given target or list of targets. If the alias exists but the target differs from the previous entry, the target(s) will be overwritten. If the alias does not exist, the alias will be created.

*name* The local user/address to assign an alias to

*target* The forwarding address

### 13.16.2 salt.states.alternatives

Configuration of the alternatives system

Control the alternatives system
{% set my_hadoop_conf = '/opt/hadoop/conf' %}

{{ my_hadoop_conf }}:
  file.directory

hadoop-0.20-conf:
  alternatives.install:
    - name: hadoop-0.20-conf
    - link: /etc/hadoop-0.20/conf
    - path: {{ my_hadoop_conf }}
    - priority: 30
    - require:
      - file: {{ my_hadoop_conf }}

hadoop-0.20-conf:
  alternatives.remove:
    - name: hadoop-0.20-conf
    - path: {{ my_hadoop_conf }}

salt.states.alternatives.auto(name)
New in version 0.17.0.

  Instruct alternatives to use the highest priority path for <name>
  name is the master name for this link group (e.g. pager)

salt.states.alternatives.install(name, link, path, priority)
Install new alternative for defined <name>
  name is the master name for this link group (e.g. pager)
  link is the symlink pointing to /etc/alternatives/<name>. (e.g. /usr/bin/pager)
  path is the location of the new alternative target. NB: This file / directory must already exist. (e.g. /usr/bin/less)
  priority is an integer; options with higher numbers have higher priority in automatic mode.

salt.states.alternatives.remove(name, path)
Removes installed alternative for defined <name> and <path> or fallback to default alternative, if some defined before.
  name is the master name for this link group (e.g. pager)
  path is the location of one of the alternative target files. (e.g. /usr/bin/less)

salt.states.alternatives.set(name, path)
New in version 0.17.0.

  Sets alternative for <name> to <path>, if <path> is defined as an alternative for <name>.
  name is the master name for this link group (e.g. pager)
  path is the location of one of the alternative target files. (e.g. /usr/bin/less)

13.16.3 salt.states.apache

Apache state
New in version 2014.7.0.

Allows for inputting a yaml dictionary into a file for apache configuration files.

The variable this is special and signifies what should be included with the above word between angle brackets (<>).
- config:
  - VirtualHost:
    this: '*:80'
  ServerName:
  - website.com
  ServerAlias:
  - www.website.com
  - dev.website.com
  ErrorLog: logs/website.com-error_log
  CustomLog: logs/website.com-access_log combined
  DocumentRoot: /var/www/vhosts/website.com
  Directory:
  this: /var/www/vhosts/website.com
  Order: Deny,Allow
  Deny from: all
  Allow from:
  - 127.0.0.1
  - 192.168.100.0/24
  Options:
  - Indexes
  - FollowSymlinks
  AllowOverride: All

salt.states.apache.configfile(name, config)

13.16.4 salt.states.apache_conf module

Manage Apache Confs

New in version 2016.3.0.

Enable and disable apache confs.

Enable security conf:
  apache_conf.enabled:
  - name: security

Disable security conf:
  apache_conf.disabled:
  - name: security

salt.states.apache_conf.disable(name)

Ensure an Apache conf is disabled.

Warning: This function is deprecated and will be removed in Salt Nitrogen.

name Name of the Apache conf

salt.states.apache_conf.disabled(name)

Ensure an Apache conf is disabled.

name Name of the Apache conf

salt.states.apache_conf.enable(name)

Ensure an Apache conf is enabled.
**Warning:** This function is deprecated and will be removed in Salt Nitrogen.

`name` Name of the Apache conf

salt.states.apache_conf.enabled(name)
Ensure an Apache conf is enabled.

- name Name of the Apache conf

### 13.16.5 salt.states.apache_module

Manage Apache Modules

New in version 2014.7.0.

Enable and disable apache modules.

Enable cgi module:
```
    apache_module.enabled:
        - name: cgi
```

Disable cgi module:
```
    apache_module.disabled:
        - name: cgi
```

salt.states.apache_module.disable(name)
Ensure an Apache module is disabled.

- name Name of the Apache module

salt.states.apache_module.disabled(name)
Ensure an Apache module is disabled.

- name Name of the Apache module

salt.states.apache_module.enable(name)
Ensure an Apache module is enabled. This function is deprecated and will be removed in Salt Nitrogen. Please use the enabled state function instead.

- name Name of the Apache module

salt.states.apache_module.enabled(name)
Ensure an Apache module is enabled.

- name Name of the Apache module

### 13.16.6 salt.states.apache_site module

Manage Apache Sites

New in version 2016.3.0.

Enable and disable apache sites.
Enable default site:
  apache_site.enabled:
    - name: default

Disable default site:
  apache_site.disabled:
    - name: default

salt.states.apache_site.disable(name)
  Ensure an Apache site is disabled.

  WARNING: This function is deprecated and will be removed in Salt Nitrogen.

  name  Name of the Apache site

salt.states.apache_site.disabled(name)
  Ensure an Apache site is disabled.
  name  Name of the Apache site

colors.states.apache_site.enable(name)
  Ensure an Apache site is enabled.

  WARNING: This function is deprecated and will be removed in Salt Nitrogen.

  name  Name of the Apache site

colors.states.apache_site.enabled(name)
  Ensure an Apache site is enabled.
  name  Name of the Apache site

13.16.7  salt.states.aptpkg

Package management operations specific to APT- and DEB-based systems

colors.states.aptpkg.held(name)
  Set package in `hold` state, meaning it will not be upgraded.
  name  The name of the package, e.g., `tmux`

13.16.8  salt.states.archive

Extract an archive
New in version 2014.1.0.

colors.states.archive.extracted(name, source, archive_format, archive_user=None, password=None, user=None, group=None, tar_options=None, source_hash=None, if_missing=None, keep=False, trim_output=False, skip_verify=False, source_hash_update=None)
  New in version 2014.1.0.

  State that make sure an archive is extracted in a directory. The downloaded archive is erased if successfully extracted. The archive is downloaded only if necessary.
Note: If if_missing is not defined, this state will check for name instead. If name exists, it will assume the archive was previously extracted successfully and will not extract it again.

Example, tar with flag for lmza compression:

```
graylog2-server:
  archive.extracted:
    - name: /opt/
    - source: https://github.com/downloads/Graylog2/graylog2-server/graylog2-
        server-0.9.6p1.tar.lzma
    - source_hash: md5=499ae16dcae71eeb7c3a30c75ea7a1a6
    - tar_options: J
    - archive_format: tar
    - if_missing: /opt/graylog2-server-0.9.6p1/
```

Example, tar with flag for verbose output:

```
graylog2-server:
  archive.extracted:
    - name: /opt/
    - source: https://github.com/downloads/Graylog2/graylog2-server/graylog2-
        server-0.9.6p1.tar.gz
    - source_hash: md5=499ae16dcae71eeb7c3a30c75ea7a1a6
    - archive_format: tar
    - tar_options: v
    - user: root
    - group: root
    - if_missing: /opt/graylog2-server-0.9.6p1/
```

Example, tar with flag for lmza compression and update based if source_hash differs from what was previously extracted:

```
graylog2-server:
  archive.extracted:
    - name: /opt/
    - source: https://github.com/downloads/Graylog2/graylog2-server/graylog2-
        server-0.9.6p1.tar.lzma
    - source_hash: md5=499ae16dcae71eeb7c3a30c75ea7a1a6
    - source_hash_update: true
    - tar_options: J
    - archive_format: tar
    - if_missing: /opt/graylog2-server-0.9.6p1/
```

name Location where archive should be extracted
password Password to use with password protected zip files. Currently only zip files with passwords are supported.

New in version 2016.3.0.
source Archive source, same syntax as file.managed source argument.
source_hash Hash of source file, or file with list of hash-to-file mappings. It uses the same syntax as the file.managed source_hash argument.
source_hash_update Set this to True if archive should be extracted if source_hash has changed. This would extract regardless of the if_missing parameter.

New in version 2016.3.0.
skip_verify:False If True, hash verification of remote file sources (http://, https://, ftp://) will be skipped, and the source_hash argument will be ignored.
New in version 2016.3.4.

**archive_format** tar, zip or rar

**archive_user** The user to own each extracted file.

Deprecated since version 2014.7.2: Replaced by **user** parameter

**user** The user to own each extracted file.

New in version 2015.8.0.

Changed in version 2016.3.0: When used in combination with **if_missing**, ownership will only be enforced if **if_missing** is a directory.

**group** The group to own each extracted file.

New in version 2015.8.0.

Changed in version 2016.3.0: When used in combination with **if_missing**, ownership will only be enforced if **if_missing** is a directory.

**if_missing** If specified, this path will be checked, and if it exists then the archive will not be extracted. This can be helpful if the archive extracts all files into a subfolder. This path can be either a directory or a file, so this option can also be used to check for a semaphore file and conditionally skip extraction.

Changed in version 2016.3.0: When used in combination with either **user** or **group**, ownership will only be enforced when **if_missing** is a directory.

**tar_options** If **archive_format** is set to tar, this option can be used to specify a string of additional arguments to pass to the tar command. If **archive_format** is set to tar and this option is not used, then the minion will attempt to use Python's native `tarfile` support to extract it. Python's native `tarfile` support can only handle gzip and bzip2 compression, however.

Changed in version 2015.8.11,2016.3.2: XZ-compressed archives no longer require J to manually be set in the **tar_options**, they are now detected automatically and Salt will extract them using `xz-utils`. This is a more platform-independent solution, as not all tar implementations support the J argument for extracting archives.

**Note:** Main operators like `-x`, `--extract`, `--get`, `-c` and `-f|--file` **should not be used** here.

Using this option means that the `tar` command will be used, which is less platform-independent, so keep this in mind when using this option; the options must be valid options for the `tar` implementation on the minion's OS.

**keep** Keep the archive in the minion's cache

**trim_output** The number of files we should output on success before the rest are trimmed, if this is set to True then it will default to 100

New in version 2016.3.0.

### 13.16.9 `salt.states.artifactory`

This state downloads artifacts from artifactory.

```
salt.states.artifactory.downloaded(name, artifact, target_dir='/tmp', target_file=None)
```

Ensures that the artifact from artifactory exists at given location. If it doesn't exist, then it will be downloaded. It it already exists then the checksum of existing file is checked against checksum in artifactory. If it is different then the step will fail.

**artifact** Details of the artifact to be downloaded from artifactory. Various options are:

- **artifact_url**: URL of the artifactory instance
- **repository**: Repository in artifactory
- **artifact_id**: Artifact ID
- **group_id**: Group ID
• packaging: Packaging
• classifier: Classifier .. versionadded:: 2015.8.0
• version: Version One of the following: - Version to download - latest - Download the latest release of this artifact - latest_snapshot - Download the latest snapshot for this artifact
• username: Artifactory username .. versionadded:: 2015.8.0
• password: Artifactory password .. versionadded:: 2015.8.0

target_dir Directory where the artifact should be downloaded. By default it is downloaded to /tmp directory.
target_file Target file to download artifact to. By default file name is resolved by artifactory.

An example to download an artifact to a specific file:

```yaml
jboss_module_downloaded:
  artifactory.downloaded:
    - artifact:
        artifactory_url: http://artifactory.intranet.example.com/artifactory
        repository: 'libs-release-local'
        artifact_id: 'module'
        group_id: 'com.company.module'
        packaging: 'jar'
        classifier: 'sources'
        version: '1.0'
    - target_file: /opt/jboss7/modules/com/company/lib/module.jar
```

Download artifact to the folder (automatically resolves file name):

```yaml
jboss_module_downloaded:
  artifactory.downloaded:
    - artifact:
        artifactory_url: http://artifactory.intranet.example.com/artifactory
        repository: 'libs-release-local'
        artifact_id: 'module'
        group_id: 'com.company.module'
        packaging: 'jar'
        classifier: 'sources'
        version: '1.0'
    - target_dir: /opt/jboss7/modules/com/company/lib
```

### 13.16.10 salt.states.at

Configuration disposable regularly scheduled tasks for at.

The at state can be add disposable regularly scheduled tasks for your system.

salt.states.at.absent(name, jobid=None, **kwargs)

Remove a job from queue The `kwargs` can include hour, minute, day, month, year

limit Target range
tag Job's tag
runas Runs user-specified jobs

```yaml
example1:
  at.absent:
    - limit: all

example2:
  at.absent:
    - limit: all
    - year: 13
```
example3:
  at.absent:
  - limit: all
  - tag: rose
  - runas: jim

example4:
  at.absent:
  - limit: all
  - tag: rose
  - day: 13
  - hour: 16

**salt.states.at.present**(name, timespec, tag=None, user=None, job=None)
Add a job to queue.

- **job** Command to run.
- **timespec** The 'timespec' follows the format documented in the at(1) manpage.
- **tag** Make a tag for the job.
- **user** The user to run the at job

New in version 2014.1.4.

rose:
  at.present:
  - job: 'echo "I love saltstack" > love'
  - timespec: '9:09 11/09/13'
  - tag: love
  - user: jam

13.16.11 **salt.states.augeas**
Configuration management using Augeas
New in version 0.17.0.
This state requires the augeas Python module.

Augeas can be used to manage configuration files.

**Warning:** Minimal installations of Debian and Ubuntu have been seen to have packaging bugs with python-augeas, causing the augeas module to fail to import. If the minion has the augeas module installed, and the state fails with a comment saying that the state is unavailable, first restart the salt-minion service. If the problem persists past that, the following command can be run from the master to determine what is causing the import to fail:

```bash
salt minion-id cmd.run 'python -c "from augeas import Augeas"'
```

For affected Debian/Ubuntu hosts, installing libpython2.7 has been known to resolve the issue.

**salt.states.augeas.change**(name, context=None, changes=None, lens=None, load_path=None, **kwargs)
New in version 2014.7.0.
This state replaces setvalue().
Issue changes to Augeas, optionally for a specific context, with a specific lens.

**name** State name

**context** A file path, prefixed by `/files`. Should resolve to an actual file (not an arbitrary augeas path). This is used to avoid duplicating the file name for each item in the changes list (for example, `set bind 0.0.0.0` in the example below operates on the file specified by `context`). If `context` is not specified, a file path prefixed by `/files` should be included with the `set` command.

The file path is examined to determine if the specified changes are already present.

```plaintext
redis-conf:
  augeas.change:
    - context: /files/etc/redis/redis.conf
    - changes:
      - set bind 0.0.0.0
      - set maxmemory 1G
```

**changes** List of changes that are issued to Augeas. Available commands are `set`, `setm`, `mv/move`, `ins/insert`, and `rm/remove`.

**lens** The lens to use, needs to be suffixed with `.lns`, e.g.: `Nginx.lns`. See the list of stock lenses shipped with Augeas.

New in version 2016.3.0.

**load_path** A list of directories that modules should be searched in. This is in addition to the standard load path and the directories in `AUGEAS_LENS_LIB`.

Usage examples:

Set the `bind` parameter in `/etc/redis/redis.conf`:

```plaintext
redis-conf:
  augeas.change:
    - changes:
      - set /files/etc/redis/redis.conf/bind 0.0.0.0
```

**Note:** Use the `context` parameter to specify the file you want to manipulate. This way you don’t have to include this in the changes every time:

```plaintext
redis-conf:
  augeas.change:
    - context: /files/etc/redis/redis.conf
    - changes:
      - set /files/etc/redis/redis.conf/bind 0.0.0.0
      - set databases 4
      - set maxmemory 1G
```

Augeas is aware of a lot of common configuration files and their syntax. It knows the difference between for example ini and yaml files, but also files with very specific syntax, like the hosts file. This is done with lenses, which provide mappings between the Augeas tree and the file.

There are many preconfigured lenses that come with Augeas by default, and they specify the common locations for configuration files. So most of the time Augeas will know how to manipulate a file. In the event that you need to manipulate a file that Augeas doesn’t know about, you can specify the lens to use like this:

```plaintext
redis-conf:
  augeas.change:
    - lens: redis
    - context: /files/etc/redis/redis.conf
    - changes:
      - set bind 0.0.0.0
```
Note: Even though Augeas knows that `/etc/redis/redis.conf` is a Redis configuration file and knows how to parse it, it is recommended to specify the lens anyway. This is because by default, Augeas loads all known lenses and their associated file paths. All these files are parsed when Augeas is loaded, which can take some time. When specifying a lens, Augeas is loaded with only that lens, which speeds things up quite a bit.

A more complex example, this adds an entry to the services file for Zabbix, and removes an obsolete service:

```bash
zabbix-service:
    augeas.change:
        - lens: services
        - context: /files/etc/services
        - changes:
            - ins service-name after service-name[last()]
            - set service-name[last()] zabbix-agent
            - set service-name[. = 'zabbix-agent']/#comment "Zabbix Agent service"
            - set service-name[. = 'zabbix-agent']/port 10050
            - set service-name[. = 'zabbix-agent']/protocol tcp
            - rm service-name[. = 'im-obsolete']
        - unless: grep "zabbix-agent" /etc/services
```

Warning: Don’t forget the `unless` here, otherwise a new entry will be added every time this state is run.

13.16.12 salt.states.aws_sqs

Manage SQS Queues

Create and destroy SQS queues. Be aware that this interacts with Amazon’s services, and so may incur charges.

This module uses the awscli tool provided by Amazon. This can be downloaded from pip. Also check the documentation for awscli for configuration information.

```bash
myqueue:
    aws_sqs.exists:
        - region: eu-west-1

salt.states.aws_sqs.absent(name, region, user=None, opts=False)
    Remove the named SQS queue if it exists.
    name Name of the SQS queue.
    region Region to remove the queue from
    user Name of the user performing the SQS operations
    opts Include additional arguments and options to the aws command line

salt.states.aws_sqs.exists(name, region, user=None, opts=False)
    Ensure the SQS queue exists.
    name Name of the SQS queue.
    region Region to create the queue
    user Name of the user performing the SQS operations
    opts Include additional arguments and options to the aws command line
```
13.16.13 salt.states.beacon

Management of the Salt beacons

New in version 2015.8.0.

```
ps:
  beacon.present:
    - enable: False
    - salt-master: running
    - apache2: stopped

sh:
  beacon.present:

load:
  beacon.present:
    - 1m:
      - 0.0
      - 2.0
    - 5m:
      - 0.0
      - 1.5
    - 15m:
      - 0.1
      - 1.0
```

salt.states.beacon.absent(name, **kwargs)
   Ensure beacon is absent.
   name The name of the beacon ensured absent.

salt.states.beacon.disabled(name, **kwargs)
   Disable a beacon.
   name The name of the beacon to enable.

salt.states.beacon.enabled(name, **kwargs)
   Enable a beacon.
   name The name of the beacon to enable.

salt.states.beacon.present(name, **kwargs)
   Ensure beacon is configured with the included beacon data.
   name The name of the beacon ensure is configured.

13.16.14 salt.states.bigip

A state module designed to enforce load-balancing configurations for F5 Big-IP entities.

   maturity develop
   platform f5_bigip_11.6

salt.states.bigip.add_pool_member(hostname, username, password, name, member)
   A function to connect to a bigip device and add a new member to an existing pool.
   hostname The host/address of the bigip device
   username The iControl REST username
   password The iControl REST password
   name The name of the pool to modify
   member The member to add to the pool
salt.states.bigip.create_monitor(hostname, username, password, monitor_type, name, **kwargs)

A function to connect to a bigip device and create a monitor.

hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
monitor_type  The type of monitor to create
name  The name of the monitor to create
kwargs  [ arg=val ] ...

Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

salt.states.bigip.create_node(hostname, username, password, name, address)

Create a new node if it does not already exist.

hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
name  The name of the node to create
address  The address of the node

salt.states.bigip.create_pool(hostname, username, password, name, members=None, allow_nat=None, allow_snat=None, description=None, gateway_failsafe_device=None, ignore_persistent_weight=None, ip_tos_to_client=None, ip_tos_to_server=None, link_qos_to_client=None, link_qos_to_server=None, load_balancing_mode=None, min_active_members=None, min_up_members=None, min_up_member_action=None, min_up_members_checking=None, monitor=None, profiles=None, queue_depth_limit=None, queue_on_connection_limit=None, queue_time_limit=None, reselect_tries=None, service_down_action=None, slow_ramp_time=None)

Create a new node if it does not already exist.

hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
name  The name of the pool to create
members  List of members to be added to the pool
allow_nat  [yes | no]
allow_snat  [yes | no]
description  [string]
gateway_failsafe_device  [string]
ignore_persistent_weight  [enabled | disabled]
ip_tos_to_client  [pass-through | [integer]]
ip_tos_to_server  [pass-through | [integer]]
link_qos_to_client  [pass-through | [integer]]
link_qos_to_server  [pass-through | [integer]]
load_balancing_mode  [dynamic-ratio-member | dynamic-ratio-node | fastest-app-response | fastest-node | least-connections-members | least-connections-node | least-sessions | observed-member | observed-node | predictive-member | predictive-node | ratio-least-connections-member | ratio-least-connections-node | ratio-member | ratio-node | ratio-session | round-robin | weighted-least-connections-member | weighted-least-connections-node]
min_active_members  [integer]
min_up_members  [integer]

queue_depth_limit [integer]
queue_on_connection_limit [enabled | disabled]
queue_time_limit [integer]
reselect_tries [integer]
service_down_action [drop | none | reselect | reset]
slow_ramp_time [integer]

salt.states.bigip.create_profile(hostname, username, password, profile_type, name, **kwargs)
A function to connect to a bigip device and create a profile.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
profile_type The type of profile to create
name The name of the profile to create
kwargs [ arg=val ] ...

Consult F5 BIGIP user guide for specific options for each profile type. Typically, tmsh arg names are used.

Special Characters |, , and : must be escaped using \ when used within strings.

salt.states.bigip.create_virtual(hostname, username, password, name, destination, pool=None, address_status=None, auto_lasthop=None, bwc_policy=None, cmp_enabled=None, connection_limit=None, dhcp_relay=None, description=None, fallback_persistence=None, flow_eviction_policy=None, gtm_score=None, ip_forward=None, ip_protocol=None, internal=None, twelve_forward=None, last_hop_pool=None, mask=None, mirror=None, nat64=None, persist=None, profiles=None, policies=None, rate_class=None, rate_limit=None, rate_limit_mode=None, rate_limit_dst=None, rate_limit_src=None, rules=None, related_rules=None, reject=None, source=None, source_address_translation=None, source_port=None, virtual_state=None, traffic_classes=None, translate_address=None, translate_port=None, vlans=None)
A function to connect to a bigip device and create a virtual server if it does not already exists.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the virtual to create
destination [ [virtual_address_name:port] | [ipv4:port] | [ipv6:port] ]

salt.states.bigip.delete_monitor(hostname, username, password, monitor_type, name)

Modify an existing monitor. If it does exists, only the parameters specified will be enforced.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
monitor_type The type of monitor to create
name The name of the monitor to create
kwargs [ arg=val ] ...

Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

salt.states.bigip.delete_node(hostname, username, password, name)

Delete an existing node.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the node which will be deleted.

salt.states.bigip.delete_pool(hostname, username, password, name)

Delete an existing pool.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the pool which will be deleted

salt.states.bigip.delete_pool_member(hostname, username, password, name, member)
Delete an existing pool member.

**hostname**  The host/address of the bigip device
**username**  The iControl REST username
**password**  The iControl REST password
**name**  The name of the pool to be modified
**member**  The name of the member to delete from the pool

```python
salt.states.bigip.delete_profile(hostname, username, password, profile_type, name)
```

Modify an existing profile. If it does exists, only the parameters specified will be enforced.

**hostname**  The host/address of the bigip device
**username**  The iControl REST username
**password**  The iControl REST password
**profile_type**  The type of profile to create
**name**  The name of the profile to create
**kwargs**  [ arg=val ] ...

Consult F5 BIGIP user guide for specific options for each profile type. Typically, tmsh arg names are used.

```python
salt.states.bigip.delete_virtual(hostname, username, password, name)
```

Delete an existing virtual.

**hostname**  The host/address of the bigip device
**username**  The iControl REST username
**password**  The iControl REST password
**name**  The name of the virtual which will be deleted

```python
salt.states.bigip.list_monitor(hostname, username, password, monitor_type, name)
```

A function to list an existing monitor.

**hostname**  The host/address of the bigip device
**username**  The iControl REST username
**password**  The iControl REST password
**monitor_type**  The type of monitor to list
**name**  The name of the monitor to list

```python
salt.states.bigip.list_node(hostname, username, password, name)
```

A function to connect to a bigip device and list a specific node.

**hostname**  The host/address of the bigip device
**username**  The iControl REST username
**password**  The iControl REST password
**name**  The name of the node to list.

```python
salt.states.bigip.list_pool(hostname, username, password, name)
```

A function to connect to a bigip device and list a specific pool.

**hostname**  The host/address of the bigip device
**username**  The iControl REST username
**password**  The iControl REST password
**name**  The name of the pool to list.

```python
salt.states.bigip.list_profile(hostname, username, password, profile_type, name)
```

A function to list an existing profile.

**hostname**  The host/address of the bigip device
**username**  The iControl REST username
**password**  The iControl REST password
**profile_type**  The type of profile to list
**name**  The name of the profile to list

```python
salt.states.bigip.list_virtual(hostname, username, password, name)
```

A function to list a specific virtual.
hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
name  The name of the virtual to list

salt.states.bigip.manage_monitor(hostname, username, password, monitor_type, name, **kwargs)
Create a new monitor if a monitor of this type and name does not already exists. If it does exists, only the
parameters specified will be enforced.
hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
monitor_type  The type of monitor to create
name  The name of the monitor to create
kwargs  [ arg=val ] ...
Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are
used.

salt.states.bigip.manage_node(hostname, username, password, name, address, connection_limit=None, description=None, dynamic_ratio=None, logging=None, monitor=None, rate_limit=None, ratio=None, session=None, node_state=None)
Manages a node of a given bigip device. If the node does not exist it will be created, otherwise, only the
properties which are different than the existing will be updated.
hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
name  The name of the node to manage.
address  The address of the node
connection_limit  [integer]
description  [string]
dynamic_ratio:  [integer]
logging  [enabled | disabled]
monitor  [[name] | none | default]
rate_limit  [integer]
ratio  [integer]
session  [user-enabled | user-disabled]
node_state (state)  [user-down | user-up ]

salt.states.bigip.manage_pool(hostname, username, password, name, allow_nat=None, allow_snat=None, description=None, gateway_failsafe_device=None, ignore_persisted_weight=None, ip_tos_to_client=None, ip_tos_to_server=None, link_qos_to_client=None, link_qos_to_server=None, load_balancing_mode=None, min_qos_to_server=None, min_up_members=None, min_up_members_action=None, min_up_members_checking=None, monitor=None, profiles=None, queue_depth_limit=None, queue_on_connection_limit=None, queue_time_limit=None, reselect_tries=None, service_down_action=None, slow_ramp_time=None)
Create a new pool if it does not already exist. Pool members are managed separately. Only the parameters
specified are enforced.
hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
name  The name of the pool to create  
allow_nat [yes | no]  
allow_snat [yes | no]  
description [string]  
gateway_failsafe_device [string]  
ignore_persisted_weight [enabled | disabled]

ip_tos_to_server [pass-through | [integer]]  
link_qos_to_client [pass-through | [integer]]  
link_qos_to_server [pass-through | [integer]]  
load_balancing_mode [dynamic-ratio-member | dynamic-ratio-node | fastest-app-response | fastest-node | least-connections-members | least-connections-node | least-sessions | observed-member | observed-node | predictive-member | predictive-node | ratio-least-connections-member | ratio-least-connections-node | ratio-member | ratio-node | ratio-session | round-robin | weighted-least-connections-member | weighted-least-connections-node]  
min_active_members [integer]  
min_up_members [integer]  
min_up_members_action [failover | reboot | restart-all]  
min_up_members_checking [enabled | disabled]  
monitor [name]  
profiles [none | profile_name]  
queue_depth_limit [integer]  
queue_on_connection_limit [enabled | disabled]  
queue_time_limit [integer]  
reselect_tries [integer]  
service_down_action [drop | none | reselect | reset]  
slow_ramp_time [integer]  

salt.states.bigip.manage_pool_members (hostname, username, password, name, members)  
Manage the members of an existing pool. This function replaces all current pool members. Only the parameters specified are enforced.  
hostname  The host/address of the bigip device  
username  The iControl REST username  
password  The iControl REST password  
name  The name of the pool to modify  
members  list of pool members to manage.  

salt.states.bigip.manage_profile (hostname, username, password, profile_type, name, **kwargs)  
Create a new profile if a monitor of this type and name does not already exists. If it does exists, only the parameters specified will be enforced.  
hostname  The host/address of the bigip device  
username  The iControl REST username  
password  The iControl REST password  
profile_type  The type of profile to create  
name  The name of the profile to create  
kwargs  [ arg=val ] …  
Consult F5 BIGIP user guide for specific options for each profile type. Typically, tmsh arg names are used.
salt.states.bigip.manage_virtual(hostname, username, password, name, destination, pool=None, address_status=None, auto_lasthop=None, bwc_policy=None, cmp_enabled=None, connection_limit=None, dhcp_relay=None, description=None, fallback_persistence=None, flow_eviction_policy=None, gtm_score=None, ip_forward=None, ip_protocol=None, internal=None, twelve_forward=None, last_hop_pool=None, mask=None, mirror=None, nat64=None, persist=None, profiles=None, policies=None, rate_class=None, rate_limit=None, rate_limit_mode=None, rate_limit_dst=None, rate_limit_src=None, rules=None, related_rules=None, reject=None, source=None, source_address_translation=None, source_port=None, virtual_state=None, traffic_classes=None, translate_address=None, translate_port=None, vlans=None)

Manage a virtual server. If a virtual does not exist it will be created, otherwise only the parameters specified will be enforced.

hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password

salt.states.bigip.modify_monitor(hostname, username, password, monitor_type, name,**kwargs)
Modify an existing monitor. If it does exists, only the parameters specified will be enforced.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
monitor_type The type of monitor to create
name The name of the monitor to create
kwargs [ arg=val ] ...
    Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.
salt.states.bigip.modify_node(hostname, username, password, name, connection_limit=None, description=None, dynamic_ratio=None, logging=None, monitor=None, rate_limit=None, ratio=None, session=None, node_state=None)
Modify an existing node. Only a node which already exists will be modified and only the parameters specified will be enforced.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the node to modify
connection_limit [integer]
description [string]

13.16.15 salt.states.blockdev

Management of Block Devices

A state module to manage blockdevices

```
/dev/sda:
    blockdev.tuned:
        - read-only: True

master-data:
    blockdev.tuned:
        - name: /dev/vg/master-data
        - read-only: True
        - read-ahead: 1024
```

New in version 2014.7.0.

salt.states.blockdev.formatted(name, fs_type='ext4', **kwargs)
Manage filesystems of partitions.
    name The name of the block device
    fs_type The filesystem it should be formatted as

salt.states.blockdev.tuned(name, **kwargs)
Manage options of block device
    name The name of the block device
    opts:
        - read-ahead Read-ahead buffer size
        - filesystem-read-ahead Filesystem Read-ahead buffer size
        - read-only Set Read-Only
        - read-write Set Read-Write
13.16.16 salt.states.boto_asg

Manage Autoscale Groups

New in version 2014.7.0.

Create and destroy autoscale groups. Be aware that this interacts with Amazon’s services, and so may incur charges. This module uses boto, which can be installed via package, or pip.

This module accepts explicit autoscale credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```yaml
asg.keyid: GKTADJGHEIQSXMKKRBJ08H
asg.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure myasg exists:

```yaml
boto_asg.present:
  - name: myasg
    - launch_config_name: mylc
    - availability_zones:
      - us-east-1a
      - us-east-1b
    - min_size: 1
    - max_size: 1
    - desired_capacity: 1
    - load_balancers:
      - myelb
    - suspended_processes:
      - AddToLoadBalancer
      - AlarmNotification
    - scaling_policies:
      - adjustment_type: ChangeInCapacity
        as_name: api-production-iad
        cooldown: 1800
        min_adjustment_step: None
        name: ScaleDown
        scaling_adjustment: -1
      - region: us-east-1
      - keyid: GKTADJGHEIQSXMKKRBJ08H
      - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

# Using a profile from pillars.

Ensure myasg exists:

```yaml
boto_asg.present:
```
It's possible to specify cloudwatch alarms that will be setup along with the ASG. Note the alarm name will be the name attribute defined, plus the ASG resource name.

```yaml
Ensure myasg exists:
boto_asg.present:
  - name: myasg
    - launch_config_name: mylc
    - availability_zones:
      - us-east-1a
      - us-east-1b
    - min_size: 1
    - max_size: 1
    - desired_capacity: 1
    - load_balancers:
      - myelb
    - profile: myprofile
    - alarms:
      - CPU:
        name: 'ASG CPU **MANAGED BY SALT**'
        attributes:
          metric: CPUUtilization
```

# Passing in a profile.
Ensure myasg exists:
boto_asg.present:
  - name: myasg
    - launch_config_name: mylc
    - availability_zones:
      - us-east-1a
      - us-east-1b
    - min_size: 1
    - max_size: 1
    - desired_capacity: 1
    - load_balancers:
      - myelb
    - profile: myprofile

# Deleting an autoscale group with running instances.
Ensure myasg is deleted:
boto_asg.absent:
  - name: myasg
  # If instances exist, we must force the deletion of the asg.
  - force: True
You can also use alarms from pillars, and override values from the pillar alarms by setting overrides on the resource.

Note that `boto_asg_alarms` will be used as a default value for all resources, if defined and can be used to ensure alarms are always set for an ASG resource.

Setting the alarms in a pillar:

```yaml
my_asg_alarm:
  CPU:
    name: 'ASG CPU **MANAGED BY SALT**'
    attributes:
      metric: CPUUtilization
      namespace: AWS/EC2
      statistic: Average
      comparison: '>='
      threshold: 65.0
      period: 60
      evaluation_periods: 30
      unit: null
      description: 'ASG CPU'
      alarm_actions: [ 'arn:aws:sns:us-east-1:12345:myalarm' ]
      insufficient_data_actions: []
      ok_actions: [ 'arn:aws:sns:us-east-1:12345:myalarm' ]
```

Overriding the alarm values on the resource:

```yaml
Ensure myasg exists:
  boto_asg.present:
    - name: myasg
    - launch_config_name: mylc
    - availability_zones:
      - us-east-1a
      - us-east-1b
    - min_size: 1
    - max_size: 1
    - desired_capacity: 1
    - load_balancers:
      - myelb
    - profile: myprofile
    - alarms_from_pillar: my_asg_alarm
      # override CPU:attributes:threshold
      - alarms:
        CPU:
          attributes:
            threshold: 50.0
```

```yaml
13.16. state modules 1913
```
salt.states.boto_asg.absent(name, force=False, region=None, key=None, keyid=None, profile=None,
remove_lc=False)

Ensure the named autoscale group is deleted.

- name: Name of the autoscale group.
- force: Force deletion of autoscale group.
- remove_lc: Delete the launch config as well.
- region: The region to connect to.
- key: Secret key to be used.
- keyid: Access key to be used.
- profile: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_asg.present(name, launch_config_name, availability_zones, min_size, max_size,
launch_config=None, desired_capacity=None, load_balancers=None, default_cooldown=None,
health_check_type=None, health_check_period=None, placement_group=None,
health_check_period=None, launch_config_name, tags=None, termination_policies=None,
suspended_processes=None, scaling_policies=None, scaling_policies_from_pillar='boto_asg_scaling_policies',
scheduled_actions=None, scheduled_actions_from_pillar='boto_asg_scheduled_actions',
alarms=None, alarms_from_pillar='boto_asg_alarms', region=None,
key=None, keyid=None, profile=None, notification_arn=None,
notification_arn_from_pillar='boto_asg_notification_arn',
notification_types=None, notification_types_from_pillar='boto_asg_notification_types')

Ensure the autoscale group exists.

- name: Name of the autoscale group.
- launch_config_name: Name of the launch config to use for the group. Or, if launch_config is specified, this will be the launch config name's prefix. (see below)
- launch_config: A dictionary of launch config attributes. If specified, a launch config will be used or created, matching this set of attributes, and the autoscale group will be set to use that launch config. The launch config name will be the launch_config_name followed by a hyphen followed by a hash of the launch_config dict contents.
- availability_zones: List of availability zones for the group.
- min_size: Minimum size of the group.
- max_size: Maximum size of the group.
- desired_capacity: The desired capacity of the group.
- load_balancers: List of load balancers for the group. Once set this can not be updated (Amazon restriction).
- default_cooldown: Number of seconds after aScaling Activity completes before any further scaling activities can start.
- health_check_type: The service you want the health status from, Amazon EC2 or Elastic Load Balancer (EC2 or ELB).
- health_check_period: Length of time in seconds after a new EC2 instance comes into service that Auto Scaling starts checking its health.
- placement_group: Physical location of your cluster placement group created in Amazon EC2. Once set this can not be updated (Amazon restriction).
- vpc_zone_identifier: A list of the subnet identifiers of the Virtual Private Cloud.
- tags: A list of tags. Example:
  ```
  - key: 'key'
    value: 'value'
  propagate_at_launch: true
  ```
- termination_policies: A list of termination policies. Valid values are:
  - OldestInstance
  - NewestInstance
• OldestLaunchConfiguration
• ClosestToNextInstanceHour
• Default

If no value is specified, the Default value is used.

**suspended_processes** List of processes to be suspended. see http://docs.aws.amazon.com/AutoScaling/latest/DeveloperGuide/US_SuspendResume.html

**scaling_policies** List of scaling policies. Each policy is a dict of key-values described by http://boto.readthedocs.org/en/latest/ref/autoscale.html#boto.ec2.autoscale.policy.ScalingPolicy

**scaling_policies_from_pillar** name of pillar dict that contains scaling policy settings. Scaling policies defined for this specific state will override those from pillar.

**scheduled_actions** a dictionary of scheduled actions. Each key is the name of scheduled action and each value is dictionary of options. For example:

```python
- scheduled_actions:
  scale_up_at_10:
    desired_capacity: 4
    min_size: 3
    max_size: 5
    recurrence: "0 9 * * 1-5"
  scale_down_at_7:
    desired_capacity: 1
    min_size: 1
    max_size: 1
    recurrence: "0 19 * * 1-5"
```

**scheduled_actions_from_pillar** name of pillar dict that contains scheduled_actions settings. Scheduled actions for this specific state will override those from pillar.

**alarms** a dictionary of name->boto_cloudwatch_alarm sections to be associated with this ASG. All attributes should be specified except for dimension which will be automatically set to this ASG.

See the salt.states.boto_cloudwatch_alarm state for information about these attributes.

If any alarm actions include "self" this will be replaced with the asg name. For example, alarm_actions reading `'[scaling_policy:self:ScaleUp]'` will map to the arn for this asg's scaling policy named `"ScaleUp"`. In addition, any alarms that have only scaling_policy as actions will be ignored if min_size is equal to max_size for this ASG.

**alarms_from_pillar** name of pillar dict that contains alarm settings. Alarms defined for this specific state will override those from pillar.

**region** The region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**notification_arn** The AWS arn that notifications will be sent to

**notification_arn_from_pillar** name of the pillar dict that contains notification_arn settings. A notification_arn defined for this specific state will override the one from pillar.

**notification_types** A list of event names that will trigger a notification. The list of valid notification types is:

- autoscaling:EC2_INSTANCE_LAUNCH
- autoscaling:EC2_INSTANCE_LAUNCH_ERROR
- autoscaling:EC2_INSTANCE_TERMINATE
- autoscaling:EC2_INSTANCE_TERMINATE_ERROR
- autoscaling:TEST_NOTIFICATION

**notification_types_from_pillar** name of the pillar dict that contains notification_types settings. notification_types defined for this specific state will override those from the pillar.
13.16.17 salt.states.boto_cfn

Connection module for Amazon Cloud Formation

New in version 2015.8.0.

**depends boto**

**configuration** This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```python
keyid: GKTADJGHEIQSXMKKRBJ08H
key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

```python
stack-present:
boto_cfn.present:
  - name: mystack
  - template_body: salt://base/mytemplate.json
  - disable_rollback: true
  - region: eu-west-1
  - keyid: 'AKIAJHMIQ2ASDFLASDF'
  - key: 'fdkjsafkljsASSADFalkfjasdf'
```

```python
stack-absent:
boto_cfn.absent:
  - name: mystack
```

**salt.states.boto_cfn.absent**(name, region=None, key=None, keyid=None, profile=None)

Ensure cloud formation stack is absent.

name (string) – The name of the stack to delete.
region (string) - Region to connect to.
key (string) - Secret key to be used.
keyid (string) - Access key to be used.
profile (dict) - A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**salt.states.boto_cfn.present**(name, template_body=None, template_url=None, parameters=None, notification_arns=None, disable_rollback=None, timeout_in_minutes=None, capabilities=None, tags=None, on_failure=None, stack_policy_body=None, stack_policy_url=None, use_previous_template=None, stack_policy_during_update_body=None, stack_policy_during_update_url=None, region=None, key=None, keyid=None, profile=None)

Ensure cloud formation stack is present.

name (string) - Name of the stack.
template_body (string) – Structure containing the template body. Can also be loaded from a file by using salt://.
template_url (string) – Location of file containing the template body. The URL must point to a template located in an S3 bucket in the same region as the stack.
parameters (list) – A list of key/value tuples that specify input parameters for the stack. A 3-tuple (key, value, bool) may be used to specify the UsePreviousValue option.

notification_arns (list) – The Simple Notification Service (SNS) topic ARNs to publish stack related events. You can find your SNS topic ARNs using the SNS console or your Command Line Interface (CLI).

disable_rollback (bool) – Indicates whether or not to rollback on failure.

timeout_in_minutes (integer) – The amount of time that can pass before the stack status becomes CREATE_FAILED; if DisableRollback is not set or is set to False, the stack will be rolled back.

capabilities (list) – The list of capabilities you want to allow in the stack. Currently, the only valid capability is 'CAPABILITY_IAM'.

tags (dict) – A set of user-defined Tags to associate with this stack, represented by key/value pairs. Tags defined for the stack are propagated to EC2 resources that are created as part of the stack. A maximum number of 10 tags can be specified.

on_failure (string) – Determines what action will be taken if stack creation fails. This must be one of: DO NOTHING, ROLLBACK, or DELETE. You can specify either OnFailure or DisableRollback, but not both.

stack_policy_body (string) – Structure containing the stack policy body. Can also be loaded from a file by using salt://.

stack_policy_url (string) – Location of a file containing the stack policy. The URL must point to a policy (max size: 16KB) located in an S3 bucket in the same region as the stack. If you pass StackPolicyBody and StackPolicyURL, only StackPolicyBody is used.

use_previous_template (boolean) – Used only when templates are not the same. Set to True to use the previous template instead of uploading a new one via TemplateBody or TemplateURL.

stack_policy_during_update_body (string) – Used only when templates are not the same. Structure containing the temporary overriding stack policy body. If you pass StackPolicyDuringUpdateBody and StackPolicyDuringUpdateURL, only StackPolicyDuringUpdateBody is used. Can also be loaded from a file by using salt://.

stack_policy_during_update_url (string) – Used only when templates are not the same. Location of a file containing the temporary overriding stack policy. The URL must point to a policy (max size: 16KB) located in an S3 bucket in the same region as the stack. If you pass StackPolicyDuringUpdateBody and StackPolicyDuringUpdateURL, only StackPolicyDuringUpdateBody is used.

region (string) - Region to connect to.

key (string) - Secret key to be used.

keyid (string) - Access key to be used.

profile (dict) - A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

13.16.18 salt.states.boto_cloudtrail module

Manage CloudTrail Objects

New in version 2016.3.0.

Create and destroy CloudTrail objects. Be aware that this interacts with Amazon's services, and so may incur charges.

depends

• boto
The dependencies listed above can be installed via package or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
    region: us-east-1
```

Ensure trail exists:
```yaml
boto_cloudtrail.present:
    - Name: mytrail
    - S3BucketName: mybucket
    - S3KeyPrefix: prefix
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

Ensure trail with passed properties is absent.
```yaml
salt.states.boto_cloudtrail.absent(name, Name=None, region=None, key=None, keyid=None, profile=None)
```

Ensure trail exists.
```yaml
salt.states.boto_cloudtrail.present(name, Name=None, S3BucketName=None, S3KeyPrefix=None, SnsTopicName=None, IncludeGlobalServiceEvents=False, EnableLogFileValidation=False, CloudWatchLogsLogGroupArn=None, CloudWatchLogsRoleArn=None, KmsKeyId=None, LoggingEnabled=True, Tags=None, region=None, key=None, keyid=None, profile=None)
```

Ensure trail with passed properties is absent.
```yaml
salt.states.boto_cloudtrail.absent(name, Name=None, S3BucketName=None, S3KeyPrefix=None, SnsTopicName=None, IncludeGlobalServiceEvents=False, EnableLogFileValidation=False, CloudWatchLogsLogGroupArn=None, CloudWatchLogsRoleArn=None, KmsKeyId=None, LoggingEnabled=True, Tags=None, region=None, key=None, keyid=None, profile=None)
```
**CloudWatchLogsLogGroupArn** Specifies a log group name using an Amazon Resource Name (ARN), a unique identifier that represents the log group to which CloudTrail logs will be delivered. Not required unless you specify CloudWatchLogsRoleArn.

**CloudWatchLogsRoleArn** Specifies the role for the CloudWatch Logs endpoint to assume to write to a user's log group.

**KmsKeyId** Specifies the KMS key ID to use to encrypt the logs delivered by CloudTrail. The value can be an alias name prefixed by ```alias/```, a fully specified ARN to an alias, a fully specified ARN to a key, or a globally unique identifier.

**LoggingEnabled** Whether logging should be enabled for the trail

**Tags** A dictionary of tags that should be set on the trail

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 13.16.19 salt.states.boto_cloudwatch_alarm

Manage Cloudwatch alarms

New in version 2014.7.0.

Create and destroy cloudwatch alarms. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```yaml
cloudwatch.keyid: GKTADJGHEIQSXMKKRBJ08H
cloudwatch.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

```yaml
my test alarm:
  boto_cloudwatch_alarm.present:
    - name: my test alarm
    - attributes:
      metric: ApproximateNumberOfMessagesVisible
      namespace: AWS/SQS
      statistic: Average
      comparison: ">="
      threshold: 20000.0
      period: 60
      evaluation_periods: 1
```

### 13.16. state modules
description: test alarm via salt

 dimensions:
  - the-sqs-queue-name

 alarm_actions:

salt.states.boto_cloudwatch_alarm.absent(name, region=None, key=None, keyid=None, profile=None)

Ensure the named cloudwatch alarm is deleted.

name Name of the alarm.

region Region to connect to.

key Secret key to be used.

keyid Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_cloudwatch_alarm.present(name, attributes, region=None, key=None, keyid=None, profile=None)

Ensure the cloudwatch alarm exists.

name Name of the alarm

attributes A dict of key/value cloudwatch alarm attributes.

region Region to connect to.

key Secret key to be used.

keyid Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

13.16.20 salt.states.boto_datapipeline module

Manage Data Pipelines

New in version 2016.3.0.

Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto3, which can be installed via package, or pip.

This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

datapipeline.keyid: GKTADJGHEIQSXMKKRBJ08H
datapipeline.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1

Ensure daily data pipeline exists:
  boto_datapipeline.present:
- name: my-datapipeline
  - pipeline_objects:
    DefaultSchedule:
      name: Every 1 day
      fields:
        period: 1 Day
        type: Schedule
        startAt: FIRST_ACTIVATION_DATE_TIME
  - parameter_values:
    myDDBTableName: my-dynamo-table

salt.states.boto_datapipeline.absent(name, region=None, key=None, keyid=None, profile=None)

Ensure a pipeline with the service_name does not exist

name Name of the service to ensure a data pipeline does not exist for.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_datapipeline.present(name,
  pipeline_objects=None,
  pipeline_objects_from_pillars='boto_datapipeline_pipeline_objects',
  parameter_objects=None,
  parameter_objects_from_pillars='boto_datapipeline_parameter_objects',
  parameter_values=None,
  parameter_values_from_pillars='boto_datapipeline_parameter_values',
  region=None, key=None, keyid=None, profile=None)

Ensure the data pipeline exists with matching definition.

name Name of the service to ensure a data pipeline exists for.
pipeline_objects Pipeline objects to use. Will override objects read from pillars.
pipeline_objects_from_pillars The pillar key to use for lookup.
parameter_objects Parameter objects to use. Will override objects read from pillars.
parameter_objects_from_pillars The pillar key to use for lookup.
parameter_values Parameter values to use. Will override values read from pillars.
parameter_values_from_pillars The pillar key to use for lookup.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

13.16.21 salt.states.boto_dynamodb

Manage DynamoDB Tables

New in version 2015.5.0.

Create and destroy DynamoDB tables. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit DynamoDB credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.
If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

<table>
<thead>
<tr>
<th>keyid: GKTADJGHEIQSXMKRBJ08H</th>
</tr>
</thead>
<tbody>
<tr>
<td>key: askdjghsdfjkgWupUjasdfklgjsdfjajkghs</td>
</tr>
<tr>
<td>region: us-east-1</td>
</tr>
</tbody>
</table>

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

| myprofile: |
| keyid: GKTADJGHEIQSXMKRBJ08H |
| key: askdjghsdfjkgWupUjasdfklgjsdfjajkghs |
| region: us-east-1 |

Ensure DynamoDB table does not exist:

```
ensure_dynamodb.absent:
  - table_name: new_table
  - keyid: GKTADJGHEIQSXMKRBJ08H
  - key: askdjghsdfjkgWupUjasdfklgjsdfjajkghs
  - region: us-east-1
```

Ensure DynamoDB table exists:

```
ensure_dynamodb.present:
  - table_name: new_table
  - read_capacity_units: 1
  - write_capacity_units: 2
  - hash_key: primary_id
  - hash_key_data_type: N
  - range_key: start_timestamp
  - range_key_data_type: N
  - keyid: GKTADJGHEIQSXMKRBJ08H
  - key: askdjghsdfjkgWupUjasdfklgjsdfjajkghs
  - region: us-east-1
  - local_indexes:
    - index:
      - name: "primary_id_end_timestamp_index"
      - hash_key: primary_id
      - hash_key_data_type: N
      - range_key: end_timestamp
      - range_key_data_type: N
  - global_indexes:
    - index:
      - name: "name_end_timestamp_index"
      - hash_key: name
      - hash_key_data_type: S
      - range_key: end_timestamp
      - range_key_data_type: N
      - read_capacity_units: 3
      - write_capacity_units: 4
```

It's possible to specify cloudwatch alarms that will be setup along with the DynamoDB table. Note the alarm name will be defined by the name attribute provided, plus the DynamoDB resource name.

Ensure DynamoDB table exists:

```
ensure_dynamodb.present:
  - name: new_table
  - read_capacity_units: 1
  - write_capacity_units: 2
```
- hash_key: primary_id
- hash_key_data_type: N
- range_key: start_timestamp
- range_key_data_type: N
- alarms:
  ConsumedWriteCapacityUnits:
    name: 'DynamoDB ConsumedWriteCapacityUnits **MANAGED BY SALT**'
    attributes:
      metric: ConsumedWriteCapacityUnits
      namespace: AWS/DynamoDB
      statistic: Sum
      comparison: '>='
      # threshold_percent is used to calculate the actual threshold
      # based on the provisioned capacity for the table.
      threshold_percent: 0.75
      period: 300
      evaluation_periods: 2
      unit: Count
      description: 'DynamoDB ConsumedWriteCapacityUnits'
    alarm_actions: [ 'arn:aws:sns:us-east-1:1234:my-alarm' ]
    insufficient_data_actions: []
    ok_actions: [ 'arn:aws:sns:us-east-1:1234:my-alarm' ]
- keyid: GKTADJGHEIQSXMKKRBJ08H
- key: askdjghsdkfjghWupUjasdflkdflgfjgsdfjajkg
- region: us-east-1

You can also use alarms from pillars, and override values from the pillar alarms by setting overrides on the resource. Note that 'boto_dynamodb_alarms' will be used as a default value for all resources, if defined and can be used to ensure alarms are always set for a resource.

Setting the alarms in a pillar:

boto_dynamodb_alarms:
  ConsumedWriteCapacityUnits:
    name: 'DynamoDB ConsumedWriteCapacityUnits **MANAGED BY SALT**'
    attributes:
      metric: ConsumedWriteCapacityUnits
      namespace: AWS/DynamoDB
      statistic: Sum
      comparison: '>='
      # threshold_percent is used to calculate the actual threshold
      # based on the provisioned capacity for the table.
      threshold_percent: 0.75
      period: 300
      evaluation_periods: 2
      unit: Count
      description: 'DynamoDB ConsumedWriteCapacityUnits'
    alarm_actions: [ 'arn:aws:sns:us-east-1:1234:my-alarm' ]
    insufficient_data_actions: []
    ok_actions: [ 'arn:aws:sns:us-east-1:1234:my-alarm' ]

Ensure DynamoDB table exists:
  boto_dynamodb.present:
    - name: new_table
    - read_capacity_units: 1
    - write_capacity_units: 2
    - hash_key: primary_id
    - hash_key_data_type: N
- range_key: start_timestamp
- range_key_data_type: N
- alarms:
  ConsumedWriteCapacityUnits:
  attributes:
    threshold_percent: 0.90
    period: 900

salt.states.boto_dynamodb.absent(name, region=None, key=None, keyid=None, profile=None)
Ensure the DynamoDB table does not exist.
name Name of the DynamoDB table.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_dynamodb.present(name=None, table_name=None, region=None, key=None, keyid=None, profile=None, read_capacity_units=None, write_capacity_units=None, alarms=None, alarms_from_pillar='boto_dynamodb_alarms', hash_key=None, hash_key_data_type=None, range_key=None, range_key_data_type=None, local_indexes=None, global_indexes=None)
Ensure the DynamoDB table exists. Note: all properties of the table can only be set during table creation.
name Name of the DynamoDB table
table_name Name of the DynamoDB table (deprecated)
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
read_capacity_units The read throughput for this table
write_capacity_units The write throughput for this table
hash_key The name of the attribute that will be used as the hash key for this table
hash_key_data_type The DynamoDB datatype of the hash key
range_key The name of the attribute that will be used as the range key for this table
range_key_data_type The DynamoDB datatype of the range key
local_indexes The local indexes you would like to create
global_indexes The local indexes you would like to create

13.16.22 salt.states.boto_ec2
Manage EC2
New in version 2015.8.0.
This module provides an interface to the Elastic Compute Cloud (EC2) service from AWS.
The below code creates a key pair:
create-key-pair:
  boto_ec2.key_present:
  - name: mykeypair
  - save_private: /root/
- region: eu-west-1
- keyid: GKTADJGHEIQSXMKKRBJ08H
- key: askdjghsdfjkgHwUpUjasdfAkflkdfklgsdfjajkg

You can also use salt:// in order to define the public key.

import-key-pair:
  boto_ec2.key_present:
    - name: mykeypair
    - upload_public: 'ssh-rsa AAAA'
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkgHwUpUjasdfAkflkdfklgsdfjajkg

The below code deletes a key pair:

delete-key-pair:
  boto_ec2.key_absent:
    - name: mykeypair
    - region: eu-west-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkgHwUpUjasdfAkflkdfklgsdfjajkg

salt.states.boto_ec2.eni_absent(name, release_eip=False, region=None, key=None, keyid=None, profile=None)

Ensure the EC2 ENI is absent.

New in version 2016.3.0.

name Name tag associated with the ENI.
release_eip True/False - release any EIP associated with the ENI
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_ec2.eni_present(name, subnet_id=None, subnet_name=None, private_ip_address=None, description=None, groups=None, source_dest_check=True, allocate_eip=False, arecords=None, region=None, key=None, keyid=None, profile=None)

Ensure the EC2 ENI exists.

New in version 2016.3.0.

name Name tag associated with the ENI.
subnet_id The VPC subnet ID the ENI will exist within.
subnet_name The VPC subnet name the ENI will exist within.
private_ip_address The private ip address to use for this ENI. If this is not specified AWS will automatically assign a private IP address to the ENI. Must be specified at creation time; will be ignored afterward.
description Description of the key.
groups A list of security groups to apply to the ENI.
source_dest_check Boolean specifying whether source/destination checking is enabled on the ENI.
allocate_eip  True/False - allocate and associate an EIP to the ENI

New in version 2016.3.0.
arecords  A list of arecord dicts with attributes needed for the DNS add_record state. By default the boto_route53.add_record state will be used, which requires: name, zone, ttl, and identifier. See the boto_route53 state for information about these attributes. Other DNS modules can be called by specifying the provider keyword. By default, the private ENI IP address will be used, set `public: True` in the arecord dict to use the ENI's public IP address

New in version 2016.3.0.
region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_ec2.instance_absent(name, instance_name=None, instance_id=None, region=None, key=None, keyid=None, profile=None)

Ensure an EC2 instance does not exist (is stopped and removed).

name  (string) - The name of the state definition. Recommended that this match the instance_name attribute (generally the FQDN of the instance).
instance_name  (string) - The name of the instance, generally its FQDN. Exclusive with `instance_id`.
instance_id  (string) - The ID of the instance (if known). Exclusive with `instance_name`.
image_id  (string) - The ID of the AMI image to run.
image_name  (string) - The name of the AMI image to run. NOT IMPLEMENTED.
tags  (dict) - Tags to apply to the instance.

New in version 2016.3.0.
salt.states.boto_ec2.instance_present(name, instance_name=None, instance_id=None, image_id=None, image_name=None, tags=None, key_name=None, security_groups=None, user_data=None, instance_type=None, placement=None, kernel_id=None, ramdisk_id=None, vpc_id=None, vpc_name=None, monitoring_enabled=None, subnet_id=None, subnet_name=None, private_ip_address=None, block_device_map=None, disable_api_termination=None, instance_initiated_shutdown_behavior=None, placement_group=None, client_token=None, security_group_ids=None, security_group_names=None, additional_info=None, tenancy=None, instance_profile_arn=None, instance_profile_name=None, ebs_optimized=None, network_interfaces=None, attributes=None, target_state=None, region=None, key=None, keyid=None, profile=None)

Ensure an EC2 instance is running with the given attributes and state.

name  (string) - The name of the state definition. Recommended that this match the instance_name attribute (generally the FQDN of the instance).
instance_name  (string) - The name of the instance, generally its FQDN. Exclusive with `instance_id`.
instance_id  (string) - The ID of the instance (if known). Exclusive with `instance_name`.
image_id  (string) - The ID of the AMI image to run.
image_name  (string) - The name of the AMI image to run. NOT IMPLEMENTED.
tags  (dict) - Tags to apply to the instance.
key_name (string) – The name of the key pair with which to launch instances.

security_groups (list of strings) – The names of the EC2 classic security groups with which to associate instances.

user_data (string) – The Base64-encoded MIME user data to be made available to the instance(s) in this reservation.

instance_type (string) – The EC2 instance size/type. Note that only certain types are compatible with HVM based AMIs.

placement (string) – The Availability Zone to launch the instance into.

kernel_id (string) – The ID of the kernel with which to launch the instances.

ramdisk_id (string) – The ID of the RAM disk with which to launch the instances.

vpc_id (string) - The ID of a VPC to attach the instance to.

vpc_name (string) - The name of a VPC to attach the instance to.

monitoring_enabled (bool) – Enable detailed CloudWatch monitoring on the instance.

subnet_id (string) – The ID of the subnet within which to launch the instances for VPC.

subnet_name (string) – The name of the subnet within which to launch the instances for VPC.

private_ip_address (string) – If you’re using VPC, you can optionally use this parameter to assign the instance a specific available IP address from the subnet (e.g., 10.0.0.25).

block_device_map (boto.ec2.blockdevicemapping.BlockDeviceMapping) – A BlockDeviceMapping data structure describing the EBS volumes associated with the Image.

disable_api_termination (bool) – If True, the instances will be locked and will not be able to be terminated via the API.

instance_initiated_shutdown_behavior (string) – Specifies whether the instance stops or terminates on instance-initiated shutdown. Valid values are:
  • ‘stop’
  • ‘terminate’

placement_group (string) – If specified, this is the name of the placement group in which the instance(s) will be launched.

client_token (string) – Unique, case-sensitive identifier you provide to ensure idempotency of the request. Maximum 64 ASCII characters.

security_group_ids (list of strings) – The IDs of the VPC security groups with which to associate instances.

security_group_names (list of strings) – The names of the VPC security groups with which to associate instances.

additional_info (string) – Specifies additional information to make available to the instance(s).

tenancy (string) – The tenancy of the instance you want to launch. An instance with a tenancy of ‘dedicated’ runs on single-tenant hardware and can only be launched into a VPC. Valid values are:"default" or "dedicated". NOTE: To use dedicated tenancy you MUST specify a VPC subnet-ID as well.

instance_profile_arn (string) – The Amazon resource name (ARN) of the IAM Instance Profile (IIP) to associate with the instances.

instance_profile_name (string) – The name of the IAM Instance Profile (IIP) to associate with the instances.

ebs_optimized (bool) – Whether the instance is optimized for EBS I/O. This optimization provides dedicated throughput to Amazon EBS and a tuned configuration stack to provide optimal EBS I/O performance. This optimization isn’t available with all instance types.

network_interfaces (boto.ec2.networkinterface.NetworkInterfaceCollection) – A NetworkInterfaceCollection data structure containing the ENI specifications for the instance.

attributes (dict) - Instance attributes and value to be applied to the instance. Available options are:
  • instanceType - A valid instance type (m1.small)
  • kernel - Kernel ID (None)
  • ramdisk - Ramdisk ID (None)
  • userData - Base64 encoded String (None)
  • disableApiTermination - Boolean (true)
  • instanceInitiatedShutdownBehavior - stop|terminate
  • blockDeviceMapping - List of strings - ie: ['/dev/sda=false']
  • sourceDestCheck - Boolean (true)
  • groupSet - Set of Security Groups or IDs
• ebsOptimized - Boolean (false)
• srivOptNetSupport - String - ie: 'simple'
target_state (string) - The desired target state of the instance. Available options are:
  • running
  • stopped
region (string) - Region to connect to.
key (string) - Secret key to be used.
keyid (string) - Access key to be used.
profile (variable) - A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
New in version 2016.3.0.
salt.states.boto_ec2.key_absent(name, region=None, key=None, keyid=None, profile=None)
Deletes a key pair
salt.states.boto_ec2.key_present(name, save_private=None, upload_public=None, region=None, key=None, keyid=None, profile=None)
Ensure key pair is present.
salt.states.boto_ec2.snapshot_created(name, ami_name, instance_name, wait_until_available=True, wait_timeout_seconds=300, **kwargs)
Create a snapshot from the given instance
New in version 2016.3.0.

13.16.23 salt.states.boto_elasticache

Manage Elasticache

New in version 2014.7.0.
Create, destroy and update Elasticache clusters. Be aware that this interacts with Amazon's services, and so may incur charges.

Note: This module currently only supports creation and deletion of elasticache resources and will not modify clusters when their configuration changes in your state files.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit elasticache credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
elasticache.keyid: GKTADJGHEIQSXMKKRBJ08H
elasticache.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```
Ensure myelasticache exists:
  boto_elasticache.present:
  - name: myelasticache
    - engine: redis
    - cache_node_type: cache.t1.micro
    - num_cache_nodes: 1
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkgHwupUjasdfklgjsdfjajkghs

# Using a profile from pillars
Ensure myelasticache exists:
  boto_elasticache.present:
  - name: myelasticache
    - engine: redis
    - cache_node_type: cache.t1.micro
    - num_cache_nodes: 1
    - region: us-east-1
    - profile: myprofile

# Passing in a profile
Ensure myelasticache exists:
  boto_elasticache.present:
  - name: myelasticache
    - engine: redis
    - cache_node_type: cache.t1.micro
    - num_cache_nodes: 1
    - region: us-east-1
    - profile:
      - keyid: GKTADJGHEIQSXMKKRBJ08H
      - key: askdjghsdfjkgHwupUjasdfklgjsdfjajkghs

salt.states.boto_elasticache.absent(name, wait=True, region=None, key=None, keyid=None, profile=None)

Ensure the named elasticache cluster is deleted.
  name Name of the cache cluster.
  wait Boolean. Wait for confirmation from boto that the cluster is in the deleting state.
  region Region to connect to.
  key Secret key to be used.
  keyid Access key to be used.
  profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_elasticache.creategroup(name, primary_cluster_id, replication_group_description, wait=None, region=None, key=None, keyid=None, profile=None)

Ensure the a replication group is create.
  name Name of replication group
  wait Waits for the group to be available
  primary_cluster_id Name of the master cache node
  replication_group_description Description for the group
  region Region to connect to.
  key Secret key to be used.
  keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

`salt.states.boto_elasticache.present`(
  name,
  engine=None,
  cache_node_type=None,
  num_cache_nodes=None,
  preferred_availability_zone=None,
  port=None,
  cache_parameter_group_name=None,
  cache_security_group_names=None,
  replication_group_id=None,
  auto_minor_version_upgrade=True,
  security_group_ids=None,
  cache_subnet_group_name=None,
  engine_version=None,
  notification_topic_arn=None,
  preferred_maintenance_window=None,
  wait=None,
  region=None,
  key=None,
  keyid=None,
  profile=None
)

Ensure the cache cluster exists.

- **name** Name of the cache cluster (cache cluster id).
- **engine** The name of the cache engine to be used for this cache cluster. Valid values are memcached or redis.
- **num_cache_nodes** The number of cache nodes that the cache cluster will have.
- **preferred_availability_zone** The EC2 Availability Zone in which the cache cluster will be created. All cache nodes belonging to a cache cluster are placed in the preferred availability zone.
- **port** The port number on which each of the cache nodes will accept connections.
- **cache_parameter_group_name** The name of the cache parameter group to associate with this cache cluster. If this argument is omitted, the default cache parameter group for the specified engine will be used.
- **cache_security_group_names** A list of cache security group names to associate with this cache cluster. Use this parameter only when you are creating a cluster outside of a VPC.
- **replication_group_id** The replication group to which this cache cluster should belong. If this parameter is specified, the cache cluster will be added to the specified replication group as a read replica; otherwise, the cache cluster will be a standalone primary that is not part of any replication group.
- **auto_minor_version_upgrade** Determines whether minor engine upgrades will be applied automatically to the cache cluster during the maintenance window. A value of True allows these upgrades to occur; False disables automatic upgrades.
- **security_group_ids** One or more VPC security groups associated with the cache cluster. Use this parameter only when you are creating a cluster in a VPC.
- **cache_subnet_group_name** The name of the cache subnet group to be used for the cache cluster. Use this parameter only when you are creating a cluster in a VPC.
- **engine_version** The version number of the cache engine to be used for this cluster.
- **notification_topic_arn** The Amazon Resource Name (ARN) of the Amazon Simple Notification Service (SNS) topic to which notifications will be sent. The Amazon SNS topic owner must be the same as the cache cluster owner.
- **preferred_maintenance_window** The weekly time range (in UTC) during which system maintenance can occur. Example: sun:05:00-sun:09:00
- **wait** Boolean. Wait for confirmation from boto that the cluster is in the available state.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

`salt.states.boto_elasticache.subnet_group_absent`(
  name,
  tags=None,
  region=None,
  key=None,
  keyid=None,
  profile=None
)

Chapter 13. Salt Module Reference
salt.states.boto_elasticache.subnet_group_present(name, subnet_ids, description, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure ElastiCache subnet group exists.

New in version 2015.8.0.

- **name**: The name for the ElastiCache subnet group. This value is stored as a lowercase string.
- **subnet_ids**: A list of VPC subnet IDs for the cache subnet group.
- **description**: Subnet group description.
- **tags**: A list of tags.
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

13.16.24 salt.states.boto_elb

Manage ELBs

New in version 2014.7.0.

Create and destroy ELBs. Be aware that this interacts with Amazon’s services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit elb credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:

```yaml
elb.keyid: GKTADJGHEIQSXMKKRBJ08H
elb.key: askdjghsdfjdkgWupUjasdflkdfklgjsdfajkgghs
```

It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjdkgWupUjasdflkdfklgjsdfajkgghs
    region: us-east-1
```

Ensure myelb ELB exists:

```yaml
boto_elb.present:
    - name: myelb
    - region: us-east-1
    - availability_zones:
        - us-east-1a
        - us-east-1b
        - us-east-1c
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjdkgWupUjasdflkdfklgjsdfajkgghs
    - listeners:
        - elb_port: 443
          instance_port: 80
          elb_protocol: HTTPS
          instance_protocol: HTTP
```

13.16. state modules 1931
certificate: 'arn:aws:iam::1111111:server-certificate/mycert'
policies:
  - my-ssl-policy
  - cookie-policy
  - elb_port: 8210
    instance_port: 8210
    elb_protocol: TCP

      policy_type: ProxyProtocolPolicyType
      policy:
        ProxyProtocol: true

# Using a profile from pillars
Ensure myelb ELB exists:
  boto_elb.present:
    - name: myelb
    - region: us-east-1
    - profile: myelbprofile

# Passing in a profile
Ensure myelb ELB exists:
  boto_elb.present:
    - name: myelb
It's possible to specify attributes from pillars by specifying a pillar. You can override the values defined in the pillar by setting the attributes on the resource. The module will use the default pillar key `boto_elb_attributes`, which allows you to set default attributes for all ELB resources.

Setting the attributes pillar:

```yaml
my_elb_attributes:
  cross_zone_load_balancing:
    enabled: true
  connection_draining:
    enabled: true
  timeout: 20
  access_log:
    enabled: true
  s3_bucket_name: 'mybucket'
  s3_bucket_prefix: 'my-logs'
  emit_interval: 5
```

Overriding the attribute values on the resource:

```yaml
Ensure myelb ELB exists:
  boto_elb.present:
    - name: myelb
    - region: us-east-1
    - attributes_from_pillar: my_elb_attributes
      # override cross_zone_load_balancing:enabled
    - attributes:
        cross_zone_load_balancing:
          enabled: false
    - profile: myelbprofile
```

It's possible to specify cloudwatch alarms that will be setup along with the ELB. Note the alarm name will be defined by the name attribute provided, plus the ELB resource name.

```yaml
Ensure myelb ELB exists:
  boto_elb.present:
    - name: myelb
    - region: us-east-1
    - profile: myelbprofile
    - alarms:
        UnHealthyHostCount:
          name: 'ELB UnHealthyHostCount **MANAGED BY SALT**'
          attributes:
            metric: UnHealthyHostCount
            namespace: AWS/ELB
            statistic: Average
            comparison: '>='
            threshold: 1.0
            period: 600
            evaluation_periods: 6
            unit: null
            description: ELB UnHealthyHostCount
```
You can also use alarms from pillars, and override values from the pillar alarms by setting overrides on the resource. Note that `boto_elb_alarms` will be used as a default value for all resources, if defined and can be used to ensure alarms are always set for a resource.

Setting the alarms in a pillar:

```
my_elb_alarm:
  UnHealthyHostCount:
    name: 'ELB UnHealthyHostCount **MANAGED BY SALT**'
    attributes:
      metric: UnHealthyHostCount
      namespace: AWS/ELB
      statistic: Average
      comparison: '>='
      threshold: 1.0
      period: 600
      evaluation_periods: 6
      unit: null
      description: ELB UnHealthyHostCount
    insufficient_data_actions: []
    ok_actions: ['arn:aws:sns:us-east-1:12345:myalarm']
```

Overriding the alarm values on the resource:

```
Ensure myelb ELB exists:
  boto_elb.present:
    - name: myelb
    - region: us-east-1
    - profile: myelbprofile
    - alarms_from_pillar: my_elb_alarm
      # override UnHealthyHostCount:attributes:threshold
    - alarms:
      UnHealthyHostCount:
        attributes:
          threshold: 2.0
```

Tags can also be set:

```
New in version 2016.3.0.
Ensure myelb ELB exists:
  boto_elb.present:
    - name: myelb
    - region: us-east-1
    - profile: myelbprofile
    - tags:
      MyTag: 'My Tag Value'
      OtherTag: 'My Other Value'
```

```
salt.states.boto_elb.absent(name, region=None, key=None, keyid=None, profile=None)
  Ensure an ELB does not exist
    name  name of the ELB
```
salt.states.boto_elb.present(name, listeners, availability_zones=None, subnets=None, security_groups=None, scheme='internet-facing', health_check=None, attributes=None, attributes_from_pillar='boto_elb_attributes', cnames=None, alarms=None, alarms_from_pillar='boto_elb_alarms', policies=None, policies_from_pillar='boto_elb_policies', backends=None, region=None, key=None, keyid=None, profile=None, wait_for_sync=True, tags=None)

Ensure the ELB exists.

name Name of the ELB.

availability_zones A list of availability zones for this ELB.

listeners A list of listener lists; example:

```
[  
  ['443', 'HTTPS', 'arn:aws:iam::111111:server-certificate/mycert'],
  ['8443', '80', 'HTTPS', 'HTTP', 'arn:aws:iam::111111:server-certificate/mycert']
]
```

subnets A list of subnet IDs in your VPC to attach to your LoadBalancer.

security_groups The security groups assigned to your LoadBalancer within your VPC. Must be passed either as a list or a comma-separated string.

For example, a list:

```
- security_groups:
  - secgroup-one
  - secgroup-two
```

Or as a comma-separated string:

```
- security_groups: secgroup-one,secgroup-two
```

scheme The type of a LoadBalancer, internet-facing or internal. Once set, can not be modified.

health_check A dict defining the health check for this ELB.

attributes A dict defining the attributes to set on this ELB. Unknown keys will be silently ignored.

See the salt.modules.boto_elb.set_attributes function for recognized attributes.

attributes_from_pillar name of pillar dict that contains attributes. Attributes defined for this specific state will override those from pillar.

cnames A list of cname dicts with attributes needed for the DNS add_record state. By default the boto_route53.add_record state will be used, which requires: name, zone, ttl, and identifier. See the boto_route53 state for information about these attributes. Other DNS modules can be called by specifying the provider keyword. the cnames dict will be passed to the state as kwargs.

See the salt.states.boto_route53 state for information about these attributes.

alarms: a dictionary of name->boto_cloudwatch_alarm sections to be associated with this ELB. All attributes should be specified except for dimension which will be automatically set to this ELB.

See the salt.states.boto_cloudwatch_alarm state for information about these attributes.

alarms_from_pillar name of pillar dict that contains alarm settings. Alarms defined for this specific state will override those from pillar.

region Region to connect to.

key Secret key to be used.

keyid Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

wait_for_sync Wait for an INSYNC change status from Route53.

tags dict of tags
salt.states.boto_elb.register_instances(name, instances, region=None, key=None, keyid=None, profile=None)

Add EC2 instance(s) to an Elastic Load Balancer. Removing an instance from the instances list does not remove it from the ELB.

name The name of the Elastic Load Balancer to add EC2 instances to.

instances A list of EC2 instance IDs that this Elastic Load Balancer should distribute traffic to. This state will only ever append new instances to the ELB. EC2 instances already associated with this ELB will not be removed if they are not in the instances list.

New in version 2015.8.0.

```
add-instances:
boto_elb.register_instances:  
  - name: myloadbalancer
  - instances:
    - instance-id1
    - instance-id2
```

13.16.25 salt.states.boto_iam

Manage IAM objects

New in version 2015.8.0.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit IAM credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
delete-user:
boto_iam.user_absent:
  - name: myuser
  - delete_keys: true
```

```
delete-keys:
boto_iam.keys_absent:
  - access_keys:
    - 'AKIAJHMTIQ2ASDFLASDF'
    - 'PQIAJHMTIQ2ASRTLASFR'
  - user_name: myuser
```

```
create-user:
boto_iam.user_present:
  - name: myuser
  - policies:
    - mypolicy: |
      {  
        "Version": "2012-10-17",
        "Statement": [{
          "Effect": "Allow",
          "Action": "+",
          "Resource": "+"}]
      }
```

  - keyid: 'AKIAJHTMIQ2ASDFLASDF'
  - key: 'fdkjsafkljsASSADFalkfjasdf'
salt.states.boto_iam.account_policy(allow_users_to_change_password=None, hard_expiry=None, max_password_age=None, minimum_password_length=None, password_reuse_prevention=None, require_lowercase_characters=None, require_numbers=None, require_symbols=None, requireuppercase_characters=None, region=None, key=None, keyid=None, profile=None)

Change account policy.

New in version 2015.8.0.

allow_users_to_change_password (bool) Allows all IAM users in your account to use the AWS Management Console to change their own passwords.

hard_expiry (bool) Prevents IAM users from setting a new password after their password has expired.

max_password_age (int) The number of days that an IAM user password is valid.

minimum_password_length (int) The minimum number of characters allowed in an IAM user password.

password_reuse_prevention (int) Specifies the number of previous passwords that IAM users are prevented from reusing.

require_lowercase_characters (bool) Specifies whether IAM user passwords must contain at least one lowercase character from the ISO basic Latin alphabet (a to z).

require_numbers (bool) Specifies whether IAM user passwords must contain at least one numeric character (0 to 9).

require_symbols (bool) Specifies whether IAM user passwords must contain at least one of the following non-alphanumeric characters: `! @ $ % ^ & * ( ) _ + - = \[ \] { } | `'

requireuppercase_characters (bool) Specifies whether IAM user passwords must contain at least one uppercase character from the ISO basic Latin alphabet (A to Z).

region (string) Region to connect to.

dash (string) Secret key to be used.

keyid (string) Access key to be used.

profile (dict) A dict with region, key and keyid, or a pillar key (string)

salt.states.boto_iam.group_present(name, policies=None, policies_from_pillars=None, users=None, path='/', region=None, key=None, keyid=None, profile=None)

New in version 2015.8.0.

Ensure the IAM group is present.

name (string) The name of the new group.

path (string) The path for the group, defaults to `/'

policies (dict) A dict of IAM group policy documents.

policies_from_pillars (list) A list of pillars that contain role policy dicts. Policies in the pillars will be merged in the order defined in the list and key conflicts will be handled by later defined keys overriding earlier defined keys. The policies defined here will be merged with the policies defined in the policies argument. If keys conflict, the keys in the policies argument will override the keys defined in policies_from_pillars.

users (list) A list of users to be added to the group.

region (string) Region to connect to.

key (string) Secret key to be used.

keyid (string) Access key to be used.

profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iam.keys_absent(access_keys, user_name, region=None, key=None, keyid=None, profile=None)

New in version 2015.8.0.

Ensure the IAM user access_key_id is absent.

access_key_id (list) A list of access key ids
user_name (string) The username of the user.
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iam.keys_present(name, number, save_dir, region=None, key=None, keyid=None, profile=None)

New in version 2015.8.0.
Ensure the IAM access keys are present.

name (string) The name of the new user.
number (int) Number of keys that user should have.
save_dir (string) The directory that the key/keys will be saved. Keys are saved to a file named according to the username provided.
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iam.server_cert_absent(name, region=None, key=None, keyid=None, profile=None)

Deletes a server certificate.

New in version 2015.8.0.

name (string) The name for the server certificate. Do not include the path in this value.
region (string) The name of the region to connect to.
key (string) The key to be used in order to connect
keyid (string) The keyid to be used in order to connect
profile (string) The profile that contains a dict of region, key, keyid

salt.states.boto_iam.server_cert_present(name, public_key, private_key, cert_chain=None, path=None, region=None, key=None, keyid=None, profile=None)

Create server certificate.

New in version 2015.8.0.

name (string) The name for the server certificate. Do not include the path in this value.
public_key (string) The contents of the public key certificate in PEM-encoded format.
private_key (string) The contents of the private key in PEM-encoded format.
cert_chain (string) The contents of the certificate chain. This is typically a concatenation of the PEM-encoded public key certificates of the chain.
path (string) The path for the server certificate.
region (string) The name of the region to connect to.
key (string) The key to be used in order to connect
keyid (string) The keyid to be used in order to connect
profile (string) The profile that contains a dict of region, key, keyid

salt.states.boto_iam.user_absent(name, delete_keys=True, delete_mfa_devices=True, delete_profile=True, region=None, key=None, keyid=None, profile=None)

New in version 2015.8.0.
Ensure the IAM user is absent. User cannot be deleted if it has keys.
name (string) The name of the new user.
delete_keys (bool) Delete all keys from user.
delete_mfa_devices (bool) Delete all mfa devices from user.

New in version 2016.3.0.

delete_profile (bool) Delete profile from user.

New in version 2016.3.0.

region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key
and keyid.

salt.states.boto_iam.user_present(name, policies=None, policies_from_pillars=None, password=None, path=None, region=None, key=None, keyid=None, profile=None)

New in version 2015.8.0.

Ensure the IAM user is present
name (string) The name of the new user.
policies (dict) A dict of IAM group policy documents.
policies_from_pillars (list) A list of pillars that contain role policy dicts. Policies in the pillars will be merged
in the order defined in the list and key conflicts will be handled by later defined keys overriding earlier
defined keys. The policies defined here will be merged with the policies defined in the policies argument.
If keys conflict, the keys in the policies argument will override the keys defined in policies_from_pillars.
password (string) The password for the new user. Must comply with account policy.
path (string) The path of the user. Default is `/`.

New in version 2015.8.2.

region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key
and keyid.

13.16.26 salt.states.boto_iam_role

Manage IAM roles

New in version 2014.7.0.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit IAM credentials but can also utilize IAM roles assigned to the instance through In-
stance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is
necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

iam.keyid: GKTADJGHEIQSXMKKRBJ08H
iam.key: askdjghsdfjkgHwupUjasdflkdfklgjdsdfjajkghs

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull
from pillars or minion config:

myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkgHwupUjasdflkdfklgjdsdfjajkghs
    region: us-east-1
Creating a role will automatically create an instance profile and associate it with the role. This is the default behavior of the AWS console.

```yaml
myrole:
  boto_iam_role.present:
    - region: us-east-1
    - key: GKTADJGHEIQSXMKKRBJ08H
    - keyid: askdjghsdfjkghWupUjasdfsdfklgjhsdgfjhsgh
    - policies_from_pillars:
        - shared_iam_bootstrap_policy
    - policies:
        MySQSPolicy:
          Statement:
            - Action:
              - sqs:*
              Effect: Allow
            Resource:
              - arn:aws:sqs:*::*
            Sid: MyPolicySQS1
        MyS3Policy:
          Statement:
            - Action:
              - s3:GetObject
              Effect: Allow
            Resource:
              - arn:aws:s3:::*::mybucket/*

# Using a credentials profile from pillars
myrole:
  boto_iam_role.present:
    - profile: myiamprofile

# Passing in a credentials profile
myrole:
  boto_iam_role.present:
    - profile:
        key: GKTADJGHEIQSXMKKRBJ08H
        keyid: askdjghsdfjkghWupUjasdfsdfklgjhsdgfjhsgh
        region: us-east-1
```

If `delete_policies: False` is specified, existing policies that are not in the given list of policies will not be deleted. This allows manual modifications on the IAM role to be persistent. This functionality was added in 2015.8.0.

Note: When using the `profile` parameter and `region` is set outside of the profile group, region is ignored and a default region will be used.

If `region` is missing from the `profile` data set, `us-east-1` will be used as the default region.

salt.states.boto_iam_role.absent(name, region=None, key=None, keyid=None, profile=None)

Ensure the IAM role is deleted.

- **name** Name of the IAM role.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_iam_role.present(name, policy_document=None, path=None, policies=None, policies_from_pillars=None, create_instance_profile=True, region=None, key=None, keyid=None, profile=None, delete_policies=True)

Ensure the IAM role exists.

name  Name of the IAM role.
policy_document  The policy that grants an entity permission to assume the role. (See http://boto.readthedocs.org/en/latest/ref/iam.html#boto.iam.connection.IAMConnection.create_role)
path  The path to the role/instance profile. (See http://boto.readthedocs.org/en/latest/ref/iam.html#boto.iam.connection.IAMConnection.create_role)
policies  A dict of IAM role policies.
policies_from_pillars  A list of pillars that contain role policy dicts. Policies in the pillars will be merged in the order defined in the list and key conflicts will be handled by later defined keys overriding earlier defined keys. The policies defined here will be merged with the policies defined in the policies argument. If keys conflict, the keys in the policies argument will override the keys defined in policies_from_pillars.
create_instance_profile  A boolean of whether or not to create an instance profile and associate it with this role.
region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
delete_policies  Deletes existing policies that are not in the given list of policies. Default value is True. If False is specified, existing policies will not be deleted allowing manual modifications on the IAM role to be persistent.

New in version 2015.8.0.

13.16.27  salt.states.boto_iot module

Manage IoT Objects

New in version 2016.3.0.

Create and destroy IoT objects. Be aware that this interacts with Amazon’s services, and so may incur charges.

depends

• boto
• boto3

The dependencies listed above can be installed via package or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:

vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs

It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgWupUjasdfklGjgsdfjajkghs
  region: us-east-1

Ensure policy exists:
    boto_iot.policy_present:
      - policyName: mypolicy
      - policyDocument:
        Version: "2012-10-17"
        Statement:
          Action:
          - iot:Publish
          Resource:
            - "*
          Effect: "Allow"
          - region: us-east-1
          - keyid: GKTADJGHEIQSXMKKRBJ08H
          - key: askdjghsdfjkgWupUjasdfklGjgsdfjajkghs

Ensure topic rule exists:
    boto_iot.topic_rule_present:
      - ruleName: myrule
      - sql: "SELECT * FROM 'iot/test"
      - description: 'test rule'
      - ruleDisabled: false
      - actions:
        - lambda:
          functionArn: "arn:aws:us-east-1:1234:function/functionname"
          - region: us-east-1
          - keyid: GKTADJGHEIQSXMKKRBJ08H
          - key: askdjghsdfjkgWupUjasdfklGjgsdfjajkghs

salt.states.boto_iot.policy_absent(name, policyName, region=None, key=None, keyid=None, profile=None)

Ensure policy with passed properties is absent.

name The name of the state definition.
policyName Name of the policy.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iot.policy_attached(name, policyName, principal, region=None, key=None, keyid=None, profile=None)

Ensure policy is attached to the given principal.

name The name of the state definition
policyName Name of the policy.
principal The principal which can be a certificate ARN or a Cognito ID.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_iot.policy_detached(\n    name, policyName, principal, region=None, key=None, \n    keyid=None, profile=None)\n
Ensure policy is attached to the given principal.\n
name  The name of the state definition.\npolicyName  Name of the policy.\nprincipal  The principal which can be a certificate ARN or a Cognito ID.\nregion  Region to connect to.\nkey  Secret key to be used.\nkeyid  Access key to be used.\nprofile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.\n
salt.states.boto_iot.policy_present(\n    name, policyName, policyDocument, region=None, key=None, keyid=None, profile=None)\n
Ensure policy exists.\n
name  The name of the state definition\npolicyName  Name of the policy.\npolicyDocument  The JSON document that describes the policy. The length of the policyDocument must be a minimum length of 1, with a maximum length of 2048, excluding whitespace.\nregion  Region to connect to.\nkey  Secret key to be used.\nkeyid  Access key to be used.\nprofile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.\n
salt.states.boto_iot.topic_rule_absent(\n    name, ruleName, region=None, key=None, keyid=None, profile=None)\n
Ensure topic rule with passed properties is absent.\n
name  The name of the state definition.\nruleName  Name of the policy.\nregion  Region to connect to.\nkey  Secret key to be used.\nkeyid  Access key to be used.\nprofile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.\n
salt.states.boto_iot.topic_rule_present(\n    name, ruleName, sql, actions, description='', \n    ruleDisabled=False, region=None, key=None, keyid=None, profile=None)\n
Ensure topic rule exists.\n
name  The name of the state definition.\nruleName  Name of the rule.\nsql  The SQL statement used to query the topic.\nactions  The actions associated with the rule.\ndescription  The description of the rule.\nruleDisabled  Specifies whether the rule is disabled.\nregion  Region to connect to.\nkey  Secret key to be used.\nkeyid  Access key to be used.\nprofile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.\n
13.16.28 salt.states.boto_kms\n
Manage KMS keys, key policies and grants.
New in version 2015.8.0.

Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit kms credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```python
elb.keyid: GKTADJGHEIQSXMKKRBJ08H
elb.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```python
myprofile:
   keyid: GKTADJGHEIQSXMKKRBJ08H
   key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
   region: us-east-1
```

```python
Ensure mykey key exists:
   boto_kms.key_present:
      - name: mykey
      - region: us-east-1
```

```python
# Using a profile from pillars
Ensure mykey key exists:
   boto_kms.key_present:
      - name: mykey
      - region: us-east-1
      - profile: myprofile
```

```python
# Passing in a profile
Ensure mykey key exists:
   boto_key.key_present:
      - name: mykey
      - region: us-east-1
      - profile:
          keyid: GKTADJGHEIQSXMKKRBJ08H
          key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

```python
salt.states.boto_kms.key_present(name, policy, description=None, key_usage=None, grants=None, manage_grants=False, key_rotation=False, enabled=True, region=None, key=None, keyid=None, profile=None)
```

Ensure the KMS key exists. KMS keys can not be deleted, so this function must be used to ensure the key is enabled or disabled.

- **name** Name of the key.
- **policy** Key usage policy.
- **description** Description of the key.
- **key_usage** Specifies the intended use of the key. Can only be set on creation, defaults to ENCRYPT_DECRYPT, which is also the only supported option.
- **grants** A list of grants to apply to the key. Not currently implemented.
- **manage_grants** Whether or not to manage grants. False by default, which will not manage any grants.
- **key_rotation** Whether or not key rotation is enabled for the key. False by default.
enabled  Whether or not the key is enabled. True by default.
region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

13.16.29  salt.states.boto_lambda module

Manage Lambda Functions

New in version 2016.3.0.
Create and destroy Lambda Functions. Be aware that this interacts with Amazon's services, and so may incur charges.

depends
-  boto
-  boto3

The dependencies listed above can be installed via package or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkgWupUjasdfklkgljgsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgWupUjasdfklkgljgsdfjajkghs
  region: us-east-1
```

Ensure function exists:
```
boto_lambda.function_present:
  - FunctionName: myfunction
  - Runtime: python2.7
  - Role: iam_role_name
  - Handler: entry_function
  - ZipFile: code.zip
  - S3Bucket: bucketname
  - S3Key: keyname
  - S3ObjectVersion: version
  - Description: "My Lambda Function"
  - Timeout: 3
  - MemorySize: 128
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkgWupUjasdfklkgljgsdfjajkghs
```
salt.states.boto_lambda.alias_absent(name, FunctionName, Name, region=None, key=None, keyid=None, profile=None)

Ensure alias with passed properties is absent.

- **name**: The name of the state definition.
- **FunctionName**: Name of the function.
- **Name**: Name of the alias.
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_lambda.alias_present(name, FunctionName, Name, FunctionVersion, Description='''', region=None, key=None, keyid=None, profile=None)

Ensure alias exists.

- **name**: The name of the state definition.
- **FunctionName**: Name of the function for which you want to create an alias.
- **Name**: The name of the alias to be created.
- **FunctionVersion**: Function version for which you are creating the alias.
- **Description**: A short, user-defined function description. Lambda does not use this value. Assign a meaningful description as you see fit.
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_lambda.event_source_mapping_absent(name, EventSourceArn, FunctionName, region=None, key=None, keyid=None, profile=None)

Ensure event source mapping with passed properties is absent.

- **name**: The name of the state definition.
- **EventSourceArn**: ARN of the event source.
- **FunctionName**: Name of the lambda function.
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_lambda.event_source_mapping_present(name, EventSourceArn, FunctionName, StartingPosition, Enabled=True, BatchSize=100, region=None, key=None, keyid=None, profile=None)

Ensure event source mapping exists.

- **name**: The name of the state definition.
- **EventSourceArn**: The Amazon Resource Name (ARN) of the Amazon Kinesis or the Amazon DynamoDB stream that is the event source.
- **FunctionName**: The Lambda function to invoke when AWS Lambda detects an event on the stream.

You can specify an unqualified function name (for example, ``Thumbnail") or you can specify Amazon Resource Name (ARN) of the function (for example, ``arn:aws:lambda:us-west-2:account-id:function:Thumbnail"). AWS Lambda also allows you to specify only the account ID qualifier (for example, ``account-id:Thumbnail"). Note that the length constraint applies only to the ARN. If you
specify only the function name, it is limited to 64 character in length.

**StartingPosition** The position in the stream where AWS Lambda should start reading. (TRIM_HORIZON | LATEST)

**Enabled** Indicates whether AWS Lambda should begin polling the event source. By default, Enabled is true.

**BatchSize** The largest number of records that AWS Lambda will retrieve from your event source at the time of invoking your function. Your function receives an event with all the retrieved records. The default is 100 records.

- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### salt.states.boto_lambda.function_absent

```
(name, FunctionName, region=None, key=None, keyid=None, profile=None)
```

Ensure function with passed properties is absent.

- **name** The name of the state definition.
- **FunctionName** Name of the function.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### salt.states.boto_lambda.function_present

```
(name, FunctionName, Runtime, Role, Handler, ZipFile=None, S3Bucket=None, S3Key=None, S3ObjectVersion=None, Description='', Timeout=3, MemorySize=128, Permissions=None, RoleRe-tries=5, region=None, key=None, keyid=None, profile=None)
```

Ensure function exists.

- **name** The name of the state definition.
- **FunctionName** Name of the function.
- **Runtime** The Runtime environment for the function. One of `nodejs`, `java8`, or `python2.7`
- **Role** The name or ARN of the IAM role that the function assumes when it executes your function to access any other AWS resources.
- **Handler** The function within your code that Lambda calls to begin execution. For Node.js it is the module-name.*export* value in your function. For Java, it can be package.classname::handler or package.classname.
- **ZipFile** A path to a .zip file containing your deployment package. If this is specified, S3Bucket and S3Key must not be specified.
- **S3Bucket** Amazon S3 bucket name where the .zip file containing your package is stored. If this is specified, S3Key must be specified and ZipFile must NOT be specified.
- **S3Key** The Amazon S3 object (the deployment package) key name you want to upload. If this is specified, S3Key must be specified and ZipFile must NOT be specified.
- **S3ObjectVersion** The version of S3 object to use. Optional, should only be specified if S3Bucket and S3Key are specified.
- **Description** A short, user-defined function description. Lambda does not use this value. Assign a meaningful description as you see fit.
- **Timeout** The function execution time at which Lambda should terminate this function. Because the execution time has cost implications, we recommend you set this value based on your expected execution time. The default is 3 seconds.
- **MemorySize** The amount of memory, in MB, your function is given. Lambda uses this memory size to infer the amount of CPU and memory allocated to your function. Your function use-case determines your CPU and memory requirements. For example, a database operation might need less memory compared
to an image processing function. The default value is 128 MB. The value must be a multiple of 64 MB.

Permissions A list of permission definitions to be added to the function's policy
RoleRetries IAM Roles may take some time to propagate to all regions once created. During that time function
creation may fail; this state will automatically retry this number of times. The default is 5.

region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and
keyid.

13.16.30 salt.states.boto_lc

Manage Launch Configurations

New in version 2014.7.0.

Create and destroy Launch Configurations. Be aware that this interacts with Amazon's services, and so may incur
charges.

A limitation of this module is that you can not modify launch configurations once they have been created. If a
launch configuration with the specified name exists, this module will always report success, even if the specified
configuration doesn't match. This is due to a limitation in Amazon's launch configuration API, as it only allows
launch configurations to be created and deleted.

Also note that a launch configuration that's in use by an autoscale group can not be deleted until the autoscale group
is no longer using it. This may affect the way in which you want to order your states.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit autoscale credentials but can also utilize IAM roles assigned to the instance through
Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration
is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

| asg.keyid: GKTADJGHEIQSXMKKRBJ08H |
| asg.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs |

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull
from pillars or minion config:

| myprofile: |
| keyid: GKTADJGHEIQSXMKKRBJ08H |
| key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs |
| region: us-east-1 |

Credential information is shared with autoscale groups as launch configurations and autoscale groups are completely
dependent on each other.

```
Ensure mylc exists:
boto_lc.present:
  - name: mylc
    - image_id: ami-0b9c9f62
    - key_name: mykey
    - security_groups:
      - mygroup
    - instance_type: m1.small
    - instance_monitoring: true
```
- block_device_mappings:
  - '/dev/sda1':
    size: 20
    volume_type: 'io1'
    iops: 220
    delete_on_termination: true
- cloud_init:
  boothooks:
  'disable-master.sh': |
  #!/bin/bash
  echo "manual" > /etc/init/salt-master.override
  scripts:
  'run_salt.sh': |
  #!/bin/bash
  add-apt-repository -y ppa:saltstack/salt
  apt-get update
  apt-get install -y salt-minion
  salt-call state.highstate
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs

# Using a profile from pillars.
Ensure mylc exists:
boto_lc.present:
  - name: mylc
  - image_id: ami-0b9c9f62
  - profile: myprofile

# Passing in a profile.
Ensure mylc exists:
boto_lc.present:
  - name: mylc
  - image_id: ami-0b9c9f62
  - profile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
    region: us-east-1

salt.states.boto_lc.absent(name, region=None, key=None, keyid=None, profile=None)
Ensure the named launch configuration is deleted.
name Name of the launch configuration.
region The region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_lc.present(name, image_id, key_name=None, security_groups=None, user_data=None, cloud_init=None, instance_type='m1.small', kernel_id=None, ramdisk_id=None, block_device_mappings=None, instance_monitoring=False, spot_price=None, instance_profile_name=None, ebs_optimized=False, associate_public_ip_address=None, region=None, key=None, keyid=None, profile=None)
Ensure the launch configuration exists.
name  Name of the launch configuration.
image_id  AMI to use for instances. AMI must exist or creation of the launch configuration will fail.
key_name  Name of the EC2 key pair to use for instances. Key must exist or creation of the launch configuration will fail.
security_groups  List of Names or security group id’s of the security groups with which to associate the EC2 instances or VPC instances, respectively. Security groups must exist, or creation of the launch configuration will fail.
user_data  The user data available to launched EC2 instances.
cloud_init  A dict of cloud_init configuration. Currently supported values: scripts, cloud-config. Mutually exclusive with user_data.
instance_type  The instance type. ex: m1.small.
kernel_id  The kernel id for the instance.
ramdisk_id  The RAM disk ID for the instance.
blob_device_mappings  A dict of block device mappings that contains a dict with volume_type, delete_on_termination, iops, size, encrypted, snapshot_id.
volume_type  Indicates what volume type to use. Valid values are standard, io1, gp2. Default is standard.
delete_on_termination  Indicates whether to delete the volume on instance termination (true) or not (false).
iops  For Provisioned IOPS (SSD) volumes only. The number of I/O operations per second (IOPS) to provision for the volume.
encrypted  Indicates whether the volume should be encrypted. Encrypted EBS volumes must be attached to instances that support Amazon EBS encryption. Volumes that are created from encrypted snapshots are automatically encrypted. There is no way to create an encrypted volume from an unencrypted snapshot or an unencrypted volume from an encrypted snapshot.
isinstance_monitoring  Whether instances in group are launched with detailed monitoring.
spot_price  The spot price you are bidding. Only applies if you are building an autoscaling group with spot instances.
isinstance_profile_name  The name or the Amazon Resource Name (ARN) of the instance profile associated with the IAM role for the instance. Instance profile must exist or the creation of the launch configuration will fail.
ebs_optimized  Specifies whether the instance is optimized for EBS I/O (true) or not (false).
associate_public_ip_address  Used for Auto Scaling groups that launch instances into an Amazon Virtual Private Cloud. Specifies whether to assign a public IP address to each instance launched in a Amazon VPC.
region  The region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

13.16.31  salt.states.boto_rds

Manage RDSs

New in version 2015.8.0.

Create and destroy RDS instances. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit rds credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:
It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure myrds RDS exists:

```yaml
boto_rds.present:
  - name: myrds
  - allocated_storage: 5
  - db_instance_class: db.t2.micro
  - engine: MySQL
  - master_username: myuser
  - master_user_password: mypass
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  - tags:
    - key1
    - value1
    - key2
    - value2
```

**Note:** This state module uses boto.rds2, which requires a different tagging syntax than some of the other boto states. The tags key and value set noted in the example above is the required yaml notation that rds2 depends upon to function properly. For more information, please see Issue #28715.

```
salt.states.boto_rds.absent(name, skip_final_snapshot=None, final_db_snapshot_identifier=None, tags=None, region=None, key=None, keyid=None, profile=None, wait_for_deletion=True, timeout=180)
```

Ensure RDS instance is absent.

- **name** Name of the RDS instance.
- **skip_final_snapshot** Whether a final db snapshot is created before the instance is deleted. If True, no snapshot is created. If False, a snapshot is created before deleting the instance.
- **final_db_snapshot_identifier** If a final snapshot is requested, this is the identifier used for that snapshot.
- **tags** A list of tags.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
- **wait_for_deletion** (bool) Wait for the RDS instance to be deleted completely before finishing the state.
- **timeout** (in seconds) The amount of time that can pass before raising an Exception.
salt.states.boto_rds.present(name, allocated_storage, db_instance_class, engine, master_username, master_user_password, db_name=None, db_security_groups=None, vpc_security_group_ids=None, availability_zone=None, db_subnet_group_name=None, preferred_maintenance_window=None, db_parameter_group_name=None, backupRetentionPeriod=None, preferred_backup_window=None, port=None, multi_az=None, engine_version=None, autoMinorVersionUpgrade=None, license_model=None, iops=None, option_group_name=None, characterSetName=None, publicly_accessible=None, wait_status=None, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure RDS instance exists.

name Name of the RDS instance.

allocated_storage The amount of storage (in gigabytes) to be initially allocated for the database instance.

db_instance_class The compute and memory capacity of the Amazon RDS DB instance.

engine The name of the database engine to be used for this instance. Supported engine types are: MySQL, oracle-se1, oracle-se, oracle-ee, sqlserver-ee, sqlserver-se, sqlserver-ex, sqlserver-web, and postgres. For more information, please see the engine argument in the boto_rds create_dbinstance documentation.

master_username The name of master user for the client DB instance.

master_user_password The password for the master database user. Can be any printable ASCII character except `/`, `"`, or `@`.

db_name The database name for the restored DB instance.

db_security_groups A list of DB security groups to associate with this DB instance.

vpc_security_group_ids A list of EC2 VPC security groups to associate with this DB instance.

availability_zone The EC2 Availability Zone that the database instance will be created in.

db_subnet_group_name A DB subnet group to associate with this DB instance.

preferred_maintenance_window The weekly time range (in UTC) during which system maintenance can occur.

backupRetentionPeriod The number of days for which automated backups are retained.

preferred_backup_window The daily time range during which automated backups are created if automated backups are enabled.

port The port number on which the database accepts connections.

multi_az Specifies if the DB instance is a Multi-AZ deployment. You cannot set the AvailabilityZone parameter if the MultiAZ parameter is set to true.

engine_version The version number of the database engine to use.

autoMinorVersionUpgrade Indicates that minor engine upgrades will be applied automatically to the DB instance during the maintenance window.

license_model License model information for this DB instance.

iops The amount of Provisioned IOPS (input/output operations per second) to be initially allocated for the DB instance.

option_group_name Indicates that the DB instance should be associated with the specified option group.

characterSetName For supported engines, indicates that the DB instance should be associated with the specified CharacterSet.

publicly_accessible Specifies the accessibility options for the DB instance. A value of true specifies an Internet-facing instance with a publicly resolvable DNS name, which resolves to a public IP address. A value of false specifies an internal instance with a DNS name that resolves to a private IP address.

wait_status Wait for the RDS instance to reach a desired status before finishing the state. Available states: available, modifying, backing-up

tags A list of tags.

region Region to connect to.

key Secret key to be used.

keyid Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_rds.replica_present(name, source, db_instance_class=None, availability_zone=None, port=None, auto_minor_version_upgrade=None, option_group_name=None, publicly_accessible=None, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure RDS replica exists.

Ensure myrds replica RDS exists:
  boto_rds.create_replica:
    - name: myreplica
    - source: mydb

salt.states.boto_rds.subnet_group_absent(name, tags=None, region=None, key=None, keyid=None, profile=None)

salt.states.boto_rds.subnet_group_present(name, description, subnet_ids=None, subnet_names=None, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure DB subnet group exists.
name The name for the DB subnet group. This value is stored as a lowercase string.
subnet_ids A list of the EC2 Subnet IDs for the DB subnet group. Either subnet_ids or subnet_names must be provided.
subnet_names A list of The EC2 Subnet names for the DB subnet group. Either subnet_ids or subnet_names must be provided.
description Subnet group description.
tags A list of tags.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

13.16.32 salt.states.boto_route53

Manage Route53 records
New in version 2014.7.0.
Create and delete Route53 records. Be aware that this interacts with Amazon's services, and so may incur charges.
This module uses boto, which can be installed via package, or pip.
This module accepts explicit route53 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.
If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
route53.keyid: GKTADJGHEIQSXMKKRBJ08H
route53.key: askdjghsdfjkgdhWupUjasdfkldfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
```
mycnamerecord:
  boto_route53.present:
    - name: test.example.com.
    - zone: example.com.
    - ttl: 60
    - record_type: CNAME
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkgghs

# Using a profile from pillars
myarecord:
  boto_route53.present:
    - name: test.example.com.
    - value: 1.1.1.1
    - zone: example.com.
    - ttl: 60
    - record_type: A
    - region: us-east-1
    - profile: myprofile

# Passing in a profile
myarecord:
  boto_route53.present:
    - name: test.example.com.
    - value: 1.1.1.1
    - zone: example.com.
    - ttl: 60
    - record_type: A
    - region: us-east-1
    - profile:
      keyid: GKTADJGHEIQSXMKKRBJ08H
      key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkgghs

salt.states.boto_route53.absent(name, zone, record_type, identifier=None, region=None,
  key=None, keyid=None, profile=None, wait_for_sync=True,
  split_dns=False, private_zone=False)

Ensure the Route53 record is deleted.

name  Name of the record.
zone  The zone to delete the record from.
record_type  The record type (A, NS, MX, TXT, etc.)
identifier  An identifier to match for deletion.
region  The region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
wait_for_sync  Wait for an INSYNC change status from Route53.
split_dns  Route53 supports a public and private DNS zone with the same names.
private_zone  If using split_dns, specify if this is the private zone.
salt.states.boto_route53.present

Ensure the Route53 record is present.

- **name** Name of the record.
- **value** Value of the record.
- **zone** The zone to create the record in.
- **record_type** The record type (A, NS, MX, TXT, etc.)
- **ttl** The time to live for the record.
- **identifier** The unique identifier to use for this record.
- **region** The region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
- **wait_for_sync** Wait for an INSYNC change status from Route53.
- **split_dns** Route53 supports a public and private DNS zone with the same names.
- **private_zone** If using split_dns, specify if this is the private zone.

13.16.33 salt.states.boto_s3_bucket module

Manage S3 Buckets

New in version 2016.3.0.

Create and destroy S3 buckets. Be aware that this interacts with Amazon's services, and so may incur charges.

- **depends**
  - boto
  - boto3

The dependencies listed above can be installed via package or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure bucket exists:

```yaml
boto_s3_bucket.present:
  - Bucket: mybucket
  - LocationConstraint: EU
  - ACL:
```
- GrantRead: "uri=http://acs.amazonaws.com/groups/global/AllUsers"
- CORSRules:
  - AllowedHeaders: []
  - AllowedMethods: ["GET"]
  - AllowedOrigins: ["*"]
  - ExposeHeaders: []
  - MaxAgeSeconds: 123
- LifecycleConfiguration:
  - Expiration:
    - Days: 123
    - ID: "idstring"
    - Prefix: "prefixstring"
    - Status: "enabled"
    - ID: "lc1"
  - Transitions:
    - Days: 123
    - StorageClass: "GLACIER"
  - NoncurrentVersionTransitions:
    - NoncurrentDays: 123
    - StorageClass: "GLACIER"
  - NoncurrentVersionExpiration:
    - NoncurrentDays: 123
- Logging:
  - TargetBucket: log_bucket
  - TargetPrefix: prefix
  - TargetGrants:
    - Grantee:
      - DisplayName: "string"
      - EmailAddress: "string"
      - ID: "string"
      - Type: "AmazonCustomerByEmail"
      - URI: "string"
      - Permission: "READ"
- NotificationConfiguration:
  - LambdaFunctionConfiguration:
    - ID: "string"
    - LambdaFunctionArn: "string"
    - Events:
      - "s3:ObjectCreated:*"
    - Filter:
      - Key:
        - FilterRules:
          - Name: "prefix"
          - Value: "string"
- Policy:
  - Version: "2012-10-17"
  - Statement:
    - Sid: "String"
    - Effect: "Allow"
    - Principal:
      - AWS: "arn:aws:iam::133434421342:root"
      - Action: "s3:PutObject"
      - Resource: "arn:aws:s3:::my-bucket/*"
  - Replication:
    - Role: myrole
    - Rules:
      - ID: "string"
      - Prefix: "string"
salt.states.boto_s3_bucket.absent(name, Bucket, region=None, key=None, keyid=None, profile=None)

Ensure bucket with passed properties is absent.
name The name of the state definition.
Bucket Name of the bucket.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_s3_bucket.present(name, Bucket, LocationConstraint=None, ACL=None, CORSRules=None, LifecycleConfiguration=None, Logging=None, NotificationConfiguration=None, Policy=None, Replication=None, RequestPayment=None, Tagging=None, Versioning=None, Website=None, region=None, key=None, keyid=None, profile=None)

Ensure bucket exists.
name The name of the state definition
Bucket Name of the bucket.
LocationConstraint 'EU'|'eu-west-1'|'us-west-1'|'us-west-2'|'ap-southeast-1'|'ap-southeast-2'|'ap-northeast-1'|'sa-east-1'|'cn-north-1'|'eu-central-1'
ACL The permissions on a bucket using access control lists (ACL).
CORSRules The cors configuration for a bucket.
LifecycleConfiguration Lifecycle configuration for your bucket
Logging The logging parameters for a bucket and to specify permissions for who can view and modify the logging parameters.

NotificationConfiguration notifications of specified events for a bucket

Policy Policy on the bucket

Replication Replication rules. You can add as many as 1,000 rules. Total replication configuration size can be up to 2 MB

RequestPayment The request payment configuration for a bucket. By default, the bucket owner pays for downloads from the bucket. This configuration parameter enables the bucket owner (only) to specify that the person requesting the download will be charged for the download

Tagging A dictionary of tags that should be set on the bucket

Versioning The versioning state of the bucket

Website The website configuration of the bucket

region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

13.16.34 salt.states.boto_secgroup

Manage Security Groups

New in version 2014.7.0.

Create and destroy Security Groups. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit EC2 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
| secgroup.keyid: GKTADJGHEIQXSXMCRB9J08H
| secgroup.key: askdjghsdfjkgHwupUjasdfklkflgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
| myprofile:
|     keyid: GKTADJGHEIQXSXMCRB9J08H
|     key: askdjghsdfjkgHwupUjasdfklkflgjsdfjajkghs
|     region: us-east-1
```

Ensure mysecgroup exists:

```
| boto_secgroup.present:
|     - name: mysecgroup
|     - description: My security group
|     - rules:
|         - ip_protocol: tcp
|             from_port: 80
|             to_port: 80
|             cidr_ip:
|                 - 10.0.0.0/0
|                 - 192.168.0.0/0
```
- ip_protocol: icmp
  from_port: -1
  to_port: -1
  source_group_name: mysecgroup
- rules_egress:
  - ip_protocol: all
    from_port: -1
    to_port: -1
    cidr_ip:
      - 10.0.0.0/0
      - 192.168.0.0/0
- tags:
  - SomeTag: 'My Tag Value'
  - SomeOtherTag: 'Other Tag Value'
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs

# Using a profile from pillars
Ensure mysecgroup exists:
  boto_secgroup.present:
    - name: mysecgroup
    - description: My security group
    - profile: myprofile

# Passing in a profile
Ensure mysecgroup exists:
  boto_secgroup.present:
    - name: mysecgroup
    - description: My security group
    - profile:
      - keyid: GKTADJGHEIQSXMKKRBJ08H
      - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
      - region: us-east-1

Note: When using the profile parameter and region is set outside of the profile group, region is ignored and a default region will be used.
If region is missing from the profile data set, us-east-1 will be used as the default region.

salt.states.boto_secgroup.absent(name, vpc_id=None, vpc_name=None, region=None, key=None, keyid=None, profile=None)

Ensure a security group with the specified name does not exist.

name Name of the security group.
vpc_id The ID of the VPC to remove the security group from, if any. Exclusive with vpc_name.
vpc_name The name of the VPC to remove the security group from, if any. Exclusive with vpc_name.

New in version 2016.3.0.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

New in version 2016.3.0.
salt.states.boto_secgroup.present(name, description, vpc_id=None, vpc_name=None, rules=None, rules_egress=None, region=None, key=None, keyid=None, profile=None, tags=None)

Ensure the security group exists with the specified rules.

name Name of the security group.
description A description of this security group.
vpc_id The ID of the VPC to create the security group in, if any. Exclusive with vpc_name.
vpc_name The name of the VPC to create the security group in, if any. Exclusive with vpc_id.

New in version 2016.3.0.

New in version 2015.8.2.

rules A list of ingress rule dicts. If not specified, rules=None, the ingress rules will be unmanaged. If set to an empty list, [], then all ingress rules will be removed.
rules_egress A list of egress rule dicts. If not specified, rules_egress=None, the egress rules will be unmanaged. If set to an empty list, [], then all egress rules will be removed.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key, and keyid.
tags List of key:value pairs of tags to set on the security group

New in version 2016.3.0.

13.16.35 salt.states.boto_sns

Manage SNS Topics

Create and destroy SNS topics. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
sns.keyid: GKTADJGHEIQSXMKKRBJ08H
sns.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

```yaml
mytopic:
  boto_sns.present:
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

# Using a profile from pillars
mytopic:
boto_sns.present:
- region: us-east-1
- profile: mysnsprofile

# Passing in a profile
mytopic:
  boto_sns.present:
    - region: us-east-1
    - profile:
      keyid: GKTADJGHEIQXSXMKKRBJ08H
      key: askdjghsdfjkghWupUjasdfklgjgsdfjajkghs

salt.states.boto_sns.absent(name, region=None, key=None, keyid=None, profile=None)
Ensure the named sns topic is deleted.
name Name of the SNS topic.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and
keyid.

salt.states.boto_sns.present(name, subscriptions=None, region=None, key=None, keyid=None, profile=None)
Ensure the SNS topic exists.
name Name of the SNS topic.
subscriptions List of SNS subscriptions.
    Each subscription is a dictionary with a protocol and endpoint key:
    
    ```
    [
      {'protocol': 'https', 'endpoint': 'https://www.example.com/sns-endpoint'},
      {'protocol': 'sqs', 'endpoint': 'arn:aws:sqs:us-west-2:123456789012:MyQueue'}
    ]
    ```
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and
keyid.

13.16.36 salt.states.boto_sqs

Manage SQS Queues

New in version 2014.7.0.
Create and destroy SQS queues. Be aware that this interacts with Amazon's services, and so may incur charges.
This module uses boto, which can be installed via package, or pip.
This module accepts explicit SQS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.
If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:
sqs.keyid: GKTADJGHEIQXSXMKKRBJ08H
sqs.key: askdjghsdfjkghWupUjasdfklgjgsdfjajkghs
It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQXSXMKKRBJ08H
  key: askdjghsdfjdkgHuwUpUsasdlfkljgjsdfjajkgks
  region: us-east-1

myqueue:
  boto_sqs.present:
    - region: us-east-1
    - keyid: GKTADJGHEIQXSXMKKRBJ08H
    - key: askdjghsdfjdkgHuwUpUsasdlfkljgjsdfjajkgks
    - attributes:
      - ReceiveMessageWaitTimeSeconds: 20

# Using a profile from pillars
myqueue:
  boto_sqs.present:
    - region: us-east-1
    - profile: mysqsprofile

# Passing in a profile
myqueue:
  boto_sqs.present:
    - region: us-east-1
    - profile:
        keyid: GKTADJGHEIQXSXMKKRBJ08H
        key: askdjghsdfjdkgHuwUpUsasdlfkljgjsdfjajkgks
```

**salt.states.boto_sqs.absent** *(name, region=None, key=None, keyid=None, profile=None)*

Ensure the named sqs queue is deleted.

- **name** Name of the SQS queue.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**salt.states.boto_sqs.present** *(name, attributes=None, region=None, key=None, keyid=None, profile=None)*

Ensure the SQS queue exists.

- **name** Name of the SQS queue.
- **attributes** A dict of key/value SQS attributes.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 13.16.37 salt.states.boto_vpc

Manage VPCs

New in version 2015.8.0.
Create and destroy VPCs. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
vpc.keyid: GKTADJGHEIQXSXMRRBOP8H
vpc.key: askdjghsdfjkgHUpUjasdfkflgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQXSXMRRBOP8H
  key: askdjghsdfjkgHUpUjasdfkflgjsdfjajkghs
  region: us-east-1
```

Ensure VPC exists:

```yaml
boto_vpc.present:
  - name: myvpc
    - cidr_block: 10.10.11.0/24
    - dns_hostnames: True
    - region: us-east-1
    - keyid: GKTADJGHEIQXSXMRRBOP8H
    - key: askdjghsdfjkgHUpUjasdfkflgjsdfjajkghs
```

Ensure subnet exists:

```yaml
boto_vpc.subnet_present:
  - name: mysubnet
    - vpc_id: vpc-123456
    - cidr_block: 10.0.0.0/16
    - region: us-east-1
    - profile: myprofile
```

{% set profile = salt['pillar.get']('aws:region:us-east-1:profile') %}

Ensure internet gateway exists:

```yaml
boto_vpc.internet_gateway_present:
  - name: myigw
    - vpc_name: myvpc
    - profile: {{ profile }}
```

Ensure route table exists:

```yaml
boto_vpc.route_table_present:
  - name: my_route_table
    - vpc_id: vpc-123456
    - routes:
      - destination_cidr_block: 0.0.0.0/0
```
instance_id: i-123456
- subnet_names:
  - subnet1
  - subnet2
- region: us-east-1
- profile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs

salt.states.boto_vpc.absent(name, tags=None, region=None, key=None, keyid=None, profile=None)
Ensure VPC with passed properties is absent.
name Name of the VPC.
tags A list of tags. All tags must match.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_vpc.dhcp_options_absent(name=None, dhcp_options_id=None, region=None, key=None, keyid=None, profile=None)
Ensure a set of DHCP options with the given settings exist.
name (string) Name of the DHCP options set.
dhcp_options_id (string) Id of the DHCP options set.
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (various) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
New in version 2016.3.0.

salt.states.boto_vpc.dhcp_options_present(name, dhcp_options_id=None, vpc_name=None, vpc_id=None, domain_name=None, domain_name_servers=None, ntp_servers=None, netbios_name_servers=None, netbios_node_type=None, tags=None, region=None, key=None, keyid=None, profile=None)
Ensure a set of DHCP options with the given settings exist. Note that the current implementation only SETS values during option set creation. It is unable to update option sets in place, and thus merely verifies the set exists via the given name and/or dhcp_options_id param.
name (string) Name of the DHCP options.
vpc_name (string) Name of a VPC to which the options should be associated. Either vpc_name or vpc_id must be provided.
vpc_id (string) Id of a VPC to which the options should be associated. Either vpc_name or vpc_id must be provided.
domain_name (string) Domain name to be associated with this option set.
domain_name_servers (list of strings) The IP address(es) of up to four domain name servers.
ntp_servers (list of strings) The IP address(es) of up to four desired NTP servers.
etbios_name_servers (list of strings) The IP address(es) of up to four NetBIOS name servers.
etbios_node_type (string) The NetBIOS node type (1, 2, 4, or 8). For more information about the allowed values, see RFC 2132. The recommended is 2 at this time (broadcast and multicast are currently not supported).
tags (dict of key:value pairs) A set of tags to be added.
region (string) Region to connect to.
key (string) Secret key to be used.  
keyid (string) Access key to be used.  
profile (various) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.  
New in version 2016.3.0.

salt.states.boto_vpc.internet_gateway_absent
(name, detach=False, region=None, key=None, keyid=None, profile=None)

Ensure the named internet gateway is absent.

name Name of the internet gateway.
detach First detach the internet gateway from a VPC, if attached.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_vpc.internet_gateway_present
(name, vpc_name=None, vpc_id=None, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure an internet gateway exists.

name Name of the internet gateway.
vpc_name Name of the VPC to which the internet gateway should be attached.
vpc_id Id of the VPC to which the internet_gateway should be attached. Only one of vpc_name or vpc_id may be provided.
tags A list of tags.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_vpc.present
(name, cidr_block, instance_tenancy=None, dns_support=None, dns_hostnames=None, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure VPC exists.

name Name of the VPC.
cidr_block The range of IPs in CIDR format, for example: 10.0.0.0/24. Block size must be between /16 and /28 netmask.
instance_tenancy Instances launched in this VPC will be single-tenant or dedicated hardware.
dns_support Indicates whether the DNS resolution is supported for the VPC.
dns_hostnames Indicates whether the instances launched in the VPC get DNS hostnames.
tag A list of tags.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_vpc.route_table_absent
(name, region=None, key=None, keyid=None, profile=None)

Ensure the named route table is absent.

name Name of the route table.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_vpc.route_table_present(name=None, vpc_name=None, vpc_id=None, routes=None, subnet_ids=None, subnet_names=None, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure route table with routes exists and is associated to a VPC.

Example:

```yaml
boto_vpc.route_table_present:
  - name: my_route_table
  - vpc_id: vpc-123456
  - routes:
    - destination_cidr_block: 0.0.0.0/0
      internet_gateway_name: InternetGateway
    - destination_cidr_block: 10.10.11.0/24
      instance_id: i-123456
    - destination_cidr_block: 10.10.12.0/24
      interface_id: eni-123456
    - destination_cidr_block: 10.10.13.0/24
      instance_name: mygatewayserver
    - subnet_names:
      - subnet1
      - subnet2
```

name Name of the route table.

vpc_name Name of the VPC with which the route table should be associated.

vpc_id Id of the VPC with which the route table should be associated. Either vpc_name or vpc_id must be provided.

routes A list of routes. Each route has a cidr and a target.

subnet_ids A list of subnet ids to associate

subnet_names A list of subnet names to associate

tags A list of tags.

region Region to connect to.

key Secret key to be used.

keyid Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_vpc.subnet_absent(name=None, subnet_id=None, region=None, key=None, keyid=None, profile=None)

Ensure subnet with passed properties is absent.

name Name of the subnet.

region Region to connect to.

key Secret key to be used.

keyid Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_vpc.subnet_present(name=None, cidr_block=None, vpc_name=None, vpc_id=None, availability_zone=None, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure a subnet exists.

name Name of the subnet.

cidr_block The range if IPs for the subnet, in CIDR format. For example: 10.0.0.0/24. Block size must be between /16 and /28 netmask.
vpc_name Name of the VPC in which the subnet should be placed. Either vpc_name or vpc_id must be provided.
vpc_id Id of the VPC in which the subnet should be placed. Either vpc_name or vpc_id must be provided.
availability_zone AZ in which the subnet should be placed.
tags A list of tags.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

13.16.38 salt.states.bower

Installation of Bower Packages

These states manage the installed packages using Bower. Note that npm, git and bower must be installed for these states to be available, so bower states should include requisites to pkg.installed states for the packages which provide npm and git (simply npm and git in most cases), and npm.installed state for the package which provides bower.

Example:

```language-yaml
npm:
  pkg.installed
git:
  pkg.installed
bower:
  npm.installed
  require:
    - pkg: npm
    - pkg: git
underscore:
  bower.installed:
    - dir: /path/to/project
    - require:
      - npm: bower
```

salt.states.bower.bootstrap(name, user=None)

Bootstraps a frontend distribution.

Will execute `bower install` on the specified directory.
user The user to run Bower with

salt.states.bower.installed(name, dir, pkg=None, user=None, env=None)

Verify that the given package is installed and is at the correct version (if specified).

```language-yaml
underscore:
  bower.installed:
    - dir: /path/to/project
    - user: someuser

jquery#2.0:
  bower.installed:
    - dir: /path/to/project
```

name The package to install
dir The target directory in which to install the package
pkgs A list of packages to install with a single Bower invocation; specifying this argument will ignore the name argument
user The user to run Bower with
eenv A list of environment variables to be set prior to execution. The format is the same as the cmd.run.state function.
salt.states.bower.removed(name, dir, user=None)
Verify that the given package is not installed.
dir The target directory in which to install the package
user The user to run Bower with

13.16.39 salt.states.cabal

Installation of Cabal Packages

New in version 2015.8.0.
These states manage the installed packages for Haskell using cabal. Note that cabal-install must be installed for these states to be available, so cabal states should include a requisite to a pkg.installed state for the package which provides cabal (cabal-install in case of Debian based distributions). Example:

```yaml
... code-block:: yaml

cabal-install: pkg.installed
ShellCheck:
    cabal.installed:
        • require: - pkg: cabal-install
```
salt.states.cabal.installed(name, pkgs=None, user=None, install_global=False, env=None)
Verify that the given package is installed and is at the correct version (if specified).

```yaml
ShellCheck-0.3.5:
    cabal:
        - installed:
```
name The package to install
user The user to run cabal install with
install_global Install package globally instead of locally
env A list of environment variables to be set prior to execution. The format is the same as the cmd.run.state function.
salt.states.cabal.removed(name, user=None, env=None)
Verify that given package is not installed.

13.16.40 salt.states.chef

Execute Chef client runs

Run chef-client or chef-solo

```yaml
my-chef-run:
    chef.client:
        - override-runlist: 'demo1,demo2'
```
- server: 'https://chef.domain.com'

default-chef-run:
  chef.client: []

my-solo-run:
  chef.solo:
    - environment: dev

salt.states.chef.client(name, **kwargs)
  name: Unique identifier for the state. Does not affect the Chef run.
  server: The chef server URL
  client_key: Set the client key file location
  config: The configuration file to use
  config-file-jail: Directory under which config files are allowed to be loaded (no client.rb or knife.rb outside
  this path will be loaded).
  environment: Set the Chef Environment on the node
  group: Group to set privilege to
  json-attributes: Load attributes from a JSON file or URL
  localmode: Point chef-client at local repository if True
  log_level: Set the log level (debug, info, warn, error, fatal)
  logfile: Set the log file location
  node-name: The node name for this client
  override-runlist: Replace current run list with specified items for a single run
  pid: Set the PID file location, defaults to /tmp/chef-client.pid
  run-lock-timeout: Set maximum duration to wait for another client run to finish, default is indefinitely.
  runlist: Permanently replace current run list with specified items
  user: User to set privilege to
  validation_key: Set the validation key file location, used for registering new clients

salt.states.chef.solo(name, **kwargs)
  name: Unique identifier for the state. Does not affect the Chef run.
  config: The configuration file to use
  environment: Set the Chef Environment on the node
  group: Group to set privilege to
  json-attributes: Load attributes from a JSON file or URL
  log_level: Set the log level (debug, info, warn, error, fatal)
  logfile: Set the log file location
  node-name: The node name for this client
  override-runlist: Replace current run list with specified items for a single run
  recipe-url: Pull down a remote gzipped tarball of recipes and untar it to the cookbook cache
  run-lock-timeout: Set maximum duration to wait for another client run to finish, default is indefinitely.
  user: User to set privilege to

13.16.41 salt.states.chocolatey module

Manage Chocolatey package installs .. versionadded:: 2016.3.0

salt.states.chocolatey.install(*args, **kwargs)
  Deprecated, please use `installed`. This function will be removed in Salt Nitrogen.

salt.states.chocolatey.installed(name, version=None, source=None, force=False, pre_versions=False, install_args=None, override_args=False, force_x86=False, package_args=None)
  Installs a package if not already installed
name  The name of the package to be installed.
version  Install a specific version of the package. Defaults to latest version.
source  Chocolatey repository (directory, share or remote URL, feed). Defaults to the official Chocolatey feed.
force  Reinstall the current version of an existing package. Default is false.
pre_versions  Include pre-release packages. Default is False.
install_args  A list of install arguments you want to pass to the installation process i.e product key or feature list
override_args  Set to true if you want to override the original install arguments (for the native installer) in the package and use your own. When this is set to False install_args will be appended to the end of the default arguments
force_x86  Force x86 (32bit) installation on 64 bit systems. Defaults to false.
package_args  A list of arguments you want to pass to the package

Installsomepackage:
chocolatey.installed:
  - name: packagename
  - version: '12.04'
  - source: 'mychocolatey/source'
  - force: True

salt.states.chocolatey.uninstall(*args, **kwargs)
Deprecated, please use `uninstalled`. This function will be removed in Salt Nitrogen.
salt.states.chocolatey.uninstalled(name, version=None, uninstall_args=None, override_args=False)
Uninstalls a package
name  The name of the package to be uninstalled
version  Uninstalls a specific version of the package. Defaults to latest version installed.
uninstall_args  A list of uninstall arguments you want to pass to the uninstallation process i.e product key or feature list
override_args  Set to true if you want to override the original uninstall arguments (for the native uninstaller) in the package and use your own. When this is set to False uninstall_args will be appended to the end of the default arguments

13.16.42 salt.states.chronos_job module

Configure Chronos jobs via a salt proxy.

my_job:
  chronos_job.config:
    - config:
      schedule: "R//PT2S"
      command: "echo 'hi'"
      owner: "me@example.com"

New in version 2015.8.2.
salt.states.chronos_job.absent(name)
Ensure that the chronos job with the given name is not present.
Parameters
name -- The app name
Returns  A standard Salt changes dictionary
salt.states.chronos_job.config(name, config)
Ensure that the chronos job with the given name is present and is configured to match the given config values.
Parameters
  • name -- The job name
- **config** -- The configuration to apply (dict)

Returns A standard Salt changes dictionary

### 13.16.43 salt.states.cloud

Using states instead of maps to deploy clouds

New in version 2014.1.0.

Use this minion to spin up a cloud instance:

```text
my-ec2-instance:
  cloud.profile:
    my-ec2-config
```

salt.states.cloud.absent(\*name, **kwargs)

Ensure that no instances with the specified names exist.

CAUTION: This is a destructive state, which will search all configured cloud providers for the named instance, and destroy it.

- **name** The name of the instance to destroy
- **onlyif** Do run the state only if is unless succeed
- **unless** Do not run the state at least unless succeed

salt.states.cloud.present(\*name, \*cloud_provider, **kwargs)

Spin up a single instance on a cloud provider, using salt-cloud. This state does not take a profile argument; rather, it takes the arguments that would normally be configured as part of the state.

Note that while this function does take any configuration argument that would normally be used to create an instance, it will not verify the state of any of those arguments on an existing instance. Stateful properties of an instance should be configured using their own individual state (i.e., cloud.tagged, cloud.untagged, etc).

- **name** The name of the instance to create
- **cloud_provider** The name of the cloud provider to use
- **onlyif** Do run the state only if is unless succeed
- **unless** Do not run the state at least unless succeed

salt.states.cloud.profile(\*name, **kwargs)

Create a single instance on a cloud provider, using a salt-cloud profile.

Note that while profiles used this function do take any configuration argument that would normally be used to create an instance using a profile, this state will not verify the state of any of those arguments on an existing instance. Stateful properties of an instance should be configured using their own individual state (i.e., cloud.tagged, cloud.untagged, etc).

- **name** The name of the instance to create
- **profile** The name of the cloud profile to use
- **onlyif** Do run the state only if is unless succeed
- **unless** Do not run the state at least unless succeed
- **kwargs** Any profile override or addition

salt.states.cloud.volume_absent(\*name, \*provider, **kwargs)

Check that a block volume exists.

salt.states.cloud.volume_attached(\*name, \*server_name, \*provider, **kwargs)

Check if a block volume is attached.

salt.states.cloud.volume_detached(\*name, \*server_name, \*provider, **kwargs)

Check if a block volume is attached.
Returns True if server or Volume do not exist.

```python
class volume_present(name, provider=None, **kwargs)
```

Check that a block volume exists.

### 13.16.44 salt.states.cmd

#### Execution of arbitrary commands

The `cmd` state module manages the enforcement of executed commands, this state can tell a command to run under certain circumstances.

A simple example to execute a command:

```bash
# Store the current date in a file
date > /tmp/salt-run:
    cmd.run
```

Only run if another execution failed, in this case truncate syslog if there is no disk space:

```bash
> /var/log/messages:
    cmd.run:
        - unless: echo 'foo' > /tmp/.test && rm -f /tmp/.test
```

Only run if the file specified by `creates` does not exist, in this case touch `/tmp/foo` if it does not exist.

```bash
touch /tmp/foo:
    cmd.run:
        - creates: /tmp/foo
```

**Note:** The `creates` option was added to version 2014.7.0

Salt determines whether the `cmd` state is successfully enforced based on the exit code returned by the command. If the command returns a zero exit code, then salt determines that the state was successfully enforced. If the script returns a non-zero exit code, then salt determines that it failed to successfully enforce the state. If a command returns a non-zero exit code but you wish to treat this as a success, then you must place the command in a script and explicitly set the exit code of the script to zero.

Please note that the success or failure of the state is not affected by whether a state change occurred nor the stateful argument.

When executing a command or script, the state (i.e., changed or not) of the command is unknown to Salt’s state system. Therefore, by default, the `cmd` state assumes that any command execution results in a changed state.

This means that if a `cmd` state is watched by another state then the state that’s watching will always be executed due to the `changed` state in the `cmd` state.

#### Using the `Stateful` Argument

Many state functions in this module now also accept a `stateful` argument. If `stateful` is specified to be true then it is assumed that the command or script will determine its own state and communicate it back by following a simple protocol described below:
1. If there's nothing in the stdout of the command, then assume no changes. Otherwise, the stdout must be either in JSON or its last non-empty line must be a string of key=value pairs delimited by spaces (no spaces on either side of =).

2. If it's JSON then it must be a JSON object (e.g., {}). If it's key=value pairs then quoting may be used to include spaces. (Python's shlex module is used to parse the key=value string)

   Two special keys or attributes are recognized in the output:

   | changed | bool (i.e., 'yes', 'no', 'true', 'false', case-insensitive) |
   | comment | str (i.e., any string) |

   So, only if changed is True then assume the command execution has changed the state, and any other key values or attributes in the output will be set as part of the changes.

3. If there's a comment then it will be used as the comment of the state.

   Here's an example of how one might write a shell script for use with a stateful command:

   ```bash
   #!/bin/bash
   #
   echo "Working hard..."
   # writing the state line
   echo # an empty line here so the next line will be the last.
   echo "changed=yes comment='something has changed' whatever=123"
   
   And an example SLS file using this module:

   Run myscript:
   cmd.run:
   - name: /path/to/myscript
   - cwd: /
   - stateful: True

   Run only if myscript changed something:
   cmd.run:
   - name: echo hello
   - cwd: /
   - onchanges:
     - cmd: Run myscript

   Note that if the second cmd.run state also specifies stateful: True it can then be watched by some other states as well.

4. The stateful argument can optionally include a test_name parameter.

   This is used to specify a command to run in test mode. This command should return stateful data for changes that would be made by the command in the name parameter.

   New in version 2015.2.0.

   Run myscript:
   cmd.run:
   - name: /path/to/myscript
   - cwd: /
   - stateful:
     - test_name: /path/to/myscript test

   Run masterscript:
**cmd.script:**
- name: masterscript
- source: salt://path/to/masterscript
- cwd: /
- stateful:
  - test_name: masterscript test

---

**Should I use `cmd.run` or `cmd.wait`?**

**Note:** Use `cmd.run` together with `onchanges` instead of `cmd.wait`.

These two states are often confused. The important thing to remember about them is that `cmd.run` states are run each time the SLS file that contains them is applied. If it is more desirable to have a command that only runs after some other state changes, then `cmd.wait` does just that. `cmd.wait` is designed to watch other states, and is executed when the state it is watching changes. Example:

```
/usr/local/bin/postinstall.sh:
  cmd.wait:
    - watch:
      - pkg: mycustompkg
  file.managed:
    - source: salt://utils/scripts/postinstall.sh

mycustompkg:
  pkg.installed:
    - require:
      - file: /usr/local/bin/postinstall.sh
```

cmd.wait itself does not do anything; all functionality is inside its `mod_watch` function, which is called by `watch` on changes.

cmd.wait will be deprecated in future due to the confusion it causes. The preferred format is using the `onchanges Requisite`, which works on `cmd.run` as well as on any other state. The example would then look as follows:

```
/usr/local/bin/postinstall.sh:
  cmd.run:
    - onchanges:
      - pkg: mycustompkg
  file.managed:
    - source: salt://utils/scripts/postinstall.sh

mycustompkg:
  pkg.installed:
    - require:
      - file: /usr/local/bin/postinstall.sh
```

---

**How do I create an environment from a pillar map?**

The map that comes from a pillar cannot be directly consumed by the `env` option. To use it one must convert it to a list. Example:

```
```
salt.states.cmd.call(name, func, args=(), kws=None, onlyif=None, unless=None, creates=None, output_loglevel='debug', use_vt=False, **kwargs)

Invoke a pre-defined Python function with arguments specified in the state declaration. This function is mainly used by the salt.renderers.pydsl renderer.

The interpretation of onlyif and unless arguments are identical to those of cmd.run, and all other arguments(cwd, runas, ...) allowed by cmd.run are allowed here, except that their effects apply only to the commands specified in onlyif and unless rather than to the function to be invoked.

In addition, the stateful argument has no effects here.

The return value of the invoked function will be interpreted as follows.

If it's a dictionary then it will be passed through to the state system, which expects it to have the usual structure returned by any salt state function.

Otherwise, the return value (denoted as result in the code below) is expected to be a JSON serializable object, and this dictionary is returned:

```json
{
    'name': name,
    'changes': {'retval': result},
    'result': True if result is None else bool(result),
    'comment': result if isinstance(result, string_types) else ''
}
```

salt.states.cmd.mod_run_check(cmd_kwargs, onlyif, unless, creates)

Execute the onlyif and unless logic. Return a result dict if: *onlyif failed (onlyif != 0)* "unless succeeded (unless == 0)" else return True

salt.states.cmd.mod_watch(name, **kwargs)

Execute a cmd function based on a watch call

salt.states.cmd.run(name, onlyif=None, unless=None, creates=None, cwd=None, runas=None, shell=None, env=None, stateful=False, umask=None, output_loglevel='debug', quiet=False, timeout=None, ignore_timeout=False, use_vt=False, **kwargs)

Run a command if certain circumstances are met. Use cmd.wait if you want to use the watch requisite.

name The command to execute, remember that the command will execute with the path and permissions of the salt-minion.

onlyif A command to run as a check, run the named command only if the command passed to the onlyif option returns true

unless A command to run as a check, only run the named command if the command passed to the unless option returns false

cwd The current working directory to execute the command in, defaults to /root

runas The user name to run the command as

shell The shell to use for execution, defaults to the shell grain

env A list of environment variables to be set prior to execution. Example:
**Warning:** The above illustrates a common PyYAML pitfall, that *yes*, *no*, *on*, *off*, *true*, and *false* are all loaded as boolean `True` and `False` values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So `$PATH` in the following example is a literal `"$PATH"`:

```yaml
script-bar:
  cmd.run:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing `PATH` by using a bit of Jinja:

```yaml
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}
mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

**stateful** The command being executed is expected to return data about executing a state. For more information, see the [Using the `Stateful` Argument section](#).

**umask** The umask (in octal) to use when running the command.

**output_loglevel** Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless `quiet` is used for this value.

**quiet** The command will be executed quietly, meaning no log entries of the actual command or its return data. This is deprecated as of the 2014.1.0 release, and is being replaced with `output_loglevel: quiet`.

**timeout** If the command has not terminated after timeout seconds, send the subprocess sigterm, and if sigterm is ignored, follow up with sigkill.

**ignore_timeout** Ignore the timeout of commands, which is useful for running nohup processes.

New in version 2015.8.0.

**creates** Only run if the file specified by `creates` does not exist.

New in version 2014.7.0.

**use_vt** Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

**bg** If `True`, run command in background and do not await or deliver it's results.

New in version 2016.3.6.

**Note:** `cmd.run` supports the usage of `reload_modules`. This functionality allows you to force Salt to reload all modules. You should only use `reload_modules` if your `cmd.run` does some sort of installation (such as `pip`), if you do not reload the modules future items in your state which rely on the software being installed will fail.

```yaml
getpip:
  cmd.run:
    - name: /usr/bin/python /usr/local/sbin/get-pip.py
    - unless: which pip
    - require:
      - pkg: python
      - file: /usr/local/sbin/get-pip.py
    - reload_modules: True
```
salt.states.cmd.script(name, source=None, template=None, onlyif=None, unless=None, creates=None, cwd=None, runas=None, shell=None, env=None, stateful=False, umask=None, timeout=None, use_vt=False, output_loglevel='debug', defaults=None, context=None, **kwargs)

Download a script and execute it with specified arguments.

**source** The location of the script to download. If the file is located on the master in the directory named spam, and is called eggs, the source string is `salt://spam/eggs`

**template** If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported

**name** Either ``cmd arg1 arg2 arg3...'' (cmd is not used) or a source ``salt://...''

**onlyif** Run the named command only if the command passed to the `onlyif` option returns true

**unless** Run the named command only if the command passed to the `unless` option returns false

**cwd** The current working directory to execute the command in, defaults to `/root`

**runas** The name of the user to run the command as

**shell** The shell to use for execution. The default is set in `grains['shell']`

**env** A list of environment variables to be set prior to execution. Example:

```yaml
salt://scripts/foo.sh:
  cmd.script:
    - env:
      - BATCH: 'yes'
```

---

**Warning:** The above illustrates a common PyYAML pitfall, that `yes`, `no`, `on`, `off`, `true`, and `false` are all loaded as boolean `True` and `False` values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So `$PATH` in the following example is a literal `'$PATH'`:

```yaml
salt://scripts/bar.sh:
  cmd.script:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing `$PATH` by using a bit of Jinja:

```python
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}

```

**saltenv** [base] The Salt environment to use

**umask** The umask (in octal) to use when running the command.

**stateful** The command being executed is expected to return data about executing a state. For more information, see the Using the `stateful` Argument section.

**timeout** If the command has not terminated after `timeout` seconds, send the subprocess sigterm, and if sigterm is ignored, follow up with sigkill

**args** String of command line `args` to pass to the script. Only used if no args are specified as part of the `name` argument. To pass a string containing spaces in YAML, you will need to doubly-quote it: ```arg1 'arg two' arg3```

**creates** Only run if the file specified by `creates` does not exist.

New in version 2014.7.0.
use_vt
Use VT utils (saltstack) to stream the command output more interactively to the console and the logs.
This is experimental.

context
New in version 2016.3.0.
Overrides default context variables passed to the template.

defaults
New in version 2016.3.0.
Default context passed to the template.

output_loglevel
Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

```
salt.states.cmd.wait(name, onlyif=None, unless=None, creates=None, cwd=None, runas=None,
                      shell=None, env=(), stateful=False, umask=None, output_loglevel='debug',
                      use_vt=False, **kwargs)
```
Run the given command only if the watch statement calls it.

**Note:** Use `cmd.run` with `onchange` instead.

name
The command to execute, remember that the command will execute with the path and permissions of the salt-minion.

onlyif
A command to run as a check, run the named command only if the command passed to the `onlyif` option returns true.

unless
A command to run as a check, only run the named command if the command passed to the `unless` option returns false.

cwd
The current working directory to execute the command in, defaults to /root

runas
The user name to run the command as

shell
The shell to use for execution, defaults to /bin/sh

env
A list of environment variables to be set prior to execution. Example:

```
script-foo:
  cmd.wait:
    - env:
      - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean `True` and `False` values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So `$PATH` in the following example is a literal `"$PATH"`:

```
script-bar:
  cmd.wait:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

umask
The umask (in octal) to use when running the command.
**stateful** The command being executed is expected to return data about executing a state. For more information, see the Using the "Stateful" Argument section.

**creates** Only run if the file specified by `creates` does not exist.

New in version 2014.7.0.

**output_loglevel** Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless `quiet` is used for this value.

**use_vt** Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

```python
salt.states.cmd.wait_call(name, func, args=(), kws=None, onlyif=None, unless=None, creates=None, stateful=False, use_vt=False, output_loglevel='debug', **kwargs)
```

```python
salt.states.cmd.wait_script(name, source=None, template=None, onlyif=None, unless=None, cwd=None, runas=None, shell=None, env=None, stateful=False, umask=None, use_vt=False, output_loglevel='debug', **kwargs)
```

Download a script from a remote source and execute it only if a watch statement calls it.

**source** The source script being downloaded to the minion, this source script is hosted on the salt master server. If the file is located on the master in the directory named spam, and is called eggs, the source string is `salt://spam/eggs`

**template** If this setting is applied then the named templating engine will be used to render the downloaded file, currently jinja, mako, and wempy are supported.

**name** The command to execute, remember that the command will execute with the path and permissions of the salt-minion.

**onlyif** A command to run as a check, run the named command only if the command passed to the `onlyif` option returns true.

**unless** A command to run as a check, only run the named command if the command passed to the `unless` option returns false.

**cwd** The current working directory to execute the command in, defaults to `/root`

**runas** The user name to run the command as.

**shell** The shell to use for execution, defaults to the shell grain.

**env** A list of environment variables to be set prior to execution. Example:

```yaml
salt://scripts/foo.sh:
  cmd.wait_script:
    - env:
      - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that `yes`, `no`, `on`, `off`, `true`, and `false` are all loaded as boolean `True` and `False` values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

Variables as values are not evaluated. So `$PATH` in the following example is a literal `PATH`:

```yaml
salt://scripts/bar.sh:
  cmd.wait_script:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing `$PATH` by using a bit of Jinja:

```yaml
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}
mycommand:
  cmd.run:
    - name: ls -l
```
- env:
  - PATH: {{ [current_path, '/my/special/bin']|join(':') }}

umask  The umask (in octal) to use when running the command.

stateful  The command being executed is expected to return data about executing a state. For more information, see the Using the `"Stateful" Argument` section.

use_vt  Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

output_loglevel  Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

13.16.45 salt.states.composer

Installation of Composer Packages

These states manage the installed packages for composer for PHP. Note that either composer is installed and accessible via a bin directory or you can pass the location of composer in the state.

get-composer:
  cmd.run:
    - name: 'CURL=`which curl`; $CURL -sS https://getcomposer.org/installer | php'
    - unless: test -f /usr/local/bin/composer
    - cwd: /root/

install-composer:
  cmd.wait:
    - name: mv /root/composer.phar /usr/local/bin/composer
    - cwd: /root/
    - watch:
      - cmd: get-composer

/path/to/project:
  composer.installed:
    - no_dev: true
    - require:
      - cmd: install-composer

# Without composer installed in your PATH
# Note: composer.phar must be executable for state to work properly
/path/to/project:
  composer.installed:
    - composer: /path/to/composer.phar
    - php: /usr/local/bin/php
    - no_dev: true

salt.states.composer.installed(name, composer=None, php=None, user=None, prefer_source=None, prefer_dist=None, no_scripts=None, no_plugins=None, optimize=None, no_dev=None, quiet=False, composer_home='/root', always_check=True)

Verify that the correct versions of composer dependencies are present.

dir  Directory location of the composer.json file.
composer Location of the composer.phar file. If not set composer will just execute `composer` as if it is installed globally. (i.e. /path/to/composer.phar)

php Location of the php executable to use with composer. (i.e. /usr/bin/php)

user Which system user to run composer as.

New in version 2014.1.4.

prefer_source --prefer-source option of composer.

prefer_dist --prefer-dist option of composer.

no_scripts --no-scripts option of composer.

no_plugins --no-plugins option of composer.

optimize --optimize-autoloader option of composer. Recommended for production.

no_dev --no-dev option for composer. Recommended for production.

quiet --quiet option for composer. Whether or not to return output from composer.

composer_home $COMPOSER_HOME environment variable

always_check If True, _always_ run composer install in the directory. This is the default behavior. If False, only run composer install if there is no vendor directory present.

salt.states.composer.update(name, composer=None, php=None, user=None, prefer_source=None, prefer_dist=None, no_scripts=None, no_plugins=None, optimize=None, no_dev=None, quiet=False, composer_home='~')

Composer update the directory to ensure we have the latest versions of all project dependencies.

dir Directory location of the composer.json file.

composer Location of the composer.phar file. If not set composer will just execute `composer` as if it is installed globally. (i.e. /path/to/composer.phar)

php Location of the php executable to use with composer. (i.e. /usr/bin/php)

user Which system user to run composer as.

New in version 2014.1.4.

prefer_source --prefer-source option of composer.

prefer_dist --prefer-dist option of composer.

no_scripts --no-scripts option of composer.

no_plugins --no-plugins option of composer.

optimize --optimize-autoloader option of composer. Recommended for production.

no_dev --no-dev option for composer. Recommended for production.

quiet --quiet option for composer. Whether or not to return output from composer.

composer_home $COMPOSER_HOME environment variable

13.16.46 salt.states.cron

Management of cron, the Unix command scheduler

Cron declarations require a number of parameters. The following are the parameters used by Salt to define the various timing values for a cron job:

• minute

• hour

• daymonth

• month

• dayweek (0 to 6 are Sunday through Saturday, 7 can also be used for Sunday)

Warning: Any timing arguments not specified take a value of *. This means that setting hour to 5, while not defining the minute param, will result in Salt adding a job that will execute every minute between 5 and 6 A.M.!
Additionally, the default user for these states is root. Therefore, if the cron job is for another user, it is necessary to specify that user with the user parameter.

A long time ago (before 2014.2), when making changes to an existing cron job, the name declaration is the parameter used to uniquely identify the job, so if an existing cron that looks like this:

```
date > /tmp/crontest:
    cron.present:
        - user: root
        - minute: 5
```

Is changed to this:

```
date > /tmp/crontest:
    cron.present:
        - user: root
        - minute: 7
        - hour: 2
```

Then the existing cron will be updated, but if the cron command is changed, then a new cron job will be added to the user's crontab.

The current behavior is still relying on that mechanism, but you can also specify an identifier to identify your crontabs:

```
date > /tmp/crontest:
    cron.present:
        - identifier: SUPERCRON
        - user: root
        - minute: 7
        - hour: 2
```

New in version 2014.1.2.

And, some months later, you modify it:

```
superscript > /tmp/crontest:
    cron.present:
        - identifier: SUPERCRON
        - user: root
        - minute: 3
        - hour: 4
```

New in version 2014.1.2.

The old date > /tmp/crontest will be replaced by superscript > /tmp/crontest.

Additionally, Salt also supports running a cron every x minutes very similarly to the Unix convention of using */5 to have a job run every five minutes. In Salt, this looks like:

```
date > /tmp/crontest:
    cron.present:
        - user: root
        - minute: '*/5'
```

The job will now run every 5 minutes.
Additionally, the temporal parameters (minute, hour, etc.) can be randomized by using `random` instead of using a specific value. For example, by using the `random` keyword in the `minute` parameter of a cron state, the same cron job can be pushed to hundreds or thousands of hosts, and they would each use a randomly-generated minute. This can be helpful when the cron job accesses a network resource, and it is not desirable for all hosts to run the job concurrently.

```
/path/to/cron/script:
cron.present:
  - user: root
  - minute: random
  - hour: 2
```

New in version 0.16.0.

Since Salt assumes a value of `*` for unspecified temporal parameters, adding a parameter to the state and setting it to `random` will change that value from `*` to a randomized numeric value. However, if that field in the cron entry on the minion already contains a numeric value, then using the `random` keyword will not modify it.

Added the opportunity to set a job with a special keyword like `@reboot` or `@hourly`.

```
/path/to/cron/script:
cron.present:
  - user: root
  - special: '@hourly'
```

The script will be executed every reboot if cron daemon support this option.

```
/path/to/cron/otherscript:
cron.absent:
  - user: root
  - special: '@daily'
```

This counter part definition will ensure than a job with a special keyword is not set.

```python
salt.states.cron.absent(name, user='root', identifier=False, special=None, **kwargs)
```

Verifies that the specified cron job is absent for the specified user; only the name is matched when removing a cron job.

- `name` The command that should be absent in the user crontab.
- `user` The name of the user whose crontab needs to be modified, defaults to the root user
- `identifier` Custom-defined identifier for tracking the cron line for future crontab edits. This defaults to the state id
- `special` The special keyword used in the job (eg. @reboot, @hourly...)

```python
salt.states.cron.env_absent(name, user='root')
```

Verifies that the specified environment variable is absent from the crontab for the specified user

- `name` The name of the environment variable to remove from the user crontab
- `user` The name of the user whose crontab needs to be modified, defaults to the root user

```python
salt.states.cron.env_present(name, value=None, user='root')
```

Verifies that the specified environment variable is present in the crontab for the specified user.

- `name` The name of the environment variable to set in the user crontab
- `user` The name of the user whose crontab needs to be modified, defaults to the root user
- `value` The value to set for the given environment variable

```python
salt.states.cron.file(name, source_hash=None, source_hash_name=None, user='root', template=None, context=None, replace=True, defaults=None, env=None, backup='~', **kwargs)
```

Provides file.managed-like functionality (templating, etc.) for a pre-made crontab file, to be assigned to a given user.
name  The source file to be used as the crontab. This source file can be hosted on either the salt master server, or on an HTTP or FTP server. For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs

If the file is hosted on a HTTP or FTP server then the source_hash argument is also required

source_hash  This can be either a file which contains a source hash string for the source, or a source hash string. The source hash string is the hash algorithm followed by the hash of the file: md5=e138491e9d5b97023cea823fe17bac22

source_hash_name  When source_hash refers to a hash file, Salt will try to find the correct hash by matching the filename/URI associated with that hash. By default, Salt will look for the filename being managed. When managing a file at path /tmp/foo.txt, then the following line in a hash file would match:

| acbd18db4cc2f85cedef654fccc4a4d8 | foo.txt |

However, sometimes a hash file will include multiple similar paths:

| 37b51d194a7513e45b56f6524f2d51f2 | ./dir1/foo.txt |
| acbd18db4cc2f85cedef654fccc4a4d8 | ./dir2/foo.txt |
| 73feffa4b7f66be8e44cf984c85f6e88 | ./dir3/foo.txt |

In cases like this, Salt may match the incorrect hash. This argument can be used to tell Salt which filename to match, to ensure that the correct hash is identified. For example:

```
foo_crontab:
  cron.file:
    - name: https://mydomain.tld/dir2/foo.txt
    - source_hash: https://mydomain.tld/hashes
    - source_hash_name: ./dir2/foo.txt
```

Note: This argument must contain the full filename entry from the checksum file, as this argument is meant to disambiguate matches for multiple files that have the same basename. So, in the example above, simply using foo.txt would not match.

New in version 2016.3.5.

user  The user to whom the crontab should be assigned. This defaults to root.

template  If this setting is applied then the named templating engine will be used to render the downloaded file. Currently, jinja and mako are supported.

context Overrides default context variables passed to the template.

replace  If the crontab should be replaced, if False then this command will be ignored if a crontab exists for the specified user. Default is True.

defaults  Default context passed to the template.

backup  Overrides the default backup mode for the user's crontab.

salt.states.cron.present(name, user='root', minute='', hour='', daymonth='', month='', dayweek='', comment=None, commented=False, identifier=False, special=None)

Verifies that the specified cron job is present for the specified user. For more advanced information about what exactly can be set in the cron timing parameters, check your cron system's documentation. Most Unix-like systems' cron documentation can be found via the crontab man page: man 5 crontab.

name  The command that should be executed by the cron job.

user  The name of the user whose crontab needs to be modified, defaults to the root user

minute  The information to be set into the minute section, this can be any string supported by your cron system's the minute field. Default is *

hour  The information to be set in the hour section. Default is *

daymonth  The information to be set in the day of month section. Default is *
month The information to be set in the month section. Default is *
dayweek The information to be set in the day of week section. Default is *
comment User comment to be added on line previous the cron job
commented The cron job is set commented (prefixed with #DISABLED#). Defaults to False.

New in version 2016.3.0.

identifier Custom-defined identifier for tracking the cron line for future crontab edits. This defaults to the state id
special A special keyword to specify periodicity (eg. @reboot, @hourly...)

New in version 2016.3.0.

13.16.47 salt.states.cyg

Installation of Cygwin packages.

A state module to manage cygwin packages. Packages can be installed or removed.

dos2unix:
cyg.installed

class salt.states.cyg.DictDiffer(current_dict, past_dict)
Calculate the difference between two dictionaries.
1. items added
2. items removed
3. keys same in both but changed values
4. keys same in both and unchanged values

added()
Return a set of additions to past_dict.

changed()
Return a set of the keys with changed values.

removed()
Return a set of things removed from past_dict.

same()
True if the two dicts are the same.

unchanged()
Return a set of the keys with unchanged values.

salt.states.cyg.installed(name, cyg_arch='x86_64', mirrors=None)
Make sure that a package is installed.
name The name of the package to install
cyg_arch [x86_64] The cygwin architecture to install the package into. Current options are x86 and x86_64
mirrors [None] List of mirrors to check. None will use a default mirror (kernel.org)

CLI Example:
rsync:
cyg.installed:
  - mirrors:
    - http://mirror/without/public/key: ""

salt.states.cyg.removed(name, cyg_arch='x86_64', mirrors=None)
Make sure that a package is not installed.
name The name of the package to uninstall
cyg_arch [x86_64] The cygwin architecture to remove the package from. Current options are x86 and x86_64

mirrors [None] List of mirrors to check. None will use a default mirror (kernel.org)

CLI Example:

rsync:
cyg.removed:
  - mirrors:
    - http://mirror/without/public/key: ""

salt.states.cyg.updated(name=None, cyg_arch='x86_64', mirrors=None)
Make sure all packages are up to date.
name [None] No affect, salt fails poorly without the arg available
cyg_arch [x86_64] The cygwin architecture to update. Current options are x86 and x86_64
mirrors [None] List of mirrors to check. None will use a default mirror (kernel.org)

CLI Example:

rsync:
cyg.updated:
  - mirrors:
    - http://mirror/without/public/key: ""

13.16.48 salt.states.ddns

Dynamic DNS updates

Ensure a DNS record is present or absent utilizing RFC 2136 type dynamic updates.

    depends
    • dnspython

Note: The dnspython module is required when managing DDNS using a TSIG key. If you are not using a TSIG key, DDNS is allowed by ACLs based on IP address and the dnspython module is not required.

Example:

webserver:
  ddns.present:
    - zone: example.com
    - ttl: 60
    - data: 111.222.333.444
    - nameserver: 123.234.345.456
    - keyfile: /srv/salt/dnspy_tsig_key.txt

salt.states.ddns.absent(name, zone, data=None, rdtype=None, **kwargs)
Ensures that the named DNS record is absent.
name The host portion of the DNS record, e.g., `webserver`. Name and zone are concatenated when the entry is created unless name includes a trailing dot, so make sure that information is not duplicated in these two arguments.
zone The zone to check
data Data for the DNS record. E.g., the IP address for an A record. If omitted, all records matching name (and rdtype, if provided) will be purged.
rdtype  DNS resource type. If omitted, all types will be purged.

**kwargs  Additional arguments the ddns.update function may need (e.g. nameserver, keyfile, keyname).
Note that the nsupdate key file can’t be reused by this function, the keyfile and other arguments must
follow the dnspython spec.

salt.states.ddns.present(name, zone, ttl, data, rdtype='A', **kwargs)
Ensures that the named DNS record is present with the given ttl.

name  The host portion of the DNS record, e.g., `webserver'. Name and zone are concatenated when the entry
is created unless name includes a trailing dot, so make sure that information is not duplicated in these
two arguments.

zone  The zone to check/update

ttl  TTL for the record

data  Data for the DNS record. E.g., the IP address for an A record.

**kwargs  Additional arguments the ddns.update function may need (e.g. nameserver, keyfile, keyname).
Note that the nsupdate key file can’t be reused by this function, the keyfile and other arguments must
follow the dnspython spec.

13.16.49  salt.states.debconfmod

Management of debconf selections

depends
  - debconf-utils package

The debconfmod state module manages the enforcement of debconf selections, this state can set those selections
prior to package installation.

Available Functions

The debconfmod state has two functions, the set and set_file functions

set  Set debconf selections from the state itself

set_file  Set debconf selections from a file

nullmailer-debconf:
  debconf.set:
    - name: nullmailer
    - data:
      'shared/mailname': {'type': 'string', 'value': 'server.domain.tld'}
      'nullmailer/relayhost': {'type': 'string', 'value': 'mail.domain.tld'}

ferm-debconf:
  debconf.set:
    - name: ferm
    - data:
      'ferm/enable': {'type': 'boolean', 'value': True}

Note:  Due to how PyYAML imports nested dicts (see here), the values in the data dict must be indented four spaces
instead of two.

salt.states.debconfmod.set(name, data, **kwargs)
Set debconf selections
name: The package name to set answers for.
data: A set of questions/answers for debconf. Note that everything under this must be indented twice.
question: The question the is being preanswered

type: The type of question that is being asked (string, boolean, select, etc.)
value: The answer to the question

salt.states.debconfmod.set_file(name, source, template=None, context=None, defaults=None, **kwargs)

Set debconf selections from a file or a template

source: The location of the file containing the package selections
template If this setting is applied then the named templating engine will be used to render the package selections file, currently jinja, mako, and wempy are supported
context Overrides default context variables passed to the template.
defaults Default context passed to the template.

13.16.50 salt.states.dellchassis

Manage chassis via Salt Proxies.
New in version 2015.8.2.
Below is an example state that sets basic parameters:
However, it is possible to place the entire set of chassis configuration data in pillar. Here’s an example pillar structure:

```yaml
proxy:
  host: 10.27.20.18
  admin_username: root
  fallback_admin_username: root
  passwords:
    - super-secret
    - old-secret
  proxytype: fx2

chassis:
  name: fx2-1
  username: root
  password: saltstack1
  datacenter: london
  location: rack-1-shelf-3
  management_mode: 2
  idrac_launch: 0
  slot_names:
    - 'server-1': blade1
    - 'server-2': blade2

servers:
  server-1:
    idrac_password: saltstack1
    ipmi_over_lan: True
    ip: 172.17.17.132
    netmask: 255.255.0.0
    gateway: 172.17.17.1
  server-2:
    idrac_password: saltstack1
    ipmi_over_lan: True
    ip: 172.17.17.2
    netmask: 255.255.0.0
    gateway: 172.17.17.1
  server-3:
    idrac_password: saltstack1
    ipmi_over_lan: True
    ip: 172.17.17.20
    netmask: 255.255.0.0
    gateway: 172.17.17.1
  server-4:
    idrac_password: saltstack1
    ipmi_over_lan: True
    ip: 172.17.17.2
    netmask: 255.255.0.0
```
gateway: 172.17.17.1

switches:
  switch-1:
    ip: 192.168.1.2
    netmask: 255.255.255.0
    gateway: 192.168.1.1
    snmp: nonpublic
    password: saltstack1
  switch-2:
    ip: 192.168.1.3
    netmask: 255.255.255.0
    gateway: 192.168.1.1
    snmp: nonpublic
    password: saltstack1

And to go with it, here's an example state that pulls the data from the pillar stated above:

```python
{% set details = pillar.get('proxy:chassis', {}) %}

standup-step1:
  dellchassis.chassis:
    - name: {{ details['name'] }}
    - location: {{ details['location'] }}
    - mode: {{ details['management_mode'] }}
    - idrac_launch: {{ details['idrac_launch'] }}
    - slot_names:
      {% for entry in details['slot_names'] %}
        - {{ entry.keys()[0] }}: {{ entry[entry.keys()[0]] }}
      {% endfor %}

blade_powercycle:
  dellchassis.chassis:
    blade_power_states:
      - server-1: powercycle
      - server-2: powercycle
      - server-3: powercycle
      - server-4: powercycle

# Set idrac_passwords for blades. racadm needs them to be called 'server-x'
{% for k, v in details['servers'].iteritems() %}
  {{ k }}:
    dellchassis.blade_idrac:
      - idrac_password: {{ v['idrac_password'] }}
{% endfor %}

# Set management ip addresses, passwords, and snmp strings for switches
{% for k, v in details['switches'].iteritems() %}
  {{ k }}-switch-setup:
    dellchassis.switch:
      - name: {{ k }}
      - ip: {{ v['ip'] }}
      - netmask: {{ v['netmask'] }}
      - gateway: {{ v['gateway'] }}
      - password: {{ v['password'] }}
      - snmp: {{ v['snmp'] }}
{% endfor %}
```
Note: This state module relies on the dracr.py execution module, which runs racadm commands on the chassis, blades, etc. The racadm command runs very slowly and, depending on your state, the proxy minion return might timeout before the racadm commands have completed. If you are repeatedly seeing minions timeout after state calls, please use the \(-t\) CLI argument to increase the timeout variable.

For example:

```
salt '*' state.sls my-dell-chassis-state-name -t 60
```

Note: The Dell CMC units perform adequately but many iDRACs are excruciatingly slow. Some functions can take minutes to execute.

```
salt.states.dellchassis.blade_idrac(name, idrac_password=None, idrac_ipmi=None, idrac_ip=None, idrac_netmask=None, idrac_gateway=None, idrac_dnsname=None, idrac_dhcp=None)
```

Set parameters for iDRAC in a blade.

**Parameters**
- **idrac_password** -- Password to use to connect to the iDRACs directly
  (idrac_ipmi and idrac_dnsname must be set directly on the iDRAC. They can’t be set through the CMC. If this password is present, use it instead of the CMC password)
- **idrac_ipmi** -- Enable/Disable IPMI over LAN
- **idrac_ip** -- Set IP address for iDRAC
- **idrac_netmask** -- Set netmask for iDRAC
- **idrac_gateway** -- Set gateway for iDRAC
- **idrac_dnsname** -- Set DNS name for iDRAC
- **idrac_dhcp** -- Turn on DHCP for iDRAC (True turns on, False does nothing because setting a static IP will disable DHCP).

**Returns** A standard Salt changes dictionary

NOTE: If any of the IP address settings is configured, all of ip, netmask, and gateway must be present

```
salt.states.dellchassis.chassis(name, chassis_name=None, password=None, datacenter=None, location=None, mode=None, idrac_launch=None, slot_names=None, blade_power_states=None)
```

Manage a Dell Chassis.

- **chassis_name** The name of the chassis.
- **datacenter** The datacenter in which the chassis is located
- **location** The location of the chassis.
- **password** Password for the chassis. Note: If this password is set for the chassis, the current implementation of this state will set this password both on the chassis and the iDRAC passwords on any configured blades. If the password for the blades should be distinct, they should be set separately with the blade_idrac function.
- **mode** The management mode of the chassis. Viable options are:
  - 0: None
  - 1: Monitor
  - 2: Manage and Monitor
- **idrac_launch** The iDRAC launch method of the chassis. Viable options are:
  - 0: Disabled (launch iDRAC using IP address)
  - 1: Enabled (launch iDRAC using DNS name)
- **slot_names** The names of the slots, provided as a list identified by their slot numbers.
- **blade_power_states** The power states of a blade server, provided as a list and identified by their server numbers. Viable options are:
  - on: Ensure the blade server is powered on.
  - off: Ensure the blade server is powered off.
  - powercycle: Power cycle the blade server.
Example:

```yaml
my-dell-chassis:
  dellchassis.chassis:
    - chassis_name: my-dell-chassis
    - location: my-location
    - datacenter: london
    - mode: 2
    - idrac_launch: 1
    - slot_names:
      - 1: my-slot-name
      - 2: my-other-slot-name
    - blade_power_states:
      - server-1: on
      - server-2: off
      - server-3: powercycle
```

generate states.dellchassis.

```python
firmware_update( hosts=None, directory='`
)
```

State to update the firmware on host using the racadm command

`firmwarefile` filename (string) starting with salt://

`host` string representing the hostname supplied to the racadm command

`directory` Directory name where firmwarefile will be downloaded

```yaml
dell-chassis-firmware-update:
  dellchassis.firmware_update:
    hosts:
      cmc:
        salt://firmware_cmc.exe
      server-1:
        salt://firmware.exe
directory: /opt/firmwares
```

`salt.states.dellchassis.switch(name, ip=None, netmask=None, gateway=None, dhcp=None, password=None, snmp=None)`

Manage switches in a Dell Chassis.

- `name` The switch designation (e.g. switch-1, switch-2)
- `ip` The Static IP Address of the switch
- `netmask` The netmask for the static IP
- `gateway` The gateway for the static IP
- `dhcp` True: Enable DHCP False: Do not change DHCP setup (disabling DHCP is automatic when a static IP is set)
- `password` The access (root) password for the switch
- `snmp` The SNMP community string for the switch

Example:

```yaml
my-dell-chassis:
  dellchassis.switch:
    - switch: switch-1
    - ip: 192.168.1.1
    - netmask: 255.255.255.0
    - gateway: 192.168.1.254
    - dhcp: True
    - password: secret
    - snmp: public
```
13.16.51 salt.states.disk

Disk monitoring state

Monitor the state of disk resources.

The `disk.status` function can be used to report that the used space of a filesystem is within the specified limits.

```
used_space:
    disk.status:
        - name: /dev/xdal
        - maximum: 79%
        - minimum: 11%
```

It can be used with an `onfail` requisite, for example, to take additional action in response to or in preparation for other states.

```
storage_threshold:
    disk.status:
        - name: /dev/xdal
        - maximum: 97%

clear_cache:
    cmd.run:
        - name: rm -r /var/cache/app
        - onfail:
            - disk: storage_threshold
```

salt.states.disk.status(name, maximum=None, minimum=None)

Return the current disk usage stats for the named mount point

- **name**: Filesystem with which to check used space
- **minimum**: The required minimum amount of used space in percent
- **maximum**: The required maximum amount of used space in percent

13.16.52 salt.states.dockerio

Manage Docker containers

Deprecated since version 2015.8.0: Future feature development will be done only in `dockerng`. See the documentation for this module for information on the deprecation path.

Docker is a lightweight, portable, self-sufficient software container wrapper. The base supported wrapper type is LXC, cgroups, and the Linux Kernel.

**Note:** This state module requires `docker-py` version >= 0.6.0 which supports Docker Remote API version 1.12.

Available Functions

- **built**

```
corp/mysuperdocker_img:
    docker.built:
        - path: /path/to/dir/container
```
• pulled

```yaml
ubuntu:
  docker.pulled:
    - tag: latest
```

• pushed

```yaml
corp/mysuperdocker_img:
  docker.pushed
```

• installed

```yaml
mysuperdocker-container:
  docker.installed:
    - name: mysuperdocker
    - hostname: superdocker
    - image: corp/mysuperdocker_img
```

• loaded

```yaml
mysuperdocker-file:
  docker.loaded:
    - name: mysuperdocker
    - source: salt://_files/tmp/docker_image.tar
```

• running

```yaml
my_service:
  docker.running:
    - container: mysuperdocker
    - image: corp/mysuperdocker_img
    - ports:
      - "5000/tcp":
        HostIp: ""
        HostPort: "5000"
```

**Note:** The `ports` argument above is a dictionary. The double indentation is required for PyYAML to load the data structure properly as a python dictionary. More information can be found [here](#).

• absent

```yaml
mys_old_uperdocker:
  docker.absent
```

• run

```yaml
/finish-install.sh:
  docker.run:
    - cid: mysuperdocker
    - unless: grep -q something /var/log/foo
    - docker_unless: grep -q done /install_log
```
Use Cases

Ensures the container is running with the latest image available

```yaml
my-service-image:
  docker.pulled:
    - name: registry/my-service:latest
      force: true

my-service-container:
  docker.installed:
    - image: registry/my-service:latest
      watch:
        - docker: my-service-image

my-service:
  docker.running:
    - container: my-service-container
      watch:
        - docker: my-service-container
```

**Note:** The `docker` modules are named `dockerio` because the name `docker` would conflict with the underlying `docker-py` library.

### salt.states.dockerio.absent(name)

Ensure that the container is absent; if not, it will will be killed and destroyed. *(docker inspect)*

- **name:** Either the container name or id

### salt.states.dockerio.built(name, tag='latest', path=None, quiet=False, nocache=False, rm=True, force=False, timeout=None, **kwargs)

Build a docker image from a path or URL to a dockerfile. *(docker build)*

- **name:** Name of the image
- **tag:** tag of the image (defaults to `latest`)
- **path:** URL (e.g. `url/branch/docker_dir/dockerfile`) or filesystem path to the dockerfile

### salt.states.dockerio.installed(name, image, tag='latest', command=None, hostname=None, user=None, detach=True, stdin_open=False, tty=False, mem_limit=None, ports=None, environment=None, dns=None, volumes=None, volumes_from=None, cpu_shares=None, cpuset=None, **kwargs)

Ensure that a container with the given name exists; if not, build a new container from the specified image. *(docker run)*

- **name:** Name for the container
- **image:** Image from which to build this container
- **tag:** tag of the image (defaults to `latest`)
- **environment:** Environment variables for the container, either
  - a mapping of key, values
  - a list of mappings of key, values
- **ports:** List of ports definitions, either:
  - a port to map
  - a mapping of mapping portInHost : PortInContainer
volumes
List of volumes (see notes for the running function)
For other parameters, see absolutely first the salt.modules.dockerio execution module and the docker-py
python bindings for docker documentation for `docker.create_container`.

Note: This command does not verify that the named container is running the specified image.

salt.states.dockerio.loaded(name, tag='latest', source=None, source_hash='`, force=False)
Load an image into the local docker registry (docker load)
name Name of the docker image
tag tag of the image (defaults to `latest')
source The source .tar file to download to the minion, created by docker save this source file can be hosted
on either the salt master server, or on an HTTP or FTP server.
If the file is hosted on a HTTP or FTP server then the source_hash argument is also required

Note: See first the documentation for Salt `file.managed`

source_hash
This can be one of the following:
1. a source hash string
2. the URI of a file that contains source hash strings
force Load even if the image exists

salt.states.dockerio.mod_watch(name, sfun=None, `args, **kw)
salt.states.dockerio.present(name, image=None, tag='latest', is_latest=False)
If a container with the given name is not present, this state will fail. Supports optionally checking for specific
image/tag (docker inspect)
name: container id
image: image the container should be running (defaults to any)
tag: tag of the image (defaults to `latest')
is_latest: also check if the container runs the latest version of the image (latest defined as the latest pulled
onto the local machine)

salt.states.dockerio.pulled(name, tag='latest', force=False, insecure_registry=False, `args,
`**kwargs)
Pull an image from a docker registry. (docker pull)

Note: See first the documentation for docker login, docker pull, docker push, and docker.import_image
(docker import). NOTE that we added in SaltStack a way to authenticate yourself with the Docker Hub Reg-
istry by supplying your credentials (username, email & password) using pillars. For more information, see
salt.modules.dockerio execution module.

name Name of the image
tag Tag of the image
force Pull even if the image is already pulled
insecure Registry Set to True to allow connections to non-HTTPS registries. Default False.

salt.states.dockerio.pushed(name, tag='latest', insecure_registry=False)
Push an image from a docker registry. (docker push)

Note: See first the documentation for docker login, docker pull, docker push, and docker.import_image
(docker import). NOTE that we added in SaltStack a way to authenticate yourself with the Docker Hub Registry by supplying your credentials (username, email & password) using pillars. For more information, see salt.modules.dockerio execution module.

name Name of the image
tag Tag of the image [Optional]
insecure_registy Set to True to allow connections to non-HTTPS registries. Default False.
salt.states.dockerio.run(name, cid=None, hostname=None, onlyif=None, unless=None, docked_onlyif=None, docked_unless=None, *args, **kwargs)
Run a command in a specific container

You can match by either name or hostname
name command to run in the container
cid Container id or name
state_id state_id
onlyif Only execute cmd if statement on the host returns 0
unless Do not execute cmd if statement on the host returns 0
docked_onlyif Only execute cmd if statement in the container returns 0
docked_unless Do not execute cmd if statement in the container returns 0

salt.states.dockerio.running(name, image, tag='latest', container=None, command=None, hostname=None, user=None, detach=True, stdin_open=False, tty=False, mem_limit=None, ports=None, environment=None, dns=None, volumes=None, volumes_from=None, start=True, cap_add=None, cap_drop=None, privileged=None, lxc_conf=None, network_mode=None, check_is_running=True, publish_all_ports=False, links=None, restart_policy=None, cpu_shares=None, cpuset=None, kill_signal=None, *args, **kwargs)
Ensure that a container is running. If the container does not exist, it will be created from the specified image.

(docker run)
name / container Name for the container
image Image from which to build this container
tag tag of the image (defaults to ‘latest’)
environment

Environment variables for the container, either

- a mapping of key, values
- a list of mappings of key, values

ports

List of ports definitions, either:

- a port to map
- a mapping of mapping portInHost : PortInContainer

"ports:
- "5000/tcp":
  HostIp: 
  HostPort: "5000"

publish_all_ports Publish all ports from the port list (default is false, only meaningful if port does not contain portinhost:portincontainer mapping)
volumes
List of volumes to mount or create in the container (like -v of docker run command), mapping host directory to container directory.

To specify a volume in the container in terse list format:
- volumes:
  - "/var/log/service" # container-only volume
  - "/srv/timezone:/etc/timezone" # bound volume
  - "/usr/local/etc/passwd:/etc/passwd:ro" # read-only bound volume

You can also use the short dictionary form (note that the notion of source:target from docker is preserved):

- volumes:
  - /var/log/service: /var/log/service # mandatory read-write implied

Or, alternatively, to specify read-only mounting, use the extended form:

- volumes:
  - /home/user1:
    bind: /mnt/vol2
    ro: True
  - /var/www:
    bind: /mnt/vol1
    ro: False

Or (for backwards compatibility) another dict style:

- volumes:
  /home/user1:
    bind: /mnt/vol2
    ro: True
  /var/www:
    bind: /mnt/vol1
    ro: False

volumes_from List of containers to share volumes with
dns List of DNS servers.

- dns:
  - 127.0.0.1

network_mode
  • 'bridge': creates a new network stack for the container on the docker bridge
  • 'none': no networking for this container
  • 'container:[name|id]': reuses another container network stack
  • 'host': use the host network stack inside the container

- network_mode: host

restart_policy Restart policy to apply when a container exits (no, on-failure[:max-retry], always)

- restart_policy:
  MaximumRetryCount: 5
  Name: on-failure

cap_add List of capabilities to add in a container.
cap_drop List of capabilities to drop in a container.
check_is_running Enable checking if a container should run or not. Useful for data-only containers that must be linked to another one. e.g. nginx <- static-files
cpu_shares CPU shares (relative weight)

- cpu_shares: 2
cpuset CPUs in which to allow execution ('0-3' or '0,1')

- cpuset: '0-3'

kill_signal If defined, its value will be sent as a kill signal to the running container. i.e. It will use client.kill(signal=kill_signal) instead of client.restart(), when the state is triggered by a watcher requisite. possible use case: Soft reload of nginx

nginx:
docker.running:
  - image: some-fictional-registry.com/nginx
  - tag: latest
  - kill_signal: SIGHUP
  - watch:
    - file: /etc/nginx/nginx.conf

This state will ask nginx to reload (instead of restart) each time the /etc/nginx/nginx.conf is modified.

New in version 2015.8.0.
For other parameters, see salt.modules.dockerio execution module and the docker-py python bindings for docker documentation <https://github.com/dotcloud/docker-py#api> for docker.create_container.

Note: This command does not verify that the named container is running the specified image.

salt.states.dockerio.script(*args, **kw)
Placeholder function for a cmd.script alike.

Note: Not yet implemented. Its implementation might be very similar from salt.states.dockerio.run

13.16.53 salt.states.dockerng

Management of Docker containers

New in version 2015.8.0.
This is the state module to accompany the dockerng execution module.

Why Make a Second Docker State Module?

We have received a lot of feedback on our Docker support. In the process of implementing recommended improvements, it became obvious that major changes needed to be made to the functions and return data. In the end, a complete rewrite was done.

The changes being too significant, it was decided that making a separate execution module and state module (called dockerng) would be the best option. This will give users a couple release cycles to modify their scripts, SLS files, etc. to use the new functionality, rather than forcing users to change everything immediately.

In the Nitrogen release of Salt (due in 2017), this execution module will take the place of the default Docker execution module, and backwards-compatible naming will be maintained for a couple releases after that to allow users time to replace references to dockerng with docker.
Note: To pull from a Docker registry, authentication must be configured. See here for more information on how to configure access to docker registries in Pillar data.

**salt.states.dockerng.absent(name, force=False)**

Ensure that a container is absent

- **name** Name of the container
- **force** [False] Set to True to remove the container even if it is running

Usage Examples:

```yaml
mycontainer:
  dockerng.absent

multiple_containers:
  dockerng.absent:
    - names:
      - foo
      - bar
      - baz
```

**salt.states.dockerng.image_absent(name=None, images=None, force=False)**

Ensure that an image is absent from the Minion. Image names can be specified either using repo:tag notation, or just the repo name (in which case a tag of latest is assumed).

- **images** Run this state on more than one image at a time. The following two examples accomplish the same thing:

```yaml
remove_images:
  dockerng.image_absent:
    - names:
      - busybox
      - centos:6
      - nginx

remove_images:
  dockerng.image_absent:
    - images:
      - busybox
      - centos:6
      - nginx
```

However, the second example will be a bit quicker since Salt will do all the deletions in a single run, rather than executing the state separately on each image (as it would in the first example).

- **force** [False] Salt will fail to remove any images currently in use by a container. Set this option to true to remove the image even if it is already present.

Note: This option can also be overridden by Pillar data. If the Minion has a pillar variable named dockerng.running.force which is set to True, it will turn on this option. This pillar variable can even be set at runtime. For example:

```bash
salt myminion state.sls docker_stuff pillar="{dockerng.force: True}"
```

If this pillar variable is present and set to False, then it will turn off this option.

For more granular control, setting a pillar variable named dockerng.force.image_name will affect only the named image.
salt.states.dockerng.image_present(name, build=None, load=None, force=False, insecure_registry=False, client_timeout=60, **kwargs)

Ensure that an image is present. The image can either be pulled from a Docker registry, built from a Dockerfile, or loaded from a saved image. Image names can be specified either using repo:tag notation, or just the repo name (in which case a tag of latest is assumed). Repo identifier is mandatory, we don’t assume the default repository is docker hub.

If neither of the build or load arguments are used, then Salt will pull from the configured registries. If the specified image already exists, it will not be pulled unless force is set to True. Here is an example of a state that will pull an image from the Docker Hub:

```
myuser/myimage:mytag:
    dockerng.image_present
```

**build** Path to directory on the Minion containing a Dockerfile

```
myuser/myimage:mytag:
    dockerng.image_present:
        - build: /home/myuser/docker/myimage
```

The image will be built using dockerng.build and the specified image name and tag will be applied to it.

**load** Loads a tar archive created with dockerng.load (or the docker load Docker CLI command), and assigns it the specified repo and tag.

```
myuser/myimage:mytag:
    dockerng.image_present:
        - load: salt://path/to/image.tar
```

**force** [False] Set this parameter to True to force Salt to pull/build/load the image even if it is already present.

**client_timeout** Timeout in seconds for the Docker client. This is not a timeout for the state, but for receiving a response from the API.

salt.states.dockerng.mod_watch(name, sfun=None, **kwargs)

salt.states.dockerng.network_absent(name, driver=None)

Ensure that a network is absent.

**name** Name of the network

Usage Examples:

```
network_foo:
    dockerng.network_absent
```

salt.states.dockerng.network_present(name, driver=None, containers=None)

Ensure that a network is present.

**name** Name of the network

**driver** Type of driver for that network.

**containers** List of container names that should be part of this network

Usage Examples:

```
network_foo:
    dockerng.network_present
```

```
network_bar:
    dockerng.network_present
        - name: bar
        - containers:
```
salt.states.dockerng.running(name, image=None, force=False, stop_timeout=10, validate_ip_addrs=True, watch_action='force', client_timeout=60, start=True, **kwargs)

Ensure that a container with a specific configuration is present and running

name Name of the container
image Image to use for the container. Image names can be specified either using repo:tag notation, or just the repo name (in which case a tag of latest is assumed).

Note: This state will pull the image if it is not present. However, if the image needs to be built from a Dockerfile or loaded from a saved image, or if you would like to use requisites to trigger a replacement of the container when the image is updated, then the dockerng.image_present should be used to manage the image.

force [False] Set this parameter to True to force Salt to re-create the container irrespective of whether or not it is configured as desired.

stop_timeout [10] If the container needs to be replaced, the container will be stopped using dockerng.stop. The value of this parameter will be passed to dockerng.stop as the timeout value, telling Docker how long to wait for a graceful shutdown before killing the container.

validate_ip_addrs [True] For parameters which accept IP addresses as input, IP address validation will be performed. To disable, set this to False.

watch_action [force] Control what type of action is taken when this state watches another state that has changes. The default action is force, which runs the state with force set to True, triggering a rebuild of the container.

If any other value is passed, it will be assumed to be a kill signal. If the container matches the specified configuration, and is running, then the action will be to send that signal to the container. Kill signals can be either strings or numbers, and are defined in the Standard Signals section of the signal(7) manpage. Run man 7 signal on a Linux host to browse this manpage. For example:

```yaml
mycontainer:
  dockerng.running:
    - image: busybox
    - watch_action: SIGHUP
    - watch:
      - file: some_file
```

Note: If the container differs from the specified configuration, or is not running, then instead of sending a signal to the container, the container will be re-created/started and no signal will be sent.

client_timeout Timeout in seconds for the Docker client. This is not a timeout for this function, but for receiving a response from the API.

Note: This is only used if Salt needs to pull the requested image.

CONTAINER CONFIGURATION PARAMETERS

command or cmd Command to run in the container

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
```
- command: bash

OR

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - cmd: bash
```

Changed in version 2015.8.1: cmd is now also accepted

**hostname** Hostname of the container. If not provided, and if a name has been provided, the hostname will default to the name that was passed.

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - hostname: web1
```

**Warning:** hostname cannot be set if network_mode is set to host. The below example will result in an error:

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - hostname: web1
    - network_mode: host
```

domainname Domain name of the container

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - hostname: domain.tld
```

**interactive** [False] Leave stdin open

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - interactive: True
```

tty [False] Attach TTYs

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - tty: True
```

detach [True] If True, run the container's command in the background (daemon mode)

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - detach: False
```

**user** User under which to run docker
### memory
[0] Memory limit. Can be specified in bytes or using single-letter units (i.e. 512M, 2G, etc.). A value of 0 (the default) means no memory limit.

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - memory: 512M
```

### memory_swap
[-1] Total memory limit (memory plus swap). Set to -1 to disable swap. A value of 0 means no swap limit.

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - memory_swap: 1G
```

### mac_address
MAC address to use for the container. If not specified, a random MAC address will be used.

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - mac_address: 01:23:45:67:89:0a
```

### network_disabled
[False] If True, networking will be disabled within the container

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - network_disabled: True
```

### working_dir
Working directory inside the container

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - working_dir: /var/log/nginx
```

### entrypoint
Entrypoint for the container

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - entrypoint: "mycmd --arg1 --arg2"
```

The entrypoint can also be specified as a list of arguments:

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - entrypoint:
      - mycmd
      - --arg1
      - --arg2
```

### environment
Either a list of variable/value mappings, or a list of strings in the format VARNAME=value.
The below two examples are equivalent:
foo:
  dockerng.running:
  - image: bar/baz:latest
  - environment:
    - VAR1: value
    - VAR2: value

foo:
  dockerng.running:
  - image: bar/baz:latest
  - environment:
    - VAR1=value
    - VAR2=value

**Note:** Values must be strings. Otherwise it will be considered as an error.

**ports** A list of ports to expose on the container. Can either be a comma-separated list or a YAML list. If the protocol is omitted, the port will be assumed to be a TCP port. The below two examples are equivalent:

foo:
  dockerng.running:
  - image: bar/baz:latest
  - ports: 1111,2222/udp

foo:
  dockerng.running:
  - image: bar/baz:latest
  - ports:
    - 1111
    - 2222/udp

**volumes** [None] List of directories to expose as volumes. Can either be a comma-separated list or a YAML list. The below two examples are equivalent:

foo:
  dockerng.running:
  - image: bar/baz:latest
  - volumes: /mnt/vol1,/mnt/vol2

foo:
  dockerng.running:
  - image: bar/baz:latest
  - volumes:
    - /mnt/vol1
    - /mnt/vol2

**cpu_shares** CPU shares (relative weight)

foo:
  dockerng.running:
  - image: bar/baz:latest
  - cpu_shares: 0.5

**cpuset** CPUs on which which to allow execution, specified as a string containing a range (e.g. 0–3) or a comma-separated list of CPUs (e.g. 0,1).
binds  Files/directories to bind mount. Each bind mount should be passed in the format 
<host_path>:<container_path>:<read_only>, where <read_only> is one of rw (for read-write access) or ro (for read-only access).

foo:
dockerng.running:
  - image: bar/baz:latest
  - binds: /srv/www:/var/www:ro,/etc/foo.conf:/usr/local/etc/foo.conf:rw

Binds can be passed as a YAML list instead of a comma-separated list:

foo:
dockerng.running:
  - image: bar/baz:latest
  - binds:
    - /srv/www:/var/www:ro
    - /home/myuser/conf/foo.conf:/etc/foo.conf:rw

Optionally, the read-only information can be left off the end and the bind mount will be assumed to be read-write. The example below is equivalent to the one above:

foo:
dockerng.running:
  - image: bar/baz:latest
  - binds:
    - /srv/www:/var/www:ro
    - /home/myuser/conf/foo.conf

port_bindings  Bind exposed ports. Port bindings should be passed in the same way as the --publish argument to the docker run CLI command:

  • ip:hostPort:containerPort - Bind a specific IP and port on the host to a specific port within the container.
  • ip:containerPort - Bind a specific IP and an ephemeral port to a specific port within the container.
  • hostPort:containerPort - Bind a specific port on all of the host's interfaces to a specific port within the container.
  • containerPort - Bind an ephemeral port on all of the host's interfaces to a specific port within the container.

Multiple bindings can be separated by commas, or passed as a Python list. The below two examples are equivalent:

foo:
dockerng.running:
  - image: bar/baz:latest
  - port_bindings: "5000:5000,2123:2123/udp,8080"

foo:
dockerng.running:
  - image: bar/baz:latest
  - port_bindings:
    - 5000:5000
    - 2123:2123/udp
Note: When configuring bindings for UDP ports, the protocol must be passed in the `containerPort` value, as seen in the examples above.

**lxc_conf** Additional LXC configuration parameters to set before starting the container.

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - lxc_conf:
        - lxc.utsname: docker
```

**Note:** These LXC configuration parameters will only have the desired effect if the container is using the LXC execution driver, which has not been the default for some time.

**publish_all_ports** [False] Allocates a random host port for each port exposed using the `ports` parameter.

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - ports: 8080
    - publish_all_ports: True
```

**links** Link this container to another. Links should be specified in the format `<container_name_or_id>:<link_alias>`. Multiple links can be passed, either as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - links: web1:link1,web2:link2
```

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - links:
        - web1:link1
        - web2:link2
```

**dns** List of DNS nameservers. Can be passed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - dns: 8.8.8.8,8.8.4.4
```

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - dns:
        - 8.8.8.8
        - 8.8.4.4
```
Note: To skip IP address validation, use `validate_ip_addrs=False`

**dns_search** List of DNS search domains. Can be passed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - dns_search: foo1.domain.tld,foo2.domain.tld

foo:
  dockerng.running:
    - image: bar/baz:latest
    - dns_search:
      - foo1.domain.tld
      - foo2.domain.tld
```

**volumes_from** Container names or IDs from which the container will get volumes. Can be passed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - volumes_from: foo

foo:
  dockerng.running:
    - image: bar/baz:latest
    - volumes_from:
      - foo
```

**network_mode** [bridge] One of the following:

- bridge - Creates a new network stack for the container on the docker bridge
- null - No networking (equivalent of the Docker CLI argument `--net=none`)
- container:<name_or_id> - Reuses another container's network stack
- host - Use the host's network stack inside the container
- Any name that identifies an existing network that might be created with `dockerng.network_present`.

**Warning:** Using host mode gives the container full access to the hosts system's services (such as D-bus), and is therefore considered insecure.

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - network_mode: null
```

**restart_policy** Set a restart policy for the container. Must be passed as a string in the format `policy[:retry_count]` where `policy` is one of `always` or `on-failure`, and `retry_count` is an optional limit to the number of retries. The retry count is ignored when using the `always` restart policy.

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
```
restart_policy: on-failure:5

bar:
dockerng.running:
  - image: bar/baz:latest
  - restart_policy: always

cap_add  List of capabilities to add within the container. Can be passed as a comma-separated list or a Python list. The below two examples are equivalent:

foo:
dockerng.running:
  - image: bar/baz:latest
  - cap_add: SYS_ADMIN,MKNOD

foo:
dockerng.running:
  - image: bar/baz:latest
  - cap_add:
    - SYS_ADMIN
    - MKNOD

Note: This option requires Docker 1.2.0 or newer.

cap_drop  List of capabilities to drop within the container. Can be passed as a comma-separated list or a Python list. The below two examples are equivalent:

foo:
dockerng.running:
  - image: bar/baz:latest
  - cap_drop: SYS_ADMIN,MKNOD

foo:
dockerng.running:
  - image: bar/baz:latest
  - cap_drop:
    - SYS_ADMIN
    - MKNOD

Note: This option requires Docker 1.2.0 or newer.

privileged  Give extended privileges to container.
extra_hosts  Additional hosts to add to the container's /etc/hosts file. Can be passed as a comma-separated list or a Python list. The below two examples are equivalent:

foo:
dockerng.running:
  - image: bar/baz:latest
  - extra_hosts: web1:10.9.8.7,web2:10.9.8.8

foo:
dockerng.running:
  - image: bar/baz:latest
  - extra_hosts:
- web1:10.9.8.7
- web2:10.9.8.8

**Note:** To skip IP address validation, use `validate_ip_addrs=False`

**Note:** This option requires Docker 1.3.0 or newer.

**pid_mode** Set to `host` to use the host container’s PID namespace within the container

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - pid_mode: host
```

**Note:** This option requires Docker 1.5.0 or newer.

**ulimits** List of ulimits. These limits should be passed in the format `<ulimit_name>:<soft_limit>:<hard_limit>`, with the hard limit being optional.

New in version 2016.3.6,2016.11.4,Nitrogen.

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - ulimits: nofile=1024:1024,nproc=60
```

Ulimits can be passed as a YAML list instead of a comma-separated list:

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - ulimits:
        - nofile=1024:1024
        - nproc=60
```

**labels** Add Metadata to the container. Can be a list of strings/dictionaries or a dictionary of strings (keys and values).

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - labels:
        - LABEL1
        - LABEL2
```

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - labels:
        KEY1: VALUE1
        KEY2: VALUE2
```
foo:

dockerng.running:
  - image: bar/baz:latest
  - labels:
    - KEY1: VALUE1
    - KEY2: VALUE2

start [True] Set to False to suppress starting of the container if it exists, matches the desired configuration, but is not running. This is useful for data-only containers, or for non-daemonized container processes, such as the django migrate and collectstatic commands. In instances such as this, the container only needs to be started the first time.

salt.states.dockerng.stopped(name=None, containers=None, stop_timeout=10, unpause=False, error_on_absent=True)

Ensure that a container (or containers) is stopped

name Name or ID of the container
containers Run this state on more than one container at a time. The following two examples accomplish the same thing:

stopped_containers:
  dockerng.stopped:
    - names:
      - foo
      - bar
      - baz

stopped_containers:
  dockerng.stopped:
    - containers:
      - foo
      - bar
      - baz

However, the second example will be a bit quicker since Salt will stop all specified containers in a single run, rather than executing the state separately on each image (as it would in the first example).

stop_timeout [10] Timeout for graceful shutdown of the container. If this timeout is exceeded, the container will be killed.

unpause [False] Set to True to unpause any paused containers before stopping. If unset, then an error will be raised for any container that was paused.

error_on_absent [True] By default, this state will return an error if any of the specified containers are absent. Set this to False to suppress that error.

salt.states.dockerng.volume_absent(name, driver=None)

Ensure that a volume is absent.

New in version 2015.8.4.

name Name of the volume

Usage Examples:

volume_foo:
  dockerng.volume_absent

salt.states.dockerng.volume_present(name, driver=None, driver_opts=None, force=False)

Ensure that a volume is present.

New in version 2015.8.4.

Changed in version 2015.8.6: This function no longer deletes and re-creates a volume if the existing volume's
driver does not match the driver parameter (unless the force parameter is set to True).

name Name of the volume
driver Type of driver for that volume. If None and the volume does not yet exist, the volume will be created using Docker's default driver. If None and the volume does exist, this function does nothing, even if the existing volume's driver is not the Docker default driver. (To ensure that an existing volume's driver matches the Docker default, you must explicitly name Docker's default driver here.)
driver_opts Options for the volume driver
force [False] If the volume already exists but the existing volume's driver does not match the driver specified by the driver parameter, this parameter controls whether the function errors out (if False) or deletes and re-creates the volume (if True).

Usage Examples:

```yaml
volume_foo:
  dockerng.volume_present

volume_bar:
  dockerng.volume_present
  - name: bar
  - driver: local
  - driver_opts:
      foo: bar

volume_bar:
  dockerng.volume_present
  - name: bar
  - driver: local
  - driver_opts:
    - foo: bar
    - option: value
```

### 13.16.54 salt.states.drac

Management of Dell DRAC

The DRAC module is used to create and manage DRAC cards on Dell servers

Ensure the user damian is present

```yaml
damian:
  drac.present:
    - name: damian
    - password: secret
    - permission: login,test_alerts,clear_logs
```

Ensure the user damian does not exist

```yaml
damian:
  drac.absent:
    - name: damian
```

Ensure DRAC network is in a consistent state

```yaml
my_network:
  drac.network:
```
- ip: 10.225.108.29
- netmask: 255.255.255.224
- gateway: 10.225.108.1

```python
salt.states.drac.absent(name)
    Ensure a user does not exist on the Dell DRAC
    name: The users username
```

```python
salt.states.drac.network(ip, netmask, gateway)
    Ensure the DRAC network settings are consistent
```

```python
salt.states.drac.present(name, password, permission)
    Ensure the user exists on the Dell DRAC
    name: The users username
    password: The password used to authenticate
    permission: The permissions that should be assigned to a user
```

13.16.55 salt.states.elasticsearch_index

State module to manage Elasticsearch indices

New in version 2015.8.0.

```python
salt.states.elasticsearch_index.absent(name)
    Ensure that the named index is absent
```

```python
salt.states.elasticsearch_index.present(name, definition)
    Ensure that the named index is present
```

13.16.56 salt.states.elasticsearch_index_template

State module to manage Elasticsearch index templates

New in version 2015.8.0.

```python
salt.states.elasticsearch_index_template.absent(name)
    Ensure that the named index template is absent
```

```python
salt.states.elasticsearch_index_template.present(name, definition=None)
    Ensure that the named index template is present
```

13.16.57 salt.states.environ

Support for getting and setting the environment variables of the current salt process.

```python
salt.states.environ.setenv(name, value, false_unsets=False, clear_all=False, update_minion=False, permanent=False)
    Set the salt process environment variables.
    name: The environment key to set. Must be a string.
    value: Either a string or dict. When string, it will be the value set for the environment key of `name' above.
    When a dict, each key/value pair represents an environment variable to set.
    false_unsets: If a key's value is False and false_unsets is True, then the key will be removed from the salt processes environment dict entirely. If a key's value is False and false_unsets is not True, then the key's value will be set to an empty string. Default: False
```
**clear_all**

USE WITH CAUTION! This option can unset environment variables needed for salt to function properly. If clear_all is True, then any environment variables not defined in the environ dict will be deleted. Default: False

**update_minion**

If True, apply these environ changes to the main salt-minion process. If False, the environ changes will only affect the current salt subprocess. Default: False

**permanent**

On Windows minions this will set the environment variable in the registry so that it is always added as an environment variable when applications open. If you want to set the variable to HKLM instead of HKCU just pass in ``HKLM`` for this parameter. On all other minion types this will be ignored. Note: This will only take affect on applications opened after this has been set.

Example:

```python
a_string_env:
    environ.setenv:
        - name: foo
        - value: bar
        - update_minion: True

a_dict_env:
    environ.setenv:
        - name: does_not_matter
        - value:
            foo: bar
            baz: quux
```

### 13.16.58 salt.states.eselect

**Management of Gentoo configuration using eselect**

A state module to manage Gentoo configuration via eselect

```python
profile:
    eselect.set:
        target: hardened/linux/amd64
```

**salt.states.eselect.set** *(name, target, module_parameter=None, action_parameter=None)*

Verify that the given module is set to the given target

- **name** The name of the module
- **target** The target to be set for this module
- **module_parameter** additional params passed to the defined module
- **action_parameter** additional params passed to the defined action

### 13.16.59 salt.states.etcd_mod

**Manage etcd Keys**

New in version 2015.8.0.

- **depends**
  - python-etcd

This state module supports setting and removing keys from etcd.
Configuration

To work with an etcd server you must configure an etcd profile. The etcd config can be set in either the Salt Minion configuration file or in pillar:

```
my_etd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001
```

It is technically possible to configure etcd without using a profile, but this is not considered to be a best practice, especially when multiple etcd servers or clusters are available.

```
etcd.host: 127.0.0.1
etcd.port: 4001
```

Note: The etcd configuration can also be set in the Salt Master config file, but in order to use any etcd configurations defined in the Salt Master config, the `pillar_opts` must be set to `True`.

Be aware that setting `pillar_opts` to `True` has security implications as this makes all master configuration settings available in all minion's pillars.

Available Functions

- **set**
  This will set a value to a key in etcd. Changes will be returned if the key has been created or the value of the key has been updated. This means you can watch these states for changes.

  ```
  /foo/bar/baz:
  etcd.set:
    - value: foo
    - profile: my_etcd_config
  ```

- **wait_set**
  Performs the same functionality as `set` but only if a watch requisite is `True`.

  ```
  /some/file.txt:
  file.managed:
    - source: salt://file.txt
  
  /foo/bar/baz:
  etcd.wait_set:
    - value: foo
    - profile: my_etcd_config
    - watch:
      - file: /some/file.txt
  ```

- **rm**
  This will delete a key from etcd. If the key exists then changes will be returned and thus you can watch for changes on the state, if the key does not exist then no changes will occur.

```yaml
/foo/bar/baz:
  etcd.rm:
    - profile: my_etcd_config

• wait_rm
  Performs the same functionality as rm but only if a watch requisite is True.

/some/file.txt:
  file.managed:
    - source: salt://file.txt

/foo/bar/baz:
  etcd.wait_rm:
    - profile: my_etcd_config
    - watch:
      - file: /some/file.txt

salt.states.etcd_mod.mod_watch(name, **kwargs)
  Execute a etcd function based on a watch call requisite.

salt.states.etcd_mod.rm(name, recurse=False, profile=None)
  Deletes a key from etcd. This function is also aliased as rm.
  name The etcd key name to remove, for example /foo/bar/baz.
  recurse Optional, defaults to False. If True performs a recursive delete.
  profile Optional, defaults to None. Sets the etcd profile to use which has been defined in the Salt Master config.

salt.states.etcd_mod.set(name, value, profile=None)
  Set a key in etcd and can be called as set.
  name The etcd key name, for example: /foo/bar/baz.
  value The value the key should contain.
  profile Optional, defaults to None. Sets the etcd profile to use which has been defined in the Salt Master config.

salt.states.etcd_mod.wait_rm(name, recurse=False, profile=None)
  Deletes a key from etcd only if the watch statement calls it. This function is also aliased as wait_rm.
  name The etcd key name to remove if the watch statement calls it, for example /foo/bar/baz.
  recurse Optional, defaults to False. If True performs a recursive delete, see: https://python-etcd.readthedocs.org/en/latest/#delete-a-key.
  profile Optional, defaults to None. Sets the etcd profile to use which has been defined in the Salt Master config.

salt.states.etcd_mod.wait_set(name, value, profile=None)
  Set a key in etcd only if the watch statement calls it. This function is also aliased as wait_set.
  name The etcd key name, for example: /foo/bar/baz.
  value The value the key should contain.
  profile The etcd profile to use that has been configured on the Salt Master, this is optional and defaults to None.
```

**13.16.60 salt.states.esxi**

Manage VMware ESXi Hosts.

New in version 2015.8.4.
Dependencies

- pyVmomi Python Module
- ESXCLI

**pyVmomi**

PyVmomi can be installed via pip:

```
pip install pyVmomi
```

**Note:** Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, Python 2.6, Python 2.7.9, or newer must be present. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the following:

```
pip install pyVmomi==5.5.0.2014.1.1
```

The 5.5.0.2014.1.1 is a known stable version that this original ESXi State Module was developed against.

**ESXCLI**

Currently, about a third of the functions used in the vSphere Execution Module require the ESXCLI package be installed on the machine running the Proxy Minion process.

The ESXCLI package is also referred to as the VMware vSphere CLI, or vCLI. VMware provides vCLI package installation instructions for vSphere 5.5 and vSphere 6.0.

Once all of the required dependencies are in place and the vCLI package is installed, you can check to see if you can connect to your ESXi host or vCenter server by running the following command:

```
esxcli -s <host-location> -u <username> -p <password> system syslog config get
```

If the connection was successful, ESXCLI was successfully installed on your system. You should see output related to the ESXi host's syslog configuration.

**Note:** Be aware that some functionality in this state module may depend on the type of license attached to the ESXi host.

For example, certain services are only available to manipulate service state or policies with a VMware vSphere Enterprise or Enterprise Plus license, while others are available with a Standard license. The ntpd service is restricted to an Enterprise Plus license, while ssh is available via the Standard license.

Please see the vSphere Comparison page for more information.
About

This state module was written to be used in conjunction with Salt’s ESXi Proxy Minion. For a tutorial on how to use Salt’s ESXi Proxy Minion, please refer to the ESXi Proxy Minion Tutorial for configuration examples, dependency installation instructions, how to run remote execution functions against ESXi hosts via a Salt Proxy Minion, and a larger state example.

salt.states.esxi.coredump_configured(name, enabled, dump_ip, host_vnic='vmk0', dump_port=6500)

Ensures a host’s core dump configuration.

- **name** Name of the state.
- **enabled** Sets whether or not ESXi core dump collection should be enabled. This is a boolean value set to True or False to enable or disable core dumps.

  Note that ESXi requires that the core dump must be enabled before any other parameters may be set. This also affects the changes results in the state return dictionary. If enabled is False, we can’t obtain any previous settings to compare other state variables, resulting in many old references returning None.

  Once enabled is True the changes dictionary comparisons will be more accurate. This is due to the way the system coredemp network configuration command returns data.

- **dump_ip** The IP address of host that will accept the dump.
- **host_vnic** Host VNic port through which to communicate. Defaults to vmk0.
- **dump_port** TCP port to use for the dump. Defaults to 6500.

Example:

```python
configure-host-coredump:
  esxi.coredump_configured:
    - enabled: True
    - dump_ip: 'my-coredump-ip.example.com'
```

salt.states.esxi.ntp_configured(name, service_running, ntp_servers=None, service_policy=None, service_restart=False, update_datetime=False)

Ensures a host’s NTP server configuration such as setting NTP servers, ensuring the NTP daemon is running or stopped, or restarting the NTP daemon for the ESXi host.

- **name** Name of the state.
- **service_running** Ensures the running state of the ntp daemon for the host. Boolean value where True indicates that ntpd should be running and False indicates that it should be stopped.
- **ntp_servers** A list of servers that should be added to the ESXi host’s NTP configuration.
- **service_policy** The policy to set for the NTP service.

**Note:** When setting the service policy to off or on, you must quote the setting. If you don’t, the yaml parser will set the string to a boolean, which will cause trouble checking for stateful changes and will error when trying to set the policy on the ESXi host.

- **service_restart** If set to True, the ntp daemon will be restarted, regardless of its previous running state. Default is False.
- **update_datetime** If set to True, the date/time on the given host will be updated to UTC. Default setting is False. This option should be used with caution since network delays and execution delays can result in time skews.

Example:

```python
configure-host-ntp:
  esxi.ntp_configured:
    - service_running: True
    - ntp_servers:
```
salt.states.esxi.password_present(name, password)

Ensures the given password is set on the ESXi host. Passwords cannot be obtained from host, so if a password is set in this state, the vsphere.update_host_password function will always run (except when using test=True functionality) and the state's changes dictionary will always be populated.

The username for which the password will change is the same username that is used to authenticate against the ESXi host via the Proxy Minion. For example, if the pillar definition for the proxy username is defined as root, then the username that the password will be updated for via this state is root.

**name** Name of the state.
**password** The new password to change on the host.

Example:

```yaml
configure-host-password:
  esxi.password_present:
    - password: 'new-bad-password'
```

salt.states.esxi.ssh_configured(name, service_running, ssh_key=None, ssh_key_file=None, service_policy=None, service_restart=False, certificate_verify=False)

Manage the SSH configuration for a host including whether or not SSH is running or the presence of a given SSH key. Note: Only one ssh key can be uploaded for root. Uploading a second key will replace any existing key.

**name** Name of the state.

**service_running** Ensures whether or not the SSH service should be running on a host. Represented as a boolean value where True indicates that SSH should be running and False indicates that SSH should stopped.

In order to update SSH keys, the SSH service must be running.

**ssh_key** Public SSH key to added to the authorized_keys file on the ESXi host. You can use ssh_key or ssh_key_file, but not both.

**ssh_key_file** File containing the public SSH key to be added to the authorized_keys file on the ESXi host. You can use ssh_key_file or ssh_key, but not both.

**service_policy** The policy to set for the NTP service.

**Note:** When setting the service policy to off or on, you must quote the setting. If you don’t, the yaml parser will set the string to a boolean, which will cause trouble checking for stateful changes and will error when trying to set the policy on the ESXi host.

**service_restart** If set to True, the SSH service will be restarted, regardless of its previous running state. Default is False.

**certificate_verify** If set to True, the SSL connection must present a valid certificate. Default is False.

Example:

```yaml
configure-host-ssh:
  esxi.ssh_configured:
    - service_running: True
    - ssh_key_file: /etc/salt/ssh_keys/my_key.pub
    - service_policy: 'on'
    - service_restart: True
    - certificate_verify: True
```
salt.states.esxi.syslog_configured(name, syslog_configs, firewall=True, reset_service=True, reset_syslog_config=False, reset_configs=None)

Ensures the specified syslog configuration parameters. By default, this state will reset the syslog service after any new or changed parameters are set successfully.

name  Name of the state.

syslog_configs  Name of parameter to set (corresponds to the command line switch for esxcli without the double dashes (--))

Valid syslog_config values are logdir, loghost, logdir-unique, default-rotate, default-size, and default-timeout.

Each syslog_config option also needs a configuration value to set. For example, loghost requires URLs or IP addresses to use for logging. Multiple log servers can be specified by listing them, comma-separated, but without spaces before or after commas

firewall  Enable the firewall rule set for syslog. Defaults to True.

reset_service  After a successful parameter set, reset the service. Defaults to True.

reset_syslog_config  Resets the syslog service to it's default settings. Defaults to False. If set to True, default settings defined by the list of syslog configs in reset_configs will be reset before running any other syslog settings.

reset_configs  A comma-delimited list of parameters to reset. Only runs if reset_syslog_config is set to True. If reset_syslog_config is set to True, but no syslog configs are listed in reset_configs, then reset_configs will be set to all by default.

Example:

```
configure-host-syslog:
esxi.syslog_configured:
  - syslog_configs:
    default-timeout: 120
  - firewall: True
  - reset_service: True
  - reset_syslog_config: True
  - reset_configs: loghost,default-timeout
```

salt.states.esxi.vmotion_configured(name, enabled, device='vmk0')

Configures a host's VMotion properties such as enabling VMotion and setting the device VirtualNic that VMotion will use.

name  Name of the state.

enabled  Ensures whether or not VMotion should be enabled on a host as a boolean value where True indicates that VMotion should be enabled and False indicates that VMotion should be disabled.

device  The device that uniquely identifies the VirtualNic that will be used for VMotion for the host. Defaults to vmk0.

Example:

```
configure-vmotion:
esxi.vmotion_configured:
  - enabled: True
  - device: sample-device
```

salt.states.esxi.vsan_configured(name, enabled, add_disks_to_vsan=False)

Configures a host's VSAN properties such as enabling or disabling VSAN, or adding VSAN-eligible disks to the VSAN system for the host.

name  Name of the state.
enabled Ensures whether or not VSAN should be enabled on a host as a boolean value where True indicates that VSAN should be enabled and False indicates that VSAN should be disabled.

add_disks_to_vsan If set to True, any VSAN-eligible disks for the given host will be added to the host’s VSAN system. Default is False.

Example:

```plaintext
configure-host-vsan:
esxi.vsan_configured:
   - enabled: True
   - add_disks_to_vsan: True
```

### 13.16.61 salt.states.event

Send events through Salt’s event system during state runs

**salt.states.event.send**

```python
salt.states.event.send(name, data=None, preload=None, with_env=False, with_grains=False,
                       with_pillar=False, **kwargs)
```

Send an event to the Salt Master

New in version 2014.7.0.

Accepts the same arguments as the **event.send** execution module of the same name.

Example:

```python
# ...snip bunch of states above
mycompany/mystaterun/status/update:
event.send:
   - data:
     status: "Half-way through the state run!"

# ...snip bunch of states below
```

**salt.states.event.wait**

Fire an event on the Salt master event bus if called from a watch statement

New in version 2014.7.0.

Example:

```python
# Stand up a new web server.
apache:
pkg:
   - installed
   - name: httpd
service:
   - running
   - enable: True
   - name: httpd

# Notify the load balancer to update the pool once Apache is running.
refresh_pool:
event:
   - wait
   - name: mycompany/loadbalancer/pool/update
   - data:
      new_web_server_ip: {{ grains['ipv4'] | first() }}
```
13.16.62 salt.states.file

Operations on regular files, special files, directories, and symlinks

Salt States can aggressively manipulate files on a system. There are a number of ways in which files can be managed.

Regular files can be enforced with the `file.managed` state. This state downloads files from the salt master and places them on the target system. Managed files can be rendered as a jinja, mako, or wempy template, adding a dynamic component to file management. An example of `file.managed` which makes use of the jinja templating system would look like this:

```
/etc/http/conf/http.conf:
file.managed:
  - source: salt://apache/http.conf
  - user: root
  - group: root
  - mode: 644
  - template: jinja
  - defaults:
    - custom_var: "default value"
    - other_var: 123
  {% if grains['os'] == 'Ubuntu' %}
    context:
    - custom_var: "override"
  {% endif %}
```

It is also possible to use the `py renderer` as a templating option. The template would be a Python script which would need to contain a function called `run()`, which returns a string. All arguments to the state will be made available to the Python script as globals. The returned string will be the contents of the managed file. For example:

```python
def run():
    lines = ['foo', 'bar', 'baz']
    lines.extend([source, name, user, context]) # Arguments as globals
    return '\n\n'.join(lines)
```

Note: The `defaults` and `context` arguments require extra indentation (four spaces instead of the normal two) in order to create a nested dictionary. More information.

If using a template, any user-defined template variables in the file defined in `source` must be passed in using the `defaults` and/or `context` arguments. The general best practice is to place default values in `defaults`, with conditional overrides going into `context`, as seen above.

The template will receive a variable `custom_var`, which would be accessed in the template using `{{ custom_var }}`. If the operating system is Ubuntu, the value of the variable `custom_var` would be `override`, otherwise it is the default `default value`

The `source` parameter can be specified as a list. If this is done, then the first file to be matched will be the one that is used. This allows you to have a default file on which to fall back if the desired file does not exist on the salt fileserver. Here's an example:
/etc/foo.conf:
    file.managed:
      - source:
          - salt://foo.conf.{{ grains['fqdn'] }}
          - salt://foo.conf.fallback
          - user: foo
          - group: users
          - mode: 644
          - backup: minion

Note: Salt supports backing up managed files via the backup option. For more details on this functionality please review the backup_mode documentation.

The source parameter can also specify a file in another Salt environment. In this example foo.conf in the dev environment will be used instead.

/etc/foo.conf:
    file.managed:
      - source:
          - salt://foo.conf?saltenv=dev
          - user: foo
          - mode: '0644'

Warning: When using a mode that includes a leading zero you must wrap the value in single quotes. If the value is not wrapped in quotes it will be read by YAML as an integer and evaluated as an octal.

The names parameter, which is part of the state compiler, can be used to expand the contents of a single state declaration into multiple, single state declarations. Each item in the names list receives its own individual state name and is converted into its own low-data structure. This is a convenient way to manage several files with similar attributes.

There is more documentation about this feature in the Names declaration section of the Highstate docs.

Special files can be managed via the mknod function. This function will create and enforce the permissions on a special file. The function supports the creation of character devices, block devices, and FIFO pipes. The function will create the directory structure up to the special file if it is needed on the minion. The function will not overwrite or operate on (change major/minor numbers) existing special files with the exception of user, group, and permissions. In most cases the creation of some special files require root permissions on the minion. This would require that the minion to be run as the root user. Here is an example of a character device:

/var/named/chroot/dev/random:
    file.mknod:
      - ntype: c
      - major: 1
      - minor: 8
      - user: named
      - group: named
      - mode: 660

Here is an example of a block device:
/var/named/chroot/dev/loop0:
  file.mknod:
    - ntype: b
    - major: 7
    - minor: 0
    - user: named
    - group: named
    - mode: 660

Here is an example of a fifo pipe:

/var/named/chroot/var/log/logfifo:
  file.mknod:
    - ntype: p
    - user: named
    - group: named
    - mode: 660

Directories can be managed via the `directory` function. This function can create and enforce the permissions on a directory. A directory statement will look like this:

/srv/stuff/substuf:
  file.directory:
    - user: fred
    - group: users
    - mode: 755
    - makedirs: True

If you need to enforce user and/or group ownership or permissions recursively on the directory's contents, you can do so by adding a `recurse` directive:

/srv/stuff/substuf:
  file.directory:
    - user: fred
    - group: users
    - mode: 755
    - makedirs: True
    - recurse:
      - user
      - group
      - mode

As a default, `mode` will resolve to `dir_mode` and `file_mode`, to specify both directory and file permissions, use this form:

/srv/stuff/substuf:
  file.directory:
    - user: fred
    - group: users
    - file_mode: 744
    - dir_mode: 755
    - makedirs: True
    - recurse:
      - user
      - group
      - mode

Symlinks can be easily created; the `symlink` function is very simple and only takes a few arguments:
Recursive directory management can also be set via the `recurse` function. Recursive directory management allows for a directory on the salt master to be recursively copied down to the minion. This is a great tool for deploying large code and configuration systems. A state using `recurse` would look something like this:

```
# /opt/code/flask:
file.recurse:
    - source: salt://code/flask
    - include_empty: True
```

A more complex `recurse` example:

```
{% set site_user = 'testuser' %}
{% set site_name = 'test_site' %}
{% set project_name = 'test_proj' %}
{% set sites_dir = 'test_dir' %}

django-project:
    file.recurse:
        - name: {{ sites_dir }}/{{ site_name }}/{{ project_name }}
        - user: {{ site_user }}
        - dir_mode: 2775
        - file_mode: '0644'
        - template: jinja
        - source: salt://project/templates_dir
        - include_empty: True
```

**Salt States**

The `salt.states.file.absent(name)`

Make sure that the named file or directory is absent. If it exists, it will be deleted. This will work to reverse any of the functions in the file state module. If a directory is supplied, it will be recursively deleted.

- **name** The path which should be deleted

The `salt.states.file.accumulated(name, filename, text, **kwargs)`

Prepare accumulator which can be used in template in file.managed state. Accumulator dictionary becomes available in template. It can also be used in file.blockreplace.

- **name** Accumulator name
- **filename** Filename which would receive this accumulator (see file.managed state documentation about name)
- **text** String or list for adding in accumulator
- **require_in / watch_in** One of them required for sure we fill up accumulator before we manage the file. Probably the same as `filename`

Example:

Given the following:

```
animals_doing_things:
    file.accumulated:
        - filename: /tmp/animal_file.txt
        - text: 'jumps over the lazy dog.'
        - require_in:
            - file: animal_file

animal_file:
    file.managed:
        - name: /tmp/animal_file.txt
```
One might write a template for `animal_file.txt` like the following:

```jinja
The quick brown fox{% for animal in accumulator['animals_doing_things'] %}{% set animal %}{% endfor %}
```

Collectively, the above states and template file will produce:

```
The quick brown fox jumps over the lazy dog.
```

Multiple accumulators can be `chained` together.

**Note:** The `accumulator` data structure is a Python dictionary. Do not expect any loop over the keys in a deterministic order!

```
salt.states.file.append(name, text=None, makedirs=False, source=None, source_hash=None, template='jinja', sources=None, source_hashes=None, defaults=None, context=None, ignore_whitespace=True)
```

Ensure that some text appears at the end of a file.

- The text will not be appended if it already exists in the file. A single string of text or a list of strings may be appended.
- `name` The location of the file to append to.
- `text` The text to be appended, which can be a single string or a list of strings.
- `makedirs` If the file is located in a path without a parent directory, then the state will fail. If makedirs is set to True, then the parent directories will be created to facilitate the creation of the named file. Defaults to False.
- `source` A single source file to append. This source file can be hosted on either the salt master server, or on an HTTP or FTP server. Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials (see `s3.get` state documentation). File retrieval from Openstack Swift object storage is supported via swiftpath URLs (see `swift.get` documentation).

For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is `salt://spam/eggs`.

If the file is hosted on an HTTP or FTP server, the `source_hash` argument is also required.

- `source_hash` This can be one of the following:
  1. a source hash string
  2. the URI of a file that contains source hash strings

The function accepts the first encountered long unbroken alphanumeric string of correct length as a valid hash, in order from most secure to least secure:

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>sha512</td>
<td>128</td>
</tr>
<tr>
<td>sha384</td>
<td>96</td>
</tr>
<tr>
<td>sha256</td>
<td>64</td>
</tr>
<tr>
<td>sha224</td>
<td>56</td>
</tr>
<tr>
<td>sha1</td>
<td>40</td>
</tr>
<tr>
<td>md5</td>
<td>32</td>
</tr>
</tbody>
</table>
See the `source_hash` parameter description for `file.managed` function for more details and examples.

**template** The named templating engine will be used to render the appended-to file. Defaults to `jinja`. The following templates are supported:

- cheetah
- genshi
- jinja
- mako
- py
- wempy

**sources** A list of source files to append. If the files are hosted on an HTTP or FTP server, the `source_hashes` argument is also required.

**source_hashes** A list of source_hashes corresponding to the sources list specified in the `sources` argument.

**defaults** Default context passed to the template.

**context** Overrides default context variables passed to the template.

**ignore_whitespace** New in version 2015.8.4.

Spaces and Tabs in text are ignored by default, when searching for the appending content, one space or multiple tabs are the same for salt. Set this option to `False` if you want to change this behavior.

### Multi-line example:

```
/etc/motd:
  file.append:
    - text:
      Thou hadst better eat salt with the Philosophers of Greece, than sugar with the Courtiers of Italy.
      - Benjamin Franklin
```

### Multiple lines of text:

```
/etc/motd:
  file.append:
    - text:
      - Trust no one unless you have eaten much salt with him.
      - "Salt is born of the purest of parents: the sun and the sea."
```

### Gather text from multiple template files:

```
/etc/motd:
  file:
    - append
    - template: jinja
    - sources:
      - salt://motd/devops-messages.tmpl
      - salt://motd/hr-messages.tmpl
      - salt://motd/general-messages.tmpl
```

New in version 0.9.5.

**salt.states.file.blockreplace**

```
(name, marker_start='## start managed zone --', marker_end='## end managed zone --', source=None, source_hash=None, template='jinja', sources=None, source_hashes=None, defaults=None, context=None, content='', append_if_not_found=False, prepend_if_not_found=False, backup='.bak', show_changes=True)
```

Maintain an edit in a file in a zone delimited by two line markers

New in version 2014.1.0.
A block of content delimited by comments can help you manage several lines entries without worrying about old entries removal. This can help you maintaining an un-managed file containing manual edits. Note: this function will store two copies of the file in-memory (the original version and the edited version) in order to detect changes and only edit the targeted file if necessary.

**name**  Filesystem path to the file to be edited

**marker_start**  The line content identifying a line as the start of the content block. Note that the whole line containing this marker will be considered, so whitespace or extra content before or after the marker is included in final output

**marker_end**  The line content identifying a line as the end of the content block. Note that the whole line containing this marker will be considered, so whitespace or extra content before or after the marker is included in final output. Note: you can use file.accumulated and target this state. All accumulated data dictionaries content will be added as new lines in the content

**content**  The content to be used between the two lines identified by marker_start and marker_end

**source**  The source file to download to the minion, this source file can be hosted on either the salt master server, or on an HTTP or FTP server. Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials. (see s3.get state documentation) File retrieval from Openstack Swift object storage is supported via swift://container/object_path URLs, see swift.get documentation. For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs. If source is left blank or None (use ~ in YAML), the file will be created as an empty file and the content will not be managed. This is also the case when a file already exists and the source is undefined; the contents of the file will not be changed or managed. If the file is hosted on a HTTP or FTP server then the source_hash argument is also required.

A list of sources can also be passed in to provide a default source and a set of fallbacks. The first source in the list that is found to exist will be used and subsequent entries in the list will be ignored.

```yaml
file_override_example:
  file.blockreplace:
    - name: /etc/example.conf
    - source:
      - salt://file_that_does_not_exist
      - salt://file_that_exists
```

**source_hash**

This can be one of the following:

1. a source hash string
2. the URI of a file that contains source hash strings

The function accepts the first encountered long unbroken alphanumeric string of correct length as a valid hash, in order from most secure to least secure:

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>sha512</td>
<td>128</td>
</tr>
<tr>
<td>sha384</td>
<td>96</td>
</tr>
<tr>
<td>sha256</td>
<td>64</td>
</tr>
<tr>
<td>sha224</td>
<td>56</td>
</tr>
<tr>
<td>sha1</td>
<td>40</td>
</tr>
<tr>
<td>md5</td>
<td>32</td>
</tr>
</tbody>
</table>

See the source_hash parameter description for file.managed function for more details and examples.

**template**  The named templating engine will be used to render the downloaded file. Defaults to jinja. The following templates are supported:

- **cheetah**
context  Overrides default context variables passed to the template.
defaults Default context passed to the template.
append_if_not_found If markers are not found and set to True then the markers and content will be appended
to the file. Default is False
prepend_if_not_found If markers are not found and set to True then the markers and content will be
prepended to the file. Default is False
backup The file extension to use for a backup of the file if any edit is made. Set this to False to skip making
a backup.
dry_run Don’t make any edits to the file
show_changes Output a unified diff of the old file and the new file. If False return a boolean if any changes
were made

Example of usage with an accumulator and with a variable:

```python
{% set myvar = 42 %
hosts-config-block-{{ myvar }}:
  file.blockreplace:
    - name: /etc/hosts
    - marker_start: "# START managed zone {{ myvar }} -DO-NOT-EDIT-"
    - marker_end: "# END managed zone {{ myvar }} --"
    - content: 'First line of content'
    - append_if_not_found: True
    - backup: '.bak'
    - show_changes: True

hosts-config-block-{{ myvar }}-accumulated1:
  file.accumulated:
    - filename: /etc/hosts
    - name: my-accumulator-{{ myvar }}
    - text: "text 2"
    - require_in:
      - file: hosts-config-block-{{ myvar }}

hosts-config-block-{{ myvar }}-accumulated2:
  file.accumulated:
    - filename: /etc/hosts
    - name: my-accumulator-{{ myvar }}
    - text: |
      text 3
      text 4
    - require_in:
      - file: hosts-config-block-{{ myvar }}
```

will generate and maintain a block of content in /etc/hosts:

```
# START managed zone 42 -DO-NOT-EDIT-
First line of content
text 2
text 3
text 4
# END managed zone 42 --
```

salt.states.file.comment(name, regex, char='#', backup='bak')
Comment out specified lines in a file.

**name** The full path to the file to be edited

**regex** A regular expression used to find the lines that are to be commented; this pattern will be wrapped in parenthesis and will move any preceding/trailing ^ or $ characters outside the parenthesis (e.g., the pattern ^foo$ will be rewritten as ^(foo)$) Note that you _need_ the leading ^, otherwise each time you run highstate, another comment char will be inserted.

**char** [#] The character to be inserted at the beginning of a line in order to comment it out

**backup** [,.bak] The file will be backed up before edit with this file extension

---

**Warning:** This backup will be overwritten each time sed / comment / uncomment is called. Meaning the backup will only be useful after the first invocation.

---

Set to False/None to not keep a backup.

**Usage:**

```
/etc/fstab:
  file.comment:
    - regex: ^bind 127.0.0.1
```

New in version 0.9.5.

```python
salt.states.file.copy(name, source, force=False, makedirs=False, preserve=False, user=None, group=None, mode=None, subdir=False, **kwargs)
```

If the source file exists on the system, copy it to the named file. The named file will not be overwritten if it already exists unless the force option is set to True.

**name** The location of the file to copy to

**source** The location of the file to copy to the location specified with name

**force** If the target location is present then the file will not be moved, specify ```force: True``` to overwrite the target file

**makedirs** If the target subdirectories don’t exist create them

**preserve** New in version 2015.5.0.

Set **preserve**: True to preserve user/group ownership and mode after copying. Default is False. If **preserve** is set to True, then user/group/mode attributes will be ignored.

**user** New in version 2015.5.0.

The user to own the copied file, this defaults to the user salt is running as on the minion. If **preserve** is set to True, then this will be ignored

**group** New in version 2015.5.0.

The group to own the copied file, this defaults to the group salt is running as on the minion. If **preserve** is set to True or on Windows this will be ignored

**mode** New in version 2015.5.0.

The permissions to set on the copied file, aka 644, `0775`, `4664`. If **preserve** is set to True, then this will be ignored. Not supported on Windows.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it’s not enforced.

**subdir** New in version 2015.5.0.

If the name is a directory then place the file inside the named directory

---

**Note:** The copy function accepts paths that are local to the Salt minion. This function does not support salt://, http://, or the other additional file paths that are supported by states.file.managed and states.file.recurse.
salt.states.file.decode(name, encoded_data=None, contents_pillar=None, encoding_type='base64', checksum='md5')

Decode an encoded file and write it to disk

New in version 2016.3.0.
name Path of the file to be written.
encoded_data The encoded file. Either this option or contents_pillar must be specified.
contents_pillar A Pillar path to the encoded file. Uses the same path syntax as pillar.get. The hashutil.base64_encodefile function can load encoded content into Pillar. Either this option or encoded_data must be specified.
encoding_type [base64] The type of encoding.
checksum [md5] The hashing algorithm to use to generate checksums. Wraps the hashutil.digest execution function.

Usage:

write_base64_encoded_string_to_a_file:
  file.decode:
    - name: /tmp/new_file
    - encoding_type: base64
    - contents_pillar: mypillar:thefile

# or
write_base64_encoded_string_to_a_file:
  file.decode:
    - name: /tmp/new_file
    - encoding_type: base64
    - encoded_data: |
      Z2V0IHNhbHRlZQ==

Be careful with multi-line strings that the YAML indentation is correct. E.g.,

write_base64_encoded_string_to_a_file:
  file.decode:
    - name: /tmp/new_file
    - encoding_type: base64
    - encoded_data: |
      {{ salt.pillar.get('path:to:data') | indent(8) }}

salt.states.file.directory(name, user=None, group=None, recurse=None, dir_mode=None, file_mode=None, makedirs=False, clean=False, require=None, exclude_pat=None, follow_symlinks=False, force=False, backup_name=None, allow_symlink=True, **kwargs)

Ensure that a named directory is present and has the right perms
name The location to create or manage a directory
user The user to own the directory; this defaults to the user salt is running as on the minion
group The group ownership set for the directory; this defaults to the group salt is running as on the minion.
On Windows, this is ignored
recurse Enforce user/group ownership and mode of directory recursively. Accepts a list of strings representing what you would like to recurse. If mode is defined, will recurse on both file_mode and dir_mode if they are defined. If ignore_files or ignore_dirs is included, files or directories will be left unchanged respectively. Example:

[/var/log/httpd:
  file.directory:
    - user: root
    - group: root

2032 Chapter 13. Salt Module Reference
- **dir_mode**: 755
- **file_mode**: 644
- **recurse**:
  - **user**
  - **group**
  - **mode**

Leave files or directories unchanged:

```
/var/log/httpd:
file.directory:
- user: root
- group: root
- dir_mode: 755
- file_mode: 644
- recurse:
  - user
  - group
  - mode
  - ignore_dirs
```

New in version 2015.5.0.

**dir_mode** / **mode**  The permissions mode to set any directories created. Not supported on Windows.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it’s not enforced.

**file_mode**  The permissions mode to set any files created if `mode` is run in `recurse`. This defaults to dir_mode. Not supported on Windows.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it’s not enforced.

**makedirs**  If the directory is located in a path without a parent directory, then the state will fail. If makedirs is set to True, then the parent directories will be created to facilitate the creation of the named file.

**clean**  Make sure that only files that are set up by salt and required by this function are kept. If this option is set then everything in this directory will be deleted unless it is required.

**require**  Require other resources such as packages or files

**exclude_pat**  When `clean` is set to True, exclude this pattern from removal list and preserve in the destination.

**follow_symlinks**  [False] If the desired path is a symlink (or `recurse` is defined and a symlink is encountered while recursing), follow it and check the permissions of the directory/file to which the symlink points.

New in version 2014.1.4.

**force**  If the name of the directory exists and is not a directory and force is set to False, the state will fail. If force is set to True, the file in the way of the directory will be deleted to make room for the directory, unless backupname is set, then it will be renamed.

New in version 2014.7.0.

**backupname**  If the name of the directory exists and is not a directory, it will be renamed to the backupname. If the backupname already exists and force is False, the state will fail. Otherwise, the backupname will be removed first.

New in version 2014.7.0.

**allow_symlink**  [True] If allow_symlink is True and the specified path is a symlink, it will be allowed to remain if it points to a directory. If allow_symlink is False then the state will fail, unless force is also set to True, in which case it will be removed or renamed, depending on the value of the backupname argument.

New in version 2014.7.0.

salt.states.file.exists(name)
Verify that the named file or directory is present or exists. Ensures pre-requisites outside of Salt's purview (e.g., keytabs, private keys, etc.) have been previously satisfied before deployment.

**name** Absolute path which must exist

### salt.states.file.line

```python
name, content, match=None, mode=None, location=None, before=None, after=None, show_changes=True, backup=False, quiet=False, indent=True)
```

Line-based editing of a file.

New in version 2015.8.0.

- **name** Filesystem path to the file to be edited.
- **content** Content of the line.
- **match** Match the target line for an action by a fragment of a string or regular expression.

If neither `before` nor `after` are provided, and `match` is also `None`, `match` becomes the `content` value.

- **mode** Defines how to edit a line. One of the following options is required:
  - `ensure` If line does not exist, it will be added.
  - `replace` If line already exists, it will be replaced.
  - `delete` Delete the line, once found.
  - `insert` Insert a line.

#### Note:
If `mode=insert` is used, at least one of the following options must also be defined: `location`, `before`, or `after`. If `location` is used, it takes precedence over the other two options.

- **location** Defines where to place content in the line. Note this option is only used when `mode=insert` is specified. If a location is passed in, it takes precedence over both the `before` and `after` kwargs. Valid locations are:
  - `start` Place the content at the beginning of the file.
  - `end` Place the content at the end of the file.

- **before** Regular expression or an exact case-sensitive fragment of the string. This option is only used when either the `ensure` or `insert` mode is defined.

- **after** Regular expression or an exact case-sensitive fragment of the string. This option is only used when either the `ensure` or `insert` mode is defined.

- **show_changes** Output a unified diff of the old file and the new file. If `False` return a boolean if any changes were made. Default is `True`

#### Note:
Using this option will store two copies of the file in-memory (the original version and the edited version) in order to generate the diff.

- **backup** Create a backup of the original file with the extension: `'Year-Month-Day-Hour-Minutes-Seconds'`.

- **quiet** Do not raise any exceptions. E.g. ignore the fact that the file that is tried to be edited does not exist and nothing really happened.

- **indent** Keep indentation with the previous line. This option is not considered when the `delete` mode is specified.

### salt.states.file.managed

```python
name, source=None, source_hash='`, source_hash_name=None, user=None, group=None, mode=None, template=None, makedirs=False, dir_mode=None, context=None, replace=True, defaults=None, env=None, backup='`, show_diff=None, show_changes=True, create=True, contents=None, contents_pillar=None, contents_grains=None, contents_newline=True, contents_delimiter=':', allow_empty=True, follow_symlinks=True, check_cmd=None, skip_verify=False, **kwargs)
```

Manage a given file, this function allows for a file to be downloaded from the salt master and potentially run through a templating system.

- **name** The location of the file to manage

- **source** The source file to download to the minion, this source file can be hosted on either the salt master
server (salt://), the salt minion local file system (/), or on an HTTP or FTP server (http(s)://, ftp:///).

Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials. (see s3.get state documentation) File retrieval from Openstack Swift object storage is supported via swift://container/object_path URLs, see swift.get documentation. For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs. If source is left blank or None (use ~ in YAML), the file will be created as an empty file and the content will not be managed. This is also the case when a file already exists and the source is undefined; the contents of the file will not be changed or managed.

If the file is hosted on a HTTP or FTP server then the source_hash argument is also required.

A list of sources can also be passed in to provide a default source and a set of fallbacks. The first source in the list that is found to exist will be used and subsequent entries in the list will be ignored. Source list functionality only supports local files and remote files hosted on the salt master server or retrievable via HTTP, HTTPS, or FTP.

```yaml
file_override_example:
  file.managed:
    - source:
      - salt://file_that_does_not_exist
      - salt://file_that_exists
```

**source_hash**

This can be one of the following:

1. a source hash string
2. the URI of a file that contains source hash strings

The function accepts the first encountered long unbroken alphanumeric string of correct length as a valid hash, in order from most secure to least secure:

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>sha512</td>
<td>128</td>
</tr>
<tr>
<td>sha384</td>
<td>96</td>
</tr>
<tr>
<td>sha256</td>
<td>64</td>
</tr>
<tr>
<td>sha224</td>
<td>56</td>
</tr>
<tr>
<td>sha1</td>
<td>40</td>
</tr>
<tr>
<td>md5</td>
<td>32</td>
</tr>
</tbody>
</table>

**Using a Source Hash File** The file can contain several checksums for several files. Each line must contain both the file name and the hash. If no file name is matched, the first hash encountered will be used, otherwise the most secure hash with the correct source file name will be used.

When using a source hash file the source_hash argument needs to be a url, the standard download urls are supported, ftp, http, salt etc:

Example:

```yaml
tomdroid-src-0.7.3.tar.gz:
  file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
    - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/
tomdroid-src-0.7.3.tar.gz
  - source_hash: https://launchpad.net/tomdroid/beta/0.7.3/+download/
tomdroid-src-0.7.3.hash
```
The following lines are all supported formats:

```
/etc/rc.conf ef6e82e4006dee563d98ada2a2a80a27
sha254c8525aee419eb649f0233be91c151178b30f0ddf8ebbdcc8de71b1d5c8bcc06a /
/etc/resolv.conf
ead484237f35093d37c4a9e6a0d53e143b6fc268
```

Debian file type *.dsc files are also supported.

**Inserting the Source Hash in the SLS Data**

**Examples:**

```
tomdroid-src-0.7.3.tar.gz:
  file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
    - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/
    - tomdroid-src-0.7.3.tar.gz
    - source_hash: md5=79eef25f9b0b2c642c62b7f737d4f53f
```

**Known issues:** If the remote server URL has the hash file as an apparent sub-directory of the source file, the module will discover that it has already cached a directory where a file should be cached. For example:

```
tomdroid-src-0.7.3.tar.gz:
  file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
    - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/
    - tomdroid-src-0.7.3.tar.gz
    - source_hash: https://launchpad.net/tomdroid/beta/0.7.3/+download/
    - tomdroid-src-0.7.3.tar.gz/+md5
```

**source_hash_name** When `source_hash` refers to a hash file, Salt will try to find the correct hash by matching the filename/URI associated with that hash. By default, Salt will look for the filename being managed. When managing a file at path `/tmp/foo.txt`, then the following line in a hash file would match:

```
acbd18db4cc2f85cedef654fccc4a4d8 foo.txt
```

However, sometimes a hash file will include multiple similar paths:

```
37b51d194a7513e45b56f6524f2d51f2 ./dir1/foo.txt
acbd18db4cc2f85cedef654fccc4a4d8 ./dir2/foo.txt
73feffa4b7f6bb68e44cf984c85f6e88 ./dir3/foo.txt
```

In cases like this, Salt may match the incorrect hash. This argument can be used to tell Salt which filename to match, to ensure that the correct hash is identified. For example:

```
/tmp/foo.txt:
  file.managed:
    - source: https://mydomain.tld/dir2/foo.txt
    - source_hash: https://mydomain.tld/_hashes
    - source_hash_name: ./dir2/foo.txt
```

**Note:** This argument must contain the full filename entry from the checksum file, as this argument is meant to disambiguate matches for multiple files that have the same basename. So, in the example above, simply using `foo.txt` would not match.

New in version 2016.3.5.

**user** The user to own the file, this defaults to the user salt is running as on the minion
group  The group ownership set for the file, this defaults to the group salt is running as on the minion. On
        Windows, this is ignored.
mode  The permissions to set on this file, aka 644, 0775, 4664. Not supported on Windows.
        The default mode for new files and directories corresponds umask of salt process. For existing files and
directories it’s not enforced.
template  If this setting is applied, the named templating engine will be used to render the downloaded file.
The following templates are supported:
        • cheetah
        • genshi
        • jinja
        • mako
        • py
        • wempy
makedirs  [False] If set to True, then the parent directories will be created to facilitate the creation of the
        named file. If False, and the parent directory of the destination file doesn’t exist, the state will fail.
dir_mode  If directories are to be created, passing this option specifies the permissions for those directories.
        If this is not set, directories will be assigned permissions from the `mode` argument.
        The default mode for new files and directories corresponds umask of salt process. For existing files and
directories it’s not enforced.
replace  [True] If set to False and the file already exists, the file will not be modified even if changes would
        otherwise be made. Permissions and ownership will still be enforced, however.
context  Overrides default context variables passed to the template.
defaults  Default context passed to the template.
backup  Overrides the default backup mode for this specific file. See backup_mode documentation for more
details.
show_diff  DEPRECATED: Please use show_changes.
        If set to False, the diff will not be shown in the return data if changes are made.
show_changes  Output a unified diff of the old file and the new file. If False return a boolean if any changes
        were made.
create  [True] If set to False, then the file will only be managed if the file already exists on the system.
contents  Specify the contents of the file. Cannot be used in combination with source. Ignores hashes and
does not use a templating engine.
        This value can be either a single string, a multiline YAML string or a list of strings. If a list of strings,
        then the strings will be joined together with newlines in the resulting file. For example, the below two
        example states would result in identical file contents:

        /path/to/file1:
        file.managed:
        - contents:
          - This is line 1
          - This is line 2

        /path/to/file2:
        file.managed:
        - contents: |
          This is line 1
          This is line 2

contents_pillar  New in version 0.17.0.
        Operates like contents, but draws from a value stored in pillar, using the pillar path syntax used in
        pillar.get. This is useful when the pillar value contains newlines, as referencing a pillar variable using
        a jinja/mako template can result in YAML formatting issues due to the newlines causing indentation
        mismatches.
For example, the following could be used to deploy an SSH private key:

```
/home/deployer/.ssh/id_rsa:
  file.managed:
    - user: deployer
    - group: deployer
    - mode: 600
    - contents_pillar: userdata:deployer:id_rsa
```

This would populate `/home/deployer/.ssh/id_rsa` with the contents of pillar['userdata']->{'deployer'}['id_rsa']. An example of this pillar setup would be like so:

```
userdata:
  deployer:
    id_rsa: |
    -----BEGIN RSA PRIVATE KEY-----
    MIIEowIBAAKCAQEAoQiwO3JhBquPAa1QF9qP1lLZNXvjYMISwMe2HcWUVBgh+vY
    U7sCwx/dH6+VvWnmCqmmNnp+8gTPKG1lvgAObJAnMTG23dMXjVkwnEagZPRJIXDy
    B/HaAre9euNiY3lvIzBTWSeMFT+rWvIKVBpwlGrfgz70m8pqXu+UyFbAGLin+
    GpxzZAMaFpZw4sSbIlRuissXZj/shPQbb9MS0e04Z3rjkcPlcxI
    -----END RSA PRIVATE KEY-----
```

**Note:** The private key above is shortened to keep the example brief, but shows how to do multiline string in YAML. The key is followed by a pipe character, and the multiline string is indented two more spaces.

To avoid the hassle of creating an indented multiline YAML string, the file_tree external pillar can be used instead. However, this will not work for binary files in Salt releases before 2015.8.4.

**contents_grains** New in version 2014.7.0.

Operates like contents, but draws from a value stored in grains, using the grains path syntax used in grains.get. This functionality works similarly to contents_pillar, but with grains.

For example, the following could be used to deploy a `message of the day` file:

```
write_motd:
  file.managed:
    - name: /etc/motd
    - contents_grains: motd
```

This would populate `/etc/motd` file with the contents of the motd grain. The motd grain is not a default grain, and would need to be set prior to running the state:

```
salt '*' grains.set motd 'Welcome! This system is managed by Salt.'
```

**contents_newline** [True] New in version 2014.7.0.

Changed in version 2015.8.4: This option is now ignored if the contents being deployed contain binary data.

If True, files managed using contents, contents_pillar, or contents_grains will have a newline added to the end of the file if one is not present. Setting this option to False will omit this final newline.

**contents_delimiter** New in version 2015.8.4.

Can be used to specify an alternate delimiter for contents_pillar or contents_grains. This delimiter will be passed through to pillar.get or grains.get when retrieving the contents.

If set to False, then the state will fail if the contents specified by contents_pillar or contents_grains are empty.

If the desired path is a symlink follow it and make changes to the file to which the symlink points.

cHECK_cmd New in version 2014.7.0.

The specified command will be run with an appended argument of a temporary file containing the new managed contents. If the command exits with a zero status the new managed contents will be written to the managed destination. If the command exits with a nonzero exit code, the state will fail and no changes will be made to the file.

For example, the following could be used to verify sudoers before making changes:

```
/etc/sudoers:
  file.managed:
    - user: root
    - group: root
    - mode: 0440
    - source: salt://sudoers/files/sudoers.jinja
    - template: jinja
    - check_cmd: /usr/sbin/visudo -c -f
```

NOTE: This check_cmd functions differently than the requisite check_cmd.

skip_verify [False] If True, hash verification of remote file sources (http://, https://, ftp://) will be skipped, and the source_hash argument will be ignored.

New in version 2016.3.0.

salt.states.file.missing(name)

Verify that the named file or directory is missing, this returns True only if the named file is missing but does not remove the file if it is present.

name Absolute path which must NOT exist

salt.states.file.mknod(name, ntype, major=0, minor=0, user=None, group=None, mode='0600')

Create a special file similar to the `nix mknod command. The supported device types are p (fifo pipe), c (character device), and b (block device). Provide the major and minor numbers when specifying a character device or block device. A fifo pipe does not require this information. The command will create the necessary dirs if needed. If a file of the same name not of the same type/major/minor exists, it will not be overwritten or unlinked (deleted). This is logically in place as a safety measure because you can really shoot yourself in the foot here and it is the behavior of `nix mknod. It is also important to note that not just anyone can create special devices. Usually this is only done as root. If the state is executed as none other than root on a minion, you may receive a permission error.

name name of the file
ntype node type `p' (fifo pipe), `c' (character device), or `b' (block device)
major major number of the device does not apply to a fifo pipe
minor minor number of the device does not apply to a fifo pipe
user owning user of the device/pipe
group owning group of the device/pipe
mode permissions on the device/pipe

Usage:

```
/dev/chr:
  file.mknod:
    - ntype: c
    - major: 180
    - minor: 31
```
New in version 0.17.0.

salt.states.file.mod_run_check_cmd(cmd, filename, **check_cmd_opts)

Execute the check_cmd logic.

Return a result dict if check_cmd succeeds (check_cmd == 0) otherwise return True

salt.states.file.patch(name, source=None, hash=None, options='`, dry_run_first=True, env=None, **kwargs)

Apply a patch to a file or directory.

**Note:** A suitable patch executable must be available on the minion when using this state function.

**name** The file or directory to which the patch will be applied.

**source** The source patch to download to the minion, this source file must be hosted on the salt master server. If the file is located in the directory named spam, and is called eggs, the source string is salt://spam/eggs. A source is required.

**hash** Hash of the patched file. If the hash of the target file matches this value then the patch is assumed to have been applied. The hash string is the hash algorithm followed by the hash of the file: md5=e138491e9d5b97023cea823fe17bac22

**options** Extra options to pass to patch.

**dry_run_first** [True] Run patch with --dry-run first to check if it will apply cleanly.

**env** Specify the environment from which to retrieve the patch file indicated by the source parameter. If not provided, this defaults to the environment from which the state is being executed.

**Usage:**

```
# Equivalent to ```patch --forward /opt/file.txt file.patch```

/opt/file.txt:
  file.patch:
    - source: salt://file.patch
    - hash: md5=e138491e9d5b97023cea823fe17bac22
```

salt.states.file.prepend(name, text=None, makedirs=False, source=None, source_hash=None, template='`jinja', sources=None, source_hashes=None, defaults=None, context=None)

Ensure that some text appears at the beginning of a file
The text will not be prepended again if it already exists in the file. You may specify a single line of text or a list of lines to append.

Multi-line example:

```
/etc/motd:
  file.prepend:
    - text: |
      Thou hadst better eat salt with the Philosophers of Greece,
      than sugar with the Courtiers of Italy.
    - text: Benjamin Franklin
```

Multiple lines of text:

```
/etc/motd:
  file.prepend:
    - text:
      - Trust no one unless you have eaten much salt with him.
      - "Salt is born of the purest of parents: the sun and the sea."
```

Gather text from multiple template files:

```
/etc/motd:
  file:
    - prepend
    - template: jinja
    - sources:
      - salt://motd/devops-messages.tmpl
      - salt://motd/hr-messages.tmpl
      - salt://motd/general-messages.tmpl
```

New in version 2014.7.0.

salt.states.file.recurse(name, source, clean=False, require=None, user=None, group=None, dir_mode=None, file_mode=None, sym_mode=None, template=None, context=None, defaults=None, env=None, include_empty=False, backup='`', include_pat=None, exclude_pat=None, maxdepth=None, keep_symlinks=False, force_symlinks=False, **kwargs)

Recurse through a subdirectory on the master and copy said subdirectory over to the specified path.

name The directory to set the recursion in
source The source directory, this directory is located on the salt master file server and is specified with the salt:// protocol. If the directory is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs
clean Make sure that only files that are set up by salt and required by this function are kept. If this option is set then everything in this directory will be deleted unless it is required.
require Require other resources such as packages or files
user The user to own the directory. This defaults to the user salt is running as on the minion
group The group ownership set for the directory. This defaults to the group salt is running as on the minion.
On Windows, this is ignored
dir_mode The permissions mode to set on any directories created. Not supported on Windows.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it's not enforced.
file_mode The permissions mode to set on any files created. Not supported on Windows.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it's not enforced.
sym_mode The permissions mode to set on any symlink created. Not supported on Windows.
The default mode for new files and directories corresponds umask of salt process. For existing files and directories it’s not enforced.

**template** If this setting is applied, the named templating engine will be used to render the downloaded file. The following templates are supported:

- cheetah
- genshi
- jinja
- mako
- py
- wempy

**Note**: The template option is required when recursively applying templates.

**context** Overrides default context variables passed to the template.

**defaults** Default context passed to the template.

**include_empty** Set this to True if empty directories should also be created (default is False)

**backup** Overrides the default backup mode for all replaced files. See `backup_mode documentation` for more details.

**include_pat** When copying, include only this pattern from the source. Default is glob match; if prefixed with `E@`, then regexp match. Example:

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>- include_pat: hello*</code></td>
<td><code>::</code> glob matches 'hello01', 'hello02'</td>
</tr>
<tr>
<td></td>
<td>... but not 'otherhello'</td>
</tr>
<tr>
<td><code>- include_pat: E@hello</code></td>
<td><code>::</code> regexp matches 'otherhello',</td>
</tr>
<tr>
<td></td>
<td>'hello01' ...</td>
</tr>
</tbody>
</table>

**exclude_pat** Exclude this pattern from the source when copying. If both `include_pat` and `exclude_pat` are supplied, then it will apply conditions cumulatively. i.e. first select based on `include_pat`, and then within that result apply `exclude_pat`.

Also, when `clean=True`, exclude this pattern from the removal list and preserve in the destination. Example:

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>- exclude_pat: APPDATA*</code></td>
<td><code>::</code> glob matches APPDATA.01, APPDATA.02,.. for exclusion</td>
</tr>
<tr>
<td>`- exclude_pat: E@(APPDATA)</td>
<td>(TEMPDATA)`</td>
</tr>
</tbody>
</table>

**maxdepth** When copying, only copy paths which are of depth `maxdepth` from the source path. Example:

<table>
<thead>
<tr>
<th>Depth</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>- maxdepth: 0</code></td>
<td><code>::</code> Only include files located in the source directory</td>
</tr>
<tr>
<td><code>- maxdepth: 1</code></td>
<td><code>::</code> Only include files located in the source or immediate subdirectories</td>
</tr>
</tbody>
</table>

**keep_symlinks** Keep symlinks when copying from the source. This option will cause the copy operation to terminate at the symlink. If desire behavior similar to rsync, then set this to True.

**force_symlinks** Force symlink creation. This option will force the symlink creation. If a file or directory is obstructing symlink creation it will be recursively removed so that symlink creation can proceed. This option is usually not needed except in special circumstances.

**salt.states.file.rename**(name, source, force=False, makedirs=False)

If the source file exists on the system, rename it to the named file. The named file will not be overwritten if it already exists unless the force option is set to True.

**name** The location of the file to rename to

**source** The location of the file to move to the location specified with name

**force** If the target location is present then the file will not be moved, specify `"force: True"` to overwrite the target file
Salt Documentation, Release 2016.3.6

makedirs If the target subdirectories don’t exist create them

salt.states.file.replace(name, pattern, repl, count=0, flags=8, bufsize=1, append_if_not_found=False, prepend_if_not_found=False, not_found_content=None, backup='.bak', show_changes=True, ignore_if_missing=False)

Maintain an edit in a file.

New in version 0.17.0.

name Filesystem path to the file to be edited.

pattern A regular expression, to be matched using Python’s search().

repl The replacement text

count Maximum number of pattern occurrences to be replaced. Defaults to 0. If count is a positive integer n, no more than n occurrences will be replaced, otherwise all occurrences will be replaced.

flags A list of flags defined in the re module documentation. Each list item should be a string that will correlate to the human-friendly flag name. E.g., ['IGNORECASE', 'MULTILINE']. Optionally, flags may be an int, with a value corresponding to the XOR (|) of all the desired flags. Defaults to 8 (which equates to ['MULTILINE']).

Note: file.replace reads the entire file as a string to support multiline regex patterns. Therefore, when using anchors such as ^ or $ in the pattern, those anchors may be relative to the line OR relative to the file. The default for file.replace is to treat anchors as relative to the line, which is implemented by setting the default value of flags to ['MULTILINE']. When overriding the default value for flags, if 'MULTILINE' is not present then anchors will be relative to the file. If the desired behavior is for anchors to be relative to the line, then simply add 'MULTILINE' to the list of flags.

bufsize How much of the file to buffer into memory at once. The default value 1 processes one line at a time.

The special value file may be specified which will read the entire file into memory before processing.

append_if_not_found [False] If set to True, and pattern is not found, then the content will be appended to the file.

New in version 2014.7.0.

prepend_if_not_found [False] If set to True and pattern is not found, then the content will be prepended to the file.

New in version 2014.7.0.

not_found_content Content to use for append/prepend if not found. If None (default), uses repl. Useful when repl uses references to group in pattern.

New in version 2014.7.0.

backup The file extension to use for a backup of the file before editing. Set to False to skip making a backup.

show_changes [True] Output a unified diff of the old file and the new file. If False return a boolean if any changes were made. Returns a boolean or a string.

ignore_if_missing [False] New in version 2016.3.4.

Controls what to do if the file is missing. If set to False, the state will display an error raised by the execution module. If set to True, the state will simply report no changes.

For complex regex patterns, it can be useful to avoid the need for complex quoting and escape sequences by making use of YAML’s multiline string syntax.

complex_search_and_replace:
  file.replace:
    # <...snip...>
    - pattern: |
      CentOS \((2.6.32[^\n]+\n\s+root[^\n]+\n\)+
**Note:** When using YAML multiline string syntax in pattern:, make sure to also use that syntax in the `repl:` part, or you might lose line feeds.

```python
salt.states.file.serialize(name, dataset=None, dataset_pillar=None, user=None, group=None, mode=None, env=None, backup='', makedirs=False, show_diff=True, create=True, merge_if_exists=False, **kwargs)
```

Serializes dataset and store it into managed file. Useful for sharing simple configuration files.

- **name** The location of the file to create
- **dataset** The dataset that will be serialized
- **dataset_pillar** Operates like `dataset`, but draws from a value stored in pillar, using the pillar path syntax used in `pillar.get`. This is useful when the pillar value contains newlines, as referencing a pillar variable using a jinja/mako template can result in YAML formatting issues due to the newlines causing indentation mismatches.

New in version 2015.8.0.

- **formatter** Write the data as this format. Supported output formats:
  - JSON
  - YAML
  - Python (via `pprint.pformat`)
- **user** The user to own the directory, this defaults to the user salt is running as on the minion
- **group** The group ownership set for the directory, this defaults to the group salt is running as on the minion
- **mode** The permissions to set on this file, aka 644, 0775, 4664.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it’s not enforced.

- **backup** Overrides the default backup mode for this specific file.
- **makedirs** Create parent directories for destination file.

New in version 2014.1.3.

- **show_diff** If set to False, the diff will not be shown.
- **create** Default is True, if create is set to False then the file will only be managed if the file already exists on the system.

- **merge_if_exists** Default is False, if merge_if_exists is True then the existing file will be parsed and the dataset passed in will be merged with the existing content

New in version 2014.7.0.

For example, this state:

```yaml
/etc/dummy/package.json:
  file.serialize:
    - dataset:
        name: naive
        description: A package using naive versioning
        author: A confused individual <iam@confused.com>
        dependencies:
          express: '>= 1.2.0'
          optimist: '>= 0.1.0'
        engine: node 0.4.1
    - formatter: json
```

will manage the file `/etc/dummy/package.json`:

```
{
  "author": "A confused individual <iam@confused.com>",
  "dependencies": {
    "express": ">= 1.2.0",
```
```python
salt.states.file.symlink(name, target, force=False, backupname=None, makedirs=False, user=None, group=None, mode=None, **kwargs)
```

Create a symbolic link (symlink, soft link)

If the file already exists and is a symlink pointing to any location other than the specified target, the symlink will be replaced. If the symlink is a regular file or directory then the state will return False. If the regular file or directory is desired to be replaced with a symlink pass force: True, if it is to be renamed, pass a backupname.

- **name**: The location of the symlink to create
- **target**: The location that the symlink points to
- **force**: If the name of the symlink exists and is not a symlink and force is set to False, the state will fail. If force is set to True, the file or directory in the way of the symlink file will be deleted to make room for the symlink, unless backupname is set, when it will be renamed.
- **backupname**: If the name of the symlink exists and is not a symlink, it will be renamed to the backupname. If the backupname already exists and force is False, the state will fail. Otherwise, the backupname will be removed first.
- **makedirs**: If the location of the symlink does not already have a parent directory then the state will fail, setting makedirs to True will allow Salt to create the parent directory.
- **user**: The user to own the file, this defaults to the user salt is running as on the minion.
- **group**: The group ownership set for the file, this defaults to the group salt is running as on the minion. On Windows, this is ignored.
- **mode**: The permissions to set on this file, aka 644, 0775, 4664. Not supported on Windows.

Note that if you just want to create a file and don't care about atime or mtime, you should use `file.managed` instead, as it is more feature-complete. (Just leave out the `source/template/contents` arguments, and it will just create the file and/or check its permissions, without messing with contents)

Usage:

```
/var/log/httpd/logrotate.empty:
    file.touch
```

New in version 0.9.5.

```python
salt.states.file.touch(name, atime=None, mtime=None, makedirs=False)
```

Replicate the `nix `touch`` command to create a new empty file or update the atime and mtime of an existing file.

```
Note that if you just want to create a file and don't care about atime or mtime, you should use `file.managed`
```

instead, as it is more feature-complete. (Just leave out the `source/template/contents` arguments, and it will just create the file and/or check its permissions, without messing with contents)

```python
name**: name of the file
- **atime**: atime of the file
- **mtime**: mtime of the file
- **makedirs**: whether we should create the parent directory/directories in order to touch the file

Usage:

```
/var/log/httpd/logrotate.empty:
    file.touch
```

New in version 0.9.5.

```python
salt.states.file.uncomment(name, regex, char='#', backup='.bak')
```

Uncomment specified commented lines in a file

```python
name**: The full path to the file to be edited
- **regex**: A regular expression used to find the lines that are to be uncommented. This regex should not include the comment character. A leading `^` character will be stripped for convenience (for easily switching between comment() and uncomment()). The regex will be searched for from the beginning of the line, ignoring leading spaces (we prepend `^[[:t:]]``

Usage:

```
/var/log/httpd/logrotate.empty:
    file.touch
```

New in version 0.9.5.

```python
salt.states.file.managed(name, source, template=None, contents=None, **kwargs)
```

Create a file or directory and set permissions, ownership, etc.

- **name**: The full path to the file or directory to be created.
- **source**: The contents to write as the file. If not given, the file will be empty.
- **template**: The location of a jinja template file to render. If not given, the file will be empty.
- **contents**: The contents to write as the file. If not given, the file will be empty.

Usage:

```
/var/log/httpd/logrotate.empty:
    file.managed
```

New in version 0.9.5.
**char** [\#] The character to remove in order to uncomment a line

**backup** [\.bak] The file will be backed up before edit with this file extension;

---

**Warning:** This backup will be overwritten each time `sed / comment / uncomment` is called. Meaning the backup will only be useful after the first invocation.

Set to False/None to not keep a backup.

Usage:

```
/etc/adduser.conf:
  file.uncomment:
    - regex: EXTRA_GROUPS
```

New in version 0.9.5.

### 13.16.63 salt.states.firewall module

State to check firewall configurations. .. versionadded:: 2016.3.0

```python
salt.states.firewall.check(name, port=None, **kwargs)
```

Checks if there is an open connection from the minion to the defined host on a specific port.

- **name** host name or ip address to test connection to
- **port** The port to test the connection on
- **kwargs**

  Additional parameters, parameters allowed are: proto (tcp or udp) family (ipv4 or ipv6) timeout

```
testgoogle:
  firewall.check:
    - name: 'google.com'
    - port: 80
    - proto: 'tcp'
```

### 13.16.64 salt.states.firewalld

Management of firewalld

New in version 2015.8.0.

The following example applies changes to the public zone, blocks echo-reply and echo-request packets, does not set the zone to be the default, enables masquerading, and allows ports 22/tcp and 25/tcp.

```
public:
  firewalld.present:
    - name: public
    - block_icmp:
      - echo-reply
      - echo-request
    - default: False
    - masquerade: True
    - ports:
      - 22/tcp
      - 25/tcp
```
The following example applies changes to the public zone, enables masquerading and configures port forwarding TCP traffic from port 22 to 2222, and forwards TCP traffic from port 80 to 443 at 192.168.0.1.

```yaml
my_zone:
  firewalld.present:
    - name: public
    - masquerade: True
    - port_fwd:
      - 22:2222:tcp
      - 80:443:tcp:192.168.0.1
```

The following example binds the public zone to interface eth0 and to all packets coming from the 192.168.1.0/24 subnet. It also removes the zone from all other interfaces or sources.

```yaml
public:
  firewalld.bind:
    - name: public
    - interfaces:
      - eth0
    - sources:
      - 192.168.1.0/24
```

```python
salt.states.firewalld.bind(name, interfaces=None, sources=None)
```
Ensure a zone is bound to specific interfaces or sources.

New in version 2016.3.0.

**Note:** This state does not enforce the existence of the zone. To ensure that the zone exists, use `firewalld.present`.

```python
salt.states.firewalld.present(name, block_icmp=None, default=None, masquerade=False, ports=None, port_fwd=None, services=None)
```
Ensure a zone has specific attributes.

### 13.16.65 salt.states.gem

**Installation of Ruby modules packaged as gems**

A state module to manage rubygems. Gems can be set up to be installed or removed. This module will use RVM or rbenv if they are installed. In that case, you can specify what ruby version and gemset to target.

```yaml
addressable:
  gem.installed:
    - user: rvm
    - ruby: jruby@jgemset
```

```python
salt.states.gem.installed(name, ruby=None, gem_bin=None, user=None, version=None, rdoc=False, ri=False, pre_releases=False, proxy=None, source=None)
```
Make sure that a gem is installed.

- **name** The name of the gem to install
- **ruby:** None Only for RVM or rbenv installations: the ruby version and gemset to target.
- **gem_bin:** None Custom `gem` command to run instead of the default. Use this to install gems to a non-default ruby install. If you are using rvm or rbenv use the ruby argument instead.
- **user:** None The user under which to run the `gem` command
New in version 0.17.0.

**version** [None] Specify the version to install for the gem. Doesn't play nice with multiple gems at once
**rdoc** [False] Generate RDoc documentation for the gem(s).
**ri** [False] Generate RI documentation for the gem(s).
**pre_releases** [False] Install pre-release version of gem(s) if available.
**proxy** [None] Use the specified HTTP proxy server for all outgoing traffic. Format: http://hostname[:port]
**source** [None] Use the specified HTTP gem source server to download gem. Format: http://hostname[:port]

```python
salt.states.gem.removed(name, ruby=None, user=None, gem_bin=None)
```

Make sure that a gem is not installed.

- **name** The name of the gem to uninstall
- **gem_bin** [None] Full path to gem binary to use.
- **ruby** [None] If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
- **user** None The user under which to run the gem command

New in version 0.17.0.

```python
salt.states.gem.sources_add(name, ruby=None, user=None)
```

Make sure that a gem source is added.

- **name** The URL of the gem source to be added
- **ruby** None For RVM or rbenv installations: the ruby version and gemset to target.
- **user** None The user under which to run the gem command

New in version 0.17.0.

```python
salt.states.gem.sources_remove(name, ruby=None, user=None)
```

Make sure that a gem source is removed.

- **name** The URL of the gem source to be removed
- **ruby** None For RVM or rbenv installations: the ruby version and gemset to target.
- **user** None The user under which to run the gem command

New in version 0.17.0.

**13.16.66 salt.states.git**

States to manage git repositories and git configuration

---

**Important:** Before using git over ssh, make sure your remote host fingerprint exists in your ~/.ssh/known_hosts file.

---

Changed in version 2015.8.8: This state module now requires git 1.6.5 (released 10 October 2009) or newer.

```python
salt.states.git.config_set(name, value=None, multivar=None, repo=None, user=None, password=None, **kwargs)
```

New in version 2014.7.0.

Changed in version 2015.8.0: Renamed from git.config to git.config_set. For earlier versions, use git.config.

Ensure that a config value is set to the desired value(s)

- **name** Name of the git config value to set
- **value** Set a single value for the config item
- **multivar** Set multiple values for the config item
Note: The order matters here, if the same parameters are set but in a different order, they will be removed and replaced in the order specified.

New in version 2015.8.0.

repo Location of the git repository for which the config value should be set. Required unless global is set to True.

user User under which to run git commands. By default, the commands are run by the user under which the minion is running.

password Windows only. Required when specifying user. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

global [False] If True, this will set a global git config option

Changed in version 2015.8.0: Option renamed from is_global to global. For earlier versions, use is_global.

Local Config Example:

```
# Single value
mylocalrepo:
    git.config_set:
    - name: user.email
    - value: foo@bar.net
    - repo: /path/to/repo

# Multiple values
mylocalrepo:
    git.config_set:
    - name: mysection.myattribute
    - multivar:
    - foo
    - bar
    - baz
    - repo: /path/to/repo
```

Global Config Example (User `foo`):

```
mylocalrepo:
    git.config_set:
    - name: user.name
    - value: Foo Bar
    - user: foo
    - global: True
```

salt.states.git.config_unset(name, value_regex=None, repo=None, user=None, password=None, **kwargs)

New in version 2015.8.0.

Ensure that the named config key is not present

name The name of the configuration key to unset. This value can be a regex, but the regex must match the entire key name. For example, foo\..+ would not match all keys in the foo section, it would be necessary to use foo\..+ to do so.

value_regex Regex indicating the values to unset for the matching key(s)

Note: This option behaves differently depending on whether or not all is set to True. If it is, then all
values matching the regex will be deleted (this is the only way to delete multiple values from a multivar).
If `all` is set to `False`, then this state will fail if the regex matches more than one value in a multivar.

all [False] If `True`, unset all matches
repo Location of the git repository for which the config value should be set. Required unless `global` is set to `True`.
user User under which to run git commands. By default, commands are run by the user under which the minion is running.
password Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.
global [False] If `True`, this will set a global git config option

Examples:

```
# Value matching 'baz'
mylocalrepo:
  git.config_unset:
    - name: foo.bar
    - value_regex: 'baz'
    - repo: /path/to/repo

# Ensure entire multivar is unset
mylocalrepo:
  git.config_unset:
    - name: foo.bar
    - all: True

# Ensure all variables in 'foo' section are unset, including multivars
mylocalrepo:
  git.config_unset:
    - name: 'foo\..+'
    - all: True

# Ensure that global config value is unset
mylocalrepo:
  git.config_unset:
    - name: foo.bar
    - global: True
```

salt.states.git.detached(name, ref, target=None, remote='origin', user=None, password=None,
force_clone=False, force_checkout=False, fetch_remote=True,
hard_reset=False, submodules=False, identity=None, https_user=None, https_pass=None, onlyif=False, unless=False, **kwargs)

New in version 2016.3.0.

Make sure a repository is cloned to the given target directory and is a detached HEAD checkout of the commit ID resolved from `ref`.

name Address of the remote repository.
ref The branch, tag, or commit ID to checkout after clone. If a branch or tag is specified it will be resolved to a commit ID and checked out.
target Name of the target directory where repository is about to be cloned.
remote [origin] Git remote to use. If this state needs to clone the repo, it will clone it using this value as the initial remote name. If the repository already exists, and a remote by this name is not present, one will be added.
user User under which to run git commands. By default, commands are run by the user under which the minion is running.
password
Windows only. Required when specifying user. This parameter will be ignored on non-Windows platforms.
New in version 2016.3.4.

force_clone [False] If the target directory exists and is not a git repository, then this state will fail. Set this argument to True to remove the contents of the target directory and clone the repo into it.

force_checkout [False] When checking out the revision ID, the state will fail if there are unwritten changes. Set this argument to True to discard unwritten changes when checking out.

fetch_remote [True] If False a fetch will not be performed and only local refs will be reachable.

hard_reset [False] If True a hard reset will be performed before the checkout and any uncommitted modifications to the working directory will be discarded. Untracked files will remain in place.

Note: Changes resulting from a hard reset will not trigger requisites.

submodules [False] Update submodules

identity A path on the minion (or a SaltStack fileserver URL, e.g. salt://path/to/identity_file) to a private key to use for SSH authentication.

https_user HTTP Basic Auth username for HTTPS (only) clones

https_pass HTTP Basic Auth password for HTTPS (only) clones

onlyif A command to run as a check, run the named command only if the command passed to the onlyif option returns true

unless A command to run as a check, only run the named command if the command passed to the unless option returns false

salt.states.git.latest(name, rev='HEAD', target=None, branch=None, user=None, password=None, update_head=True, force_checkout=False, force_clone=False, force_fetch=False, force_reset=False, submodules=False, bare=False, mirror=False, remote='origin', fetch_tags=True, depth=None, identity=None, https_user=None, https_pass=None, onlyif=False, unless=False, **kwargs)

Make sure the repository is cloned to the given directory and is up-to-date.

name Address of the remote repository, as passed to git clone

Note: From the Git documentation, there are two URL formats supported for SSH authentication. The below two examples are equivalent:

<table>
<thead>
<tr>
<th># ssh:// URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>ssh://user@server/project.git</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th># SCP-like syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>user@server:project.git</td>
</tr>
</tbody>
</table>

A common mistake is to use an ssh:// URL, but with a colon after the domain instead of a slash. This is invalid syntax in Git, and will therefore not work in Salt. When in doubt, confirm that a git clone works for the URL before using it in Salt.

It has been reported by some users that SCP-like syntax is incompatible with git repos hosted on Atlassian Stash/BitBucket Server. In these cases, it may be necessary to use ssh:// URLs for SSH authentication.

rev [HEAD] The remote branch, tag, or revision ID to checkout after clone / before update. If specified, then Salt will also ensure that the tracking branch is set to <remote>/<rev>, unless rev refers to a tag or SHA1, in which case Salt will ensure that the tracking branch is unset.

If rev is not specified, it will be assumed to be HEAD, and Salt will not manage the tracking branch at all.
Changed in version 2015.8.0: If not specified, `rev` now defaults to the remote repository's HEAD.

**target**  Name of the target directory where repository is about to be cloned

**branch**  Name of the local branch into which to checkout the specified rev. If not specified, then Salt will not care what branch is being used locally and will just use whatever branch is currently there.

New in version 2015.8.0.

**Note:** If this argument is not specified, this means that Salt will not change the local branch if the repository is reset to another branch/tag/SHA1. For example, assume that the following state was run initially:

```
foo_app:
  git.latest:
    - name: https://mydomain.tld/apps/foo.git
    - target: /var/www/foo
    - user: www
```

This would have cloned the HEAD of that repo (since a `rev` wasn't specified), and because `branch` is not specified, the branch in the local clone at `/var/www/foo` would be whatever the default branch is on the remote repository (usually `master`, but not always). Now, assume that it becomes necessary to switch this checkout to the `dev` branch. This would require `rev` to be set, and probably would also require `force_reset` to be enabled:

```
foo_app:
  git.latest:
    - name: https://mydomain.tld/apps/foo.git
    - target: /var/www/foo
    - user: www
    - rev: dev
    - force_reset: True
```

The result of this state would be to perform a hard-reset to `origin/dev`. Since `branch` was not specified though, while `/var/www/foo` would reflect the contents of the remote repo's `dev` branch, the local branch would still remain whatever it was when it was cloned. To make the local branch match the remote one, set `branch` as well, like so:

```
foo_app:
  git.latest:
    - name: https://mydomain.tld/apps/foo.git
    - target: /var/www/foo
    - user: www
    - rev: dev
    - branch: dev
    - force_reset: True
```

This may seem redundant, but Salt tries to support a wide variety of use cases, and doing it this way allows for the use case where the local branch doesn't need to be strictly managed.

**user**  Local system user under which to run git commands. By default, commands are run by the user under which the minion is running.

**Note:** This is not to be confused with the username for http(s)/SSH authentication.

New in version 0.17.0.
password  Windows only. Required when specifying user. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

update_head  [True] If set to False, then the remote repository will be fetched (if necessary) to ensure that the commit to which rev points exists in the local checkout, but no changes will be made to the local HEAD.

New in version 2015.8.3.

force  [False] Deprecated since version 2015.8.0: Use force_ clone instead. For earlier Salt versions, force must be used.

force_checkout  [False] When checking out the local branch, the state will fail if there are unwritten changes. Set this argument to True to discard unwritten changes when checking out.

force_ clone  [False] If the target directory exists and is not a git repository, then this state will fail. Set this argument to True to remove the contents of the target directory and clone the repo into it.

force_fetch  [False] If a fetch needs to be performed, non-fast-forward fetches will cause this state to fail. Set this argument to True to force the fetch even if it is a non-fast-forward update.

New in version 2015.8.0.

force_reset  [False] If the update is not a fast-forward, this state will fail. Set this argument to True to force a hard-reset to the remote revision in these cases.

submodules  [False] Update submodules on clone or branch change

bare  [False] Set to True if the repository is to be a bare clone of the remote repository.

mirror  Set to True if the repository is to be a mirror of the remote repository. This implies that bare set to True, and thus is incompatible with rev.

remote  [origin] Git remote to use. If this state needs to clone the repo, it will clone it using this value as the initial remote name. If the repository already exists, and a remote by this name is not present, one will be added.

remote_name  Deprecated since version 2015.8.0: Use remote instead. For earlier Salt versions, remote_name must be used.

fetch_tags  [True] If True, then when a fetch is performed all tags will be fetched, even those which are not reachable by any branch on the remote.

depth  Defines depth in history when git a clone is needed in order to ensure latest. E.g. depth: 1 is useful when deploying from a repository with a long history. Use rev to specify branch. This is not compatible with tags or revision IDs.

identity  Path to a private key to use for ssh URLs. This can be either a single string, or a list of strings. For example:

```
# Single key
git@github.com:user/repo.git:
git.latest:
  - user: deployer
  - identity: /home/deployer/.ssh/id_rsa

# Two keys
git@github.com:user/repo.git:
git.latest:
  - user: deployer
  - identity:
    - /home/deployer/.ssh/id_rsa
    - /home/deployer/.ssh/id_rsa_alternate
```

If multiple keys are specified, they will be tried one-by-one in order for each git command which needs to authenticate.
**Warning:** Unless Salt is invoked from the minion using `salt-call`, the key(s) must be passphrase-less. For greater security with passphraseless private keys, see the `sshd(8)` manpage for information on securing the keypair from the remote side in the `authorized_keys` file.

Changed in version 2015.8.7: Salt will no longer attempt to use passphrase-protected keys unless invoked from the minion using `salt-call`, to prevent blocking waiting for user input.

Changed in version 2016.3.0: Key can now be specified as a SaltStack fileserver URL (e.g. `salt://path/to/identity_file`).

- **https_user** HTTP Basic Auth username for HTTPS (only) clones
  
  New in version 2015.5.0.

- **https_pass** HTTP Basic Auth password for HTTPS (only) clones
  
  New in version 2015.5.0.

- **onlyif** A command to run as a check, run the named command only if the command passed to the `onlyif` option returns true

- **unless** A command to run as a check, only run the named command if the command passed to the `unless` option returns false

---

**Note:** Clashing ID declarations can be avoided when including different branches from the same git repository in the same SLS file by using the `name` argument. The example below checks out the `gh-pages` and `gh-pages-prod` branches from the same repository into separate directories. The example also sets up the `ssh_known_hosts ssh` key required to perform the git checkout.

Also, it has been reported that the SCP-like syntax for

```bash
gitlab.example.com:
  ssh_known_hosts:
    - present
    - user: root
    - enc: ecdsa

git-website-staging:
git.latest:
  - name: git@gitlab.example.com:user/website.git
  - rev: gh-pages
  - target: /usr/share/nginx/staging
  - identity: /root/.ssh/website_id_rsa
  - require:
    - pkg: git
    - ssh_known_hosts: gitlab.example.com

git-website-staging:
git.latest:
  - name: git@gitlab.example.com:user/website.git
  - rev: gh-pages
  - target: /usr/share/nginx/staging
  - identity: salt://website/id_rsa
  - require:
    - pkg: git
    - ssh_known_hosts: gitlab.example.com

git-website-prod:
git.latest:
  - name: git@gitlab.example.com:user/website.git
```
salt.states.git.

salt.states.git.mod_run_check(cmd_kwargs, onlyif, unless)
Execute the onlyif and unless logic. Return a result dict if:
  • onlyif failed (onlyif != 0)
  • unless succeeded (unless == 0)
Otherwise, returns True

salt.states.git.present(name, force=False, bare=True, template=None, separate_git_dir=None, shared=None, user=None, password=None)
Ensure that a repository exists in the given directory

**Warning:** If the minion has Git 2.5 or later installed, `name` points to a worktree, and `force` is set to True, then the worktree will be deleted. This has been corrected in Salt 2015.8.0.

**name** Path to the directory
Changed in version 2015.8.0: This path must now be absolute

**force** [False] If True, and if `name` points to an existing directory which does not contain a git repository, then the contents of that directory will be recursively removed and a new repository will be initialized in its place.

**bare** [True] If True, and a repository must be initialized, then the repository will be a bare repository.

**Note:** This differs from the default behavior of `git.init`, make sure to set this value to False if a bare repo is not desired.

**template** If a new repository is initialized, this argument will specify an alternate `template directory`
New in version 2015.8.0.

**separate_git_dir** If a new repository is initialized, this argument will specify an alternate $GIT_DIR
New in version 2015.8.0.

**shared** Set sharing permissions on git repo. See `git-init(1)` for more details.
New in version 2015.5.0.

**user** User under which to run git commands. By default, commands are run by the user under which the minion is running.
New in version 0.17.0.

**password**
Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.
New in version 2016.3.4.

### 13.16.67 salt.states.github module

Github User State Module
New in version 2016.3.0..
This state is used to ensure presence of users in the Organization.

```yaml
ensure user test is present in github:
  github.present:
    - name: 'Example TestUser1'
    - email: example@domain.com
    - username: 'gitexample'
```

salt.states.github.absent(name, profile='github', **kwargs)
Ensure a github user is absent

```yaml
ensure user test is absent in github:
  github.absent:
    - name: 'Example TestUser1'
    - email: example@domain.com
    - username: 'gitexample'
```

The following parameters are required:
- name  Github handle of the user in organization

salt.states.github.present(name, profile='github', **kwargs)
Ensure a user is present

```yaml
ensure user test is present in github:
  github.present:
    - fullname: 'Example TestUser1'
    - email: 'example@domain.com'
    - name: 'gitexample'
```

The following parameters are required:
- name  This is the github handle of the user in the organization

### 13.16.68 salt.states.glance

Managing Images in OpenStack Glance

salt.states.glance.image_present(name, visibility='public', protected=None, checksum=None, location=None, wait_for=None, timeout=30)
Checks if given image is present with properties set as specified.

An image should go through the stages `queued`, `saving` before becoming `active`. The attribute `checksum` can only be checked once the image is active. If you don't specify `wait_for` but `checksum` the function will wait for the image to become active before comparing checksums. If you don't specify checksum either the function will return when the image reached `saving`. The default timeout for both is 30 seconds.

**Supported properties:**
- visibility ('public' or 'private')
- protected (bool)
- checksum (string, md5sum)
- location (URL, to copy from)

### 13.16.69 salt.states.glusterfs

Manage glusterfs pool.

salt.states.glusterfs.add_volume_bricks(name, bricks)
Add brick(s) to an existing volume
name Volume name
bricks List of bricks to add to the volume

```
myvolume:
    glusterfs.add_volume_bricks:
        - bricks:
            - host1:/srv/gluster/drive1
            - host2:/srv/gluster/drive2

Replicated Volume:
    glusterfs.add_volume_bricks:
        - name: volume2
          bricks:
            - host1:/srv/gluster/drive2
            - host2:/srv/gluster/drive3
```

salt.states.glusterfs.created(name, bricks, stripe=False, replica=False, device_vg=False, transport='tcp', start=False, force=False)

Check if volume already exists

```
myvolume:
    glusterfs.created:
        - bricks:
            - host1:/srv/gluster/drive1
            - host2:/srv/gluster/drive2

Replicated Volume:
    glusterfs.created:
        - name: volume2
          bricks:
            - host1:/srv/gluster/drive2
            - host2:/srv/gluster/drive3
            - replica: 2
            - start: True
```

salt.states.glusterfs.peered(name)
Check if node is peered.

```
peer-cluster:
    glusterfs.peered:
        - name: two

peer-clusters:
    glusterfs.peered:
        - names:
            - one
            - two
            - three
            - four
```

salt.states.glusterfs.started(name)
Check if volume has been started

```
mycluster:
    glusterfs.started: []
```
13.16.70 salt.states.gnomedesktop

Configuration of the GNOME desktop

Control the GNOME settings

```python
localdesktop_wmPrefs:
    gnomedesktop.wm_preferences:
        - user: username
        - audible_bell: false
        - action_double_click_titlebar: 'toggle-maximize'
        - visual_bell: true
        - num_workspaces: 6

localdesktop_lockdown:
    gnomedesktop.desktop_lockdown:
        - user: username
        - disable_user_switching: true

localdesktop_interface:
    gnomedesktop.desktop_interface:
        - user: username
        - clock_show_date: true
        - clock_format: 12h
```

```python
salt.states.gnomedesktop.desktop_interface(name, user=None, automatic_mnemonics=None, buttons_have_icons=None, can_change_accels=None, clock_format=None, clock_show_date=None, clock_show_seconds=None, cursor_blink=None, cursor_blink_time=None, cursor_blink_timeout=None, cursor_size=None, cursor_theme=None, document_font_name=None, enable_animations=None, font_name=None, gtk_color_palette=None, gtk_color_scheme=None, gtk_im_module=None, gtk_im_preedit_style=None, gtk_im_status_style=None, gtk_key_theme=None, gtk_theme=None, gtk_timeout_initial=None, gtk_timeout_repeat=None, icon_theme=None, menubar_accel=None, menubar detachable=None, menus_have_icons=None, menus_have_tearoff=None, monospace_font_name=None, show_input_method_menu=None, show_unicode_menu=None, text_scaling_factor=None, toolbar detachable=None, toolbar_icons_size=None, toolbar_style=None, toolkit_accessibility=None, **kwargs)
```

desktop_interface: sets values in the org.gnome.desktop.interface schema
13.16.71 salt.states.gpg module

Management of the GPG keychains

New in version 2016.3.0.

salt.states.gpg.absent(name, keys=None, user=None, gnupghome=None, **kwargs)

Ensure GPG public key is absent in keychain

name  The unique name or keyid for the GPG public key.
keys  The keyId or keyIds to add to the GPG keychain.
user  Add GPG keys to the user's keychain

gnupghome  Override GNUPG Home directory

salt.states.gpg.present(name, keys=None, user=None, keyserver=None, gnupghome=None, trust=None, **kwargs)

Ensure GPG public key is present in keychain

name  The unique name or keyid for the GPG public key.
keys  The keyId or keyIds to add to the GPG keychain.
user  Add GPG keys to the user's keychain

keyserver  The keyserver to retrieve the keys from.

gnupghome  Override GNUPG Home directory

trust  Trust level for the key in the keychain, ignored by default. Valid trust levels: expired, unknown, not_trusted, marginally, fully, ultimately

13.16.72 salt.states.grafana

Manage Grafana Dashboards

13.16. state modules 2059
This module uses `elasticsearch`, which can be installed via package, or pip.

You can specify `elasticsearch` hosts directly to the module, or you can use an `elasticsearch` profile via pillars:

```yaml
mygrafanaprofile:
  hosts:
    - es1.example.com:9200
    - es2.example.com:9200
  index: grafana-dash
```

# Basic usage (uses default pillar profile key 'grafana')
Ensure myservice dashboard is managed:

```yaml
grafana.dashboard_present:
  - name: myservice
  - dashboard_from_pillar: default
  - rows_from_pillar:
    - systemhealth
    - requests
```

# Passing hosts in
Ensure myservice dashboard is managed:

```yaml
grafana.dashboard_present:
  - name: myservice
  - dashboard_from_pillar: default
  - rows:
    - collapse: false
      editable: true
      height: 150px
      title: System Health
      panels:
        - aliasColors: {}
          id: 200000
          annotate:
            enable: false
          bars: false
          datasource: null
          editable: true
          error: false
          fill: 7
          grid:
            leftMax: 100
            leftMin: null
            rightMax: null
            rightMin: null
            threshold1: 60
            threshold1Color: rgb(216, 27, 27)
            threshold2: null
            threshold2Color: rgba(234, 112, 112, 0.22)
            leftYAxisLabel: ''
          legend:
            avg: false
            current: false
            max: false
            min: false
            show: false
            total: false
            values: false
          lines: true
          linewidth: 1
```
nullPointMode: connected
percentage: false
pointRadius: 5
points: false
renderer: flot
resolution: 100
scale: 1
seriesOverrides: []
span: 4
stack: false
steppedLine: false
targets:
  - target: cloudwatch.aws.ec2.mysrv.cpuutilization.average
title: CPU (asg average)
tooltip:
  queryAsAlias: true

  - short
zerofill: true
rows_from_pillar:
  - systemhealth
  - requests
  - profile:
    hosts:
      - es1.example.com:9200
      - es2.example.com:9200
    index: grafana-dash

# Using a profile from pillars
Ensure myservice dashboard is managed:
grafana.dashboard_present:
  - name: myservice
  - dashboard:
    annotations:
      enable: true
      list: []
    editable: true
    hideAllLegends: false
    hideControls: false
    nav:
      - collapse: false
        enable: true
        notice: false
        now: true
        refresh_intervals:
          - 10s
          - 30s
          - 1m
          - 5m
          - 15m
          - 30m
          - 1h
The behavior of this module is to create dashboards if they do not exist, to add rows if they do not exist in existing dashboards, and to update rows if they exist in dashboards. The module will not manage rows that are not defined, allowing users to manage their own custom rows.

salt.states.grafana.dashboard_absent(name, hosts=None, profile='grafana')

Ensure the named grafana dashboard is deleted.

- name Name of the grafana dashboard.
- profile A pillar key or dict that contains a list of hosts and an elasticsearch index to use.

salt.states.grafana.dashboard_present(name, dashboard=None, dashboard_from_pillar=None, rows=None, rows_from_pillar=None, profile='grafana')

Ensure the grafana dashboard exists and is managed.

- name Name of the grafana dashboard.
- dashboard A dict that defines a dashboard that should be managed.
- dashboard_from_pillar A pillar key that contains a grafana dashboard dict. Mutually exclusive with dashboard.
- rows A list of grafana rows.
- rows_from_pillar A list of pillar keys that contain lists of grafana dashboard rows. Rows defined in the pillars will be appended to the rows defined in the state.
profile  A pillar key or dict that contains a list of hosts and an elasticsearch index to use.

13.16.73 salt.states.grafana_dashboard module

Manage Grafana v2.0 Dashboards

New in version 2016.3.0.

```
grafana:
    grafana_timeout: 3
    grafana_token: qwertyuiop
    grafana_url: 'https://url.com'
```

Ensure minimum dashboard is managed:

```
grafana_dashboard.present:
    - name: insightful-dashboard
    - base_dashboards_from_pillar: default_dashboard
    - base_rows_from_pillar: default_row
    - base_panels_from_pillar: default_panel
    - dashboard:
        rows:
            - title: Usage
                panels:
                    - targets:
                        - target: alias(constantLine(50), 'max')
        title: Imaginary
        type: graph
```

The behavior of this module is to create dashboards if they do not exist, to add rows if they do not exist in existing dashboards, and to update rows if they exist in dashboards. The module will not manage rows that are not defined, allowing users to manage their own custom rows.

```
salt.states.grafana_dashboard.absent(name, profile='grafana')
```

Ensure the named grafana dashboard is absent.

- **name**: Name of the grafana dashboard.
- **profile**: A pillar key or dict that contains grafana information

```
salt.states.grafana_dashboard.present(name, base_dashboards_from_pillar= None, base_rows_from_pillar= None, base_panels_from_pillar= None, dashboard= None, profile='grafana')
```

Ensure the grafana dashboard exists and is managed.

- **name**: Name of the grafana dashboard.
- **base_dashboards_from_pillar**: A pillar key that contains a list of dashboards to inherit from
- **base_rows_from_pillar**: A pillar key that contains a list of rows to inherit from
- **base_panels_from_pillar**: A pillar key that contains a list of panels to inherit from
- **dashboard**: A dict that defines a dashboard that should be managed.
- **profile**: A pillar key or dict that contains grafana information

13.16.74 salt.states.grafana_datasource module

Manage Grafana v2.0 data sources
New in version 2016.3.0.

```yaml
grafana:
    grafana_timeout: 3
    grafana_token: qwertyuiop
    grafana_url: 'https://url.com'
```

Ensure influxdb data source is present:
```yaml
grafana_datasource.present:
    - name: influxdb
    - type: influxdb
    - url: http://localhost:8086
    - access: proxy
    - basic_auth: true
    - basic_auth_user: myuser
    - basic_auth_password: mypass
    - is_default: true
```

salt.states.grafana_datasource.absent(name, profile='grafana')

Ensure that a data source is present.
```yaml
name
```

salt.states.grafana_datasource.present(name, type, url, access='proxy', user='', password='',
    database='', basic_auth=False, basic_auth_user='',
    basic_auth_password='', is_default=False,
    json_data=None, profile='grafana')

Ensure that a data source is present.
```yaml
name
```

salt.states.grains.absent(name, destructive=False, delimiter=';', force=False)

New in version 2014.7.0.
```yaml
name
```

Manage grains on the minion

This state allows for grains to be set. Grains set or altered this way are stored in the `grains' file on the minions, by default at: /etc/salt/grains

Note: This does NOT override any grains set in the minion file.

salt.states.grains.absent(name, destructive=False, delimiter=';', force=False)

New in version 2014.7.0.
```yaml
name
```

13.16.75 salt.states.grains

Manage grains on the minion

This state allows for grains to be set. Grains set or altered this way are stored in the `grains' file on the minions, by default at: /etc/salt/grains

Note: This does NOT override any grains set in the minion file.

salt.states.grains.absent(name, destructive=False, delimiter=';', force=False)

New in version 2014.7.0.
```yaml
name
```
**delimiter** A delimiter different from the default can be provided.

- New in version v2015.8.2.
- Changed in version v2015.8.2.

This state now support nested grains and complex values. It is also more conservative: if a grain has a value that is a list or a dict, it will not be removed unless the `force` parameter is True.

```python
grain_name:
grains.absent: []
```

**salt.states.grains.append** *(name, value, convert=False, delimiter=':')*

- New in version 2014.7.0.

Append a value to a list in the grains config file. The grain that is being appended to (name) must exist before the new value can be added.

- `name` The grain name.
- `value` The value to append.
- `convert` If convert is True, convert non-list contents into a list. If convert is False and the grain contains non-list contents, an error is given. Defaults to False.
- `delimiter` A delimiter different from the default can be provided.

- New in version v2015.8.2.

```python
grain_name:
grains.append:
- value: to_be_appended
```

**salt.states.grains.list_absent** *(name, value, delimiter=':')*

Delete a value from a grain formed as a list.

- New in version 2014.1.0.

- `name` The grain name.
- `value` The value to delete from the grain list.
- `delimiter` A delimiter different from the default can be provided.

- New in version v2015.8.2.

The grain should be list type

```python
roles:
grains.list_absent:
- value: db
```

For multiple grains, the syntax looks like:

```python
roles:
grains.list_absent:
- value:
  - web
  - dev
```

**salt.states.grains.list_present** *(name, value, delimiter=':')*

- New in version 2014.1.0.

Ensure the value is present in the list-type grain. Note: If the grain that is provided in `name` is not present on the system, this new grain will be created with the corresponding provided value.

- `name` The grain name.
- `value` The value is present in the list type grain.
**delimiter**  A delimiter different from the default : can be provided.

New in version v2015.8.2.
The grain should be list type

```
roles:
grains.list_present:
  - value: web
```

For multiple grains, the syntax looks like:

```
roles:
grains.list_present:
  - value:
    - web
    - dev
```

`salt.states.grains.present(name, value, delimiter=':', force=False)`

Ensure that a grain is set

Changed in version v2015.8.2.
**name**  The grain name
**value**  The value to set on the grain
**force**  If force is True, the existing grain will be overwritten regardless of its existing or provided value type.
  Defaults to False

New in version v2015.8.2.

**delimiter**  A delimiter different from the default can be provided.

New in version v2015.8.2.

It is now capable to set a grain to a complex value (ie. lists and dicts) and supports nested grains as well.

If the grain does not yet exist, a new grain is set to the given value. For a nested grain, the necessary keys are created if they don’t exist. If a given key is an existing value, it will be converted, but an existing value different from the given key will fail the state.

If the grain with the given name exists, its value is updated to the new value unless its existing or provided value is complex (list or dict). Use `force: True` to overwrite.

```
cheese:
grains.present:
  - value: edam

nested_grain_with_complex_value:
grains.present:
  - name: icinga:Apache SSL
  - value:
    - command: check_https
    - params: -H localhost -p 443 -S

with,a,custom,delimiter:
grains.present:
  - value: yay
  - delimiter: ,
```
13.16.76 salt.states.group

Management of user groups

The group module is used to create and manage unix group settings, groups can be either present or absent:

```yaml
cheese:
  group.present:
    - gid: 7648
    - system: True
    - addusers:
      - user1
      - users2
    - delusers:
      - foo

cheese:
  group.present:
    - gid: 7648
    - system: True
    - members:
      - foo
      - bar
      - user1
      - user2
```

salt.states.group.absent(name)
Ensure that the named group is absent

name The name of the group to remove

salt.states.group.present(name, gid=None, system=False, addusers=None, delusers=None, members=None)
Ensure that a group is present

name The name of the group to manage

gid The group id to assign to the named group; if left empty, then the next available group id will be assigned

system Whether or not the named group is a system group. This is essentially the `-r' option of `groupadd'.

addusers List of additional users to be added as a group members.

delusers Ensure these user are removed from the group membership.

members Replace existing group members with a list of new members.

Note: Options `members' and `addusers/delusers' are mutually exclusive and can not be used together.

13.16.77 salt.states.hg

Interaction with Mercurial repositories

Before using hg over ssh, make sure the remote host fingerprint already exists in ~/.ssh/known_hosts, and the remote host has this host's public key.

```bash
https://bitbucket.org/example_user/example_repo:
  hg.latest:
    - rev: tip
    - target: /tmp/example_repo
```

salt.states.hg.latest(name, rev=None, target=None, clean=False, user=None, identity=None, force=False, opts=False)
Make sure the repository is cloned to the given directory and is up to date
name Address of the remote repository as passed to `''hg clone''
rev The remote branch, tag, or revision hash to clone/pull
target Target destination directory path on minion to clone into
clean Force a clean update with -C (Default: False)
user Name of the user performing repository management operations

New in version 0.17.0.

identity Private SSH key on the minion server for authentication (ssh://)

New in version 2015.5.0.

force Force hg to clone into pre-existing directories (deletes contents)

opts Include additional arguments and options to the hg command line

13.16.78 salt.states.hipchat

Send a message to Hipchat

This state is useful for sending messages to Hipchat during state runs.

New in version 2015.5.0.

```yaml
hipchat-message:
  hipchat.send_message:
    - room_id: 123456
    - from_name: SuperAdmin
    - message: This state was executed successfully.
    - api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
    - api_version: v1
```

The api key can be specified in the master or minion configuration like below:

```yaml
hipchat:
  api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
  api_version: v1
```

salt.states.hipchat.send_message(name, room_id, from_name, message, api_key=None, api_version=None, message_color='yellow', notify=False)

Send a message to a Hipchat room.

```yaml
hipchat-message:
  hipchat.send_message:
    - room_id: 123456
    - from_name: SuperAdmin
    - message: 'This state was executed successfully.'
    - api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
    - api_version: v1
    - color: green
    - notify: True
```

The following parameters are required:

name The unique name for this event.
room_id The room to send the message to. Can either be the ID or the name.
from_name The name of that is to be shown in the "from" field. If not specified, defaults to.
message The message that is to be sent to the Hipchat room.

The following parameters are optional:

api_key The api key for Hipchat to use for authentication, if not specified in the configuration options of master or minion.
**api_version** The api version for Hipchat to use, if not specified in the configuration options of master or minion.

**color** The color the Hipchat message should be displayed in. One of the following, default: yellow "yellow", "red", "green", "purple", "gray", or "random".

**notify** Should a notification in the room be raised.

### 13.16.79 salt.states.host

**Management of addresses and names in hosts file**

The `/etc/hosts` file can be managed to contain definitions for specific hosts:

```
salt-master:
  host.present:
    - ip: 192.168.0.42
```

Or using the `names` directive, you can put several names for the same IP. (Do not try one name with space-separated values).

```
server1:
  host.present:
    - ip: 192.168.0.42
    - names:
      - server1
      - florida
```

**Note:** Changing the `names` in `host.present` does not cause an update to remove the old entry.

```
server1:
  host.present:
    - ip:
      - 192.168.0.42
      - 192.168.0.43
      - 192.168.0.44
    - names:
      - server1
```

You can replace all existing names for a particular IP address:

```
127.0.1.1:
  host.only:
    - hostnames:
      - foo.example.com
      - foo
```

Or delete all existing names for an address:

```
203.0.113.25:
  host.only:
    - hostnames: []
```

**salt.states.host.absent**(name, ip)

Ensure that the named host is absent

name The host to remove
ip  The ip addr(s) of the host to remove

salt.states.host.only(name, hostnames)
Ensure that only the given hostnames are associated with the given IP address.
New in version 2016.3.0.
name  The IP address to associate with the given hostnames.
hostnames  Either a single hostname or a list of hostnames to associate with the given IP address in the given order. Any other hostname associated with the IP address is removed. If no hostnames are specified, all hostnames associated with the given IP address are removed.

salt.states.host.present(name, ip)
Ensures that the named host is present with the given ip
name  The host to assign an ip to
ip  The ip addr(s) to apply to the host

13.16.80 salt.states.htpasswd
Support for htpasswd module. Requires the apache2-utils package for Debian-based distros.
New in version 2014.7.0.

username:
webutil.user_exists:
  - password: secr3t
  - htpasswd_file: /etc/nginx/htpasswd
  - options: d
  - force: true

salt.states.htpasswd.user_exists(name, password=None, htpasswd_file=None, options='`, force=False, runas=None)
Make sure the user is inside the specified htpasswd file
name  User name
password  User password
htpasswd_file  Path to the htpasswd file
options  See salt.modules.htpasswd.useradd
force  Touch the file even if user already created
runas  The system user to run htpasswd command with

13.16.81 salt.states.http
HTTP monitoring states
Perform an HTTP query and statefully return the result
New in version 2015.5.0.

salt.states.http.query(name, match=None, match_type='string', status=None, **kwargs)
Perform an HTTP query and statefully return the result
New in version 2015.5.0.
name  The name of the query.
match  Specifies a pattern to look for in the return text. By default, this will perform a string comparison of looking for the value of match in the return text.
match_type  Specifies the type of pattern matching to use. Default is string, but can also be set to pcre to use regular expression matching if a more complex pattern matching is required.
Note: Despite the name of `match_type` for this argument, this setting actually uses Python's `re.search()` function rather than Python's `re.match()` function.

**status** The status code for a URL for which to be checked. Can be used instead of or in addition to the `match` setting.

If both `match` and `status` options are set, both settings will be checked. However, note that if only one option is `True` and the other is `False`, then `False` will be returned. If this case is reached, the comments in the return data will contain troubleshooting information.

For more information about the `http.query` state, refer to the [HTTP Tutorial](#).

```yaml
def query_example():
    http.query:
        - name: 'http://example.com/'
        - status: '200'
```

### 13.16.82 salt.states.ifttt

**Trigger an event in IFTTT**

This state is useful for triggering events in IFTTT.

New in version 2015.8.0.

```python
ifttt-event:
    ifttt.trigger_event:
        - event: TestEvent
        - value1: 'This state was executed successfully.'
        - value2: 'Another value we can send.'
        - value3: 'A third value we can send.'
```

The api key can be specified in the master or minion configuration like below: .. code-block:: yaml

```yaml
ifttt: secret_key: bzMRb-KKIAaNOwKEEw792J7Eh-B3z7muHdhYbJn4V6
```

**salt.states.ifttt.trigger_event**(name, event, value1=None, value2=None, value3=None)

Trigger an event in IFTTT

```python
ifttt-event:
    ifttt.trigger_event:
        - event: TestEvent
        - value1: 'A value that we want to send.'
        - value2: 'A second value that we want to send.'
        - value3: 'A third value that we want to send.'
```

The following parameters are required:

- **name** The unique name for this event.
- **event** The name of the event to trigger in IFTTT.

The following parameters are optional:

- **value1** One of the values that we can send to IFTTT.
- **value2** One of the values that we can send to IFTTT.
- **value3** One of the values that we can send to IFTTT.
13.16.83 salt.states.incron

Management of incron, the inotify cron

The incron state module allows for user incrontabs to be cleanly managed.

Incron declarations require a number of parameters. The parameters needed to be declared: path, mask, and cmd. The user whose incrontab is to be edited also needs to be defined.

When making changes to an existing incron job, the path declaration is the unique factor, so if an existing cron that looks like this:

```
Watch for modifications in /home/user:
  incron.present:
    - user: root
    - path: /home/user
    - mask:
      - IN_MODIFY
    - cmd: 'echo "$$ $"'
```

Is changed to this:

```
Watch for modifications and access in /home/user:
  incron.present:
    - user: root
    - path: /home/user
    - mask:
      - IN_MODIFY
      - IN_ACCESS
    - cmd: 'echo "$$ $"'
```

Then the existing cron will be updated, but if the cron command is changed, then a new cron job will be added to the user's crontab.

New in version 0.17.0.

salt.states.incron.absent(name, path, mask, cmd, user='root')
  Verifies that the specified incron job is absent for the specified user; only the name is matched when removing a incron job.
  name Unique comment describing the entry
  path The path that should be watched
  user The name of the user who's crontab needs to be modified, defaults to the root user
  mask The mask of events that should be monitored for
  cmd The cmd that should be executed

salt.states.incron.present(name, path, mask, cmd, user='root')
  Verifies that the specified incron job is present for the specified user. For more advanced information about what exactly can be set in the cron timing parameters, check your incron system's documentation. Most Unix-like systems' incron documentation can be found via the incrontab man page: man 5 incrontab.
  name Unique comment describing the entry
  path The path that should be watched
  user The name of the user who's crontab needs to be modified, defaults to the root user
  mask The mask of events that should be monitored for
  cmd The cmd that should be executed
13.16.84 salt.states.influxdb_database

Management of InfluxDB databases

(compatible with InfluxDB version 0.5+)

New in version 2014.7.0.

`salt.states.influxdb_database.absent(name, user=None, password=None, host=None, port=None)`

Ensure that the named database is absent

- **name** The name of the database to remove
- **user** The user to connect as (must be able to remove the database)
- **password** The password of the user
- **host** The host to connect to
- **port** The port to connect to

`salt.states.influxdb_database.present(name, user=None, password=None, host=None, port=None)`

Ensure that the named database is present

- **name** The name of the database to create
- **user** The user to connect as (must be able to remove the database)
- **password** The password of the user
- **host** The host to connect to
- **port** The port to connect to

13.16.85 salt.states.influxdb_user

Management of InfluxDB users

(compatible with InfluxDB version 0.5+)

New in version 2014.7.0.

`salt.states.influxdb_user.absent(name, database=None, user=None, password=None, host=None, port=None)`

Ensure that the named cluster admin or database user is absent.

- **name** The name of the user to remove
- **database** The database to remove the user from
- **user** The user to connect as (must be able to remove the user)
- **password** The password of the user
- **host** The host to connect to
- **port** The port to connect to

`salt.states.influxdb_user.present(name, passwd, database=None, user=None, password=None, host=None, port=None)`

Ensure that the cluster admin or database user is present.

- **name** The name of the user to manage
- **passwd** The password of the user
- **database** The database to create the user in
- **user** The user to connect as (must be able to create the user)
- **password** The password of the user
- **host** The host to connect to
- **port** The port to connect to
13.16.86 salt.states.infoblox module

states for infoblox stuff

ensures a record is either present or absent in an Infoblox DNS system

New in version 2016.3.0.

salt.states.infoblox.absent(name, record_type, dns_view, infoblox_server=None, infoblox_user=None, infoblox_password=None, infoblox_api_version='v1.4.2', sslVerify=True)

Ensure a record does not exist

name Name of the record
record_type record type (host, a, cname, etc)
dns_view DNS View
infoblox_server infoblox server to connect to (will try pillar if not specified)
infoblox_user username to use to connect to infoblox (will try pillar if not specified)
infoblox_password password to use to connect to infoblox (will try pillar if not specified)
verify_ssl verify SSL certificates

Example:

```
some-state:
  infoblox.absent:
    - name: some.dns.record
    - record_type: host
    - dns_view: MyView
    - sslVerify: False
```

salt.states.infoblox.present(name, value, record_type, dns_view, infoblox_server=None, infoblox_user=None, infoblox_password=None, infoblox_api_version='v1.4.2', sslVerify=True)

Ensure a record exists

name Name of the record
value Value of the record
record_type record type (host, a, cname, etc)
dns_view DNS View
infoblox_server infoblox server to connect to (will try pillar if not specified)
infoblox_user username to use to connect to infoblox (will try pillar if not specified)
infoblox_password password to use to connect to infoblox (will try pillar if not specified)
verify_ssl verify SSL certificates

Example:

```
some-state:
  infoblox.present:
    - name: some.dns.record
    - value: 10.1.1.3
    - record_type: host
    - sslVerify: False
```

13.16.87 salt.states.ini_manage

Manage ini files

maintainer <akilesh1597@gmail.com>
maturity new
depends re
platform all

salt.states.ini_manage.options_absent(name, sections=None)

```
/home/saltminion/api-paste.ini:
ini.options_absent:
  - sections:
    test:
      - testkey
      - secondoption
    test1:
      - testkey1
```

options present in file and not specified in sections dict will be untouched
changes dict will contain the list of changes made

salt.states.ini_manage.options_present(name, sections=None)

```
/home/saltminion/api-paste.ini:
in.options_present:
  - sections:
    test:
      testkey: 'testval'
      secondoption: 'secondvalue'
    test1:
      testkey1: 'testval121'
```

options present in file and not specified in sections dict will be untouched
changes dict will contain the list of changes made

salt.states.ini_manage.sections_absent(name, sections=None)

```
/home/saltminion/api-paste.ini:
in.sections_absent:
  - sections:
    - test
    - test1
```

options present in file and not specified in sections will be deleted changes dict will contain the sections that changed

salt.states.ini_manage.sections_present(name, sections=None)

```
/home/saltminion/api-paste.ini:
in.sections_present:
  - sections:
    - section_one
    - section_two
```

This will only create empty sections. To also create options, use options_present state

options present in file and not specified in sections will be deleted changes dict will contain the sections that changed

13.16. state modules
13.16.88 salt.states.ipmi

Manage IPMI devices over LAN

The following configuration defaults can be defined in the minion, master config or pillar:

```
ipmi.config:
  api_host: 127.0.0.1
  api_user: admin
  api_pass: apassword
  api_port: 623
  api_kg: None
```

Every call can override the config defaults:

```
ensure myipmi system is set to network boot:
  ipmi.boot_device:
    - name: network
    - api_host: myipmi.hostname.com
    - api_user: root
    - api_pass: apassword
    - api_kg: None

ensure myipmi system is powered on:
  ipmi.power:
    - name: boot
    - api_host: myipmi.hostname.com
    - api_user: root
    - api_pass: apassword
```

```
salt.states.ipmi.boot_device(name='default', **kwargs)
  Request power state change
  name = default
    - network -- Request network boot
    - hd -- Boot from hard drive
    - safe -- Boot from hard drive, requesting `safe mode`
    - optical -- boot from CD/DVD/BD drive
    - setup -- Boot into setup utility
    - default -- remove any IPMI directed boot device request

  kwargs
    - api_host=localhost
    - api_user=admin
    - api_pass=
    - api_port=623
    - api_kg=None
```

```
salt.states.ipmi.power(name='power_on', wait=300, **kwargs)
  Request power state change
  name
    Ensure power state one of:
      - power_on -- system turn on
      - power_off -- system turn off (without waiting for OS)
      - shutdown -- request OS proper shutdown
      - reset -- reset (without waiting for OS)
```
- boot -- If system is off, then `on', else `reset'

wait wait X seconds for the job to complete before forcing. (defaults to 300 seconds)

kwargs

- api_host=localhost
- api_user=admin
- api_pass=
- api_port=623
- api_kg=None

salt.states.ipmi.user_absent(name, channel=14, **kwargs)
Remove user Delete all user (uid) records having the matching name.
name string name of user to delete
channel channel to remove user access from defaults to 14 for auto.

kwargs

- api_host=localhost
- api_user=admin
- api_pass=
- api_port=623
- api_kg=None

salt.states.ipmi.user_present(name, uid, password, channel=14, callback=False, link_auth=True, ipmi_msg=True, privilege_level='administrator', **kwargs)
Ensure IPMI user and user privileges.
name name of user (limit 16 bytes)
uid user id number (1 to 7)
password user password (limit 16 bytes)
channel ipmi channel defaults to 14 for auto
callback User Restricted to Callback
False = User Privilege Limit is determined by the User Privilege Limit parameter privilege_level, for both callback and non-callback connections.
True = User Privilege Limit is determined by the privilege_level parameter for callback connections, but is restricted to Callback level for non-callback connections. Thus, a user can only initiate a Callback when they `call in' to the BMC, but once the callback connection has been made, the user could potentially establish a session as an Operator.

link_auth User Link authentication True/False user name and password information will be used for link authentication, e.g. PPP CHAP) for the given channel. Link authentication itself is a global setting for the channel and is enabled/disabled via the serial/modem configuration parameters.
ipmi_msg User IPMI Messaging True/False user name and password information will be used for IPMI Messaging. In this case, `IPMI Messaging' refers to the ability to execute generic IPMI commands that are not associated with a particular payload type. For example, if IPMI Messaging is disabled for a user, but that user is enabled for activating the SOL payload type, then IPMI commands associated with SOL and session management, such as Get SOL Configuration Parameters and Close Session are available, but generic IPMI commands such as Get SEL Time are unavailable.) ipmi_msg

privilege_level
- callback
- user
- operator
- administrator
- proprietary
- no_access

kwargs

- api_host=localhost
- api_user=admin
- api_pass=
- api_port=623

13.16. state modules
13.16.89 salt.states.ipset

Management of ipsets

This is an ipset-specific module designed to manage IPSets for use in IPTables Firewalls.

```yaml
setname:
ipset.set_present:
  - set_type: bitmap:ip
  - range: 192.168.0.0/16
  - comment: True

setname:
ipset.set_absent:
  - set_type: bitmap:ip
  - range: 192.168.0.0/16
  - comment: True

setname_entries:
ipset.present:
  - set_name: setname
  - entry: 192.168.0.3
  - comment: Hello
  - require:
    - ipset: baz

setname_entries:
ipset.present:
  - set_name: setname
  - entry:
    - 192.168.0.3
    - 192.168.1.3
  - comment: Hello
  - require:
    - ipset: baz

setname_entries:
ipset.absent:
  - set_name: setname
  - entry:
    - 192.168.0.3
    - 192.168.1.3
  - comment: Hello
  - require:
    - ipset: baz

setname:
ipset.flush:

salt.states.ipset.absent(name, entry=None, entries=None, family='ipv4', **kwargs)
New in version 2014.7.0.

Remove a entry or entries from a chain
name A user-defined name to call this entry by in another part of a state or formula. This should not be an actual entry.
family  Network family, ipv4 or ipv6.

salt.states.ipset.flush(name, family='ipv4', **kwargs)
   New in version 2014.7.0.
   Flush current ipset set
   family  Networking family, either ipv4 or ipv6

salt.states.ipset.present(name, entry=None, family='ipv4', **kwargs)
   New in version 2014.7.0.
   Append a entry to a set
   name  A user-defined name to call this entry by in another part of a state or formula. This should not be an actual entry.
   entry  A single entry to add to a set or a list of entries to add to a set
   family  Networking family, ipv4 or ipv6.

salt.states.ipset.set_absent(name, family='ipv4', **kwargs)
   New in version 2014.7.0.
   Verify the set is absent.
   family  Networking family, either ipv4 or ipv6

salt.states.ipset.set_present(name, set_type, family='ipv4', **kwargs)
   New in version 2014.7.0.
   Verify the chain is exist.
   name  A user-defined set name.
   set_type  The type for the set
   family  Networking family, either ipv4 or ipv6

13.16.90 salt.states.iptables

Management of iptables

This is an iptables-specific module designed to manage Linux firewalls. It is expected that this state module, and other system-specific firewall states, may at some point be deprecated in favor of a more generic firewall state.

```
httpd:
   iptables.append:
      - table: filter
      - chain: INPUT
      - jump: ACCEPT
      - match: state
      - connstate: NEW
      - dport: 80
      - proto: tcp
      - sport: 1025:65535
      - save: True

httpd:
   iptables.append:
      - table: filter
      - chain: INPUT
      - jump: ACCEPT
      - match:
         - state
         - comment
      - comment: "Allow HTTP"
```

13.16. state modules
- connstate: NEW
- dport: 80
- proto: tcp
- sport: 1025:65535
- save: True

httpd:
iptables.append:
  - table: filter
  - chain: INPUT
  - jump: ACCEPT
  - match:
    - state
    - comment
    - comment: "Allow HTTP"
  - connstate: NEW
  - source: '127.0.0.1'
  - dport: 80
  - proto: tcp
  - sport: 1025:65535
  - save: True

.. Invert Rule
httpd:
iptables.append:
  - table: filter
  - chain: INPUT
  - jump: ACCEPT
  - match:
    - state
    - comment
    - comment: "Allow HTTP"
  - connstate: NEW
  - source: '! 127.0.0.1'
  - dport: 80
  - proto: tcp

- connstate: NEW
- dport: 80
- proto: tcp
- sport: 1025:65535
- save: True

httpd:
iptables.delete:
- table: filter
- family: ipv6
- chain: INPUT
- jump: ACCEPT
- match: state
- connstate: NEW
- dport: 80
- proto: tcp
- sport: 1025:65535
- save: True

default to accept:
iptables.set_policy:
- chain: INPUT
- policy: ACCEPT

---

**Note:** Various functions of the `iptables` module use the `--check` option. If the version of `iptables` on the target system does not include this option, an alternate version of this check will be performed using the output of `iptables-save`. This may have unintended consequences on legacy releases of `iptables`.

---

```python
salt.states.iptables.append(name, table='filter', family='ipv4', **kwargs)
```

New in version 0.17.0.

Add a rule to the end of the specified chain.

**name** A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.

**table** The table that owns the chain which should be modified

**family** Network family, ipv4 or ipv6.

All other arguments are passed in with the same name as the long option that would normally be used for `iptables`, with one exception: `--state` is specified as `connstate` instead of `state` (not to be confused with `ctstate`).

Jump options that don't take arguments should be passed in with an empty string.

```python
salt.states.iptables.chain_absent(name, table='filter', family='ipv4')
```
New in version 2014.1.0.

Verify the chain is absent.

**name**
The table to remove the chain from.

**family**
Networking family, either ipv4 or ipv6

```python
salt.states.iptables.chain_present(name, table='filter', family='ipv4')
```

New in version 2014.1.0.

Verify the chain is exist.

**name**
A user-defined chain name.

**table**
The table to own the chain.

**family**
Networking family, either ipv4 or ipv6

```python
salt.states.iptables.delete(name, table='filter', family='ipv4', **kwargs)
```

New in version 2014.1.0.

Delete a rule to a chain

**name**
A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.

**table**
The table that owns the chain that should be modified

**family**
Networking family, either ipv4 or ipv6

All other arguments are passed in with the same name as the long option that would normally be used for `iptables`, with one exception: `--state` is specified as `connstate` instead of `state` (not to be confused with `ctstate`).

Jump options that doesn’t take arguments should be passed in with an empty string.

```python
salt.states.iptables.flush(name, table='filter', family='ipv4', **kwargs)
```

New in version 2014.1.0.

Flush current iptables state

**table**
The table that owns the chain that should be modified

**family**
Networking family, either ipv4 or ipv6

```python
salt.states.iptables.insert(name, table='filter', family='ipv4', **kwargs)
```

New in version 2014.1.0.

Insert a rule into a chain

**name**
A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.

**table**
The table that owns the chain that should be modified

**family**
Networking family, either ipv4 or ipv6

**position**
The numerical representation of where the rule should be inserted into the chain. Note that -1 is not a supported position value.

All other arguments are passed in with the same name as the long option that would normally be used for `iptables`, with one exception: `--state` is specified as `connstate` instead of `state` (not to be confused with `ctstate`).

Jump options that doesn’t take arguments should be passed in with an empty string.

```python
salt.states.iptables.mod_aggregate(low, chunks, running)
```

The mod_aggregate function which looks up all rules in the available low chunks and merges them into a single rules ref in the present low data

```python
salt.states.iptables.set_policy(name, table='filter', family='ipv4', **kwargs)
```

New in version 2014.1.0.

Sets the default policy for iptables firewall tables

**table**
The table that owns the chain that should be modified

**family**
Networking family, either ipv4 or ipv6
policy The requested table policy

13.16.91 salt.states.jboss7

Manage JBoss 7 Application Server via CLI interface

New in version 2015.5.0.

This state uses the jboss-cli.sh script from a JBoss or Wildfly installation and parses its output to determine the execution result.

In order to run each state, a jboss_config dictionary with the following properties must be passed:

```
jboss:
  cli_path: '/opt/jboss/jboss-7.0/bin/jboss-cli.sh'
  controller: 10.11.12.13:9999
  cli_user: 'jbossadm'
  cli_password: 'jbossadm'
```

If the controller doesn’t require a password, then the cli_user and cli_password parameters are optional.

Since same dictionary with configuration will be used in all the states, it may be more convenient to move JBoss configuration and other properties to the pillar.

Example of application deployment from local filesystem:

```
application_deployed:
jboss7.deployed:
  - salt_source:
    target_file: '/tmp/webapp.war'
  - jboss_config: {{ pillar['jboss'] }}
```

For the sake of brevity, examples for each state assume that jboss_config is contained in the pillar.

salt.states.jboss7.bindings_exist(name, jboss_config, bindings, profile=None)

Ensures that given JNDI binding are present on the server. If a binding doesn’t exist on the server it will be created. If it already exists its value will be changed.

**jboss_config:** Dict with connection properties (see state description)

**bindings:** Dict with bindings to set.

**profile:** The profile name (domain mode only)

Example:

```
jndi_entries_created:
jboss7.bindings_exist:
  - bindings:
    'java:global/sampleapp/environment': 'DEV'
    'java:global/sampleapp/configurationFile': '/var/opt/sampleapp/config.'
  - jboss_config: {{ pillar['jboss'] }}
```

salt.states.jboss7.datasource_exists(name, jboss_config, datasource_properties, recreate=False, profile=None)

Ensures that a datasource with given properties exist on the jboss instance. If datasource doesn’t exist, it is created, otherwise only the properties that are different will be updated.

**name** Datasource property name

**jboss_config:** Dict with connection properties (see state description)

**datasource_properties** Dict with datasource properties
**recreate** [False] If set to True and datasource exists it will be removed and created again. However, if there are deployments that depend on the datasource, it will not be possible to remove it.

**profile** [None] The profile name for this datasource (domain mode only)

Example:

```
sampleDS:
  jboss7.datasource_exists:
    - recreate: False
    - datasource_properties:
        driver-name: mysql
        connection-url: 'jdbc:mysql://localhost:3306/sampleDatabase'
        jndi-name: 'java:jboss/datasources/sampleDS'
        user-name: sampleuser
        password: secret
        min-pool-size: 3
        use-java-context: True
    - jboss_config: {{ pillar['jboss'] }}
    - profile: full-ha
```

**salt.states.jboss7.deployed**(name, jboss_config, salt_source=None)

Ensures that the given application is deployed on server.

**jboss_config**: Dict with connection properties (see state description)

**salt_source**: How to find the artifact to be deployed.

**target_file**: Where to look in the minion's file system for the artifact to be deployed (e.g. '/tmp/application-web-0.39.war'). When source is specified, also specifies where to save the retrieved file.

**source**: (optional) File on salt master (e.g. salt://application-web-0.39.war). If absent, no files will be retrieved and the artifact in target_file will be used for the deployment.

**undeploy**: (optional) Regular expression to match against existing deployments. When present, if there is a deployment that matches the regular expression, it will be undeployed before the new artifact is deployed.

Examples:

Deployment of a file from minion's local file system:

```
application_deployed:
    jboss7.deployed:
      - salt_source: '/tmp/webapp.war'
      - target_file: '/tmp/webapp.war'
      - jboss_config: {{ pillar['jboss'] }}
```

It is assumed that /tmp/webapp.war was made available by some other means. No applications will be undeployed; if an existing deployment that shares that name exists, then it will be replaced with the updated version.

Deployment of a file from the Salt master's file system:

```
application_deployed:
    jboss7.deployed:
      - salt_source:
          source: salt://application-web-0.39.war
          target_file: '/tmp/application-web-0.39.war'
          undeploy: 'application-web-.*'
      - jboss_config: {{ pillar['jboss'] }}
```
Here, application-web-0.39.war file is downloaded from Salt file system to /tmp/application-web-0.39.war file on minion. Existing deployments are checked if any of them matches `application-web-.*' regular expression, and if so then it is undeployed before deploying the application. This is useful to automate deployment of new application versions.

If the source parameter of salt_source is specified, it can use any protocol that the file states use. This includes not only downloading from the master but also HTTP, HTTPS, FTP, Amazon S3, and OpenStack Swift.

salt.states.jboss7.reloaded(name, jboss_config, timeout=60, interval=5)
Rello configuration of jboss server.

jboss_config: Dict with connection properties (see state description)

timeout: Time to wait until jboss is back in running state. Default timeout is 60s.

interval: Interval between state checks. Default interval is 5s. Decreasing the interval may slightly decrease waiting time but be aware that every status check is a call to jboss-cli which is a java process. If interval is smaller than process cleanup time it may easily lead to excessive resource consumption.

This step performs the following operations:

- Ensures that server is in running or reload-required state (by reading server-state attribute)
- Reloads configuration
- Waits for server to reload and be in running state

Example:

```
classification_reloaded:
  jboss7.reloaded:
    - jboss_config: {{ pillar['jboss'] }}
```

13.16.92 salt.states.jenkins module

Management of Jenkins

New in version 2016.3.0.

salt.states.jenkins.absent(name, **kwargs)
Ensure the job is present in the Jenkins configured jobs

name: The name of the Jenkins job to remove.

salt.states.jenkins.present(name, config=None, **kwargs)
Ensure the job is present in the Jenkins configured jobs

name: The unique name for the Jenkins job
config: The Salt URL for the file to use for configuring the job.

13.16.93 salt.states.k8s

Manage Kubernetes

New in version 2016.3.0.

```
kube_label_1:
  k8s.label_present:
    - name: mylabel
    - value: myvalue
    - node: myothernodename
    - apiserver: http://mykubeapiserver:8080

kube_label_2:
  k8s.label_absent:
```
- name: mylabel
- node: myothernodename
- apiserver: http://mykubeapiserer:8080

kube_label_3:
  k8s.label_folder_present:
  - name: mylabel
  - node: myothernodename
  - apiserver: http://mykubeapiserer:8080

salt.states.k8s.label_absent(name, node=None, apiserver=None)
Ensure the label doesn't exist on the kube node.
  name  Name of the label.
  node  Override node ID.
  apiserver  K8S apiserver URL.

salt.states.k8s.label_folder_absent(name, node=None, apiserver=None)
Ensure the label folder doesn't exist on the kube node.
  name  Name of the label folder.
  node  Override node ID.
  apiserver  K8S apiserver URL.

salt.states.k8s.label_present(name, value, node=None, apiserver=None)
Ensure the label exists on the kube node.
  name  Name of the label.
  value  Value of the label.
  node  Override node ID.
  apiserver  K8S apiserver URL.

13.16.94  salt.states.keyboard

Management of keyboard layouts

The keyboard layout can be managed for the system:

us:
  keyboard.system

Or it can be managed for XOrg:

us:
  keyboard.xorg

salt.states.keyboard.system(name)
  Set the keyboard layout for the system
  name  The keyboard layout to use

salt.states.keyboard.xorg(name)
  Set the keyboard layout for XOrg
  layout  The keyboard layout to use
13.16.95 salt.states.keystone

Management of Keystone users

depends

- keystoneclient Python module

configuration

See salt.modules.keystone for setup instructions.

salt.states.keystone.endpoint_absent(name, profile=None, **connection_args)

Ensure that the endpoint for a service doesn't exist in Keystone catalog

name The name of the service whose endpoints should not exist

salt.states.keystone.endpoint_present(name, public_url=None, internal_url=None, admin_url=None, region='RegionOne', profile=None, **connection_args)

Ensure the specified endpoints exists for service

name The Service name
public url The public url of service endpoint
internal url The internal url of service endpoint
admin url The admin url of the service endpoint
region The region of the endpoint

salt.states.keystone.role_absent(name, profile=None, **connection_args)

Ensure that the keystone role is absent.

name The name of the role that should not exist

salt.states.keystone.role_present(name, role=None, **connection_args)

Ensure that the keystone role exists

name The name of the role that should be present

salt.states.keystone.service_absent(name, profile=None, **connection_args)

Ensure that the service doesn't exist in Keystone catalog

name The name of the service that should not exist

salt.states.keystone.service_present(name, service_type, description=None, profile=None, **connection_args)

Ensure service present in Keystone catalog

name The name of the service
service_type The type of Openstack Service
description (optional) Description of the service

salt.states.keystone.tenant_absent(name, profile=None, **connection_args)

Ensure that the keystone tenant is absent.

name The name of the tenant that should not exist

class tenant_present

salt.states.keystone.tenant_present(name, description=None, enabled=True, profile=None, **connection_args)

Ensures that the keystone tenant exists

name The name of the tenant to manage
description The description to use for this tenant
enabled Availability state for this tenant

class user_absent

salt.states.keystone.user_absent(name, profile=None, **connection_args)

Ensure that the keystone user is absent.

name The name of the user that should not exist

class user_present

salt.states.keystone.user_present(name, password, email, tenant=None, enabled=True, roles=None, profile=None, password_reset=True, **connection_args)
Ensure that the keystone user is present with the specified properties.

- **name** The name of the user to manage
- **password** The password to use for this user.

**Note:** If the user already exists and a different password was set for the user than the one specified here, the password for the user will be updated. Please set the `password_reset` option to `False` if this is not the desired behavior.

- **password_reset** Whether or not to reset password after initial set. Defaults to `True`.
- **email** The email address for this user
- **tenant** The tenant for this user
- **enabled** Availability state for this user
- **roles** The roles the user should have under given tenants. Passed as a dictionary mapping tenant names to a list of roles in this tenant, i.e.:

```yaml
roles:
  admin: # tenant
    - admin # role
  service:
    - admin
    - Member
```

## 13.16.96 salt.states.kmod

### Loading and unloading of kernel modules

The Kernel modules on a system can be managed cleanly with the kmod state module:

```yaml
add_kvm:
  kmod.present:
    - name: kvm_amd
remove_bEEP:
  kmod.absent:
    - name: pcspkr
```

Multiple modules can be specified for both `kmod.present` and `kmod.absent`.

```yaml
add_sound:
  kmod.present:
    - mods:
      - snd_hda_codec_hdmi
      - snd_hda_codec
      - snd_hwdep
      - snd_hda_core
      - snd_pcm
      - snd_timer
      - snd
```

### salt.states.kmod.absent(

Verify that the named kernel module is not loaded

- **name** The name of the kernel module to verify is not loaded
- **persist** Remove module from `/etc/modules`
- **comment** Comment out module in `/etc/modules` rather than remove it
mods A list of modules to verify are unloaded. If this argument is used, the name argument, although still required, is not used, and becomes a placeholder

New in version 2016.3.0.

call.states.kmod.present(name, persist=False, mods=None)
Ensure that the specified kernel module is loaded
name The name of the kernel module to verify is loaded
persist Also add module to /etc/modules
mods A list of modules to verify are loaded. If this argument is used, the name argument, although still required, is not used, and becomes a placeholder

New in version 2016.3.0.

13.16.97 salt.states.layman

Management of Gentoo Overlays using layman

A state module to manage Gentoo package overlays via layman

sunrise:
  layman.present

salt.states.layman.absent(name)
Verify that the overlay is absent
name The name of the overlay to delete

salt.states.layman.present(name)
Verify that the overlay is present
name The name of the overlay to add

13.16.98 salt.states.ldap

Manage entries in an LDAP database

New in version 2016.3.0.

The states.ldap state module allows you to manage LDAP entries and their attributes.

salt.states.ldap.managed(name, entries, connect_spec=None)
Ensure the existence (or not) of LDAP entries and their attributes

Example:

ldap://:
  ldap.managed:
    - connect_spec:
      bind:
        method: sasl
    - entries:
      # make sure the entry doesn't exist
      - cn=foo,ou=users,dc=example,dc=com:
        - delete_others: True
      # make sure the entry exists with only the specified

13.16. state modules
# attribute values
- cn=admin,dc=example,dc=com:
  - delete_others: True
  - replace:
    cn:
    - admin
description:
    - LDAP administrator
objectClass:
  - simpleSecurityObject
  - organizationalRole
userPassword:
  - {{pillar.ldap_admin_password}}

# make sure the entry exists, its olcRootDN attribute
# has only the specified value, the olcRootDN attribute
# doesn't exist, and all other attributes are ignored
- 'olcDatabase={1}hdb,cn=config':
  - replace:
    olcRootDN:
    - cn=admin,dc=example,dc=com
    # the admin entry has its own password attribute
    olcRootPW: []

# note the use of 'default'. also note how you don't
# have to use list syntax if there is only one attribute
# value
- cn=foo,ou=users,dc=example,dc=com:
  - delete_others: True
  - default:
    userPassword: changeme
    shadowLastChange: 0
    # keep sshPublicKey if present, but don't create
    # the attribute if it is missing
    sshPublicKey: []
  - replace:
    cn: foo
    uid: foo
    uidNumber: 1000
    gidNumber: 1000
    gecos: Foo Bar
    givenName: Foo
    sn: Bar
    homeDirectory: /home/foo
    loginShell: /bin/bash
    objectClass:
    - inetOrgPerson
    - posixAccount
    - top
    - ldapPublicKey
    - shadowAccount

Parameters

- **name** -- The URL of the LDAP server. This is ignored if connect_spec is either a
  connection object or a dict with a 'url' entry.

- **entries** -- A description of the desired state of zero or more LDAP entries.
**entries** is an iterable of dicts. Each of these dict's keys are the distinguished names (DNs) of LDAP entries to manage. Each of these dicts is processed in order. A later dict can reference an LDAP entry that was already mentioned in an earlier dict, which makes it possible for later dicts to enhance or alter the desired state of an LDAP entry.

The DNs are mapped to a description of the LDAP entry's desired state. These LDAP entry descriptions are themselves iterables of dicts. Each dict in the iterable is processed in order. They contain directives controlling the entry's state. The key names the directive type and the value is state information for the directive. The specific structure of the state information depends on the directive type.

The structure of **entries** looks like this:

```python
[{dn1: [{directive1: directive1_state,  
directive2: directive2_state},  
directive3: directive3_state}],  
dn2: [{directive4: directive4_state,  
directive5: directive5_state}],  
{dn3: [{directive6: directive6_state}]}]
```

These are the directives:

- **'delete_others'** Boolean indicating whether to delete attributes not mentioned in this dict or any of the other directive dicts for this DN. Defaults to False.

  If you don't want to delete an attribute if present, but you also don't want to add it if it is missing or modify it if it is present, you can use either the 'default' directive or the 'add' directive with an empty value list.

- **'default'** A dict mapping an attribute name to an iterable of default values for that attribute. If the attribute already exists, it is left alone. If not, it is created using the given list of values.

  An empty value list is useful when you don't want to create an attribute if it is missing but you do want to preserve it if the 'delete_others' key is True.

- **'add'** Attribute values to add to the entry. This is a dict mapping an attribute name to an iterable of values to add.

  An empty value list is useful when you don't want to create an attribute if it is missing but you do want to preserve it if the 'delete_others' key is True.

- **'delete'** Attribute values to remove from the entry. This is a dict mapping an attribute name to an iterable of values to delete from the attribute. If the iterable is empty, all of the attribute's values are deleted.

- **'replace'** Attributes to replace. This is a dict mapping an attribute name to an iterable of values. Any existing values for the attribute are deleted, then the given values are added. The iterable may be empty.

In the above directives, the iterables of attribute values may instead be None, in which case an empty list is used, or a scalar such as a string or number, in which case a new list containing the scalar is used.

Note that if all attribute values are removed from an entry, the entire entry is deleted.

- **connect_spec** -- See the description of the `connect_spec` parameter of the `ldap3.connect` function in the `ldap3` execution module. If this is a dict and
the 'url' entry is not specified, the 'url' entry is set to the value of the name parameter.

Returns

A dict with the following keys:

- 'name' This is the same object passed to the name parameter.
- 'changes' This is a dict describing the changes made (or, in test mode, the changes that would have been attempted). If no changes were made (or no changes would have been attempted), then this dict is empty. Only successful changes are included.

Each key is a DN of an entry that was changed (or would have been changed). Entries that were not changed (or would not have been changed) are not included. The value is a dict with two keys:

  - 'old' The state of the entry before modification. If the entry did not previously exist, this key maps to None. Otherwise, the value is a dict mapping each of the old entry’s attributes to a list of its values before any modifications were made. Unchanged attributes are excluded from this dict.

  - 'new' The state of the entry after modification. If the entry was deleted, this key maps to None. Otherwise, the value is a dict mapping each of the entry’s attributes to a list of its values after the modifications were made. Unchanged attributes are excluded from this dict.

Example 'changes' dict where a new entry was created with a single attribute containing two values:

```
{'dn1': {'old': None,
