Salt Module Index

Index
CHAPTER 1

Installation

This section contains instructions to install Salt. If you are setting up your environment for the first time, you should install a Salt master on a dedicated management server or VM, and then install a Salt minion on each system that you want to manage using Salt. For now you don’t need to worry about your architecture, you can easily add components and modify your configuration later without needing to reinstall anything.

The general installation process is as follows:

1. Install a Salt master using the instructions for your platform or by running the Salt bootstrap script. If you use the bootstrap script, be sure to include the -M option to install the Salt master.
2. Make sure that your Salt minions can find the Salt master.
3. Install the Salt minion on each system that you want to manage.
4. Accept the Salt minion keys after the Salt minion connects.

After this, you should be able to run a simple command and receive returns from all connected Salt minions.

```sh
salt '*' test.ping
```

1.1 Quick Install

On most distributions, you can set up a Salt Minion with the Salt bootstrap.

1.2 Platform-specific Installation Instructions

These guides go into detail how to install Salt on a given platform.

1.2.1 Arch Linux

Installation

Salt (stable) is currently available via the Arch Linux Official repositories. There are currently -git packages available in the Arch User repositories (AUR) as well.
Stable Release

Install Salt stable releases from the Arch Linux Official repositories as follows:

```
pacman -S salt
```

Tracking develop

To install the bleeding edge version of Salt (may include bugs!), use the -git package. Installing the -git package as follows:

```
wget https://aur.archlinux.org/packages/sa/salt-git/salt-git.tar.gz
tar xf salt-git.tar.gz
cd salt-git/
makpkg -is
```

Note: yaourt

If a tool such as Yaourt is used, the dependencies will be gathered and built automatically.

The command to install salt using the yaourt tool is:

```
yaourt salt-git
```

Post-installation tasks

systemd

Activate the Salt Master and/or Minion via systemctl as follows:

```
systemctl enable salt-master.service
systemctl enable salt-minion.service
```

Start the Master

Once you’ve completed all of these steps you’re ready to start your Salt Master. You should be able to start your Salt Master now using the command seen here:

```
systemctl start salt-master
```

Now go to the Configuring Salt page.

1.2.2 Debian GNU/Linux / Raspbian

Debian GNU/Linux distribution and some derivatives such as Raspbian already have included Salt packages to their repositories. However, current stable release codenamed “Jessie” contains old outdated Salt release. It is recommended to use SaltStack repository for Debian as described below.

Installation from official Debian and Raspbian repositories is described here.
Installation from the Official SaltStack Repository

Packages for Debian 8 (Jessie) and Debian 7 (Wheezy) are available in the Official SaltStack repository. Instructions are at https://repo.saltstack.com/#debian.

Note: Regular security support for Debian 7 ended on April 25th 2016. As a result, 2016.3.1 and 2015.8.10 will be the last Salt releases for which Debian 7 packages are created.

Installation from the Debian / Raspbian Official Repository

Stretch (Testing) and Sid (Unstable) distributions are already contain mostly up-to-date Salt packages built by Debian Salt Team. You can install Salt components directly from Debian.

On Jessie (Stable) there is an option to install Salt minion from Stretch with python-tornado dependency from jessie-backports repositories.

To install fresh release of Salt minion on Jessie:

1. Add jessie-backports and stretch repositories:

   Debian:
   ```bash
   echo 'deb http://httpredir.debian.org/debian jessie-backports main' >> /etc/apt/sources.list
   echo 'deb http://httpredir.debian.org/debian stretch main' >> /etc/apt/sources.list
   ```

   Raspbian:
   ```bash
   echo 'deb http://archive.raspbian.org/raspbian/ stretch main' >> /etc/apt/sources.list
   ```

2. Make Jessie a default release:

   ```bash
   echo 'APT::Default-Release "jessie";' > /etc/apt/apt.conf.d/10apt
   ```

3. Install Salt dependencies:

   Debian:
   ```bash
   apt-get update
   apt-get install python-zmq python-tornado/jessie-backports salt-common/stretch
   ```

   Raspbian:
   ```bash
   apt-get update
   apt-get install python-zmq python-tornado/stretch salt-common/stretch
   ```

4. Install Salt minion package from Stretch:

   ```bash
   apt-get install salt-minion/stretch
   ```

Install Packages

Install the Salt master, minion or other packages from the repository with the apt-get command. These examples each install one of Salt components, but more than one package name may be given at a time:
• apt-get install salt-api
• apt-get install salt-cloud
• apt-get install salt-master
• apt-get install salt-minion
• apt-get install salt-ssh
• apt-get install salt-syndic

Post-installation tasks

Now, go to the Configuring Salt page.

1.2.3 Fedora

Beginning with version 0.9.4, Salt has been available in the primary Fedora repositories and EPEL. It is installable using yum or dnf, depending on your version of Fedora.

Note: Released versions of Salt starting with 2015.5.2 through 2016.3.2 do not have Fedora packages available though EPEL. To install a version of Salt within this release array, please use SaltStack’s Bootstrap Script and use the git method of installing Salt using the version's associated release tag.

Release 2016.3.3 and onward will have packaged versions available via EPEL.

WARNING: Fedora 19 comes with systemd 204. Systemd has known bugs fixed in later revisions that prevent the salt-master from starting reliably or opening the network connections that it needs to. It's not likely that a salt-master will start or run reliably on any distribution that uses systemd version 204 or earlier. Running salt-minions should be OK.

Installation

Salt can be installed using yum and is available in the standard Fedora repositories.

Stable Release

Salt is packaged separately for the minion and the master. It is necessary only to install the appropriate package for the role the machine will play. Typically, there will be one master and multiple minions.

```
yum install salt-master
yum install salt-minion
```

Installing from updates-testing

When a new Salt release is packaged, it is first admitted into the updates-testing repository, before being moved to the stable repo.

To install from updates-testing, use the enablerepo argument for yum:
yum --enablerepo=updates-testing install salt-master
yum --enablerepo=updates-testing install salt-minion

Installation Using pip

Since Salt is on PyPI, it can be installed using pip, though most users prefer to install using a package manager.

Installing from pip has a few additional requirements:

• Install the group `Development Tools'; `dnf groupinstall 'Development Tools'

• Install the `zeromq-devel' package if it fails on linking against that afterwards as well.

A pip install does not make the init scripts or the /etc/salt directory, and you will need to provide your own systemd service unit.

Installation from pip:

pip install salt

Warning: If installing from pip (or from source using setup.py install), be advised that the yum-utils package is needed for Salt to manage packages. Also, if the Python dependencies are not already installed, then you will need additional libraries/tools installed to build some of them. More information on this can be found here.

Post-installation tasks

Master
To have the Master start automatically at boot time:

systemctl enable salt-master.service

To start the Master:

systemctl start salt-master.service

Minion
To have the Minion start automatically at boot time:

systemctl enable salt-minion.service

To start the Minion:

systemctl start salt-minion.service

Now go to the Configuring Salt page.
1.2.4 FreeBSD

Installation

Salt is available in binary package form from both the FreeBSD pkgng repository or directly from SaltStack. The instructions below outline installation via both methods:

FreeBSD repo

The FreeBSD pkgng repository is preconfigured on systems 10.x and above. No configuration is needed to pull from these repositories.

```
pkg install py27-salt
```

These packages are usually available within a few days of upstream release.

SaltStack repo

SaltStack also hosts internal binary builds of the Salt package, available from https://repo.saltstack.com/freebsd/. To make use of this repository, add the following file to your system:

```
/usr/local/etc/pkg/repos/saltstack.conf:
```

```
saltstack: {
  url: "https://repo.saltstack.com/freebsd/${ABI}/",
  enabled: yes
}
```

You should now be able to install Salt from this new repository:

```
pkg install py27-salt
```

These packages are usually available earlier than upstream FreeBSD. Also available are release candidates and development releases. Use these pre-release packages with caution.

Post-installation tasks

Master

Copy the sample configuration file:

```
cp /usr/local/etc/salt/master.sample /usr/local/etc/salt/master
```

rc.conf

Activate the Salt Master in /etc/rc.conf:

```
sysrc salt_master_enable="YES"
```

Start the Master

Start the Salt Master as follows:

```
service salt_master start
```
Minion
Copy the sample configuration file:

```
cp /usr/local/etc/salt/minion.sample /usr/local/etc/salt/minion
```

rc.conf
Activate the Salt Minion in /etc/rc.conf:

```
sysrc salt_minion_enable="YES"
```

Start the Minion
Start the Salt Minion as follows:

```
service salt_minion start
```

Now go to the Configuring Salt page.

### 1.2.5 Gentoo
Salt can be easily installed on Gentoo via Portage:

```
emerge app-admin/salt
```

Post-installation tasks
Now go to the Configuring Salt page.

### 1.2.6 OpenBSD
Salt was added to the OpenBSD ports tree on Aug 10th 2013. It has been tested on OpenBSD 5.5 onwards.
Salt is dependent on the following additional ports. These will be installed as dependencies of the sysutils/salt port:

```text
devel/py-futures
devel/py-progressbar
net/py-msgpack
net/py-zmq
security/py-crypto
security/py-M2Crypto
textproc/py-MarkupSafe
textproc/py-yaml
www/py-jinja2
www/py-requests
www/py-tornado
```

Installation
To install Salt from the OpenBSD pkg repo, use the command:
pkg_add salt

Post-installation tasks

Master
To have the Master start automatically at boot time:

```
rcctl enable salt_master
```

To start the Master:

```
rcctl start salt_master
```

Minion
To have the Minion start automatically at boot time:

```
rcctl enable salt_minion
```

To start the Minion:

```
rcctl start salt_minion
```

Now go to the Configuring Salt page.

1.2.7 OS X

Installation from the Official SaltStack Repository

Latest stable build from the selected branch:
The output of `md5 <salt pkg>` should match the contents of the corresponding md5 file.

Earlier builds from supported branches
Archived builds from unsupported branches

Installation from Homebrew

```
brew install saltstack
```

It should be noted that Homebrew explicitly discourages the use of sudo:

Homebrew is designed to work without using sudo. You can decide to use it but we strongly recommend not to do so. If you have used sudo and run into a bug then it is likely to be the cause. Please don't file a bug report unless you can reproduce it after reinstalling Homebrew from scratch without using sudo

Installation from MacPorts

```
sudo port install salt
```
Installation from Pip

When only using the OS X system's pip, install this way:

```
sudo pip install salt
```

Salt-Master Customizations

**Note:** Salt master on OS X is not tested or supported by SaltStack. See SaltStack Platform Support for more information.

To run salt-master on OS X, sudo add this configuration option to the `/etc/salt/master` file:

```
max_open_files: 8192
```

On versions previous to OS X 10.10 (Yosemite), increase the root user maxfiles limit:

```
sudo launchctl limit maxfiles 4096 8192
```

**Note:** On OS X 10.10 (Yosemite) and higher, maxfiles should not be adjusted. The default limits are sufficient in all but the most extreme scenarios. Overriding these values with the setting below will cause system instability!

Now the salt-master should run without errors:

```
sudo salt-master --log-level=all
```

Post-installation tasks

Now go to the Configuring Salt page.

### 1.2.8 RHEL / CentOS / Scientific Linux / Amazon Linux / Oracle Linux

Salt should work properly with all mainstream derivatives of Red Hat Enterprise Linux, including CentOS, Scientific Linux, Oracle Linux, and Amazon Linux. Report any bugs or issues on the [issue tracker](#).

**Installation from the Official SaltStack Repository**

Packages for Redhat, CentOS, and Amazon Linux are available in the SaltStack Repository.

- Red Hat / CentOS
- Amazon Linux

**Note:** As of 2015.8.0, EPEL repository is no longer required for installing on RHEL systems. SaltStack repository provides all needed dependencies.
Warning: If installing on Red Hat Enterprise Linux 7 with disabled (not subscribed on) 'RHEL Server Releases' or 'RHEL Server Optional Channel' repositories, append CentOS 7 GPG key URL to SaltStack yum repository configuration to install required base packages:

```
[saltstack-repo]
name=SaltStack repo for Red Hat Enterprise Linux $releasever
baseurl=https://repo.saltstack.com/yum/redhat/$releasever/$basearch/latest
enabled=1
gpgcheck=1
gpgkey=https://repo.saltstack.com/yum/redhat/$releasever/$basearch/latest/SALTSTACK-GPG-KEY.pub
```

Note: systemd and systemctl-python are required by Salt, but are not installed by the Red Hat 7 @base installation or by the Salt installation. These dependencies might need to be installed before Salt.

Installation from the Community-Maintained Repository

Beginning with version 0.9.4, Salt has been available in EPEL. For RHEL/CentOS 5, Fedora COPR is a single community repository that provides Salt packages due to the removal from EPEL5.

Note: Packages in these repositories are built by community, and it can take a little while until the latest stable SaltStack release become available.

RHEL/CentOS 6 and 7, Scientific Linux, etc.

Warning: Salt 2015.8 is currently not available in EPEL due to unsatisfied dependencies: python-crypto 2.6.1 or higher, and python-tornado version 4.2.1 or higher. These packages are not currently available in EPEL for Red Hat Enterprise Linux 6 and 7.

Enabling EPEL

If the EPEL repository is not installed on your system, you can download the RPM for RHEL/CentOS 6 or for RHEL/CentOS 7 and install it using the following command:

```
rpm -Uvh epel-release-X-Y.rpm
```

Replace `epel-release-X-Y.rpm` with the appropriate filename.

Installing Stable Release

Salt is packaged separately for the minion and the master. It is necessary to install only the appropriate package for the role the machine will play. Typically, there will be one master and multiple minions.

• yum install salt-master
• yum install salt-minion
• yum install salt-ssh
• yum install salt-syndic
• yum install salt-cloud

**Installing from epel-testing**

When a new Salt release is packaged, it is first admitted into the epel-testing repository, before being moved to the stable EPEL repository.

To install from epel-testing, use the enablerepo argument for yum:

```
yum --enablerepo=epel-testing install salt-minion
```

**Installation Using pip**

Since Salt is on PyPI, it can be installed using pip, though most users prefer to install using RPM packages (which can be installed from EPEL).

Installing from pip has a few additional requirements:

- Install the group `Development Tools', `yum groupinstall 'Development Tools'
- Install the `zeromq-devel' package if it fails on linking against that afterwards as well.

A pip install does not make the init scripts or the /etc/salt directory, and you will need to provide your own systemd service unit.

Installation from pip:

```
pip install salt
```

**Warning:** If installing from pip (or from source using `setup.py install`), be advised that the `yum-utils` package is needed for Salt to manage packages. Also, if the Python dependencies are not already installed, then you will need additional libraries/tools installed to build some of them. More information on this can be found [here](#).

**ZeroMQ 4**

We recommend using ZeroMQ 4 where available. SaltStack provides ZeroMQ 4.0.5 and pyzmq 14.5.0 in the `SaltStack Repository` as well as a separate `zeromq4 COPR` repository.

If this repository is added before Salt is installed, then installing either salt-master or salt-minion will automatically pull in ZeroMQ 4.0.5, and additional steps to upgrade ZeroMQ and pyzmq are unnecessary.

**Warning:** RHEL/CentOS 5 Users Using COPR repos on RHEL/CentOS 5 requires that the `python-hashlib` package be installed. Not having it present will result in checksum errors because YUM will not be able to process the SHA256 checksums used by COPR.
For RHEL/CentOS 5 installations, if using the SaltStack repo or Fedora COPR to install Salt (as described above), then it is not necessary to enable the zeromq4 COPR, because those repositories already include ZeroMQ 4.

Package Management

Salt's interface to *yum* makes heavy use of the *repoquery* utility, from the *yum-utils* package. This package will be installed as a dependency if salt is installed via EPEL. However, if salt has been installed using pip, or a host is being managed using salt-ssh, then as of version 2014.7.0 *yum-utils* will be installed automatically to satisfy this dependency.

Post-installation tasks

Master

To have the Master start automatically at boot time:

RHEL/CentOS 5 and 6

```
chkconfig salt-master on
```

RHEL/CentOS 7

```
systemctl enable salt-master.service
```

To start the Master:

RHEL/CentOS 5 and 6

```
service salt-master start
```

RHEL/CentOS 7

```
 systemctl start salt-master.service
```

Minion

To have the Minion start automatically at boot time:

RHEL/CentOS 5 and 6

```
chkconfig salt-minion on
```

RHEL/CentOS 7

```
 systemctl enable salt-minion.service
```

To start the Minion:

RHEL/CentOS 5 and 6

```
 service salt-minion start
```

RHEL/CentOS 7
systemctl start salt-minion.service

Now go to the Configuring Salt page.

1.2.9 Solaris

Salt was added to the OpenCSW package repository in September of 2012 by Romeo Theriault <romeot@hawaii.edu> at version 0.10.2 of Salt. It has mainly been tested on Solaris 10 (sparc), though it is built for and has been tested minimally on Solaris 10 (x86), Solaris 9 (sparc/x86) and 11 (sparc/x86). (Please let me know if you’re using it on these platforms!) Most of the testing has also just focused on the minion, though it has verified that the master starts up successfully on Solaris 10.

Comments and patches for better support on these platforms is very welcome.

As of version 0.10.4, Solaris is well supported under salt, with all of the following working well:

1. remote execution
2. grain detection
3. service control with SMF
4. ’pkg’ states with `pkgadd` and `pkgutil` modules
5. cron modules/states
6. user and group modules/states
7. shadow password management modules/states

Salt is dependent on the following additional packages. These will automatically be installed as dependencies of the py_salt package:

- py_yaml
- py_pyzmq
- py_jinja2
- py_msgpack_python
- py_m2crypto
- py_crypto
- python

Installation

To install Salt from the OpenCSW package repository you first need to install pkgutil assuming you don’t already have it installed:

On Solaris 10:

```
pkgadd -d http://get.opencsw.org/now
```

On Solaris 9:

```
wget http://mirror.opencsw.org/opencsw/pkgutil.pkg
pkgadd -d pkgutil.pkg all
```
Once pkgutil is installed you’ll need to edit it’s config file `/etc/opt/csw/pkgutil.conf` to point it at the unstable catalog:

```
- #mirror=http://mirror.opencsw.org/opencsw/testing
+ mirror=http://mirror.opencsw.org/opencsw/unstable
```

OK, time to install salt.

```
# Update the catalog
going> /opt/csw/bin/pkgutil -U
# Install salt
going> /opt/csw/bin/pkgutil -i -y py_salt
```

**Minion Configuration**

Now that salt is installed you can find it’s configuration files in `/etc/opt/csw/salt/`.

You’ll want to edit the minion config file to set the name of your salt master server:

```
- #master: salt
+ master: your-salt-server
```

If you would like to use pkgutil as the default package provider for your Solaris minions, you can do so using the `providers` option in the minion config file.

You can now start the salt minion like so:

On Solaris 10:

```
svcadm enable salt-minion
```

On Solaris 9:

```
/etc/init.d/salt-minion start
```

You should now be able to log onto the salt master and check to see if the salt-minion key is awaiting acceptance:

```
salt-key -l un
```

Accept the key:

```
salt-key -a <your-salt-minion>
```

Run a simple test against the minion:

```
salt '<your-salt-minion>' test.ping
```

**Troubleshooting**

Logs are in `/var/log/salt`
1.2.10 Ubuntu

Installation from the Official SaltStack Repository

Packages for Ubuntu 16 (Xenial), Ubuntu 14 (Trusty), and Ubuntu 12 (Precise) are available in the SaltStack repository. Instructions are at https://repo.saltstack.com/#ubuntu.

Install Packages

Install the Salt master, minion or other packages from the repository with the `apt-get` command. These examples each install one of Salt components, but more than one package name may be given at a time:

- `apt-get install salt-api`
- `apt-get install salt-cloud`
- `apt-get install salt-master`
- `apt-get install salt-minion`
- `apt-get install salt-ssh`
- `apt-get install salt-syndic`

Post-installation tasks

Now go to the Configuring Salt page.

1.2.11 Windows

Salt has full support for running the Salt Minion on Windows.

You must connect Windows Salt minions to a Salt master on a supported operating system to control your Salt Minions.

Many of the standard Salt modules have been ported to work on Windows and many of the Salt States currently work on Windows as well.

Installation from the Official SaltStack Repository

Latest stable build from the selected branch:

The output of `md5sum <salt minion exe>` should match the contents of the corresponding md5 file.

Earlier builds from supported branches

Archived builds from unsupported branches

Note: The installation executable installs dependencies that the Salt minion requires.

The 64bit installer has been tested on Windows 7 64bit and Windows Server 2008R2 64bit. The 32bit installer has been tested on Windows 2008 Server 32bit. Please file a bug report on our GitHub repo if issues for other platforms are found.
The installer asks for 2 bits of information; the master hostname and the minion name. The installer will update the minion config with these options and then start the minion.

The `salt-minion` service will appear in the Windows Service Manager and can be started and stopped there or with the command line program `sc` like any other Windows service.

```
sc start salt-minion
net start salt-minion
```

If the minion won't start, try installing the Microsoft Visual C++ 2008 x64 SP1 redistributable. Allow all Windows updates to run salt-minion smoothly.

### Installation Prerequisites

Most Salt functionality should work just fine right out of the box. A few Salt modules rely on PowerShell. The minimum version of PowerShell required for Salt is version 3. If you intend to work with DSC then Powershell version 5 is the minimum.

### Silent Installer Options

The installer can be run silently by providing the `/S` option at the command line. The installer also accepts the following options for configuring the Salt Minion silently:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/minion-name=</td>
<td>A string value to set the minion name. Default is <code>hostname</code></td>
</tr>
<tr>
<td>/master=</td>
<td>A string value to set the IP address or host name of the master. Default value is <code>salt</code></td>
</tr>
<tr>
<td>/start-service=</td>
<td>Either a 1 or 0. <code>1</code> will start the service, <code>0</code> will not. Default is to start the service after installation.</td>
</tr>
</tbody>
</table>

Here's an example of using the silent installer:

```
Salt-Minion-2016.3.3-Setup-amd64.exe /S /master=yoursaltmaster /minion-name=yourminionname /start-service=0
```

### Running the Salt Minion on Windows as an Unprivileged User

**Notes:**

- These instructions were tested with Windows Server 2008 R2
- They are generalizable to any version of Windows that supports a salt-minion

**Create the Unprivileged User that the Salt Minion will Run As**

1. Click Start > Control Panel > User Accounts.
2. Click Add or remove user accounts.
3. Click Create new account.
4. Enter salt-user (or a name of your preference) in the New account name field.
5. Select the Standard user radio button.
6. Click the Create Account button.
7. Click on the newly created user account.

8. Click the Create a password link.

9. In the New password and Confirm new password fields, provide a password (e.g. `SuperSecretMinionPassword4Me!`).

10. In the Type a password hint field, provide appropriate text (e.g. `My Salt Password`).

11. Click the Create password button.

12. Close the Change an Account window.

Add the New User to the Access Control List for the Salt Folder

1. In a File Explorer window, browse to the path where Salt is installed (the default path is C:\Salt).

2. Right-click on the Salt folder and select Properties.

3. Click on the Security tab.

4. Click the Edit button.

5. Click the Add button.

6. Type the name of your designated Salt user and click the OK button.

7. Check the box to Allow the Modify permission.

8. Click the OK button.

9. Click the OK button to close the Salt Properties window.

Update the Windows Service User for the salt-minion Service

1. Click Start > Administrative Tools > Services.

2. In the Services list, right-click on salt-minion and select Properties.

3. Click the Log On tab.

4. Click the This account radio button.

5. Provide the account credentials created in section A.

6. Click the OK button.

7. Click the OK button to the prompt confirming that the user has been granted the Log On As A Service right.

8. Click the OK button to the prompt confirming that The new logon name will not take effect until you stop and restart the service.

9. Right-Click on salt-minion and select Stop.

10. Right-Click on salt-minion and select Start.
### Building and Developing on Windows

This document will explain how to set up a development environment for Salt on Windows. The development environment allows you to work with the source code to customize or fix bugs. It will also allow you to build your own installation.

There are several scripts to automate creating a Windows installer as well as setting up an environment that facilitates developing and troubleshooting Salt code. They are located in the `pkg\windows` directory in the Salt repo [here](#).

**Scripts:**

<table>
<thead>
<tr>
<th>Script</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>build_env.ps1</code></td>
<td>A PowerShell script that sets up the build environment</td>
</tr>
<tr>
<td><code>build_pkg.bat</code></td>
<td>A batch file that builds a Windows installer based on the contents of the <code>C:\Python27</code> directory</td>
</tr>
<tr>
<td><code>build.bat</code></td>
<td>A batch file that fully automates the building of the Windows installer using the above two scripts</td>
</tr>
</tbody>
</table>

Note: The `build.bat` and `build_pkg.bat` scripts both accept a single parameter to specify the version of Salt that will be displayed in the Windows installer. If no version is passed, the version will be determined using git.

**Prerequisite Software**

The only prerequisite is [Git for Windows](#).

**Create a Build Environment**

1. **Working Directory**

Create a `Salt-Dev` directory on the root of `C:`. This will be our working directory. Navigate to `Salt-Dev` and clone the Salt repo from GitHub.

Open a command line and type:

```bash
cd "\ md Salt-Dev
cd Salt-Dev
git clone https://github.com/saltstack/salt
```

Go into the `salt` directory and checkout the version of salt to work with (2016.3 or higher).

```bash
cd salt
git checkout 2016.3
```

2. **Setup the Python Environment**

Navigate to the `pkg\windows` directory and execute the `build_env.ps1` PowerShell script.

```bash
cd pkg\windows
powershell -file build_env.ps1
```
Note: You can also do this from Explorer by navigating to the pkg\windows directory, right clicking the build_env.ps1 powershell script and selecting Run with PowerShell

This will download and install Python with all the dependencies needed to develop and build Salt.

Note: If you get an error or the script fails to run you may need to change the execution policy. Open a powershell window and type the following command:

```bash
Set-ExecutionPolicy RemoteSigned
```

3. Salt in Editable Mode

Editable mode allows you to more easily modify and test the source code. For more information see the Pip documentation.

Navigate to the root of the salt directory and install Salt in editable mode with pip

```bash
cd \Salt-Dev\salt
pip install -e .
```

Note: The . is important

Note: If pip is not recognized, you may need to restart your shell to get the updated path

4. Setup Salt Configuration

Salt requires a minion configuration file and a few other directories. The default config file is named minion located in C:salt\conf. The easiest way to set this up is to copy the contents of the salt\pkg\windows\buildenv directory to C:salt.

```bash
cd \
md salt
xcopy /s /e \Salt-Dev\salt\pkg\windows\buildenv\* \salt\n```

Now go into the C:salt\conf directory and edit the file name minion (no extension). You need to configure the master and id parameters in this file. Edit the following lines:

```
master: <ip or name of your master>
id: <name of your minion>
```

Create a Windows Installer

To create a Windows installer, follow steps 1 and 2 from Create a Build Environment above. Then proceed to 3 below:
3. Install Salt

To create the installer for Windows we install Salt using Python instead of pip. Navigate to the root \salt directory and install Salt.

```bash
cd \Salt-Dev\salt
python setup.py install
```

4. Create the Windows Installer

Navigate to the pkg\windows directory and run the `build_pkg.bat` with the build version (2016.3) script.

```bash
cd pkg\windows
build_pkg.bat 2016.3
```

Note: If no version is passed, the `build_pkg.bat` will guess the version number using git.

Creating a Windows Installer: Alternate Method (Easier)

Clone the Salt repo from GitHub into the directory of your choice. We're going to use Salt-Dev.

```bash
cd \md Salt-Dev
cd Salt-Dev
git clone https://github.com/saltstack/salt
```

Go into the salt directory and checkout the version of Salt you want to build.

```bash
cd salt
git checkout 2016.3
```

Then navigate to pkg\windows and run the `build.bat` script with the version you're building.

```bash
cd pkg\windows
build.bat 2016.3
```

This will install everything needed to build a Windows installer for Salt. The binary will be in the salt\pkg\windows\installer directory.

Testing the Salt minion

1. Create the directory C:\salt (if it doesn’t exist already)
2. Copy the example conf and var directories from pkg\windows\buildenv into C:\salt
3. Edit C:\salt\conf\minion
   ```text
   master: ipaddress or hostname of your salt-master
   ```
4. Start the salt-minion
5. On the salt-master accept the new minion's key

```
sudo salt-key -A
```

This accepts all unaccepted keys. If you're concerned about security just accept the key for this specific minion.

6. Test that your minion is responding

On the salt-master run:

```
sudo salt '*' test.ping
```

You should get the following response: `{ 'your minion hostname': True }`

---

**Packages Management Under Windows 2003**

Windows Server 2003 and Windows XP have both reached End of Support. Though Salt is not officially supported on operating systems that are EoL, some functionality may continue to work.

On Windows Server 2003, you need to install optional component `WMI Windows Installer Provider` to get a full list of installed packages. If you don't have this, salt-minion can't report some installed software.

---

**1.2.12 SUSE**

**Installation from the Official SaltStack Repository**

Packages for SUSE 12 SP1, SUSE 12, SUSE 11, openSUSE 13 and openSUSE Leap 42.1 are available in the SaltStack Repository.

Instructions are at https://repo.saltstack.com/#suse.

**Installation from the SUSE Repository**

Since openSUSE 13.2, Salt 2014.1.11 is available in the primary repositories. With the release of SUSE manager 3 a new repository setup has been created. The new repo will by systemsmanagement:saltstack, which is the source for newer stable packages. For backward compatibility a linkpackage will be created to the old devel:language:python repo. All development of suse packages will be done in systemsmanagement:saltstack:testing. This will ensure that salt will be in mainline suse repo's, a stable release repo and a testing repo for further enhancements.

**Installation**

Salt can be installed using `zypper` and is available in the standard openSUSE/SLES repositories.

**Stable Release**

Salt is packaged separately for the minion and the master. It is necessary only to install the appropriate package for the role the machine will play. Typically, there will be one master and multiple minions.
zypper install salt-master
zypper install salt-minion

Post-installation tasks openSUSE

Master
To have the Master start automatically at boot time:

```bash
systemctl enable salt-master.service
```

To start the Master:

```bash
systemctl start salt-master.service
```

Minion
To have the Minion start automatically at boot time:

```bash
systemctl enable salt-minion.service
```

To start the Minion:

```bash
systemctl start salt-minion.service
```

Post-installation tasks SLES

Master
To have the Master start automatically at boot time:

```bash
chkconfig salt-master on
```

To start the Master:

```bash
rcsalt-master start
```

Minion
To have the Minion start automatically at boot time:

```bash
chkconfig salt-minion on
```

To start the Minion:

```bash
rcsalt-minion start
```

Unstable Release

openSUSE

For openSUSE Tumbleweed run the following as root:
zypper addrepo http://download.opensuse.org/repositories/systemsmanagement:/saltstack/ openSUSE_Tumbleweed/systemsmanagement:saltstack.repo
zypper refresh
zypper install salt salt-minion salt-master

For openSUSE 42.1 Leap run the following as root:
zypper addrepo http://download.opensuse.org/repositories/systemsmanagement:/saltstack/ openSUSE_Leap_42.1/systemsmanagement:saltstack.repo
zypper refresh
zypper install salt salt-minion salt-master

For openSUSE 13.2 run the following as root:
zypper addrepo http://download.opensuse.org/repositories/systemsmanagement:/saltstack/ openSUSE_13.2/systemsmanagement:saltstack.repo
zypper refresh
zypper install salt salt-minion salt-master

Suse Linux Enterprise

For SLE 12 run the following as root:
zypper addrepo http://download.opensuse.org/repositories/systemsmanagement:/saltstack/ SLE_12/systemsmanagement:saltstack.repo
zypper refresh
zypper install salt salt-minion salt-master

For SLE 11 SP4 run the following as root:
zypper addrepo http://download.opensuse.org/repositories/systemsmanagement:/saltstack/ SLE_11_SP4/systemsmanagement:saltstack.repo
zypper refresh
zypper install salt salt-minion salt-master

Now go to the Configuring Salt page.

1.3 Initial Configuration

1.3.1 Configuring Salt

Salt configuration is very simple. The default configuration for the master will work for most installations and the only requirement for setting up a minion is to set the location of the master in the minion configuration file.

The configuration files will be installed to /etc/salt and are named after the respective components, /etc/salt/master, and /etc/salt/minion.

Master Configuration

By default the Salt master listens on ports 4505 and 4506 on all interfaces (0.0.0.0). To bind Salt to a specific IP, redefine the "interface" directive in the master configuration file, typically /etc/salt/master, as follows:
After updating the configuration file, restart the Salt master. See the master configuration reference for more details about other configurable options.

Minion Configuration

Although there are many Salt Minion configuration options, configuring a Salt Minion is very simple. By default a Salt Minion will try to connect to the DNS name `salt`; if the Minion is able to resolve that name correctly, no configuration is needed.

If the DNS name `salt` does not resolve to point to the correct location of the Master, redefine the `master` directive in the minion configuration file, typically `/etc/salt/minion`, as follows:

```
- #master: salt
+ master: 10.0.0.1
```

After updating the configuration file, restart the Salt minion. See the minion configuration reference for more details about other configurable options.

Running Salt

1. Start the master in the foreground (to daemonize the process, pass the `-d` flag):

   ```
salt-master
   ```

2. Start the minion in the foreground (to daemonize the process, pass the `-d` flag):

   ```
salt-minion
   ```

Having trouble?

The simplest way to troubleshoot Salt is to run the master and minion in the foreground with `log level` set to `debug`:

```
salt-master --log-level=debug
```

For information on salt's logging system please see the logging document.

Run as an unprivileged (non-root) user

To run Salt as another user, set the `user` parameter in the master config file.

Additionally, ownership, and permissions need to be set such that the desired user can read from and write to the following directories (and their subdirectories, where applicable):

- `/etc/salt`
- `/var/cache/salt`
- `/var/log/salt`
- `/var/run/salt`
More information about running salt as a non-privileged user can be found here.

There is also a full troubleshooting guide available.

**Key Identity**

Salt provides commands to validate the identity of your Salt master and Salt minions before the initial key exchange. Validating key identity helps avoid inadvertently connecting to the wrong Salt master, and helps prevent a potential MiTM attack when establishing the initial connection.

**Master Key Fingerprint**

Print the master key fingerprint by running the following command on the Salt master:

```
salt-key -F master
```

Copy the master.pub fingerprint from the Local Keys section, and then set this value as the master_finger in the minion configuration file. Save the configuration file and then restart the Salt minion.

**Minion Key Fingerprint**

Run the following command on each Salt minion to view the minion key fingerprint:

```
salt-call --local key.finger
```

Compare this value to the value that is displayed when you run the `salt-key --finger <MINION_ID>` command on the Salt master.

**Key Management**

Salt uses AES encryption for all communication between the Master and the Minion. This ensures that the commands sent to the Minions cannot be tampered with, and that communication between Master and Minion is authenticated through trusted, accepted keys.

Before commands can be sent to a Minion, its key must be accepted on the Master. Run the `salt-key` command to list the keys known to the Salt Master:

```
[root@master ~]# salt-key -L
Unaccepted Keys:
alpha
bravo
charlie
delta
Accepted Keys:
```

This example shows that the Salt Master is aware of four Minions, but none of the keys has been accepted. To accept the keys and allow the Minions to be controlled by the Master, again use the `salt-key` command:

```
[root@master ~]# salt-key -A
[root@master ~]# salt-key -L
Unaccepted Keys:
Accepted Keys:
```

1.3. Initial Configuration
The `salt-key` command allows for signing keys individually or in bulk. The example above, using `-A` bulk-accepts all pending keys. To accept keys individually use the lowercase of the same option, `-a keyname`.

See also:

`salt-key` manpage

## Sending Commands

Communication between the Master and a Minion may be verified by running the `test.ping` command:

```
[root@master ~]# salt alpha test.ping
alpha:
    True
```

Communication between the Master and all Minions may be tested in a similar way:

```
[root@master ~]# salt '*' test.ping
alpha:
    True
bravo:
    True
charlie:
    True
delta:
    True
```

Each of the Minions should send a `True` response as shown above.

## What’s Next?

Understanding *targeting* is important. From there, depending on the way you wish to use Salt, you should also proceed to learn about Remote Execution and Configuration Management.

### 1.4 Additional Installation Guides

#### 1.4.1 Salt Bootstrap

The Salt Bootstrap script allows for a user to install the Salt Minion or Master on a variety of system distributions and versions. This shell script known as `bootstrap-salt.sh` runs through a series of checks to determine the operating system type and version. It then installs the Salt binaries using the appropriate methods. The Salt Bootstrap script installs the minimum number of packages required to run Salt. This means that in the event you run the bootstrap to install via package, Git will not be installed. Installing the minimum number of packages helps ensure the script stays as lightweight as possible, assuming the user will install any other required packages after the Salt binaries are present on the system. The script source is available on GitHub: [https://github.com/saltstack/salt-bootstrap](https://github.com/saltstack/salt-bootstrap)
Supported Operating Systems

Note: In the event you do not see your distribution or version available please review the develop branch on GitHub as it main contain updates that are not present in the stable release: https://github.com/saltstack/salt-bootstrap/tree/develop

Debian and derivatives

- Debian GNU/Linux 7/8
- Linux Mint Debian Edition 1 (based on Debian 8)
- Kali Linux 1.0 (based on Debian 7)

Red Hat family

- Amazon Linux 2012.09/2013.03/2013.09/2014.03/2014.09
- CentOS 5/6/7
- Fedora 17/18/20/21/22
- Oracle Linux 5/6/7
- Red Hat Enterprise Linux 5/6/7
- Scientific Linux 5/6/7

SUSE family

- openSUSE 12/13
- openSUSE Leap 42
- openSUSE Tumbleweed 2015
- SUSE Linux Enterprise Server 11 SP1/11 SP2/11 SP3/12

Ubuntu and derivatives

- Elementary OS 0.2 (based on Ubuntu 12.04)
- Linaro 12.04
- Linux Mint 13/14/16/17
- Trisquel GNU/Linux 6 (based on Ubuntu 12.04)
- Ubuntu 10.x/11.x/12.x/13.x/14.x/15.x/16.x

Other Linux distro

- Arch Linux
- Gentoo
UNIX systems

BSD:
  • OpenBSD (pip installation)
  • FreeBSD 9/10/11

SunOS:
  • SmartOS

Example Usage

If you're looking for the one-liner to install Salt, please scroll to the bottom and use the instructions for Installing via an Insecure One-Liner

Note: In every two-step example, you would be well-served to examine the downloaded file and examine it to ensure that it does what you expect.

The Salt Bootstrap script has a wide variety of options that can be passed as well as several ways of obtaining the bootstrap script itself.

Note: These examples below show how to bootstrap Salt directly from GitHub or other Git repository. Run the script without any parameters to get latest stable Salt packages for your system from SaltStack corporate repository. See first example in the Install using wget section.

Install using curl

Using curl to install latest development version from GitHub:

```
curl -o bootstrap_salt.sh -L https://bootstrap.saltstack.com
sudo sh bootstrap_salt.sh git develop
```

If you want to install a specific release version (based on the Git tags):

```
curl -o bootstrap_salt.sh -L https://bootstrap.saltstack.com
sudo sh bootstrap_salt.sh git v2015.8.8
```

To install a specific branch from a Git fork:

```
curl -o bootstrap_salt.sh -L https://bootstrap.saltstack.com
sudo sh bootstrap_salt.sh -g https://github.com/myuser/salt.git mybranch
```

If all you want is to install a salt-master using latest Git:

```
curl -o bootstrap_salt.sh -L https://bootstrap.saltstack.com
sudo sh bootstrap_salt.sh -M -N git develop
```

If your host has Internet access only via HTTP proxy:
PROXY='http://user:password@myproxy.example.com:3128'
curl -o bootstrap_salt.sh -L -x "$PROXY" https://bootstrap.saltstack.com
sudo sh bootstrap_salt.sh -G -H "$PROXY" git

Install using wget

Using wget to install your distribution's stable packages:

```
wget -O bootstrap_salt.sh https://bootstrap.saltstack.com
sudo sh bootstrap_salt.sh
```

Downloading the script from develop branch:

```
wget -O bootstrap_salt.sh https://bootstrap.saltstack.com/develop
sudo sh bootstrap_salt.sh
```

Installing a specific version from git using wget:

```
wget -O bootstrap_salt.sh https://bootstrap.saltstack.com
sudo sh bootstrap_salt.sh -P git v2015.8.8
```

Note: On the above example we added -P which will allow PIP packages to be installed if required but it's not a necessary flag for Git based bootstraps.

Install using Python

If you already have Python installed, python 2.6, then it's as easy as:

```
python -m urllib "https://bootstrap.saltstack.com" > bootstrap_salt.sh
sudo sh bootstrap_salt.sh git develop
```

All Python versions should support the following in-line code:

```
python -c "import urllib; print urllib.urlopen("https://bootstrap.saltstack.com").read()" > bootstrap_salt.sh
sudo sh bootstrap_salt.sh git develop
```

Install using fetch

On a FreeBSD base system you usually don't have either of the above binaries available. You do have fetch available though:

```
fetch -o bootstrap_salt.sh https://bootstrap.saltstack.com
sudo sh bootstrap_salt.sh
```

If you have any SSL issues install ca_root_nssp:

```
pkg install ca_root_nssp
```

And either copy the certificates to the place where fetch can find them:
cp /usr/local/share/certs/ca-root-nss.crt /etc/ssl/cert.pem

Or link them to the right place:

ln -s /usr/local/share/certs/ca-root-nss.crt /etc/ssl/cert.pem

### Installing via an Insecure One-Liner

The following examples illustrate how to install Salt via a one-liner.

**Note:** Warning! These methods do not involve a verification step and assume that the delivered file is trustworthy.

Any of the example above which use two-lines can be made to run in a single-line configuration with minor modifications.

For example, using `curl` to install your distribution’s stable packages:

```bash
curl -L https://bootstrap.saltstack.com | sudo sh
```

Using `wget` to install your distribution’s stable packages:

```bash
wget -O - https://bootstrap.saltstack.com | sudo sh
```

Installing the latest develop branch of Salt:

```bash
curl -L https://bootstrap.saltstack.com | sudo sh -s -- git develop
```

### Command Line Options

Here’s a summary of the command line options:

```bash
$ sh bootstrap-salt.sh -h

Usage: bootstrap-salt.sh [options] <install-type> <install-type-args>

Installation types:
- stable (default)
- stable [version] (ubuntu specific)
- daily (ubuntu specific)
- testing (redhat specific)
- git

Examples:
- bootstrap-salt.sh
- bootstrap-salt.sh stable
- bootstrap-salt.sh stable 2014.7
- bootstrap-salt.sh daily
- bootstrap-salt.sh testing
- bootstrap-salt.sh git
- bootstrap-salt.sh git develop
- bootstrap-salt.sh git v0.17.0
- bootstrap-salt.sh git 8c3fadf15ec183e5ce8c63739850d543617e4357

Options:
```
-h Display this message
-v Display script version
-n No colours.
-D Show debug output.
-c Temporary configuration directory
-g Salt repository URL. (default: git://github.com/saltstack/salt.git)
-G Instead of cloning from git://github.com/saltstack/salt.git, clone from https://
github.com/saltstack/salt.git (Usually necessary on systems which have the regular
git protocol port blocked, where https usually is not)
-k Temporary directory holding the minion keys which will pre-seed
the master.
-s Sleep time used when waiting for daemons to start, restart and when checking
for the services running. Default: 3
-M Also install salt-master
-S Also install salt-syndic
-N Do not install salt-minion
-X Do not start daemons after installation
-C Only run the configuration function. This option automatically
bypasses any installation.
-P Allow pip based installations. On some distributions the required salt
packages or its dependencies are not available as a package for that
distribution. Using this flag allows the script to use pip as a last
resort method. NOTE: This only works for functions which actually
implement pip based installations.
-F Allow copied files to overwrite existing(config, init.d, etc)
-U If set, fully upgrade the system prior to bootstrapping salt
-K If set, keep the temporary files in the temporary directories specified
with -c and -k.
-I If set, allow insecure connections while downloading any files. For
example, pass '--no-check-certificate' to 'wget' or '--insecure' to 'curl'
-A Pass the salt-master DNS name or IP. This will be stored under
  ${BS_SALT_ETC_DIR}/minion.d/99-master-address.conf
-i Pass the salt-minion id. This will be stored under
  ${BS_SALT_ETC_DIR}/minion_id
-L Install the Apache Libcloud package if possible(required for salt-cloud)
-p Extra-package to install while installing salt dependencies. One package
per -p flag. You're responsible for providing the proper package name.
-d Disable check_service functions. Setting this flag disables the
  'install_<distro>_check_services' checks. You can also do this by
touching /tmp/disable_salt_checks on the target host. Defaults ${BS_FALSE}
-H Use the specified http proxy for the installation
-Z Enable external software source for newer ZeroMQ(Only available for RHEL/CentOS/
  Fedora/Ubuntu based distributions)
-b Assume that dependencies are already installed and software sources are set up.
  If git is selected, git tree is still checked out as dependency step.

1.4.2 Opening the Firewall up for Salt

The Salt master communicates with the minions using an AES-encrypted ZeroMQ connection. These communications are done over TCP ports 4505 and 4506, which need to be accessible on the master only. This document outlines suggested firewall rules for allowing these incoming connections to the master.

Note: No firewall configuration needs to be done on Salt minions. These changes refer to the master only.
Fedora 18 and beyond / RHEL 7 / CentOS 7

Starting with Fedora 18 FirewallD is the tool that is used to dynamically manage the firewall rules on a host. It has support for IPv4/6 settings and the separation of runtime and permanent configurations. To interact with FirewallD use the command line client `firewall-cmd`.

```bash
firewall-cmd --permanent --zone=<zone> --add-port=4505-4506/tcp
```

Please choose the desired zone according to your setup. Don't forget to reload after you made your changes.

```bash
firewall-cmd --reload
```

RHEL 6 / CentOS 6

The `lokkit` command packaged with some Linux distributions makes opening iptables firewall ports very simple via the command line. Just be careful to not lock out access to the server by neglecting to open the ssh port.

```bash
```

The `system-config-firewall-tui` command provides a text-based interface to modifying the firewall.

```bash
system-config-firewall-tui
```

openSUSE

Salt installs firewall rules in `/etc/sysconfig/SuSEfirewall2.d/services/salt`. Enable with:

```bash
SuSEfirewall2 open
SuSEfirewall2 start
```

If you have an older package of Salt where the above configuration file is not included, the `SuSEfirewall2` command makes opening iptables firewall ports very simple via the command line.

```bash
SuSEfirewall2 open EXT TCP 4505
SuSEfirewall2 open EXT TCP 4506
```

The firewall module in YaST2 provides a text-based interface to modifying the firewall.

```bash
yast2 firewall
```

iptables

Different Linux distributions store their `iptables` (also known as `netfilter`) rules in different places, which makes it difficult to standardize firewall documentation. Included are some of the more common locations, but your mileage may vary.
Fedora / RHEL / CentOS:

/etc/sysconfig/iptables

Arch Linux:

/etc/iptables/iptables.rules

Debian

Follow these instructions: [https://wiki.debian.org/iptables](https://wiki.debian.org/iptables)

Once you've found your firewall rules, you'll need to add the two lines below to allow traffic on tcp/4505 and tcp/4506:

- A INPUT -m state --state new -m tcp -p tcp --dport 4505 -j ACCEPT
- A INPUT -m state --state new -m tcp -p tcp --dport 4506 -j ACCEPT

Ubuntu

Salt installs firewall rules in /etc/ufw/applications.d/salt.ufw. Enable with:

ufw allow salt

**pf.conf**

The BSD-family of operating systems uses packet filter (pf). The following example describes the additions to pf.conf needed to access the Salt master.

```
pass in on $int_if proto tcp from any to $int_if port 4505
pass in on $int_if proto tcp from any to $int_if port 4506
```

Once these additions have been made to the pf.conf the rules will need to be reloaded. This can be done using the pfctl command.

```
 pfctl -vf /etc/pf.conf
```

### 1.4.3 Whitelist communication to Master

There are situations where you want to selectively allow Minion traffic from specific hosts or networks into your Salt Master. The first scenario which comes to mind is to prevent unwanted traffic to your Master out of security concerns, but another scenario is to handle Minion upgrades when there are backwards incompatible changes between the installed Salt versions in your environment.

Here is an example Linux iptables ruleset to be set on the Master:

```
# Allow Minions from these networks
-I INPUT -s 10.1.2.0/24 -p tcp -m multiport --dports 4505,4506 -j ACCEPT
-I INPUT -s 10.1.3.0/24 -p tcp -m multiport --dports 4505,4506 -j ACCEPT
# Allow Salt to communicate with Master on the loopback interface
-A INPUT -i lo -p tcp -m multiport --dports 4505,4506 -j ACCEPT
# Reject everything else
-A INPUT -p tcp -m multiport --dports 4505,4506 -j REJECT
```
Note: The important thing to note here is that the `salt` command needs to communicate with the listening network socket of `salt-master` on the `loopback` interface. Without this you will see no outgoing Salt traffic from the master, even for a simple `salt '*' test.ping`, because the salt client never reached the `salt-master` to tell it to carry out the execution.

### 1.4.4 Preseed Minion with Accepted Key

In some situations, it is not convenient to wait for a minion to start before accepting its key on the master. For instance, you may want the minion to bootstrap itself as soon as it comes online. You may also want to let your developers provision new development machines on the fly.

See also:

Many ways to preseed minion keys

Salt has other ways to generate and pre-accept minion keys in addition to the manual steps outlined below.

salt-cloud performs these same steps automatically when new cloud VMs are created (unless instructed not to).

salt-api exposes an HTTP call to Salt's REST API to *generate and download the new minion keys as a tarball*.

There is a general four step process to do this:

1. Generate the keys on the master:

   ```bash
   root@saltmaster# salt-key --gen-keys=[key_name]
   ```

   Pick a name for the key, such as the minion's id.

2. Add the public key to the accepted minion folder:

   ```bash
   root@saltmaster# cp key_name.pub /etc/salt/pki/master/minions/[minion_id]
   ```

   It is necessary that the public key file has the same name as your minion id. This is how Salt matches minions with their keys. Also note that the pki folder could be in a different location, depending on your OS or if specified in the master config file.

3. Distribute the minion keys.

   There is no single method to get the keypair to your minion. The difficulty is finding a distribution method which is secure. For Amazon EC2 only, an AWS best practice is to use IAM Roles to pass credentials. (See blog post, [http://blogs.aws.amazon.com/security/post/Tx610S2MLVZWEA/Using-IAM-roles-to-distribute-non-AWS-credentials-to-your-EC2-instances](http://blogs.aws.amazon.com/security/post/Tx610S2MLVZWEA/Using-IAM-roles-to-distribute-non-AWS-credentials-to-your-EC2-instances))

**Security Warning**

Since the minion key is already accepted on the master, distributing the private key poses a potential security risk. A malicious party will have access to your entire state tree and other sensitive data if they gain access to a preseeded minion key.

4. Preseed the Minion with the keys

   You will want to place the minion keys before starting the salt-minion daemon:

   ```bash
   /etc/salt/pki/minion/minion.pem
   /etc/salt/pki/minion/minion.pub
   ```
Once in place, you should be able to start salt-minion and run `salt-call state.apply` or any other salt commands that require master authentication.

### 1.4.5 The MacOS X (Maverick) Developer Step By Step Guide To Salt Installation

This document provides a step-by-step guide to installing a Salt cluster consisting of one master, and one minion running on a local VM hosted on Mac OS X.

**Note:** This guide is aimed at developers who wish to run Salt in a virtual machine. The official (Linux) walkthrough can be found [here](#).

---

**The 5 Cent Salt Intro**

Since you’re here you’ve probably already heard about Salt, so you already know Salt lets you configure and run commands on hordes of servers easily. Here’s a brief overview of a Salt cluster:

- Salt works by having a `master` server sending commands to one or multiple `minion` servers. The master server is the `command center`. It is going to be the place where you store your configuration files, aka: `which server is the db, which is the web server, and what libraries and software they should have installed`. The minions receive orders from the master. Minions are the servers actually performing work for your business.

- Salt has two types of configuration files:
  1. the `salt communication channels` or `meta` or `config` configuration files (not official names): one for the master (usually is `/etc/salt/master`, on the master server), and one for minions (default is `/etc/salt/minion` or `/etc/salt/minion.conf`, on the minion servers). Those files are used to determine things like the Salt Master IP, port, Salt folder locations, etc.. If these are configured incorrectly, your minions will probably be unable to receive orders from the master, or the master will not know which software a given minion should install.
  2. the `business` or `service` configuration files (once again, not an official name): these are configuration files, ending with `.sls` extension, that describe which software should run on which server, along with particular configuration properties for the software that is being installed. These files should be created in the `/srv/salt` folder by default, but their location can be changed using `... /etc/salt/master configuration file`!

**Note:** This tutorial contains a third important configuration file, not to be confused with the previous two: the virtual machine provisioning configuration file. This in itself is not specifically tied to Salt, but it also contains some Salt configuration. More on that in step 3. Also note that all configuration files are YAML files. So indentation matters.

---

**Before Digging In, The Architecture Of The Salt Cluster**

**Salt Master**

The `Salt master` server is going to be the Mac OS machine, directly. Commands will be run from a terminal app, so Salt will need to be installed on the Mac. This is going to be more convenient for toying around with configuration files.

---

1 Salt also works with `masterless` configuration where a minion is autonomous (in which case salt can be seen as a local configuration tool), or in `multiple master` configuration. See the documentation for more on that.
Salt Minion

We'll only have one ``Salt minion'' server. It is going to be running on a Virtual Machine running on the Mac, using VirtualBox. It will run an Ubuntu distribution.

Step 1 - Configuring The Salt Master On Your Mac

official documentation

Because Salt has a lot of dependencies that are not built in Mac OS X, we will use Homebrew to install Salt. Homebrew is a package manager for Mac, it's great, use it (for this tutorial at least!). Some people spend a lot of time installing libs by hand to better understand dependencies, and then realize how useful a package manager is once they're configuring a brand new machine and have to do it all over again. It also lets you *uninstall* things easily.

---

**Note:** Brew is a Ruby program (Ruby is installed by default with your Mac). Brew downloads, compiles, and links software. The linking phase is when compiled software is deployed on your machine. It may conflict with manually installed software, especially in the /usr/local directory. It's ok, remove the manually installed version then refresh the link by typing `brew link 'packageName'`. Brew has a *brew doctor* command that can help you troubleshoot. It's a great command, use it often. Brew requires xcode command line tools. When you run brew the first time it asks you to install them if they're not already on your system. Brew installs software in /usr/local/bin (system bins are in /usr/bin). In order to use those bins you need your $PATH to search there first. Brew tells you if your $PATH needs to be fixed.

---

**Tip:** Use the keyboard shortcut cmd + shift + period in the ``open`` Mac OS X dialog box to display hidden files and folders, such as .profile.

---

Install Homebrew

Install Homebrew here [http://brew.sh/](http://brew.sh/) Or just type

```
ruby -e "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/install/master/install)"
```

Now type the following commands in your terminal (you may want to type brew doctor after each to make sure everything's fine):

```
brew install python
brew install swig
brew install zmq
```

**Note:** zmq is ZeroMQ. It's a fantastic library used for server to server network communication and is at the core of Salt efficiency.

---

Install Salt

You should now have everything ready to launch this command:
pip install salt

Note: There should be no need for `sudo pip install salt`. Brew installed Python for your user, so you should have all the access. In case you would like to check, type `which python` to ensure that it's `/usr/local/bin/python`, and `which pip` which should be `/usr/local/bin/pip`. Now type `python` in a terminal then, `import salt`. There should be no errors. Now exit the Python terminal using `exit()`.

Create The Master Configuration

If the default `/etc/salt/master` configuration file was not created, copy-paste it from here: http://docs.saltstack.com/ref/configuration/examples.html#configuration-examples-master

Note: `/etc/salt/master` is a file, not a folder.

Salt Master configuration changes. The Salt master needs a few customization to be able to run on Mac OS X:

```
sudo launchctl limit maxfiles 4096 8192
```

In the `/etc/salt/master` file, change `max_open_files` to 8192 (or just add the line: `max_open_files: 8192` (no quote) if it doesn't already exists).

You should now be able to launch the Salt master:

```
sudo salt-master --log-level=all
```

There should be no errors when running the above command.

Note: This command is supposed to be a daemon, but for toying around, we'll keep it running on a terminal to monitor the activity.

Now that the master is set, let’s configure a minion on a VM.

The Salt minion is going to run on a Virtual Machine. There are a lot of software options that let you run virtual machines on a mac, But for this tutorial we're going to use VirtualBox. In addition to virtualBox, we will use Vagrant, which allows you to create the base VM configuration.

Vagrant lets you build ready to use VM images, starting from an OS image and customizing it using `"provisioners"`. In our case, we'll use it to:

- Download the base Ubuntu image
- Install salt on that Ubuntu image (Salt is going to be the `"provisioner"` for the VM).
- Launch the VM
- SSH into the VM to debug
- Stop the VM once you're done.
Install VirtualBox

Go get it here: https://www.virtualBox.org/wiki/Downloads (click on VirtualBox for OS X hosts => x86/amd64)

Install Vagrant

Go get it here: http://downloads.vagrantup.com/ and choose the latest version (1.3.5 at time of writing), then the .dmg file. Double-click to install it. Make sure the vagrant command is found when run in the terminal. Type vagrant. It should display a list of commands.

Create The Minion VM Folder

Create a folder in which you will store your minion's VM. In this tutorial, it's going to be a minion folder in the $home directory.

```bash
cd $home
mkdir minion
```

Initialize Vagrant

From the minion folder, type

```
vagrant init
```

This command creates a default Vagrantfile configuration file. This configuration file will be used to pass configuration parameters to the Salt provisioner in Step 3.

Import Precise64 Ubuntu Box

```
vagrant box add precise64 http://files.vagrantup.com/precise64.box
```

Note: This box is added at the global Vagrant level. You only need to do it once as each VM will use this same file.

Modify the Vagrantfile

Modify ./minion/Vagrantfile to use th precise64 box. Change the config.vm.box line to:

```
config.vm.box = "precise64"
```

Uncomment the line creating a host-only IP. This is the ip of your minion (you can change it to something else if that IP is already in use):

```
config.vm.network :private_network, ip: "192.168.33.10"
```

At this point you should have a VM that can run, although there won't be much in it. Let's check that.
Checking The VM

From the $home/minion folder type:

```
vagrant up
```

A log showing the VM booting should be present. Once it's done you'll be back to the terminal:

```
ping 192.168.33.10
```

The VM should respond to your ping request.

Now log into the VM in ssh using Vagrant again:

```
vagrant ssh
```

You should see the shell prompt change to something similar to `vagrant@precise64:~$` meaning you're inside the VM. From there, enter the following:

```
ping 10.0.2.2
```

**Note:** That ip is the ip of your VM host (the Mac OS X OS). The number is a VirtualBox default and is displayed in the log after the Vagrant ssh command. We'll use that IP to tell the minion where the Salt master is. Once you're done, end the ssh session by typing `exit`.

It's now time to connect the VM to the salt master

Creating The Minion Configuration File

Create the `/etc/salt/minion` file. In that file, put the following lines, giving the ID for this minion, and the IP of the master:

```
master: 10.0.2.2
id: 'minion1'
file_client: remote
```

Minions authenticate with the master using keys. Keys are generated automatically if you don't provide one and can accept them later on. However, this requires accepting the minion key every time the minion is destroyed or created (which could be quite often). A better way is to create those keys in advance, feed them to the minion, and authorize them once.

Preseed minion keys

From the minion folder on your Mac run:

```
sudo salt-key --gen-keys=minion1
```

This should create two files: minion1.pem, and minion1.pub. Since those files have been created using sudo, but will be used by vagrant, you need to change ownership:

```
sudo chown youruser:yourgroup minion1.pem
sudo chown youruser:yourgroup minion1.pub
```
Then copy the .pub file into the list of accepted minions:

```bash
sudo cp minion1.pub /etc/salt/pki/master/minions/minion1
```

Modify Vagrantfile to Use Salt Provisioner

Let’s now modify the Vagrantfile used to provision the Salt VM. Add the following section in the Vagrantfile (note: it should be at the same indentation level as the other properties):

```ruby
# salt-vagrant config
config.vm.provision :salt do |salt|
  salt.run_highstate = true
  salt.minion_config = "/etc/salt/minion"
  salt.minion_key = "/minion1.pem"
  salt.minion_pub = "/minion1.pub"
end
```

Now destroy the vm and recreate it from the /minion folder:

```bash
vagrant destroy
vagrant up
```

If everything is fine you should see the following message:

"Bootstrapping Salt... (this may take a while)
Salt successfully configured and installed!"

Checking Master-Minion Communication

To make sure the master and minion are talking to each other, enter the following:

```bash
sudo salt '*' test.ping
```

You should see your minion answering the ping. It’s now time to do some configuration.

In this step we’ll use the Salt master to instruct our minion to install Nginx.

Checking the system’s original state

First, make sure that an HTTP server is not installed on our minion. When opening a browser directed at http://192.168.33.10/ You should get an error saying the site cannot be reached.

Initialize the top.sls file

System configuration is done in /srv/salt/top.sls (and subfiles/folders), and then applied by running the state.apply function to have the Salt master order its minions to update their instructions and run the associated commands.

First Create an empty file on your Salt master (Mac OS X machine):

```bash
touch /srv/salt/top.sls
```

When the file is empty, or if no configuration is found for our minion an error is reported:
Create The Nginx Configuration

Now is finally the time to enter the real meat of our server's configuration. For this tutorial our minion will be treated as a web server that needs to have Nginx installed.

Insert the following lines into /srv/salt/top.sls (which should currently be empty).

```yaml
base:
  'minion1':
    - bin.nginx
```

Now create /srv/salt/bin/nginx.sls containing the following:

```yaml
nginx:
  pkg.installed:
    - name: nginx
  service.running:
    - enable: True
    - reload: True
```

Check Minion State

Finally, run the state.apply function again:

```bash
sudo salt 'minion1' state.apply
```

You should see a log showing that the Nginx package has been installed and the service configured. To prove it, open your browser and navigate to http://192.168.33.10/, you should see the standard Nginx welcome page.

Congratulations!

Where To Go From Here

A full description of configuration management within Salt (sls files among other things) is available here: http://docs.saltstack.com/en/latest/index.html#configuration-management

1.4.6 running salt as normal user tutorial

Before continuing make sure you have a working Salt installation by following the Installation and the configuration instructions.

Stuck?

There are many ways to get help from the Salt community including our mailing list and our IRC channel #salt.
Running Salt functions as non root user

If you don’t want to run salt cloud as root or even install it you can configure it to have a virtual root in your working directory.

The salt system uses the `salt.syspath` module to find the variables

If you run the salt-build, it will generated in:

```
./build/lib.linux-x86_64-2.7/salt/_syspaths.py
```

To generate it, run the command:

```
python setup.py build
```

Copy the generated module into your salt directory

```
cp ./build/lib.linux-x86_64-2.7/salt/_syspaths.py salt/_syspaths.py
```

Edit it to include needed variables and your new paths

```python
# you need to edit this
ROOT_DIR = *your current dir* + '/salt/root'

# you need to edit this
INSTALL_DIR = *location of source code*

CONFIG_DIR = ROOT_DIR + '/etc/salt'
CACHE_DIR = ROOT_DIR + '/var/cache/salt'
SOCK_DIR = ROOT_DIR + '/var/run/salt'
SRV_ROOT_DIR = ROOT_DIR + '/srv'
BASE_FILE_ROOTS_DIR = ROOT_DIR + '/srv/salt'
BASE_PILLAR_ROOTS_DIR = ROOT_DIR + '/srv/pillar'
BASE_MASTER_ROOTS_DIR = ROOT_DIR + '/srv/salt-master'
LOGS_DIR = ROOT_DIR + '/var/log/salt'
PIDFILE_DIR = ROOT_DIR + '/var/run'
CLOUD_DIR = INSTALL_DIR + '/cloud'
BOOTSTRAP = CLOUD_DIR + '/deploy/bootstrap-salt.sh'
```

Create the directory structure

```
```

Populate the configuration files:

```
cp -r conf/* root/etc/salt/
```

Edit your `root/etc/salt/master` configuration that is used by salt-cloud:

```
user: *your user name*
```

Run like this:

```
PYTHONPATH=`pwd` scripts/salt-cloud
```
1.4.7 Standalone Minion

Since the Salt minion contains such extensive functionality it can be useful to run it standalone. A standalone minion can be used to do a number of things:

- Use salt-call commands on a system without connectivity to a master
- Masterless States, run states entirely from files local to the minion

Note: When running Salt in masterless mode, do not run the salt-minion daemon. Otherwise, it will attempt to connect to a master and fail. The salt-call command stands on its own and does not need the salt-minion daemon.

Minion Configuration

Throughout this document there are several references to setting different options to configure a masterless Minion. Salt Minions are easy to configure via a configuration file that is located, by default, in `/etc/salt/minion`. Note, however, that on FreeBSD systems, the minion configuration file is located in `/usr/local/etc/salt/minion`.

You can learn more about minion configuration options in the *Configuring the Salt Minion* docs.

Telling Salt Call to Run Masterless

The salt-call command is used to run module functions locally on a minion instead of executing them from the master. Normally the salt-call command checks into the master to retrieve file server and pillar data, but when running standalone salt-call needs to be instructed to not check the master for this data. To instruct the minion to not look for a master when running salt-call the `file_client` configuration option needs to be set. By default the `file_client` is set to `remote` so that the minion knows that file server and pillar data are to be gathered from the master. When setting the `file_client` option to `local` the minion is configured to not gather this data from the master.

```
file_client: local
```

Now the salt-call command will not look for a master and will assume that the local system has all of the file and pillar resources.

Running States Masterless

The state system can be easily run without a Salt master, with all needed files local to the minion. To do this the minion configuration file needs to be set up to know how to return file_roots information like the master. The `file_roots` setting defaults to `/srv/salt` for the base environment just like on the master:

```
file_roots:
  base:
    - /srv/salt
```

Now set up the Salt State Tree, top file, and SLS modules in the same way that they would be set up on a master. Now, with the `file_client` option set to `local` and an available state tree then calls to functions in the state module will use the information in the `file_roots` on the minion instead of checking in with the master.

Remember that when creating a state tree on a minion there are no syntax or path changes needed, SLS modules written to be used from a master do not need to be modified in any way to work with a minion.
This makes it easy to "script" deployments with Salt states without having to set up a master, and allows for these SLS modules to be easily moved into a Salt master as the deployment grows.

The declared state can now be executed with:

```bash
salt-call state.apply
```

Or the salt-call command can be executed with the `--local` flag, this makes it unnecessary to change the configuration file:

```bash
salt-call state.apply --local
```

**External Pillars**

*External pillars* are supported when running in masterless mode.

### 1.4.8 Salt Masterless Quickstart

Running a masterless salt-minion lets you use Salt’s configuration management for a single machine without calling out to a Salt master on another machine.

Since the Salt minion contains such extensive functionality it can be useful to run it standalone. A standalone minion can be used to do a number of things:

- Stand up a master server via States (Salting a Salt Master)
- Use salt-call commands on a system without connectivity to a master
- Masterless States, run states entirely from files local to the minion

It is also useful for testing out state trees before deploying to a production setup.

**Bootstrap Salt Minion**

The `salt-bootstrap` script makes bootstrapping a server with Salt simple for any OS with a Bourne shell:

```bash
curl -L https://bootstrap.saltstack.com -o bootstrap_salt.sh
sudo sh bootstrap_salt.sh
```

See the `salt-bootstrap` documentation for other one liners. When using Vagrant to test out salt, the Vagrant salt provisioner will provision the VM for you.

**Telling Salt to Run Masterless**

To instruct the minion to not look for a master, the `file_client` configuration option needs to be set in the minion configuration file. By default the `file_client` is set to `remote` so that the minion gathers file server and pillar data from the salt master. When setting the `file_client` option to `local` the minion is configured to not gather this data from the master.

```yaml
file_client: local
```

Now the salt minion will not look for a master and will assume that the local system has all of the file and pillar resources.
Configuration which resided in the master configuration (e.g. /etc/salt/master) should be moved to the minion configuration since the minion does not read the master configuration.

Note: When running Salt in masterless mode, do not run the salt-minion daemon. Otherwise, it will attempt to connect to a master and fail. The salt-call command stands on its own and does not need the salt-minion daemon.

Create State Tree

Following the successful installation of a salt-minion, the next step is to create a state tree, which is where the SLS files that comprise the possible states of the minion are stored.

The following example walks through the steps necessary to create a state tree that ensures that the server has the Apache webserver installed.

Note: For a complete explanation on Salt States, see the tutorial.

1. Create the top.sls file:

/srv/salt/top.sls:

```
base:
  '*':
    - webserver
```

2. Create the webserver state tree:

/srv/salt/webserver.sls:

```
apache:       # ID declaration
pkg:         # state declaration
  - installed # function declaration
```

Note: The apache package has different names on different platforms, for instance on Debian/Ubuntu it is apache2, on Fedora/RHEL it is httpd and on Arch it is apache

The only thing left is to provision our minion using salt-call.

Salt-call

The salt-call command is used to run remote execution functions locally on a minion instead of executing them from the master. Normally the salt-call command checks into the master to retrieve file server and pillar data, but when running standalone salt-call needs to be instructed to not check the master for this data:

```
salt-call --local state.apply
```

The --local flag tells the salt-minion to look for the state tree in the local file system and not to contact a Salt Master for instructions.

To provide verbose output, use -l debug:

```
salt-call --local state.apply -l debug
```
The minion first examines the `top.sls` file and determines that it is a part of the group matched by `*` glob and that the `webserver` SLS should be applied.

It then examines the `webserver.sls` file and finds the `apache` state, which installs the Apache package.

The minion should now have Apache installed, and the next step is to begin learning how to write more complex states.

1.5 Dependencies

Salt should run on any Unix-like platform so long as the dependencies are met.

- **Python 2.6 >= 2.6 <3.0**
- `msgpack-python` - High-performance message interchange format
- `YAML` - Python YAML bindings
- `Jinja2` - parsing Salt States (configurable in the master settings)
- `MarkupSafe` - Implements a XML/HTML/XHTML Markup safe string for Python
- `apache-libcloud` - Python lib for interacting with many of the popular cloud service providers using a unified API
- `Requests` - HTTP library
- `Tornado` - Web framework and asynchronous networking library
- `futures` - Backport of the concurrent.futures package from Python 3.2

Depending on the chosen Salt transport, ZeroMQ or RAET, dependencies vary:

- **ZeroMQ**:
  - ZeroMQ >= 3.2.0
  - `pyzmq` >= 2.2.0 - ZeroMQ Python bindings
  - `PyCrypto` - The Python cryptography toolkit

- **RAET**:
  - `libnacl` - Python bindings to `libsodium`
  - `ioflo` - The flo programming interface `raet` and `salt-raet` is built on
  - `RAET` - The worlds most awesome UDP protocol

Salt defaults to the ZeroMQ transport, and the choice can be made at install time, for example:

```bash
git clone https://github.com/saltstack/salt
cd salt
python setup.py --salt-transport=raet install
```

This way, only the required dependencies are pulled by the setup script if need be.

If installing using `pip`, the `--salt-transport` install option can be provided like:

```bash
pip install --install-option="--salt-transport=raet" salt
```

**Note:** Salt does not bundle dependencies that are typically distributed as part of the base OS. If you have unmet dependencies and are using a custom or minimal installation, you might need to install some additional packages from your OS vendor.
1.6 Optional Dependencies

- mako - an optional parser for Salt States (configurable in the master settings)
- gcc - dynamic Cython module compiling

1.7 Upgrading Salt

When upgrading Salt, the master(s) should always be upgraded first. Backward compatibility for minions running newer versions of salt than their masters is not guaranteed.

Whenever possible, backward compatibility between new masters and old minions will be preserved. Generally, the only exception to this policy is in case of a security vulnerability.

See also:

*Installing Salt for development* and contributing to the project.

1.8 Building Packages using Salt Pack

Salt-pack is an open-source package builder for most commonly used Linux platforms, for example: Redhat/CentOS and Debian/Ubuntu families, utilizing SaltStack states and execution modules to build Salt and a specified set of dependencies, from which a platform specific repository can be built.

https://github.com/saltstack/salt-pack
This section explains how to configure user access, view and store job results, secure and troubleshoot, and how to perform many other administrative tasks.

### 2.1 Configuring the Salt Master

The Salt system is amazingly simple and easy to configure, the two components of the Salt system each have a respective configuration file. The `salt-master` is configured via the master configuration file, and the `salt-minion` is configured via the minion configuration file.

See also:

*Example master configuration file.*

The configuration file for the salt-master is located at `/etc/salt/master` by default. A notable exception is FreeBSD, where the configuration file is located at `/usr/local/etc/salt`. The available options are as follows:

#### 2.1.1 Primary Master Configuration

**interface**

Default: `0.0.0.0` (all interfaces)

The local interface to bind to, must be an IP address.

```
interface: 192.168.0.1
```

**ipv6**

Default: `False`

Whether the master should listen for IPv6 connections. If this is set to True, the interface option must be adjusted too (for example: `interface: '::'`)

```
ipv6: True
```
**publish_port**

Default: 4505
The network port to set up the publication interface.

```
publish_port: 4505
```

**master_id**

Default: None
The id to be passed in the publish job to minions. This is used for MultiSyndics to return the job to the requesting master.

**Note:** This must be the same string as the syndic is configured with.

```
master_id: MasterOfMaster
```

**user**

Default: root
The user to run the Salt processes

```
user: root
```

**max_open_files**

Default: 100000
Each minion connecting to the master uses AT LEAST one file descriptor, the master subscription connection. If enough minions connect you might start seeing on the console (and then salt-master crashes):

```
Too many open files (tcp_listener.cpp:335)
Aborted (core dumped)
```

```
max_open_files: 100000
```

By default this value will be the one of `ulimit -Hn`, i.e., the hard limit for max open files.
To set a different value than the default one, uncomment, and configure this setting. Remember that this value CANNOT be higher than the hard limit. Raising the hard limit depends on the OS and/or distribution, a good way to find the limit is to search the internet for something like this:

```
raise max open files hard limit debian
```

**worker_threads**

Default: 5
The number of threads to start for receiving commands and replies from minions. If minions are stalling on replies because you have many minions, raise the worker_threads value.

Worker threads should not be put below 3 when using the peer system, but can drop down to 1 worker otherwise.

Note: When the master daemon starts, it is expected behaviour to see multiple salt-master processes, even if \texttt{worker_threads} is set to 1. At a minimum, a controlling process will start along with a Publisher, an EventPublisher, and a number of MWorker processes will be started. The number of MWorker processes is tuneable by the \texttt{worker_threads} configuration value while the others are not.

\begin{verbatim}
worker_threads: 5
\end{verbatim}

\textbf{ret_port}

Default: 4506

The port used by the return server, this is the server used by Salt to receive execution returns and command executions.

\begin{verbatim}
ret_port: 4506
\end{verbatim}

\textbf{pidfile}

Default: /var/run/salt-master.pid

Specify the location of the master pidfile.

\begin{verbatim}
pidfile: /var/run/salt-master.pid
\end{verbatim}

\textbf{root_dir}

Default: /

The system root directory to operate from, change this to make Salt run from an alternative root.

\begin{verbatim}
root_dir: /
\end{verbatim}

Note: This directory is prepended to the following options: \texttt{pki_dir, cachedir, sock_dir, log_file, autosign_file, autoreject_file, pidfile}.

\textbf{conf_file}

Default: /etc/salt/master

The path to the master’s configuration file.

\begin{verbatim}
conf_file: /etc/salt/master
\end{verbatim}
**pki_dir**

Default: /etc/salt/pki/master

The directory to store the pki authentication keys.

```
pki_dir: /etc/salt/pki/master
```

**extension_modules**

Changed in version 2016.3.0: The default location for this directory has been moved. Prior to this version, the location was a directory named `extmods` in the Salt cachedir (on most platforms, `/var/cache/salt/extmods`). It has been moved into the master cachedir (on most platforms, `/var/cache/salt/master/extmods`).

Directory for custom modules. This directory can contain subdirectories for each of Salt’s module types such as `runners`, `output`, `wheel`, `modules`, `states`, `returners`, `engines`, etc. This path is appended to `root_dir`.

```
extension_modules: /root/salt_extmods
```

**module_dirs**

Default: []

Like `extension_modules`, but a list of extra directories to search for Salt modules.

```
module_dirs:
  - /var/cache/salt/minion/extmods
```

**cachedir**

Default: /var/cache/salt/master

The location used to store cache information, particularly the job information for executed salt commands. This directory may contain sensitive data and should be protected accordingly.

```
cachedir: /var/cache/salt/master
```

**verify_env**

Default: True

Verify and set permissions on configuration directories at startup.

```
verify_env: True
```

**keep_jobs**

Default: 24

Set the number of hours to keep old job information. Note that setting this option to 0 disables the cache cleaner.
keep_jobs: 24

**gather_job_timeout**

New in version 2014.7.0.
Default: 10
The number of seconds to wait when the client is requesting information about running jobs.

```
gather_job_timeout: 10
```

**timeout**

Default: 5
Set the default timeout for the salt command and api.

**loop_interval**

Default: 60
The loop interval option controls the seconds for the master's maintenance process check cycle. This process updates file server backends, cleans the job cache and executes the scheduler.

**output**

Default: nested
Set the default outputter used by the salt command.

**output_file**

Default: None
Set the default output file used by the salt command. Default is to output to the CLI and not to a file. Functions the same way as the `--out-file` CLI option, only sets this to a single file for all salt commands.

```
output_file: /path/output/file
```

**color**

Default: True
By default output is colored, to disable colored output set the color value to False.

```
color: False
```
**cli_summary**

Default: False

When set to True, displays a summary of the number of minions targeted, the number of minions returned, and the number of minions that did not return.

```
cli_summary: False
```

**sock_dir**

Default: /var/run/salt/master

Set the location to use for creating Unix sockets for master process communication.

```
sock_dir: /var/run/salt/master
```

**enable_gpu_grains**

Default: True

Enable GPU hardware data for your master. Be aware that the master can take a while to start up when lspci and/or dmidecode is used to populate the grains for the master.

**job_cache**

Default: True

The master maintains a temporary job cache. While this is a great addition, it can be a burden on the master for larger deployments (over 5000 minions). Disabling the job cache will make previously executed jobs unavailable to the jobs system and is not generally recommended. Normally it is wise to make sure the master has access to a faster IO system or a tmpfs is mounted to the jobs dir.

```
job_cache: True
```

**minion_data_cache**

Default: True

The minion data cache is a cache of information about the minions stored on the master, this information is primarily the pillar and grains data. The data is cached in the Master cachedir under the name of the minion and used to predetermine what minions are expected to reply from executions.
minion_data_cache: True

**ext_job_cache**

Default: ''

Used to specify a default returner for all minions. When this option is set, the specified returner needs to be properly configured and the minions will always default to sending returns to this returner. This will also disable the local job cache on the master.

ext_job_cache: redis

**event_return**

New in version 2015.5.0.

Default: ''

Specify the returner to use to log events. A returner may have installation and configuration requirements. Read the returner’s documentation.

Note: Not all returners support event returns. Verify that a returner has an `event_return()` function before configuring this option with a returner.

event_return: cassandra_cql

**event_return_queue**

New in version 2015.5.0.

Default: 0

On busy systems, enabling event_returns can cause a considerable load on the storage system for returners. Events can be queued on the master and stored in a batched fashion using a single transaction for multiple events. By default, events are not queued.

event_return_queue: 0

**event_return_whitelist**

New in version 2015.5.0.

Default: []

Only return events matching tags in a whitelist.

event_return_whitelist:
- salt/master/a_tag
- salt/master/another_tag

2.1. Configuring the Salt Master
**event_return_blacklist**

New in version 2015.5.0.
Default: `[]`
Store all event returns _except_ the tags in a blacklist.

```
    event_return_blacklist:
        - salt/master/not_this_tag
        - salt/master/or_this_one
```

**max_event_size**

New in version 2014.7.0.
Default: `1048576`
Passing very large events can cause the minion to consume large amounts of memory. This value tunes the maximum size of a message allowed onto the master event bus. The value is expressed in bytes.

```
    max_event_size: 1048576
```

**master_job_cache**

New in version 2014.7.0.
Default: `local_cache`
Specify the returner to use for the job cache. The job cache will only be interacted with from the salt master and therefore does not need to be accessible from the minions.

```
    master_job_cache: redis
```

**enforce_mine_cache**

Default: False
By-default when disabling the minion_data_cache mine will stop working since it is based on cached data, by enabling this option we explicitly enabling only the cache for the mine system.

```
    enforce_mine_cache: False
```

**max_minions**

Default: 0
The maximum number of minion connections allowed by the master. Use this to accommodate the number of minions per master if you have different types of hardware serving your minions. The default of 0 means unlimited connections. Please note that this can slow down the authentication process a bit in large setups.

```
    max_minions: 100
```
**con_cache**

Default: False

If max_minions is used in large installations, the master might experience high-load situations because of having to check the number of connected minions for every authentication. This cache provides the minion-ids of all connected minions to all MWorker-processes and greatly improves the performance of max_minions.

```yaml
con_cache: True
```

**presence_events**

Default: False

Causes the master to periodically look for actively connected minions. Presence events are fired on the event bus on a regular interval with a list of connected minions, as well as events with lists of newly connected or disconnected minions. This is a master-only operation that does not send executions to minions. Note, this does not detect minions that connect to a master via localhost.

```yaml
presence_events: False
```

**transport**

Default: zeromq

Changes the underlying transport layer. ZeroMQ is the recommended transport while additional transport layers are under development. Supported values are zeromq, raet (experimental), and tcp (experimental). This setting has a significant impact on performance and should not be changed unless you know what you are doing! Transports are explained in Salt Transports.

```yaml
transport: zeromq
```

**transport_opts**

Default: {}

(Experimental) Starts multiple transports and overrides options for each transport with the provided dictionary This setting has a significant impact on performance and should not be changed unless you know what you are doing! Transports are explained in Salt Transports. The following example shows how to start a TCP transport alongside a ZMQ transport.

```yaml
transport_opts:
  tcp:
    publish_port: 4605
    ret_port: 4606
  zeromq: []
```

### 2.1.2 Salt-SSH Configuration

**roster_file**

Default: /etc/salt/roster

---

**2.1. Configuring the Salt Master**
Pass in an alternative location for the salt-ssh roster file.

| roster_file: /root/roster |

**ssh_log_file**

New in version 2016.3.5.

Default: /var/log/salt/ssh

Specify the log file of the salt-ssh command.

| ssh_log_file: /var/log/salt/ssh |

**ssh_minion_opts**

Default: None

Pass in minion option overrides that will be inserted into the SHIM for salt-ssh calls. The local minion config is not used for salt-ssh. Can be overridden on a per-minion basis in the roster (minion_opts)

<table>
<thead>
<tr>
<th>minion_opts:</th>
</tr>
</thead>
<tbody>
<tr>
<td>gpg_keydir: /root/gpg</td>
</tr>
</tbody>
</table>

**thin_extra_mods**

Default: None

List of additional modules, needed to be included into the Salt Thin. Pass a list of importable Python modules that are typically located in the `site-packages` Python directory so they will be also always included into the Salt Thin, once generated.

### 2.1.3 Master Security Settings

**open_mode**

Default: False

Open mode is a dangerous security feature. One problem encountered with pki authentication systems is that keys can become ``mixed up'' and authentication begins to fail. Open mode turns off authentication and tells the master to accept all authentication. This will clean up the pki keys received from the minions. Open mode should not be turned on for general use. Open mode should only be used for a short period of time to clean up pki keys. To turn on open mode set this value to True.

| open_mode: False |

**auto_accept**

Default: False

Enable auto_accept. This setting will automatically accept all incoming public keys from minions.
auto_accept: False

**autosign_timeout**

New in version 2014.7.0.

Default: 120

Time in minutes that a incoming public key with a matching name found in pki_dir/minion_autosign/keyid is automatically accepted. Expired autosign keys are removed when the master checks the minion_autosign directory. This method to auto accept minions can be safer than an autosign_file because the keyid record can expire and is limited to being an exact name match. This should still be considered a less than secure option, due to the fact that trust is based on just the requesting minion id.

**autosign_file**

Default: not defined

If the autosign_file is specified incoming keys specified in the autosign_file will be automatically accepted. Matches will be searched for first by string comparison, then by globbing, then by full-string regex matching. This should still be considered a less than secure option, due to the fact that trust is based on just the requesting minion id.

**autoreject_file**

New in version 2014.1.0.

Default: not defined

Works like autosign_file, but instead allows you to specify minion IDs for which keys will automatically be rejected. Will override both membership in the autosign_file and the auto_accept setting.

**publisher_acl**

Default: {} 

Enable user accounts on the master to execute specific modules. These modules can be expressed as regular expressions. Note that client_acl option is deprecated by publisher_acl option and will be removed in future releases.

```yaml
publisher_acl:
  fred:
    - test.ping
    - pkg.*
```

**publisher_acl_blacklist**

Default: {} 

Blacklist users or modules

This example would blacklist all non sudo users, including root from running any commands. It would also blacklist any use of the `cmd` module. Note that client_acl_blacklist option is deprecated by publisher_acl_blacklist option and will be removed in future releases.

2.1. Configuring the Salt Master
This is completely disabled by default.

```
publisher_acl_blacklist:
    users:
    - root
    - '^(!sudo_).*'$  # all non sudo users
    modules:
    - cmd
```

**external_auth**

Default: {}

The external auth system uses the Salt auth modules to authenticate and validate users to access areas of the Salt system.

```
external_auth:
    pam:
    - fred:
      - test.*
```

**token_expire**

Default: 43200

Time (in seconds) for a newly generated token to live.

Default: 12 hours

```
token_expire: 43200
```

**file_recv**

Default: False

Allow minions to push files to the master. This is disabled by default, for security purposes.

```
file_recv: False
```

**file_recv_max_size**

New in version 2014.7.0.

Default: 100

Set a hard-limit on the size of the files that can be pushed to the master. It will be interpreted as megabytes.

```
file_recv_max_size: 100
```
**master_sign_pubkey**

Default: False

Sign the master auth-replies with a cryptographic signature of the master's public key. Please see the tutorial how to use these settings in the Multimaster-PKI with Failover Tutorial

```
master_sign_pubkey: True
```

**master_sign_key_name**

Default: master_sign

The customizable name of the signing-key-pair without suffix.

```
master_sign_key_name: <filename_without_suffix>
```

**master_pubkey_signature**

Default: master_pubkey_signature

The name of the file in the master's pki-directory that holds the pre-calculated signature of the master's public-key.

```
master_pubkey_signature: <filename>
```

**master_use_pubkey_signature**

Default: False

Instead of computing the signature for each auth-reply, use a pre-calculated signature. The `master_pubkey_signature` must also be set for this.

```
master_use_pubkey_signature: True
```

**rotate_aes_key**

Default: True

Rotate the salt-masters AES-key when a minion-public is deleted with salt-key. This is a very important security-setting. Disabling it will enable deleted minions to still listen in on the messages published by the salt-master. Do not disable this unless it is absolutely clear what this does.

```
rotate_aes_key: True
```

**allow_minion_key_revoke**

Default: True

Controls whether a minion can request its own key revocation. When True the master will honor the minion's request and revoke its key. When False, the master will drop the request and the minion's key will remain accepted.
2.1.4 Master Module Management

runner_dirs
Default: []
Set additional directories to search for runner modules.

```yaml
runner_dirs:
  - /var/lib/salt/runners
```

cython_enable
Default: False
Set to true to enable Cython modules (.pyx files) to be compiled on the fly on the Salt master.

cython_enable: False

2.1.5 Master State System Settings

state_top
Default: top.sls
The state system uses a "top" file to tell the minions what environment to use and what modules to use. The state_top file is defined relative to the root of the base environment.

```yaml
state_top: top.sls
```

master_tops
Default: {}
The master_top option replaces the external_nodes option by creating a pluggable system for the generation of external top data. The external_nodes option is deprecated by the master_top option. To gain the capabilities of the classic external_nodes system, use the following configuration:

```yaml
master_tops:
  ext_nodes: <Shell command which returns yaml>
```

external_nodes
Default: None
The external_nodes option allows Salt to gather data that would normally be placed in a top file from and external node controller. The external_nodes option is the executable that will return the ENC data. Remember that Salt will look for external nodes AND top files and combine the results if both are enabled and available!
external_nodes: cobbler-ext-nodes

**renderer**

Default: yaml_jinja

The renderer to use on the minions to render the state data.

renderer: yaml_jinja

**jinja_trim_blocks**

New in version 2014.1.0.

Default: False

If this is set to True, the first newline after a Jinja block is removed (block, not variable tag!). Defaults to False and corresponds to the Jinja environment init variable trim_blocks.

jinja_trim_blocks: False

**jinja_lstrip_blocks**

New in version 2014.1.0.

Default: False

If this is set to True, leading spaces and tabs are stripped from the start of a line to a block. Defaults to False and corresponds to the Jinja environment init variable lstrip_blocks.

jinja_lstrip_blocks: False

**failhard**

Default: False

Set the global failhard flag. This informs all states to stop running states at the moment a single state fails.

failhard: False

**state_verbose**

Default: True

Controls the verbosity of state runs. By default, the results of all states are returned, but setting this value to False will cause salt to only display output for states that failed or states that have changes.

state_verbose: False
**state_output**

Default: full

The `state_output` setting changes if the output is the full multi line output for each changed state if set to `full`, but if set to `terse` the output will be shortened to a single line. If set to `mixed`, the output will be terse unless a state failed, in which case that output will be full. If set to `changes`, the output will be full unless the state didn't change.

```
state_output: full
```

**state_aggregate**

Default: False

Automatically aggregate all states that have support for `mod_aggregate` by setting to True. Or pass a list of state module names to automatically aggregate just those types.

```
state_aggregate:
  - pkg

state_aggregate: True
```

**state_events**

Default: False

Send progress events as each function in a state run completes execution by setting to True. Progress events are in the format `salt/job/<JID>/prog/<MID>/<RUN_NUM>`.

```
state_events: True
```

**yaml_utf8**

Default: False

Enable extra routines for YAML renderer used states containing UTF characters.

```
yaml_utf8: False
```

**test**

Default: False

Set all state calls to only test if they are going to actually make changes or just post what changes are going to be made.

```
test: False
```
2.1.6 Master File Server Settings

**fileserver_backend**

Default: ['roots']

Salt supports a modular fileserver backend system, this system allows the salt master to link directly to third party systems to gather and manage the files available to minions. Multiple backends can be configured and will be searched for the requested file in the order in which they are defined here. The default setting only enables the standard backend *roots*, which is configured using the *file_roots* option.

Example:

```yaml
fileserver_backend:
- roots
- git
```

Note: For masterless Salt, this parameter must be specified in the minion config file.

**fileserver_followsymlinks**

New in version 2014.1.0.

Default: True

By default, the file_server follows symlinks when walking the filesystem tree. Currently this only applies to the default roots fileserver_backend.

```yaml
fileserver_followsymlinks: True
```

**fileserver_ignoresymlinks**

New in version 2014.1.0.

Default: False

If you do not want symlinks to be treated as the files they are pointing to, set *fileserver_ignoresymlinks* to True. By default this is set to False. When set to True, any detected symlink while listing files on the Master will not be returned to the Minion.

```yaml
fileserver_ignoresymlinks: False
```

**fileserver_limit_traversal**

New in version 2014.1.0.

Default: False

By default, the Salt fileserver recurses fully into all defined environments to attempt to find files. To limit this behavior so that the fileserver only traverses directories with SLS files and special Salt directories like _modules, set *fileserver_limit_traversal* to True. This might be useful for installations where a file root has a very large number of files and performance is impacted.
**fileserver_limit_traversal**: False

**hash_type**

Default: md5

The hash_type is the hash to use when discovering the hash of a file on the master server. The default is md5, but sha1, sha224, sha256, sha384, and sha512 are also supported.

```plaintext
hash_type: md5
```

**file_buffer_size**

Default: 1048576

The buffer size in the file server in bytes.

```plaintext
file_buffer_size: 1048576
```

**file_ignore_regex**

Default: ''

A regular expression (or a list of expressions) that will be matched against the file path before syncing the modules and states to the minions. This includes files affected by the file.recurse state. For example, if you manage your custom modules and states in subversion and don't want all the `.svn` folders and content synced to your minions, you could set this to `'/\.svn($|/)'. By default nothing is ignored.

```plaintext
file_ignore_regex:
- '/.svn($|/)'
- '/.git($|/)'
```

**file_ignore_glob**

Default ''

A file glob (or list of file globs) that will be matched against the file path before syncing the modules and states to the minions. This is similar to file_ignore_regex above, but works on globs instead of regex. By default nothing is ignored.

```plaintext
file_ignore_glob:
- '/*.pyc'
- '*/somefolder/.*.bak'
- '/*.swp'
```

**Note:** Vim's .swp files are a common cause of Unicode errors in file.recurse states which use templating. Unless there is a good reason to distribute them via the filesaver, it is good practice to include '/*.swp' in the file_ignore_glob.
roots: Master's Local File Server

**file_roots**

Default:

```
base:
  - /srv/salt
```

Salt runs a lightweight file server written in ZeroMQ to deliver files to minions. This file server is built into the master daemon and does not require a dedicated port.

The file server works on environments passed to the master. Each environment can have multiple root directories. The subdirectories in the multiple file roots cannot match, otherwise the downloaded files will not be able to be reliably ensured. A base environment is required to house the top file.

Example:

```
file_roots:
  base:
    - /srv/salt
  dev:
    - /srv/salt/dev/services
    - /srv/salt/dev/states
  prod:
    - /srv/salt/prod/services
    - /srv/salt/prod/states
```

**Note:** For masterless Salt, this parameter must be specified in the minion config file.

---

**git:** Git Remote File Server Backend

**gitfs_remotes**

Default: `[]`

When using the `git` fileserver backend at least one git remote needs to be defined. The user running the salt master will need read access to the repo.

The repos will be searched in order to find the file requested by a client and the first repo to have the file will return it. Branches and tags are translated into salt environments.

```
gitfs_remotes:
  - git://github.com/saltstack/salt-states.git
  - file:///var/git/saltmaster
```

**Note:** `file://` repos will be treated as a remote and copied into the master’s gitfs cache, so only the `local` refs for those repos will be exposed as fileserver environments.

As of 2014.7.0, it is possible to have per-repo versions of several of the gitfs configuration parameters. For more information, see the *GitFS Walkthrough*.
**gitfs_provider**

New in version 2014.7.0.

Optional parameter used to specify the provider to be used for gitfs. More information can be found in the *GitFS Walkthrough*.

Must be one of the following: pygit2, gitpython, or dulwich. If unset, then each will be tried in that same order, and the first one with a compatible version installed will be the provider that is used.

```
gitfs_provider: dulwich
```

**gitfs_ssl_verify**

Default: False

Specifies whether or not to ignore SSL certificate errors when contacting the remote repository. The False setting is useful if you're using a git repo that uses a self-signed certificate. However, keep in mind that setting this to anything other True is a considered insecure, and using an SSH-based transport (if available) may be a better option.

```
gitfs_ssl_verify: True
```

**gitfs_mountpoint**

New in version 2014.7.0.

Default: ''

Specifies a path on the salt fileserver which will be prepended to all files served by gitfs. This option can be used in conjunction with *gitfs_root*. It can also be configured on a per-remote basis, see here for more info.

```
gitfs_mountpoint: salt://foo/bar
```

**Note:** The *salt://* protocol designation can be left off (in other words, foo/bar and salt://foo/bar are equivalent). Assuming a file baz.sh in the root of a gitfs remote, and the above example mountpoint, this file would be served up via salt://foo/bar/baz.sh.

**gitfs_root**

Default: ''

Relative path to a subdirectory within the repository from which Salt should begin to serve files. This is useful when there are files in the repository that should not be available to the Salt fileserver. Can be used in conjunction with *gitfs_mountpoint*. If used, then from Salt's perspective the directories above the one specified will be ignored and the relative path will (for the purposes of gitfs) be considered as the root of the repo.

```
gitfs_root: somefolder/otherfolder
```

Changed in version 2014.7.0: Ability to specify gitfs roots on a per-remote basis was added. See here for more info.
**gitfs_base**

Default: master

Defines which branch/tag should be used as the base environment.

```
gitfs_base: salt
```

Changed in version 2014.7.0: Ability to specify the base on a per-remote basis was added. See here for more info.

**gitfs_env_whitelist**

New in version 2014.7.0.

Default: []

Used to restrict which environments are made available. Can speed up state runs if the repos in `gitfs_remotes` contain many branches/tags. More information can be found in the GitFS Walkthrough.

```
gitfs_env_whitelist:
  - base
  - v1.*
  - 'mybranch\d+'
```

**gitfs_env_blacklist**

New in version 2014.7.0.

Default: []

Used to restrict which environments are made available. Can speed up state runs if the repos in `gitfs_remotes` contain many branches/tags. More information can be found in the GitFS Walkthrough.

```
gitfs_env_blacklist:
  - base
  - v1.*
  - 'mybranch\d+'
```

**gitfs_global_lock**

New in version 2015.8.9.

Default: True

When set to False, if there is an update lock for a gitfs remote and the pid written to it is not running on the master, the lock file will be automatically cleared and a new lock will be obtained. When set to True, Salt will simply log a warning when there is an update lock present.

On single-master deployments, disabling this option can help automatically deal with instances where the master was shutdown/restarted during the middle of a gitfs update, leaving a update lock in place.

However, on multi-master deployments with the gitfs cachedir shared via GlusterFS, nfs, or another network filesystem, it is strongly recommended not to disable this option as doing so will cause lock files to be removed if they were created by a different master.
# Disable global lock

gitfs_global_lock: False

## GitFS Authentication Options

These parameters only currently apply to the pygit2 gitfs provider. Examples of how to use these can be found in the [GitFS Walkthrough](#).

### gitfs_user

New in version 2014.7.0.
Default: ''
Along with `gitfs_password`, is used to authenticate to HTTPS remotes.

gitfs_user: git

### gitfs_password

New in version 2014.7.0.
Default: ''
Along with `gitfs_user`, is used to authenticate to HTTPS remotes. This parameter is not required if the repository does not use authentication.

gitfs_password: mypassword

### gitfs_insecure_auth

New in version 2014.7.0.
Default: False
By default, Salt will not authenticate to an HTTP (non-HTTPS) remote. This parameter enables authentication over HTTP. Enable this at your own risk.

gitfs_insecure_auth: True

### gitfs_pubkey

New in version 2014.7.0.
Default: ''
Along with `gitfs_privkey` (and optionally `gitfs_passphrase`), is used to authenticate to SSH remotes. This parameter (or its per-remote counterpart) is required for SSH remotes.

gitfs_pubkey: /path/to/key.pub
**gitfs_privkey**

New in version 2014.7.0.
Default: ''

Along with **gitfs_pubkey** (and optionally **gitfs_passphrase**), is used to authenticate to SSH remotes. This parameter (or its per-remote counterpart) is required for SSH remotes.

```
gitfs_privkey: /path/to/key
```

**gitfs_passphrase**

New in version 2014.7.0.
Default: ''

This parameter is optional, required only when the SSH key being used to authenticate is protected by a passphrase.

```
gitfs_passphrase: mypassphrase
```

**hg: Mercurial Remote File Server Backend**

**hgfs_remotes**

New in version 0.17.0.
Default: []

When using the hg fileserver backend at least one mercurial remote needs to be defined. The user running the salt master will need read access to the repo.

The repos will be searched in order to find the file requested by a client and the first repo to have the file will return it. Branches and/or bookmarks are translated into salt environments, as defined by the **hgfs_branch_method** parameter.

```
hgfs_remotes:
  - https://username@bitbucket.org/username/reponame
```

**Note:** As of 2014.7.0, it is possible to have per-repo versions of the **hgfs_root**, **hgfs_mountpoint**, **hgfs_base**, and **hgfs_branch_method** parameters. For example:

```
hgfs_remotes:
  - https://username@bitbucket.org/username/repo1
    - base: saltstates
  - https://username@bitbucket.org/username/repo2:
    - root: salt
    - mountpoint: salt://foo/bar/baz
  - https://username@bitbucket.org/username/repo3:
    - root: salt/states
    - branch_method: mixed
```

---

2.1. Configuring the Salt Master 71
**hgfs_branch_method**

New in version 0.17.0.

Default: branches

Defines the objects that will be used as fileservers environments.

- branches - Only branches and tags will be used
- bookmarks - Only bookmarks and tags will be used
- mixed - Branches, bookmarks, and tags will be used

| hgfs_branch_method: mixed |

Note: Starting in version 2014.1.0, the value of the `hgfs_base` parameter defines which branch is used as the base environment, allowing for a base environment to be used with an `hgfs_branch_method` of bookmarks.

Prior to this release, the default branch will be used as the base environment.

**hgfs_mountpoint**

New in version 2014.7.0.

Default: ''

Specifies a path on the salt fileserver which will be prepended to all files served by hgfs. This option can be used in conjunction with `hgfs_root`. It can also be configured on a per-remote basis, see [here](#) for more info.

| hgfs_mountpoint: salt://foo/bar |

Note: The `salt://` protocol designation can be left off (in other words, `foo/bar` and `salt://foo/bar` are equivalent). Assuming a file `baz.sh` in the root of an hgfs remote, this file would be served up via `salt://foo/bar/baz.sh`.

**hgfs_root**

New in version 0.17.0.

Default: ''

Relative path to a subdirectory within the repository from which Salt should begin to serve files. This is useful when there are files in the repository that should not be available to the Salt fileserver. Can be used in conjunction with `hgfs_mountpoint`. If used, then from Salt's perspective the directories above the one specified will be ignored and the relative path will (for the purposes of hgfs) be considered as the root of the repo.

| hgfs_root: somefolder/otherfolder |

Changed in version 2014.7.0: Ability to specify hgfs roots on a per-remote basis was added. See [here](#) for more info.
**hgfs_base**

New in version 2014.1.0.
Default: default

Defines which branch should be used as the base environment. Change this if `hgfs_branch_method` is set to bookmarks to specify which bookmark should be used as the base environment.

```
hgfs_base: salt
```

**hgfs_env_whitelist**

New in version 2014.7.0.
Default: `[]`

Used to restrict which environments are made available. Can speed up state runs if your hgfs remotes contain many branches/bookmarks/tags. Full names, globs, and regular expressions are supported. If using a regular expression, the expression must match the entire minion ID.

If used, only branches/bookmarks/tags which match one of the specified expressions will be exposed as fileserver environments.

If used in conjunction with `hgfs_env_blacklist`, then the subset of branches/bookmarks/tags which match the whitelist but do not match the blacklist will be exposed as fileserver environments.

```
hgfs_env_whitelist:
    - base
    - v1.*
    - 'mybranch\d+'
```

**hgfs_env_blacklist**

New in version 2014.7.0.
Default: `[]`

Used to restrict which environments are made available. Can speed up state runs if your hgfs remotes contain many branches/bookmarks/tags. Full names, globs, and regular expressions are supported. If using a regular expression, the expression must match the entire minion ID.

If used, branches/bookmarks/tags which match one of the specified expressions will not be exposed as fileserver environments.

If used in conjunction with `hgfs_env_whitelist`, then the subset of branches/bookmarks/tags which match the whitelist but do not match the blacklist will be exposed as fileserver environments.

```
hgfs_env_blacklist:
    - base
    - v1.*
    - 'mybranch\d+'
```
**svn: Subversion Remote File Server Backend**

**svnfs_remotes**

New in version 0.17.0.

Default: `[]`

When using the `svn` fileserver backend at least one subversion remote needs to be defined. The user running the salt master will need read access to the repo.

The repos will be searched in order to find the file requested by a client and the first repo to have the file will return it. The trunk, branches, and tags become environments, with the trunk being the `base` environment.

```yaml
evns_remotes:
  - svn://foo.com/svn/myproject
```

**Note:** As of 2014.7.0, it is possible to have per-repo versions of the following configuration parameters:

- `svnfs_root`
- `svnfs_mountpoint`
- `svnfs_trunk`
- `svnfs_branches`
- `svnfs_tags`

For example:

```yaml
evns_remotes:
  - svn://foo.com/svn/project1
  - svn://foo.com/svn/project2:
    - root: salt
    - mountpoint: salt://foo/bar/baz
  - svn://foo.com/svn/project3:
    - root: salt/states
    - branches: branch
    - tags: tag
```

**svnfs_mountpoint**

New in version 2014.7.0.

Default: `'`

Specifies a path on the salt fileserver which will be prepended to all files served by hgfs. This option can be used in conjunction with `svnfs_root`. It can also be configured on a per-remote basis, see [here](#) for more info.

```yaml
evnsfs_mountpoint: salt://foo/bar
```

**Note:** The `salt://` protocol designation can be left off (in other words, `foo/bar` and `salt://foo/bar` are equivalent). Assuming a file `baz.sh` in the root of an svnfs remote, this file would be served up via `salt://foo/bar/baz.sh`. 
**svnfs_root**

New in version 0.17.0.
Default: ''
Relative path to a subdirectory within the repository from which Salt should begin to serve files. This is useful when there are files in the repository that should not be available to the Salt fileserver. Can be used in conjunction with `svnfs_mountpoint`. If used, then from Salt’s perspective the directories above the one specified will be ignored and the relative path will (for the purposes of svnfs) be considered as the root of the repo.

| svnfs_root: somefolder/otherfolder |

Changed in version 2014.7.0: Ability to specify svnfs roots on a per-remote basis was added. See [here](#) for more info.

**svnfs_trunk**

New in version 2014.7.0.
Default: trunk
Path relative to the root of the repository where the trunk is located. Can also be configured on a per-remote basis, see [here](#) for more info.

| svnfs_trunk: trunk |

**svnfs_branches**

New in version 2014.7.0.
Default: branches
Path relative to the root of the repository where the branches are located. Can also be configured on a per-remote basis, see [here](#) for more info.

| svnfs_branches: branches |

**svnfs_tags**

New in version 2014.7.0.
Default: tags
Path relative to the root of the repository where the tags are located. Can also be configured on a per-remote basis, see [here](#) for more info.

| svnfs_tags: tags |

**svnfs_env_whitelist**

New in version 2014.7.0.
Default: []

---

2.1. Configuring the Salt Master 75
Used to restrict which environments are made available. Can speed up state runs if your svnfs remotes contain many branches/tags. Full names, globs, and regular expressions are supported. If using a regular expression, the expression must match the entire minion ID.

If used, only branches/tags which match one of the specified expressions will be exposed as fileserver environments.

If used in conjunction with `svnfs_env_blacklist`, then the subset of branches/tags which match the whitelist but do not match the blacklist will be exposed as fileserver environments.

```
svnfs_env_whitelist:
  - base
  - v1.*
  - 'mybranch\d+'
```

**svnfs_env_blacklist**

New in version 2014.7.0.

Default: `[]`

Used to restrict which environments are made available. Can speed up state runs if your svnfs remotes contain many branches/tags. Full names, globs, and regular expressions are supported. If using a regular expression, the expression must match the entire minion ID.

If used, branches/tags which match one of the specified expressions will *not* be exposed as fileserver environments.

If used in conjunction with `svnfs_env_whitelist`, then the subset of branches/tags which match the whitelist but do not match the blacklist will be exposed as fileserver environments.

```
svnfs_env_blacklist:
  - base
  - v1.*
  - 'mybranch\d+'
```

**minion: MinionFS Remote File Server Backend**

**minionfs_env**

New in version 2014.7.0.

Default: `base`

Environment from which MinionFS files are made available.

```
minionfs_env: minionfs
```

**minionfs_mountpoint**

New in version 2014.7.0.

Default: `''`

Specifies a path on the salt fileserver from which minionfs files are served.

```
minionfs_mountpoint: salt://foo/bar
```
Note: The `salt://` protocol designation can be left off (in other words, `foo/bar` and `salt://foo/bar` are equivalent).

### minionfs_whitelist

New in version 2014.7.0.

Default: `[]`

Used to restrict which minions' pushed files are exposed via minionfs. If using a regular expression, the expression must match the entire minion ID.

If used, only the pushed files from minions which match one of the specified expressions will be exposed.

If used in conjunction with `minionfs_blacklist`, then the subset of hosts which match the whitelist but do not match the blacklist will be exposed.

```
minionfs_whitelist:
- server01
- dev*
- 'mail\d+.mydomain.tld'
```

### minionfs_blacklist

New in version 2014.7.0.

Default: `[]`

Used to restrict which minions' pushed files are exposed via minionfs. If using a regular expression, the expression must match the entire minion ID.

If used, only the pushed files from minions which match one of the specified expressions will not be exposed.

If used in conjunction with `minionfs_whitelist`, then the subset of hosts which match the whitelist but do not match the blacklist will be exposed.

```
minionfs_blacklist:
- server01
- dev*
- 'mail\d+.mydomain.tld'
```

### 2.1.7 Pillar Configuration

#### pillar_roots

Default:

```
base:
- /srv/pillar
```

Set the environments and directories used to hold pillar sls data. This configuration is the same as `file_roots`:
pillar_roots:
- base:
  - /srv/pillar
- dev:
  - /srv/pillar/dev
- prod:
  - /srv/pillar/prod

on_demand_ext_pillar

New in version 2016.3.6,2016.11.3,Nitrogen.
Default: ['libvirt','virtkey']
The external pillars permitted to be used on-demand using pillar.ext.

on_demand_ext_pillar:
- libvirt
- virtkey
- git

Warning: This will allow minions to request specific pillar data via pillar.ext, and may be considered a security risk. However, pillar data generated in this way will not affect the in-memory pillar data, so this risk is limited to instances in which states/modules/etc. (built-in or custom) rely upon pillar data generated by pillar.ext.

pillar_opts

Default: False
The pillar_opts option adds the master configuration file data to a dict in the pillar called master. This can be used to set simple configurations in the master config file that can then be used on minions.

Note that setting this option to True means the master config file will be included in all minion's pillars. While this makes global configuration of services and systems easy, it may not be desired if sensitive data is stored in the master configuration.

pillar_opts: False

ext_pillar

The ext_pillar option allows for any number of external pillar interfaces to be called when populating pillar data. The configuration is based on ext_pillar functions. The available ext_pillar functions can be found herein:

https://github.com/saltstack/salt/blob/develop/salt/pillar

By default, the ext_pillar interface is not configured to run.
Default: []

ext_pillar:
- hiera: /etc/hiera.yaml
- cmd_yaml: cat /etc/salt/yaml
- reclass:
  inventory_base_uri: /etc/reclass

There are additional details at salt-pillars

**ext_pillar_first**

New in version 2015.5.0.
Default: False

This option allows for external pillar sources to be evaluated before pillar_roots. External pillar data is evaluated separately from pillar_roots pillar data, and then both sets of pillar data are merged into a single pillar dictionary, so the value of this config option will have an impact on which key "wins" when there is one of the same name in both the external pillar data and pillar_roots pillar data. By setting this option to True, ext_pillar keys will be overridden by pillar_roots, while leaving it as False will allow ext_pillar keys to override those from pillar_roots.

Note: For a while, this config option did not work as specified above, because of a bug in Pillar compilation. This bug has been resolved in version 2016.3.4 and later.

**ext_pillar_first: False**

**Git External Pillar (git_pillar) Configuration Options**

**git_pillar_provider**

New in version 2015.8.0.

Specify the provider to be used for git_pillar. Must be either pygit2 or gitpython. If unset, then both will be tried in that same order, and the first one with a compatible version installed will be the provider that is used.

**git_pillar_provider: gitpython**

**git_pillar_base**

New in version 2015.8.0.
Default: master

If the desired branch matches this value, and the environment is omitted from the git_pillar configuration, then the environment for that git_pillar remote will be base. For example, in the configuration below, the foo branch/tag would be assigned to the base environment, while bar would be mapped to the bar environment.

**git_pillar_base: foo**

**ext_pillar:**
- git:
  - foo https://mygitserver/git-pillar.git
  - bar https://mygitserver/git-pillar.git**
**git_pillar_branch**

New in version 2015.8.0.

Default: master

If the branch is omitted from a git_pillar remote, then this branch will be used instead. For example, in the configuration below, the first two remotes would use the pillardata branch/tag, while the third would use the foo branch/tag.

```yaml
git_pillar_branch: pillardata
ext_pillar:
  - git:
      - https://mygitserver/pillar1.git
      - https://mygitserver/pillar2.git:
        - root: pillar
        - foo https://mygitserver/pillar3.git
```

**git_pillar_env**

New in version 2015.8.0.

Default: '' (unset)

Environment to use for git_pillar remotes. This is normally derived from the branch/tag (or from a per-remote env parameter), but if set this will override the process of deriving the env from the branch/tag name. For example, in the configuration below the foo branch would be assigned to the base environment, while the bar branch would need to explicitly have bar configured as it's environment to keep it from also being mapped to the base environment.

```yaml
git_pillar_env: base
ext_pillar:
  - git:
      - foo https://mygitserver/git-pillar.git
      - bar https://mygitserver/git-pillar.git:
        - env: bar
```

For this reason, this option is recommended to be left unset, unless the use case calls for all (or almost all) of the git_pillar remotes to use the same environment irrespective of the branch/tag being used.

**git_pillar_root**

New in version 2015.8.0.

Default: ''

Path relative to the root of the repository where the git_pillar top file and SLS files are located. In the below configuration, the pillar top file and SLS files would be looked for in a subdirectory called pillar.

```yaml
git_pillar_root: pillar
ext_pillar:
  - git:
      - master https://mygitserver/pillar1.git
      - master https://mygitserver/pillar2.git
```
**Note:** This is a global option. If only one or two repos need to have their files sourced from a subdirectory, then `git_pillar_root` can be omitted and the root can be specified on a per-remote basis, like so:

```
ext_pillar:
  - git:
    - master https://mygitserver/pillar1.git
    - master https://mygitserver/pillar2.git:
      - root: pillar
```

In this example, for the first remote the top file and SLS files would be looked for in the root of the repository, while in the second remote the pillar data would be retrieved from the `pillar` subdirectory.

---

**git_pillar_ssl_verify**

New in version 2015.8.0.

Default: False

Specifies whether or not to ignore SSL certificate errors when contacting the remote repository. The False setting is useful if you’re using a git repo that uses a self-signed certificate. However, keep in mind that setting this to anything other than True is considered insecure, and using an SSH-based transport (if available) may be a better option.

```
git_pillar_ssl_verify: True
```

---

**git_pillar_global_lock**

New in version 2015.8.9.

Default: True

When set to False, if there is an update/checkout lock for a git_pillar remote and the pid written to it is not running on the master, the lock file will be automatically cleared and a new lock will be obtained. When set to True, Salt will simply log a warning when there is an lock present.

On single-master deployments, disabling this option can help automatically deal with instances where the master was shutdown/restarted during the middle of a git_pillar update/checkout, leaving a lock in place.

However, on multi-master deployments with the git_pillar cachedir shared via GlusterFS, nfs, or another network filesystem, it is strongly recommended not to disable this option as doing so will cause lock files to be removed if they were created by a different master.

```
# Disable global lock
git_pillar_global_lock: False
```

---

**Git External Pillar Authentication Options**

These parameters only currently apply to the pygit2 `git_pillar_provider`. Authentication works the same as it does in gitfs, as outlined in the GitFS Walkthrough, though the global configuration options are named differently to reflect that they are for git_pillar instead of gitfs.
**git_pillar_user**

New in version 2015.8.0.
Default: ''
Along with *git_pillar_password*, is used to authenticate to HTTPS remotes.

```
git_pillar_user: git
```

**git_pillar_password**

New in version 2015.8.0.
Default: ''
Along with *git_pillar_user*, is used to authenticate to HTTPS remotes. This parameter is not required if the repository does not use authentication.

```
git_pillar_password: mypassword
```

**git_pillar_insecure_auth**

New in version 2015.8.0.
Default: False
By default, Salt will not authenticate to an HTTP (non-HTTPS) remote. This parameter enables authentication over HTTP. Enable this at your own risk.

```
git_pillar_insecure_auth: True
```

**git_pillar_pubkey**

New in version 2015.8.0.
Default: ''
Along with *git_pillar_privkey* (and optionally *git_pillar_passphrase*), is used to authenticate to SSH remotes.

```
git_pillar_pubkey: /path/to/key.pub
```

**git_pillar_privkey**

New in version 2015.8.0.
Default: ''
Along with *git_pillar_pubkey* (and optionally *git_pillar_passphrase*), is used to authenticate to SSH remotes.

```
git_pillar_privkey: /path/to/key
```
**git_pillar_passphrase**

New in version 2015.8.0.
Default: ''
This parameter is optional, required only when the SSH key being used to authenticate is protected by a passphrase.

```
git_pillar_passphrase: mypassphrase
```

**Pillar Merging Options**

**pillar_source_merging_strategy**

New in version 2014.7.0.
Default: smart

The pillar_source_merging_strategy option allows you to configure merging strategy between different sources. It accepts 5 values:

- **none**: New in version 2016.3.4: It will not do any merging at all and only parse the pillar data from the passed environment and `base` if no environment was specified.
- **recurse**: it will merge recursively mapping of data. For example, theses 2 sources:

```
foo: 42
bar:
    element1: True

bar:
    element2: True
baz: quux
```

will be merged as:

```
foo: 42
bar:
    element1: True
    element2: True
baz: quux
```

- **aggregate**: instructs aggregation of elements between sources that use the `!yamlex` renderer.

For example, these two documents:

```
#!yamlex
foo: 42
bar: !aggregate {
    element1: True
}
baz: !aggregate quux
```
```yaml
#!/yamlex
bar: !aggregate {
   element2: True
}
baz: !aggregate quux2
```

will be merged as:

```yaml
foo: 42
bar:
   element1: True
   element2: True
baz:
   - quux
   - quux2
```

- `overwrite`:
  
  Will use the behaviour of the 2014.1 branch and earlier.

  Overwrites elements according the order in which they are processed.

  First pillar processed:

  ```yaml
  A:
     first_key: blah
     second_key: blah
  ```

  Second pillar processed:

  ```yaml
  A:
     third_key: blah
     fourth_key: blah
  ```

  will be merged as:

  ```yaml
  A:
     third_key: blah
     fourth_key: blah
  ```

- `smart` (default):
  
  Guesses the best strategy based on the `renderer` setting.

`pillar_merge_lists`  

New in version 2015.8.0.

Default: False

Recursively merge lists by aggregating them instead of replacing them.

`pillar_merge_lists: False`
Pillar Cache Options

pillar_cache

Default: False
A master can cache pillars locally to bypass the expense of having to render them for each minion on every request. This feature should only be enabled in cases where pillar rendering time is known to be unsatisfactory and any attendant security concerns about storing pillars in a master cache have been addressed.

When enabling this feature, be certain to read through the additional pillar_cache_* configuration options to fully understand the tunable parameters and their implications.

```
pillar_cache: False
```

Note: Setting pillar_cache: True has no effect on targeting minions with pillar.

pillar_cache_ttl

Default: 3600
If and only if a master has set pillar_cache: True, the cache TTL controls the amount of time, in seconds, before the cache is considered invalid by a master and a fresh pillar is recompiled and stored.

pillar_cache_backend

Default: disk
If an only if a master has set pillar_cache: True, one of several storage providers can be utilized:

* disk (default):
  
  The default storage backend. This caches rendered pillars to the master cache. Rendered pillars are serialized and deserialized as msgpack structures for speed. Note that pillars are stored UNENCRYPTED. Ensure that the master cache has permissions set appropriately (sane defaults are provided).

* memory [EXPERIMENTAL]:
  
  An optional backend for pillar caches which uses a pure-Python in-memory data structure for maximal performance. There are several caveats, however. First, because each master worker contains its own in-memory cache, there is no guarantee of cache consistency between minion requests. This works best in situations where the pillar rarely if ever changes. Secondly, and perhaps more importantly, this means that unencrypted pillars will be accessible to any process which can examine the memory of the salt-master! This may represent a substantial security risk.

```
pillar_cache_backend: disk
```
2.1.8 Syndic Server Settings

A Salt syndic is a Salt master used to pass commands from a higher Salt master to minions below the syndic. Using the syndic is simple. If this is a master that will have syndic servers(s) below it, set the `order_masters` setting to `True`.

If this is a master that will be running a syndic daemon for passthrough the `syndic_master` setting needs to be set to the location of the master server.

Do not forget that, in other words, it means that it shares with the local minion its ID and PKI directory.

**order_masters**

Default: `False`

Extra data needs to be sent with publications if the master is controlling a lower level master via a syndic minion. If this is the case the `order_masters` value must be set to `True`

| order_masters: False |

**syndic_master**

Changed in version 2016.3.5,2016.11.1: Set default higher level master address.

Default: `masterofmasters`

If this master will be running the `salt-syndic` to connect to a higher level master, specify the higher level master with this configuration value.

| syndic_master: masterofmasters |

You can optionally connect a syndic to multiple higher level masters by setting the `syndic_master` value to a list:

| syndic_master: |
| - masterofmasters1 |
| - masterofmasters2 |

Each higher level master must be set up in a multi-master configuration.

**syndic_master_port**

Default: `4506`

If this master will be running the `salt-syndic` to connect to a higher level master, specify the higher level master port with this configuration value.

| syndic_master_port: 4506 |

**syndic_pidfile**

Default: `/var/run/salt-syndic.pid`

If this master will be running the `salt-syndic` to connect to a higher level master, specify the pidfile of the syndic daemon.
**syndic_pidfile**: /var/run/syndic.pid

**syndic_log_file**

Default: /var/log/salt/syndic

If this master will be running the salt-syndic to connect to a higher level master, specify the log file of the syndic daemon.

**syndic_log_file**: /var/log/salt-syndic.log

**syndic_failover**

New in version 2016.3.0.

Default: random

The behaviour of the multi-syndic when connection to a master of masters failed. Can specify random (default) or ordered. If set to random, masters will be iterated in random order. If ordered is specified, the configured order will be used.

**syndic_failover**: random

**syndic_wait**

Default: 5

The number of seconds for the salt client to wait for additional syndics to check in with their lists of expected minions before giving up.

**syndic_wait**: 5

### 2.1.9 Peer Publish Settings

Salt minions can send commands to other minions, but only if the minion is allowed to. By default "Peer Publication" is disabled, and when enabled it is enabled for specific minions and specific commands. This allows secure compartmentalization of commands based on individual minions.

**peer**

Default: {}

The configuration uses regular expressions to match minions and then a list of regular expressions to match functions. The following will allow the minion authenticated as foo.example.com to execute functions from the test and pkg modules.

```
peer:
  foo.example.com:
    - test.*
    - pkg.*
```

This will allow all minions to execute all commands.

2.1. Configuring the Salt Master
peer:
  .*:
    - .*

This is not recommended, since it would allow anyone who gets root on any single minion to instantly have root on all of the minions!

By adding an additional layer you can limit the target hosts in addition to the accessible commands:

peer:
  foo.example.com:
    'db*':
      - test.*
      - pkg.*

peer_run

Default: {}

The peer_run option is used to open up runners on the master to access from the minions. The peer_run configuration matches the format of the peer configuration.

The following example would allow foo.example.com to execute the manage.up runner:

peer_run:
  foo.example.com:
    - manage.up

2.1.10 Master Logging Settings

log_file

Default: /var/log/salt/master

The master log can be sent to a regular file, local path name, or network location. See also log_file.

Examples:

log_file: /var/log/salt/master

log_file: file:///dev/log

log_file: udp://loghost:10514

log_level

Default: warning

The level of messages to send to the console. See also log_level.

log_level: warning
**log_level_logfile**

Default: warning

The level of messages to send to the log file. See also `log_level_logfile`. When it is not set explicitly it will inherit the level set by `log_level` option.

```
log_level_logfile: warning
```

**log_datefmt**

Default: %H:%M:%S

The date and time format used in console log messages. See also `log_datefmt`.

```
log_datefmt: '%H:%M:%S'
```

**log_datefmt_logfile**

Default: %Y-%m-%d %H:%M:%S

The date and time format used in log file messages. See also `log_datefmt_logfile`.

```
log_datefmt_logfile: '%Y-%m-%d %H:%M:%S'
```

**log_fmt_console**

Default: [%levelname]-8s] %(message)s

The format of the console logging messages. See also `log_fmt_console`.

**Note:** Log colors are enabled in `log_fmt_console` rather than the `color` config since the logging system is loaded before the master config.

Console log colors are specified by these additional formatters:

%(colorlevel)s %(colormsg)s

Since it is desirable to include the surrounding brackets, `[` and `]`, in the coloring of the messages, these color formatters also include padding as well. Color LogRecord attributes are only available for console logging.

```
log_fmt_console: '%(colorlevel)s %(colormsg)s'
log_fmt_console: '[%levelname]-8s] %(message)s'
```

**log_fmt_logfile**

Default: %(asctime)s,%(msecs)03.0f [%(name)-17s][%(levelname)-8s] %(message)s

The format of the log file logging messages. See also `log_fmt_logfile`.

```
log_fmt_logfile: '%(asctime)s,%(msecs)03.0f [%(name)-17s][%(levelname)-8s] %(message)s'
```
**log_granular_levels**

Default: `{}`

This can be used to control logging levels more specifically. See also `log_granular_levels`.

### 2.1.11 Node Groups

Default: `{}`

Node groups allow for logical groupings of minion nodes. A group consists of a group name and a compound target.

```yaml
nodegroups:
  group1: 'L@foo.domain.com,bar.domain.com,baz.domain.com or bl*.domain.com'
  group2: 'G@os:Debian and foo.domain.com'
  group3: 'G@os:Debian and N@group1'
  group4:
    - 'G@foo:bar'
    - 'or'
    - 'G@foo:baz'
```

More information on using nodegroups can be found [here](#).

### 2.1.12 Range Cluster Settings

**range_server**

Default: `{range:80}`

The range server (and optional port) that serves your cluster information. See [https://github.com/ytoolshed/range/wiki/%22yamlfile%22-module-file-spec](https://github.com/ytoolshed/range/wiki/%22yamlfile%22-module-file-spec)

```yaml
range_server: range:80
```

### 2.1.13 Include Configuration

**default_include**

Default: `master.d/.*.conf`

The master can include configuration from other files. Per default the master will automatically include all config files from `master.d/.*.conf` where `master.d` is relative to the directory of the master configuration file.

**Note:** Salt creates files in the `master.d` directory for its own use. These files are prefixed with an underscore. A common example of this is the `_schedule.conf` file.

**include**

Default: `not defined`

The master can include configuration from other files. To enable this, pass a list of paths to this option. The paths can be either relative or absolute; if relative, they are considered to be relative to the directory the main minion
configuration file lives in. Paths can make use of shell-style globbing. If no files are matched by a path passed to this option then the master will log a warning message.

```yaml
# Include files from a master.d directory in the same directory as the master config file
include: master.d/*

# Include a single extra file into the configuration
include: /etc/roles/webserver

# Include several files and the master.d directory
include:
  - extra_config
  - master.d/*
  - /etc/roles/webserver
```

### 2.1.14 Windows Software Repo Settings

**winrepo_provider**

New in version 2015.8.0.

Specify the provider to be used for winrepo. Must be either `pygit2` or `gitpython`. If unset, then both will be tried in that same order, and the first one with a compatible version installed will be the provider that is used.

```yaml
winrepo_provider: gitpython
```

**winrepo_dir**

Changed in version 2015.8.0: Renamed from `win_repo` to `winrepo_dir`.

Default: `/srv/salt/win/repo`

Location on the master where the `winrepo_remotes` are checked out for pre-2015.8.0 minions. 2015.8.0 and later minions use `winrepo_remotes_ng` instead.

```yaml
winrepo_dir: /srv/salt/win/repo
```

**winrepo_dir_ng**

New in version 2015.8.0: A new `ng` repo was added.

Default: `/srv/salt/win/repo-ng`

Location on the master where the `winrepo_remotes_ng` are checked out for 2015.8.0 and later minions.

```yaml
winrepo_dir_ng: /srv/salt/win/repo-ng
```

**winrepo_cachefile**

Changed in version 2015.8.0: Renamed from `win_repo_mastercachefile` to `winrepo_cachefile`
Note: 2015.8.0 and later minions do not use this setting since the cachefile is now located on the minion.

Default: winrepo.p

Path relative to winrepo_dir where the winrepo cache should be created.

**winrepo_cachefile:** winrepo.p

**winrepo_remotes**

Changed in version 2015.8.0: Renamed from win_gitrepos to winrepo_remotes.

Default: ['https://github.com/saltstack/salt-winrepo.git']

List of git repositories to checkout and include in the winrepo for pre-2015.8.0 minions. 2015.8.0 and later minions use **winrepo_remotes_ng** instead.

**winrepo_remotes:**

- https://github.com/saltstack/salt-winrepo.git

To specify a specific revision of the repository, prepend a commit ID to the URL of the repository:

**winrepo_remotes:**

- '<commit_id> https://github.com/saltstack/salt-winrepo.git'

Replace `<commit_id>` with the SHA1 hash of a commit ID. Specifying a commit ID is useful in that it allows one to revert back to a previous version in the event that an error is introduced in the latest revision of the repo.

**winrepo_remotes_ng**

New in version 2015.8.0: A new ng repo was added.

Default: ['https://github.com/saltstack/salt-winrepo-ng.git']

List of git repositories to checkout and include in the winrepo for 2015.8.0 and later minions.

**winrepo_remotes_ng:**

- https://github.com/saltstack/salt-winrepo-ng.git

To specify a specific revision of the repository, prepend a commit ID to the URL of the repository:

**winrepo_remotes:**

- '<commit_id> https://github.com/saltstack/salt-winrepo-ng.git'

Replace `<commit_id>` with the SHA1 hash of a commit ID. Specifying a commit ID is useful in that it allows one to revert back to a previous version in the event that an error is introduced in the latest revision of the repo.

**winrepo_branch**

New in version 2015.8.0.

Default: master
If the branch is omitted from a winrepo remote, then this branch will be used instead. For example, in the configuration below, the first two remotes would use the `winrepo` branch/tag, while the third would use the `foo` branch/tag.

```yaml
winrepo_branch: winrepo
ext_pillar:
  git:
    - https://mygitserver/winrepo1.git
    - https://mygitserver/winrepo2.git:
    - foo https://mygitserver/winrepo3.git
```

**winrepo_ssl_verify**

New in version 2015.8.0.

Default: False

Specifies whether or not to ignore SSL certificate errors when contacting the remote repository. The False setting is useful if you're using a git repo that uses a self-signed certificate. However, keep in mind that setting this to anything other True is considered insecure, and using an SSH-based transport (if available) may be a better option.

```yaml
winrepo_ssl_verify: True
```

**Winrepo Authentication Options**

These parameters only currently apply to the `pygit2 winrepo_provider`. Authentication works the same as it does in gitfs, as outlined in the [GitFS Walkthrough](#), though the global configuration options are named differently to reflect that they are for winrepo instead of gitfs.

**winrepo_user**

New in version 2015.8.0.

Default: ''

Along with `winrepo_password`, is used to authenticate to HTTPS remotes.

```yaml
winrepo_user: git
```

**winrepo_password**

New in version 2015.8.0.

Default: ''

Along with `winrepo_user`, is used to authenticate to HTTPS remotes. This parameter is not required if the repository does not use authentication.

```yaml
winrepo_password: mypassword
```
**winrepo_insecure_auth**

New in version 2015.8.0.
Default: False

By default, Salt will not authenticate to an HTTP (non-HTTPS) remote. This parameter enables authentication over HTTP. Enable this at your own risk.

```
winrepo_insecure_auth: True
```

**winrepo_pubkey**

New in version 2015.8.0.
Default: ''

Along with `winrepo_privkey` (and optionally `winrepo_passphrase`), is used to authenticate to SSH remotes.

```
winrepo_pubkey: /path/to/key.pub
```

**winrepo_privkey**

New in version 2015.8.0.
Default: ''

Along with `winrepo_pubkey` (and optionally `winrepo_passphrase`), is used to authenticate to SSH remotes.

```
winrepo_privkey: /path/to/key
```

**winrepo_passphrase**

New in version 2015.8.0.
Default: ''

This parameter is optional, required only when the SSH key being used to authenticate is protected by a passphrase.

```
winrepo_passphrase: mypassphrase
```

### 2.2 Configuring the Salt Minion

The Salt system is amazingly simple and easy to configure. The two components of the Salt system each have a respective configuration file. The **salt-master** is configured via the master configuration file, and the **salt-minion** is configured via the minion configuration file.

See also:

* example minion configuration file*

The Salt Minion configuration is very simple. Typically, the only value that needs to be set is the master value so the minion knows where to locate its master.
By default, the salt-minion configuration will be in /etc/salt/minion. A notable exception is FreeBSD, where the configuration will be in /usr/local/etc/salt/minion.

### 2.2.1 Minion Primary Configuration

**master**

Default: salt

The hostname or IP address of the master. See `ipv6` for IPv6 connections to the master.

Default: salt

| master: salt |

**master:port Syntax**

New in version 2015.8.0.

The `master` config option can also be set to use the master’s IP in conjunction with a port number by default.

| master: localhost:1234 |

For IPv6 formatting with a port, remember to add brackets around the IP address before adding the port and enclose the line in single quotes to make it a string:

**Note:** If a port is specified in the `master` as well as `master_port`, the `master_port` setting will be overridden by the `master` configuration.

**List of Masters Syntax**

The option can also be set to a list of masters, enabling multi-master mode.

| master: |
| - address1 |
| - address2 |

Changed in version 2014.7.0: The master can be dynamically configured. The `master` value can be set to an module function which will be executed and will assume that the returning value is the IP or hostname of the desired master. If a function is being specified, then the `master_type` option must be set to `func`, to tell the minion that the value is a function to be run and not a fully-qualified domain name.

| master: module.function |
| master_type: func |

In addition, instead of using multi-master mode, the minion can be configured to use the list of master addresses as a failover list, trying the first address, then the second, etc. until the minion successfully connects. To enable this behavior, set `master_type` to `failover`.
master:
  - address1
  - address2
master_type: failover

**ipv6**

Default: None

Whether the master should be connected over IPv6. By default salt minion will try to automatically detect IPv6 connectivity to master.

`ipv6: True`

**master_uri_format**

New in version 2015.8.0.

Specify the format in which the master address will be evaluated. Valid options are `default` or `ip_only`. If `ip_only` is specified, then the master address will not be split into IP and PORT, so be sure that only an IP (or domain name) is set in the `master` configuration setting.

`master_uri_format: ip_only`

**master_type**

New in version 2014.7.0.

Default: `str`

The type of the `master` variable. Can be `str`, `failover` or `func`.

`master_type: failover`

If this option is set to `failover`, `master` must be a list of master addresses. The minion will then try each master in the order specified in the list until it successfully connects. `master_alive_interval` must also be set, this determines how often the minion will verify the presence of the master.

`master_type: func`

If the master needs to be dynamically assigned by executing a function instead of reading in the static master value, set this to `func`. This can be used to manage the minion’s master setting from an execution module. By simply changing the algorithm in the module to return a new master ip/fqdn, restart the minion and it will connect to the new master.

**max_event_size**

New in version 2014.7.0.

Default: 1048576

Passing very large events can cause the minion to consume large amounts of memory. This value tunes the maximum size of a message allowed onto the minion event bus. The value is expressed in bytes.
max_event_size: 1048576

master_failback

New in version 2016.3.0.
Default: False

If the minion is in multi-master mode and the `conf_minion\textquotesingle master_type\textquotesingle` configuration option is set to `failover`, this setting can be set to `True` to force the minion to fail back to the first master in the list if the first master is back online.

\texttt{master_failback: False}

master_failback_interval

New in version 2016.3.0.
Default: 0

If the minion is in multi-master mode, the `conf_minion\textquotesingle master_type\textquotesingle` configuration is set to `failover`, and the `master_failback` option is enabled, the master failback interval can be set to ping the top master with this interval, in seconds.

\texttt{master_failback_interval: 0}

master_alive_interval

Default: 0

Configures how often, in seconds, the minion will verify that the current master is alive and responding. The minion will try to establish a connection to the next master in the list if it finds the existing one is dead.

\texttt{master_alive_interval: 30}

master_shuffle

New in version 2014.7.0.
Default: False

If `\texttt{master}` is a list of addresses and `\texttt{conf_minion\textquotesingle master_type\textquotesingle}` is `\texttt{failover}`, shuffle them before trying to connect to distribute the minions over all available masters. This uses Python's `\texttt{random.shuffle}` method.

\texttt{master_shuffle: True}

random_master

Default: False

If `\texttt{master}` is a list of addresses, shuffle them before trying to connect to distribute the minions over all available masters. This uses Python's `\texttt{random.randint}` method.
random_master: True

retry_dns
Default: 30
Set the number of seconds to wait before attempting to resolve the master hostname if name resolution fails. Defaults to 30 seconds. Set to zero if the minion should shutdown and not retry.

retry_dns: 30

master_port
Default: 4506
The port of the master ret server, this needs to coincide with the ret_port option on the Salt master.

master_port: 4506

user
Default: root
The user to run the Salt processes

user: root

sudo_user
Default: ''
The user to run salt remote execution commands as via sudo. If this option is enabled then sudo will be used to change the active user executing the remote command. If enabled the user will need to be allowed access via the sudoers file for the user that the salt minion is configured to run as. The most common option would be to use the root user. If this option is set the user option should also be set to a non-root user. If migrating from a root minion to a non root minion the minion cache should be cleared and the minion pki directory will need to be changed to the ownership of the new user.

sudo_user: root

pidfile
Default: /var/run/salt-minion.pid
The location of the daemon’s process ID file

pidfile: /var/run/salt-minion.pid
**root_dir**

Default: /

This directory is prepended to the following options: `pki_dir, cachedir, log_file, sock_dir, and pid-file`.

```
root_dir: /
```

**conf_file**

Default: /etc/salt/minion

The path to the minion's configuration file.

```
conf_file: /etc/salt/minion
```

**pki_dir**

Default: /etc/salt/pki/minion

The directory used to store the minion's public and private keys.

```
pki_dir: /etc/salt/pki/minion
```

**id**

Default: the system's hostname

See also:

Salt Walkthrough

The Setting up a Salt Minion section contains detailed information on how the hostname is determined.

Explicitly declare the id for this minion to use. Since Salt uses detached ids it is possible to run multiple minions on the same machine but with different ids.

```
id: foo.bar.com
```

**minion_id_caching**

New in version 0.17.2.

Default: True

Caches the minion id to a file when the minion's `minion_conf:`id` is not statically defined in the minion config. This setting prevents potential problems when automatic minion id resolution changes, which can cause the minion to lose connection with the master. To turn off minion id caching, set this config to False.

For more information, please see Issue #7558 and Pull Request #8488.

```
minion_id_caching: True
```
append_domain

Default: None

Append a domain to a hostname in the event that it does not exist. This is useful for systems where `socket.getfqdn()` does not actually result in a FQDN (for instance, Solaris).

```
append_domain: foo.org
```

cachedir

Default: /var/cache/salt/minion

The location for minion cache data. This directory may contain sensitive data and should be protected accordingly.

```
cachedir: /var/cache/salt/minion
```

append_minionid_config_dirs

Default: [] (the empty list) for regular minions, ['cachedir'] for proxy minions.

Append minion_id to these configuration directories. Helps with multiple proxies and minions running on the same machine. Allowed elements in the list: pki_dir, cachedir, extension_modules. Normally not needed unless running several proxies and/or minions on the same machine.

```
append_minionid_config_dirs:
  - pki_dir
  - cachedir
```

verify_env

Default: True

Verify and set permissions on configuration directories at startup.

```
verify_env: True
```

Note: When set to True the verify_env option requires WRITE access to the configuration directory (/etc/salt/). In certain situations such as mounting /etc/salt/ as read-only for templating this will create a stack trace when `state.apply` is called.

cache_jobs

Default: False

The minion can locally cache the return data from jobs sent to it, this can be a good way to keep track of the minion side of the jobs the minion has executed. By default this feature is disabled, to enable set cache_jobs to True.

```
cache_jobs: False
```
grains

Default: (empty)

See also:

Grains in the Minion Config

Statically assigns grains to the minion.

```
grains:
  roles:
    - webserver
    - memcache
  deployment: datacenter4
  cabinet: 13
  cab_u: 14-15
```

grains_cache

Default: False

The minion can locally cache grain data instead of refreshing the data each time the grain is referenced. By default this feature is disabled, to enable set grains_cache to True.

```
grains_cache: False
```

grains_deep_merge

New in version 2016.3.0.

Default: False

The grains can be merged, instead of overridden, using this option. This allows custom grains to defined different subvalues of a dictionary grain. By default this feature is disabled, to enable set grains_deep_merge to True.

```
grains_deep_merge: False
```

For example, with these custom grains functions:

```
def custom1_k1():
    return {'custom1': {'k1': 'v1'}}

def custom1_k2():
    return {'custom1': {'k2': 'v2'}}
```

Without grains_deep_merge, the result would be:

```
custom1:
  k1: v1
```

With grains_deep_merge, the result will be:

```
custom1:
  k1: v1
  k2: v2
```
**mine_enabled**

New in version 2015.8.10.
Default: True

Determines whether or not the salt minion should run scheduled mine updates. If this is set to False then the mine update function will not get added to the scheduler for the minion.

```
mine_enabled: True
```

**mine_return_job**

New in version 2015.8.10.
Default: False

Determines whether or not scheduled mine updates should be accompanied by a job return for the job cache.

```
mine_return_job: False
```

**mine_functions**

Default: Empty

Designate which functions should be executed at mine_interval intervals on each minion. See this documentation on the Salt Mine for more information. Note these can be defined in the pillar for a minion as well.

```
example minion configuration file
```

```
mine_functions:
    test.ping: []
    network.ip_addrs:
        interface: eth0
        cidr: '10.0.0.0/8'
```

**sock_dir**

Default: /var/run/salt/minion

The directory where Unix sockets will be kept.

```
sock_dir: /var/run/salt/minion
```

**backup_mode**

Default: ''

Make backups of files replaced by file.managed and file.recurse state modules under cachedir in file_backup subdirectory preserving original paths. Refer to File State Backups documentation for more details.

```
backup_mode: minion
```
**acceptance_wait_time**

Default: 10

The number of seconds to wait until attempting to re-authenticate with the master.

```
acceptance_wait_time: 10
```

**acceptance_wait_time_max**

Default: 0

The maximum number of seconds to wait until attempting to re-authenticate with the master. If set, the wait will increase by `acceptance_wait_time` seconds each iteration.

```
acceptance_wait_time_max: 0
```

**random_reauth_delay**

Default: 10

When the master key changes, the minion will try to re-auth itself to receive the new master key. In larger environments this can cause a syn-flood on the master because all minions try to re-auth immediately. To prevent this and have a minion wait for a random amount of time, use this optional parameter. The wait-time will be a random number of seconds between 0 and the defined value.

```
random_reauth_delay: 60
```

**master_tries**

New in version 2016.3.0.

Default: 1

The number of attempts to connect to a master before giving up. Set this to -1 for unlimited attempts. This allows for a master to have downtime and the minion to reconnect to it later when it comes back up. In `failover` mode, which is set in the `master_type` configuration, this value is the number of attempts for each set of masters. In this mode, it will cycle through the list of masters for each attempt.

`master_tries` is different than `auth_tries` because `auth_tries` attempts to retry auth attempts with a single master. `auth_tries` is under the assumption that you can connect to the master but not gain authorization from it. `master_tries` will still cycle through all of the masters in a given try, so it is appropriate if you expect occasional downtime from the master(s).

```
master_tries: 1
```

**auth_tries**

New in version 2014.7.0.

Default: 7

The number of attempts to authenticate to a master before giving up. Or, more technically, the number of consecutive SaltReqTimeoutErrors that are acceptable when trying to authenticate to the master.
auth_tries: 7

**auth_timeout**

New in version 2014.7.0.
Default: 60
When waiting for a master to accept the minion’s public key, salt will continuously attempt to reconnect until successful. This is the timeout value, in seconds, for each individual attempt. After this timeout expires, the minion will wait for `acceptance_wait_time` seconds before trying again. Unless your master is under unusually heavy load, this should be left at the default.

auth_timeout: 60

**auth_safemode**

New in version 2014.7.0.
Default: False
If authentication fails due to SaltReqTimeoutError during a ping_interval, this setting, when set to True, will cause a sub-minion process to restart.

auth_safemode: False

**recon_default**

Default: 1000
The interval in milliseconds that the socket should wait before trying to reconnect to the master (1000ms = 1 second).

recon_default: 1000

**recon_max**

Default: 10000
The maximum time a socket should wait. Each interval the time to wait is calculated by doubling the previous time. If recon_max is reached, it starts again at the recon_default.

**Short example:**

- reconnect 1: the socket will wait `recon_default` milliseconds
- reconnect 2: `recon_default` * 2
- reconnect 3: (`recon_default` * 2) * 2
- reconnect 4: value from previous interval * 2
- reconnect 5: value from previous interval * 2
- reconnect x: if value >= recon_max, it starts again with recon_default
**recon_max**

Default: 10000
Generate a random wait time on minion start. The wait time will be a random value between recon_default and recon_default + recon_max. Having all minions reconnect with the same recon_default and recon_max value kind of defeats the purpose of being able to change these settings. If all minions have the same values and the setup is quite large (several thousand minions), they will still flood the master. The desired behavior is to have time-frame within all minions try to reconnect.

**recon_randomize**

Default: True

**return_retry_timer**

Default: 5
The default timeout for a minion return attempt.

**return_retry_timer_max**

Default: 10
The maximum timeout for a minion return attempt. If non-zero the minion return retry timeout will be a random int between return_retry_timer and return_retry_timer_max

**cache_sreqs**

Default: True
The connection to the master ret_port is kept open. When set to False, the minion creates a new connection for every return to the master.

**ipc_mode**

Default: ipc
Windows platforms lack POSIX IPC and must rely on slower TCP based inter-process communications. Set ipc_mode to tcp on such systems.
**tcp_pub_port**

Default: 4510

Publish port used when `ipc_mode` is set to tcp.

```
tcp_pub_port: 4510
```

**tcp_pull_port**

Default: 4511

Pull port used when `ipc_mode` is set to tcp.

```
tcp_pull_port: 4511
```

**transport**

Default: zeromq

Changes the underlying transport layer. ZeroMQ is the recommended transport while additional transport layers are under development. Supported values are `zeromq`, `raet` (experimental), and `tcp` (experimental). This setting has a significant impact on performance and should not be changed unless you know what you are doing! Transports are explained in Salt Transports.

```
transport: zeromq
```

**syndic_finger**

Default: ''

The key fingerprint of the higher-level master for the syndic to verify it is talking to the intended master.

```
```

**proxy_host**

Default: ''

The hostname used for HTTP proxy access.

```
proxy_host: proxy.my-domain
```

**proxy_port**

Default: 0

The port number used for HTTP proxy access.

```
proxy_port: 31337
```
proxy_username

Default: ''
The username used for HTTP proxy access.

```
proxy_username: charon
```

proxy_password

Default: ''
The password used for HTTP proxy access.

```
proxy_password: obolus
```

### 2.2.2 Minion Module Management

**disable_modules**

Default: [] (all modules are enabled by default)
The event may occur in which the administrator desires that a minion should not be able to execute a certain module. The sys module is built into the minion and cannot be disabled.

This setting can also tune the minion. Because all modules are loaded into system memory, disabling modules will lower the minion's memory footprint.

Modules should be specified according to their file name on the system and not by their virtual name. For example, to disable cmd, use the string cmdmod which corresponds to salt.modules.cmdmod.

```
disable_modules:
  - test
  - solr
```

**disable_returners**

Default: [] (all returners are enabled by default)
If certain returners should be disabled, this is the place

```
disable_returners:
  - mongo_return
```

**module_dirs**

Default: []
A list of extra directories to search for Salt modules

```
module_dirs:
  - /var/lib/salt/modules
```
**returner_dirs**

Default: `[]`

A list of extra directories to search for Salt returners

```
returner_dirs:
  - /var/lib/salt/returners
```

**states_dirs**

Default: `[]`

A list of extra directories to search for Salt states

```
states_dirs:
  - /var/lib/salt/states
```

**grains_dirs**

Default: `[]`

A list of extra directories to search for Salt grains

```
grains_dirs:
  - /var/lib/salt/grains
```

**render_dirs**

Default: `[]`

A list of extra directories to search for Salt renderers

```
render_dirs:
  - /var/lib/salt/renderers
```

**cython_enable**

Default: `False`

Set this value to true to enable auto-loading and compiling of `.pyx` modules. This setting requires that `gcc` and `cython` are installed on the minion.

```
cython_enable: False
```

**enable_zip_modules**

New in version 2015.8.0.

Default: `False`

Set this value to true to enable loading of zip archives as extension modules. This allows for packing module code with specific dependencies to avoid conflicts and/or having to install specific modules' dependencies in system libraries.
enable_zip_modules: False

**providers**

Default: (empty)

A module provider can be statically overwritten or extended for the minion via the `providers` option. This can be done on an individual basis in an SLS file, or globally here in the minion config, like below.

```yaml
providers:
  service: systemd
```

### 2.2.3 State Management Settings

**renderer**

Default: yaml_jinja

The default renderer used for local state executions

```yaml
renderer: yaml_jinja
```

**state_verbose**

Default: True

Controls the verbosity of state runs. By default, the results of all states are returned, but setting this value to False will cause salt to only display output for states that failed or states that have changes.

```yaml
state_verbose: True
```

**state_output**

Default: full

The `state_output` setting changes if the output is the full multi line output for each changed state if set to `full`, but if set to `terse` the output will be shortened to a single line.

```yaml
state_output: full
```

**autoload_dynamic_modules**

Default: True

`autoload_dynamic_modules` turns on automatic loading of modules found in the environments on the master. This is turned on by default. To turn off auto-loading modules when states run, set this value to False.

```yaml
autoload_dynamic_modules: True
```
Default: True

clean_dynamic_modules keeps the dynamic modules on the minion in sync with the dynamic modules on the master. This means that if a dynamic module is not on the master it will be deleted from the minion. By default this is enabled and can be disabled by changing this value to False.

| clean_dynamic_modules: True |

**environment**

Normally the minion is not isolated to any single environment on the master when running states, but the environment can be isolated on the minion side by statically setting it. Remember that the recommended way to manage environments is to isolate via the top file.

| environment: dev |

**state_top_saltenv**

This option has no default value. Set it to an environment name to ensure that only the top file from that environment is considered during a highstate.

**Note:** Using this value does not change the merging strategy. For instance, if top_file_merging_strategy is left at its default, and state_top_saltenv is set to foo, then any sections for environments other than foo in the top file for the foo environment will be ignored. With state_top_saltenv set to base, all states from all environments in the base top file will be applied, while all other top files are ignored.

| state_top_saltenv: dev |

**top_file_merging_strategy**

Default: merge

When no specific fileserver environment (a.k.a. saltenv) has been specified for a highstate, all environments' top files are inspected. This config option determines how the SLS targets in those top files are handled.

When set to the default value of merge, all SLS files are interpreted. The first target expression for a given environment is kept, and when the same target expression is used in a different top file evaluated later, it is ignored. The environments will be evaluated in no specific order, for greater control over the order in which the environments are evaluated use env_order.

When set to same, then for each environment, only that environment's top file is processed, with the others being ignored. For example, only the dev environment's top file will be processed for the dev environment, and any SLS targets defined for dev in the base environment's (or any other environment's) top file will be ignored. If an environment does not have a top file, then the top file from the default_top config parameter will be used as a fallback.

| top_file_merging_strategy: same |
**env_order**

Default: 

When `top_file_merging_strategy` is set to `merge`, and no environment is specified for a `highstate`, this config option allows for the order in which top files are evaluated to be explicitly defined.

```yaml
env_order:
- base
- dev
- qa
```

**default_top**

Default: base

When `top_file_merging_strategy` is set to `same`, and no environment is specified for a `highstate`, this config option specifies a fallback environment in which to look for a top file if an environment lacks one.

```yaml
default_top: dev
```

### 2.2.4 File Directory Settings

**file_client**

Default: remote

The client defaults to looking on the master server for files, but can be directed to look on the minion by setting this parameter to `local`.

```yaml
file_client: remote
```

**use_master_when_local**

Default: False

When using a local `file_client`, this parameter is used to allow the client to connect to a master for remote execution.

```yaml
use_master_when_local: False
```

**file_roots**

Default:

```yaml
base:
- /srv/salt
```

When using a local `file_client`, this parameter is used to setup the fileserver's environments. This parameter operates identically to the `master config parameter` of the same name.
file_roots:
  base:
    - /srv/salt
  dev:
    - /srv/salt/dev/services
    - /srv/salt/dev/states
  prod:
    - /srv/salt/prod/services
    - /srv/salt/prod/states

fileserv_followsymlinks

New in version 2014.1.0.
Default: True

By default, the file_server follows symlinks when walking the filesystem tree. Currently this only applies to the default roots fileserver_backend.

fileserv_followsymlinks: True

fileserv_ignoresymlinks

New in version 2014.1.0.
Default: False

If you do not want symlinks to be treated as the files they are pointing to, set fileserv_ignoresymlinks to True. By default this is set to False. When set to True, any detected symlink while listing files on the Master will not be returned to the Minion.

fileserv_ignoresymlinks: False

fileserv_limit_traversal

New in version 2014.1.0.
Default: False

By default, the Salt fileserver recurses fully into all defined environments to attempt to find files. To limit this behavior so that the fileserver only traverses directories with SLS files and special Salt directories like _modules, set fileserv_limit_traversal to True. This might be useful for installations where a file root has a very large number of files and performance is impacted.

fileserv_limit_traversal: False

hash_type

Default: md5

The hash_type is the hash to use when discovering the hash of a file on the local fileserv. The default is md5, but sha1, sha224, sha256, sha384, and sha512 are also supported.
hash_type: md5

2.2.5 Pillar Configuration

pillar_roots

Default:

base:
- /srv/pillar

When using a local file_client, this parameter is used to setup the pillar environments.

pillar_roots:
  base:
  - /srv/pillar
  dev:
  - /srv/pillar/dev
  prod:
  - /srv/pillar/prod

on_demand_ext_pillar

New in version 2016.3.6, 2016.11.3, Nitrogen.

Default: ['libvirt', 'virtkey']

When using a local file_client, this option controls which external pillars are permitted to be used on-demand using pillar.ext.

on_demand_ext_pillar:
  - libvirt
  - virtkey
  - git

Warning: This will allow a masterless minion to request specific pillar data via pillar.ext, and may be considered a security risk. However, pillar data generated in this way will not affect the in-memory pillar data, so this risk is limited to instances in which states/modules/etc. (built-in or custom) rely upon pillar data generated by pillar.ext.

pillarenv

Default: None

Isolates the pillar environment on the minion side. This functions the same as the environment setting, but for pillar instead of states.

pillarenv: None
**minion_pillar_cache**

New in version 2016.3.0.

Default: False

The minion can locally cache rendered pillar data under `cachedir/pillar`. This allows a temporarily disconnected minion to access previously cached pillar data by invoking salt-call with the `--local` and `--pillar_root=conf_minion:cachedir/pillar` options. Before enabling this setting consider that the rendered pillar may contain security sensitive data. Appropriate access restrictions should be in place. By default the saved pillar data will be readable only by the user account running salt. By default this feature is disabled, to enable set `minion_pillar_cache` to True.

```
minion_pillar_cache: False
```

**file_recv_max_size**

New in version 2014.7.0.

Default: 100

Set a hard-limit on the size of the files that can be pushed to the master. It will be interpreted as megabytes.

```
file_recv_max_size: 100
```

### 2.2.6 Security Settings

**open_mode**

Default: False

Open mode can be used to clean out the PKI key received from the Salt master, turn on open mode, restart the minion, then turn off open mode and restart the minion to clean the keys.

```
open_mode: False
```

**master_finger**

Default: 

Fingerprint of the master public key to validate the identity of your Salt master before the initial key exchange. The master fingerprint can be found by running ``salt-key -F master`` on the Salt master.

```
```

**verify_master_pubkey_sign**

Default: False

Enables verification of the master-public-signature returned by the master in auth-replies. Please see the tutorial on how to configure this properly [Multimaster-PKI with Failover Tutorial](#).

New in version 2014.7.0.
If this is set to True, *master_sign_pubkey* must be also set to True in the master configuration file.

**master_sign_key_name**

Default: master_sign

The filename without the .pub suffix of the public key that should be used for verifying the signature from the master. The file must be located in the minion’s pki directory.

New in version 2014.7.0.

**always_verify_signature**

Default: False

If *verify_master_pubkey_sign* is enabled, the signature is only verified if the public-key of the master changes. If the signature should always be verified, this can be set to True.

New in version 2014.7.0.

**2.2.7 Thread Settings**

Default: True

If *multiprocessing* is enabled when a minion receives a publication a new process is spawned and the command is executed therein. Conversely, if *multiprocessing* is disabled the new publication will be run executed in a thread.

**2.2.8 Minion Logging Settings**

**log_file**

Default: /var/log/salt/minion

The minion log can be sent to a regular file, local path name, or network location. See also *log_file*.

Examples:

**log_file: /var/log/salt/minion**

**log_file: file:///dev/log**

**log_file: udp://loghost:10514**
log_level

Default: warning

The level of messages to send to the console. See also log_level.

log_level: warning

log_level_logfile

Default: info

The level of messages to send to the log file. See also log_level_logfile. When it is not set explicitly it will inherit the level set by log_level option.

log_level_logfile: warning

log_datefmt

Default: %H:%M:%S

The date and time format used in console log messages. See also log_datefmt.

log_datefmt: '%H:%M:%S'

log_datefmt_logfile

Default: %Y-%m-%d %H:%M:%S

The date and time format used in log file messages. See also log_datefmt_logfile.

log_datefmt_logfile: '%Y-%m-%d %H:%M:%S'

log_fmt_console

Default: [%levelname]-8s %message

The format of the console logging messages. See also log_fmt_console.

Note: Log colors are enabled in log_fmt_console rather than the color config since the logging system is loaded before the minion config.

Console log colors are specified by these additional formatters:
%(colorlevel)s %(colormsg)s
Since it is desirable to include the surrounding brackets, `[' and `]`, in the coloring of the messages, these color formatters also include padding as well. Color LogRecord attributes are only available for console logging.

log_fmt_console: '%(colorlevel)s%(colormsg)s'
log_fmt_console: ' [%(levelname)-8s] %(message)s'
**log_fmt_logfile**

Default: `%asctime%,%msecs03.0f [%(name)-17s][%(levelname)-8s] %(message)s`

The format of the log file logging messages. See also `log_fmt_logfile`.

```
log_fmt_logfile: '%asctime%,%msecs03.0f [%(name)-17s][%(levelname)-8s] %(message)s'
```

**log_granular_levels**

Default: `{}`

This can be used to control logging levels more specifically. See also `log_granular_levels`.

**zmq_monitor**

Default: False

To diagnose issues with minions disconnecting or missing returns, ZeroMQ supports the use of monitor sockets to log connection events. This feature requires ZeroMQ 4.0 or higher.

To enable ZeroMQ monitor sockets, set `zmq_monitor` to `True` and log at a debug level or higher.

A sample log event is as follows:

```
[DEBUG ] ZeroMQ event: {'endpoint': 'tcp://127.0.0.1:4505', 'event': 512, 'value': 27, 'description': 'EVENT_DISCONNECTED'}
```

All events logged will include the string `ZeroMQ event`. A connection event should be logged as the minion starts up and initially connects to the master. If not, check for debug log level and that the necessary version of ZeroMQ is installed.

**failhard**

Default: False

Set the global failhard flag. This informs all states to stop running states at the moment a single state fails.

```
failhard: False
```

### 2.2.9 Include Configuration

**default_include**

Default: `minion.d/*.conf`

The minion can include configuration from other files. Per default the minion will automatically include all config files from `minion.d/*.conf` where minion.d is relative to the directory of the minion configuration file.

Note: Salt creates files in the `minion.d` directory for its own use. These files are prefixed with an underscore. A common example of this is the `_schedule.conf` file.
**include**

Default: not defined

The minion can include configuration from other files. To enable this, pass a list of paths to this option. The paths can be either relative or absolute; if relative, they are considered to be relative to the directory the main minion configuration file lives in. Paths can make use of shell-style globbing. If no files are matched by a path passed to this option then the minion will log a warning message.

```plaintext
# Include files from a minion.d directory in the same directory as the minion config file
include: minion.d/*

# Include a single extra file into the configuration
include: /etc/roles/webserver

# Include several files and the minion.d directory
include:
  - extra_config
  - minion.d/*
  - /etc/roles/webserver
```

### 2.2.10 Frozen Build Update Settings

These options control how `salt.modules.saltutil.update()` works with esky frozen apps. For more information look at [https://github.com/cloudmatrix/esky/](https://github.com/cloudmatrix/esky/).

**update_url**

Default: `False` (Update feature is disabled)

The url to use when looking for application updates. Esky depends on directory listings to search for new versions. A webserver running on your Master is a good starting point for most setups.

```plaintext
update_url: 'http://salt.example.com/minion-updates'
```

**update_restart_services**

Default: `[]` (service restarting on update is disabled)

A list of services to restart when the minion software is updated. This would typically just be a list containing the minion's service name, but you may have other services that need to go with it.

```plaintext
update_restart_services: ['salt-minion']
```

### 2.2.11 Standalone Minion Windows Software Repo Settings

**Important:** To use these config options, the minion must be running in masterless mode (set `file_client` to `local`).
**winrepo_dir**

Changed in version 2015.8.0: Renamed from win_repo to winrepo_dir. Also, this option did not have a default value until this version.

Default: C:\salt\srv\salt\win\repo

Location on the minion where the **winrepo_remotes** are checked out.

```
winrepo_dir: 'D:\winrepo'
```

**winrepo_cachefile**

Changed in version 2015.8.0: Renamed from win_repo_cachefile to winrepo_cachefile. Also, this option did not have a default value until this version.

Default: winrepo.p

Path relative to **winrepo_dir** where the winrepo cache should be created.

```
winrepo_cachefile: winrepo.p
```

**winrepo_remotes**

Changed in version 2015.8.0: Renamed from win_gitrepos to winrepo_remotes. Also, this option did not have a default value until this version.

New in version 2015.8.0.

Default: ['https://github.com/saltstack/salt-winrepo.git']

List of git repositories to checkout and include in the winrepo

```
winrepo_remotes:
  - https://github.com/saltstack/salt-winrepo.git
```

To specify a specific revision of the repository, prepend a commit ID to the URL of the the repository:

```
winrepo_remotes:
  - '<commit_id> https://github.com/saltstack/salt-winrepo.git'
```

Replace <commit_id> with the SHA1 hash of a commit ID. Specifying a commit ID is useful in that it allows one to revert back to a previous version in the event that an error is introduced in the latest revision of the repo.

### 2.3 Configuration file examples

- Example master configuration file
- Example minion configuration file
### Primary configuration settings

# This configuration file is used to manage the behavior of the Salt Master.
# Values that are commented out but have an empty line after the comment are
# defaults that do not need to be set in the config. If there is no blank line
# after the comment then the value is presented as an example and is not the
# default.

# Per default, the master will automatically include all config files
# from master.d//*.conf (master.d is a directory in the same directory
# as the main master config file).
#default_include: master.d//*.conf

# The address of the interface to bind to:
#interface: 0.0.0.0

# Whether the master should listen for IPv6 connections. If this is set to True,
# the interface option must be adjusted, too. (For example: "interface: '::'"
#ipv6: False

# The tcp port used by the publisher:
#publish_port: 4505

# The user under which the salt master will run. Salt will update all
# permissions to allow the specified user to run the master. The exception is
# the job cache, which must be deleted if this user is changed. If the
# modified files cause conflicts, set verify_env to False.
#user: root

# The port used by the communication interface. The ret (return) port is the
# interface used for the file server, authentication, job returns, etc.
#ret_port: 4506

# Specify the location of the daemon process ID file:
#pidfile: /var/run/salt-master.pid

# The root directory prepended to these options: pki_dir, cachedir,
#sock_dir, log_file, autosign_file, autoreject_file, extension_modules,
#key_logfile, pidfile:
#root_dir: /

# The path to the master's configuration file.
#conf_file: /etc/salt/master

# Directory used to store public key data:
pki_dir: /etc/salt/pki/master

# Directory to store job and cache data:
cachedir: /var/cache/salt/master

# Directory for custom modules. This directory can contain subdirectories for
# each of Salt's module types such as "runners", "output", "wheel", "modules",
# "states", "returners", etc.
extension_modules: <no default>

---

Chapter 2. Configuring Salt
# Directory for custom modules. This directory can contain subdirectories for
# each of Salt's module types such as "runners", "output", "wheel", "modules",
# "states", "returners", "engines", etc.
# Like 'extension_modules' but can take an array of paths
#module_dirs: <no default>
#   - /var/cache/salt/minion/extmods

# Verify and set permissions on configuration directories at startup:
#verify_env: True

# Set the number of hours to keep old job information in the job cache:
#keep_jobs: 24

# The number of seconds to wait when the client is requesting information
# about running jobs.
#gather_job_timeout: 10

# Set the default timeout for the salt command and api. The default is 5
# seconds.
#timeout: 5

# The loop_interval option controls the seconds for the master's maintenance
# process check cycle. This process updates file server backends, cleans the
# job cache and executes the scheduler.
#loop_interval: 60

# Set the default outputter used by the salt command. The default is "nested".
#output: nested

# Set the default output file used by the salt command. Default is to output
# to the CLI and not to a file. Functions the same way as the "--out-file"
# CLI option, only sets this to a single file for all salt commands.
#output_file: None

# Return minions that timeout when running commands like test.ping
#show_timeout: True

# By default, output is colored. To disable colored output, set the color value
# to False.
#color: True

# Do not strip off the colored output from nested results and state outputs
# (true by default).
#strip_colors: False

# To display a summary of the number of minions targeted, the number of
# minions returned, and the number of minions that did not return, set the
# cli_summary value to True. (False by default.)
#cli_summary: False

# Set the directory used to hold unix sockets:
#sock_dir: /var/run/salt/master

# The master can take a while to start up when lspci and/or dmidecode is used
# to populate the grains for the master. Enable if you want to see GPU hardware
# data for your master.
# enable_gpu_grains: False

# The master maintains a job cache. While this is a great addition, it can be
# a burden on the master for larger deployments (over 5000 minions).
# Disabling the job cache will make previously executed jobs unavailable to
# the jobs system and is not generally recommended.
#job_cache: True

# Cache minion grains and pillar data in the cachedir.
#minion_data_cache: True

# Store all returns in the given returner.
# Setting this option requires that any returner-specific configuration also
# be set. See various returners in salt/returners for details on required
# configuration values. (See also, event_return_queue below.)
#event_return: mysql

# On busy systems, enabling event_returns can cause a considerable load on
# the storage system for returners. Events can be queued on the master and
# stored in a batched fashion using a single transaction for multiple events.
# By default, events are not queued.
#event_return_queue: 0

# Only return events matching tags in a whitelist,
#event_return_whitelist:
#  - salt/master/a_tag
#  - salt/master/another_tag

# Store all event returns _except_ the tags in a blacklist.
#event_return_blacklist:
#  - salt/master/not_this_tag
#  - salt/master/or_this_one

# Passing very large events can cause the minion to consume large amounts of
# memory. This value tunes the maximum size of a message allowed onto the
# master event bus. The value is expressed in bytes.
#max_event_size: 1048576

# By default, the master AES key rotates every 24 hours. The next command
# following a key rotation will trigger a key refresh from the minion which may
# result in minions which do not respond to the first command after a key refresh.
#
# To tell the master to ping all minions immediately after an AES key refresh, set
# ping_on_rotate to True. This should mitigate the issue where a minion does not
# appear to initially respond after a key is rotated.
#
# Note that ping_on_rotate may cause high load on the master immediately after
# the key rotation event as minions reconnect. Consider this carefully if this
# salt master is managing a large number of minions.
#
# If disabled, it is recommended to handle this event by listening for the
# 'aes_key_rotate' event with the 'key' tag and acting appropriately.
#ping_on_rotate: False

# By default, the master deletes its cache of minion data when the key for that
# minion is removed. To preserve the cache after key deletion, set
# 'preserve_minion_cache' to True.
# WARNING: This may have security implications if compromised minions auth with
# a previous deleted minion ID.
#preserve_minion_cache: False

# Allow or deny minions from requesting their own key revocation
#allow_minion_key_revoke: True

# If max_minions is used in large installations, the master might experience
# high-load situations because of having to check the number of connected
# minions for every authentication. This cache provides the minion-ids of
# all connected minions to all MWorker-processes and greatly improves the
# performance of max_minions.
#con_cache: False

# The master can include configuration from other files. To enable this,
# pass a list of paths to this option. The paths can be either relative or
# absolute; if relative, they are considered to be relative to the directory
# the main master configuration file lives in (this file). Paths can make use
# of shell-style globbing. If no files are matched by a path passed to this
# option, then the master will log a warning message.
#
# Include a config file from some other path:
#include: /etc/salt/extra_config
#
# Include config from several files and directories:
#include:
#  - /etc/salt/extra_config

##### Large-scale tuning settings #####
##########################################
# Max open files
#
# Each minion connecting to the master uses AT LEAST one file descriptor, the
# master subscription connection. If enough minions connect you might start
# seeing on the console (and then salt-master crashes):
# Too many open files (tcp_listener.cpp:335)
# Aborted (core dumped)
#
# By default this value will be the one of `ulimit -Hn`, ie, the hard limit for
# max open files.
#
# If you wish to set a different value than the default one, uncomment and
# configure this setting. Remember that this value CANNOT be higher than the
# hard limit. Raising the hard limit depends on your OS and/or distribution,
# a good way to find the limit is to search the internet. For example:
# raise max open files hard limit debian
#max_open_files: 100000

# The number of worker threads to start. These threads are used to manage
# return calls made from minions to the master. If the master seems to be
# running slowly, increase the number of threads. This setting can not be
# set lower than 3.
#worker_threads: 5

# Set the ZeroMQ high water marks
# http://api.zeromq.org/3-2:zmq-setsockopt

# The publisher interface ZeroMQPubServerChannel
#pub_hwm: 1000

# These two ZMQ HWM settings, salt_event_pub_hwm and event_publisher_pub_hwm
# are significant for masters with thousands of minions. When these are
# insufficiently high it will manifest in random responses missing in the CLI
# and even missing from the job cache. Masters that have fast CPUs and many
# cores with appropriate worker_threads will not need these set as high.

# On deployment with 8,000 minions, 2.4GHz CPUs, 24 cores, 32GiB memory has
# these settings:
#
# salt_event_pub_hwm: 128000
# event_publisher_pub_hwm: 64000

# ZMQ high-water-mark for SaltEvent pub socket
#salt_event_pub_hwm: 20000

# ZMQ high-water-mark for EventPublisher pub socket
#event_publisher_pub_hwm: 10000

# The master may allocate memory per-event and not
# reclaim it.
# To set a high-water mark for memory allocation, use
# ipc_write_buffer to set a high-water mark for message
# buffering.
# Value: In bytes. Set to 'dynamic' to have Salt select
# a value for you. Default is disabled.
# ipc_write_buffer: 'dynamic'

##### Security settings #####
##########################################
# Enable "open mode", this mode still maintains encryption, but turns off
# authentication, this is only intended for highly secure environments or for
# the situation where your keys end up in a bad state. If you run in open mode
# you do so at your own risk!
#open_mode: False

# Enable auto_accept, this setting will automatically accept all incoming
# public keys from the minions. Note that this is insecure.
#auto_accept: False

# Time in minutes that a incoming public key with a matching name found in
# pki_dir/minion_autosign/keyid is automatically accepted. Expired autosign keys
# are removed when the master checks the minion_autosign directory.
# 0 equals no timeout
# autosign_timeout: 120

# If the autosign_file is specified, incoming keys specified in the
# autosign_file will be automatically accepted. This is insecure. Regular
# expressions as well as globing lines are supported.
#autosign_file: /etc/salt/autosign.conf

# Works like autosign_file, but instead allows you to specify minion IDs for
# which keys will automatically be rejected. Will override both membership in
# Enable permissive access to the salt keys. This allows you to run the
# master or minion as root, but have a non-root group be given access to
# your pki_dir. To make the access explicit, root must belong to the group
# you've given access to. This is potentially quite insecure. If an autosign_file
# is specified, enabling permissive_pki_access will allow group access to that
# specific file.
#permissive_pki_access: False

# Allow users on the master access to execute specific commands on minions.
# This setting should be treated with care since it opens up execution
# capabilities to non root users. By default this capability is completely
# disabled.
publisher_acl:
  # larry:
  #  - test.ping
  #  - network.*
  #
  # Blacklist any of the following users or modules
  #
  # This example would blacklist all non sudo users, including root from
  # running any commands. It would also blacklist any use of the "cmd"
  # module. This is completely disabled by default.
  #
  # Check the list of configured users in client ACL against users on the
  # system and throw errors if they do not exist.
  client_acl_verify: True

  #publisher_acl_blacklist:
  # users:
  #  - root
  #  - '^(?!sudo_).*$'  # all non sudo users
  # modules:
  #  - cmd
  #
  # WARNING: client_acl and client_acl_blacklist options are deprecated and will
  # be removed in the future releases. Use publisher_acl and
  # publisher_acl_blacklist instead.

  # Enforce publisher_acl & publisher_acl_blacklist when users have sudo
  # access to the salt command.
  #sudo_acl: False

  # The external auth system uses the Salt auth modules to authenticate and
  # validate users to access areas of the Salt system.
  external_auth:
    # pam:
    #  fred:
    #    - test.*
    #
    # Time (in seconds) for a newly generated token to live. Default: 12 hours
token_expire: 43200

  # Allow minions to push files to the master. This is disabled by default, for

# security purposes.
#file_recv: False

# Set a hard-limit on the size of the files that can be pushed to the master.  
# It will be interpreted as megabytes. Default: 100
#file_recv_max_size: 100

# Signature verification on messages published from the master.  
# This causes the master to cryptographically sign all messages published to its event  
# bus, and minions then verify that signature before acting on the message.  
# This is False by default.
# sign_pub_messages: False

# Note that to facilitate interoperability with masters and minions that are different  
# versions, if sign_pub_messages is True but a message is received by a minion with  
# no signature, it will still be accepted, and a warning message will be logged.
# Conversely, if sign_pub_messages is False, but a minion receives a signed  
# message it will be accepted, the signature will not be checked, and a warning message  
# will be logged. This behavior went away in Salt 2014.1.0 and these two situations  
# will cause minion to throw an exception and drop the message.
# sign_pub_messages: False

# Signature verification on messages published from minions  
# This requires that minions cryptographically sign the messages they  
# publish to the master. If minions are not signing, then log this information  
# at loglevel 'INFO' and drop the message without acting on it.
# require_minion_sign_messages: False

# The below will drop messages when their signatures do not validate.  
# Note that when this option is False but `require_minion_sign_messages` is True  
# minions MUST sign their messages but the validity of their signatures  
# is ignored.
# These two config options exist so a Salt infrastructure can be moved  
# to signing minion messages gradually.
# drop_messages_signature_fail: False

####### Salt-SSH Configuration #######
####################################

# Pass in an alternative location for the salt-ssh roster file  
#roster_file: /etc/salt/roster

# Define a location for roster files so they can be chosen when using Salt API.  
# An administrator can place roster files into these locations. Then when  
# calling Salt API, parameter 'roster_file' should contain a relative path to  
# these locations. That is, "roster_file=/foo/roster" will be resolved as  
# "/etc/salt/roster.d/foo/roster" etc. This feature prevents passing insecure  
# custom rosters through the Salt API.
# rasters:
# - /etc/salt/roster.d
# - /opt/salt/some/more/rosters

# The log file of the salt-ssh command:  
#ssh_log_file: /var/log/salt/ssh

# Pass in minion option overrides that will be inserted into the SHIM for  
# salt-ssh calls. The local minion config is not used for salt-ssh. Can be
# The state_verbose and state_output settings can be used to change the way
# state system data is printed to the display. By default all data is printed.
# The state_verbose setting can be set to True or False, when set to False
# all data that has a result of True and no changes will be suppressed.
#state_verbose: True

# The state_output setting changes if the output is the full multi line
# output for each changed state if set to 'full', but if set to 'terse'
# the output will be shortened to a single line. If set to 'mixed', the output
# will be terse unless a state failed, in which case that output will be full.
# If set to 'changes', the output will be full unless the state didn't change.
#state_output: full

# Automatically aggregate all states that have support for mod_aggregate by
# setting to 'True'. Or pass a list of state module names to automatically
# aggregate just those types.
#
#state_aggregate:
#  - pkg
#
#state_aggregate: False

# Send progress events as each function in a state run completes execution
# by setting to 'True'. Progress events are in the format
# 'salt/job/<JID>/prog/<MID>/<RUN NUM>'.
#state_events: False

##### File Server settings #####
##########################################
# Salt runs a lightweight file server written in zeromq to deliver files to
# minions. This file server is built into the master daemon and does not
# require a dedicated port.

# The file server works on environments passed to the master, each environment
# can have multiple root directories, the subdirectories in the multiple file
# roots cannot match, otherwise the downloaded files will not be able to be
# reliably ensured. A base environment is required to house the top file.
# Example:
#
#Example:
#file_roots:
#  base:
#    - /srv/salt/
#    - /srv/salt/dev/services
#    - /srv/salt/dev/states
#  dev:
#    - /srv/salt/prod/services
#    - /srv/salt/prod/states
#
#file_roots:
#  base:
#    - /srv/salt
#
# When using multiple environments, each with their own top file, the
# default behaviour is an unordered merge. To prevent top files from
# being merged together and instead to only use the top file from the
# requested environment, set this value to 'same'.

#top_file_merging_strategy: merge

# To specify the order in which environments are merged, set the ordering
# in the env_order option. Given a conflict, the last matching value will
# win.
#env_order: ['base', 'dev', 'prod']

# If top_file_merging_strategy is set to 'same' and an environment does not
# contain a top file, the top file in the environment specified by default_top
# will be used instead.
#default_top: base

# The hash_type is the hash to use when discovering the hash of a file on
# the master server. The default is md5 but sha1, sha224, sha256, sha384
# and sha512 are also supported.
#hash_type: md5

# The buffer size in the file server can be adjusted here:
#file_buffer_size: 1048576

# A regular expression (or a list of expressions) that will be matched
# against the file path before syncing the modules and states to the minions.
# This includes files affected by the file.recurse state.
# For example, if you manage your custom modules and states in subversion
# and don't want all the '.svn' folders and content synced to your minions,
# you could set this to '/\.svn($|/)'. By default nothing is ignored.
#file_ignore_regex:
# - '/\.svn($|/)'
# - '/\.git($|/)'

# A file glob (or list of file globs) that will be matched against the file
# path before syncing the modules and states to the minions. This is similar
# to file_ignore_regex above, but works on globs instead of regex. By default
# nothing is ignored.
#file_ignore_glob:
# - '*.pyc'
# - '*.swp'
# - '*/somefolder/*.bak'

# File Server Backend
#
# Salt supports a modular fileserver backend system, this system allows
# the salt master to link directly to third party systems to gather and
# manage the files available to minions. Multiple backends can be
# configured and will be searched for the requested file in the order in which
# they are defined here. The default setting only enables the standard backend
# "roots" which uses the "file_roots" option.
#fileserver_backend:
# - roots
#
# To use multiple backends list them in the order they are searched:
#fileserver_backend:
# - git
# - roots
#
# Uncomment the line below if you do not want the file_server to follow
# symlinks when walking the filesystem tree. This is set to True
# by default. Currently this only applies to the default roots
# fileserver_backend.
# fileserver_followsymlinks: False
#
# Uncomment the line below if you do not want symlinks to be
# treated as the files they are pointing to. By default this is set to
# False. By uncommenting the line below, any detected symlink while listing
# files on the Master will not be returned to the Minion.
# fileserver_ignoresymlinks: True
#
# By default, the Salt fileserver recurses fully into all defined environments
# to attempt to find files. To limit this behavior so that the fileserver only
# traverses directories with SLS files and special Salt directories like _modules,
# enable the option below. This might be useful for installations where a file root
# has a very large number of files and performance is impacted. Default is False.
# fileserver_limit_traversal: False
#
# The fileserver can fire events off every time the fileserver is updated,
# these are disabled by default, but can be easily turned on by setting this
# flag to True
# fileserver_events: False

# Git File Server Backend Configuration
#
# Optional parameter used to specify the provider to be used for gitfs. Must
# be one of the following: pygit2, gitpython, or dulwich. If unset, then each
# will be tried in that same order, and the first one with a compatible
# version installed will be the provider that is used.
# gitfs_provider: pygit2
#
# Along with gitfs_password, is used to authenticate to HTTPS remotes.
# gitfs_user: ''
#
# Along with gitfs_user, is used to authenticate to HTTPS remotes.
# This parameter is not required if the repository does not use authentication.
# gitfs_password: ''
#
# By default, Salt will not authenticate to an HTTP (non-HTTPS) remote.
# This parameter enables authentication over HTTP. Enable this at your own risk.
# gitfs_insecure_auth: False
#
# Along with gitfs_privkey (and optionally gitfs_passphrase), is used to
# authenticate to SSH remotes. This parameter (or its per-remote counterpart)
# is required for SSH remotes.
# gitfs_pubkey: ''
#
# Along with gitfs_pubkey (and optionally gitfs_passphrase), is used to
# authenticate to SSH remotes. This parameter (or its per-remote counterpart)
# is required for SSH remotes.
# gitfs_privkey: ''
#
# This parameter is optional, required only when the SSH key being used to
# authenticate is protected by a passphrase.
# Salt Documentation, Release 2016.3.6

2.3. **Configuration file examples**

```yaml
#gitfs_passphrase: ''

# When using the git fileserver backend at least one git remote needs to be
# defined. The user running the salt master will need read access to the repo.
# The repos will be searched in order to find the file requested by a client
# and the first repo to have the file will return it.
# When using the git backend branches and tags are translated into salt
# environments.
# Note: file:// repos will be treated as a remote, so refs you want used must
# exist in that repo as *local* refs.
#gitfs_remotes:
# - git://github.com/saltstack/salt-states.git
# - file:///var/git/saltmaster

# The gitfs_ssl_verify option specifies whether to ignore ssl certificate
# errors when contacting the gitfs backend. You might want to set this to
# false if you're using a git backend that uses a self-signed certificate but
# keep in mind that setting this flag to anything other than the default of True
# is a security concern, you may want to try using the ssh transport.
#gitfs_ssl_verify: True

# The gitfs_root option gives the ability to serve files from a subdirectory
# within the repository. The path is defined relative to the root of the
# repository and defaults to the repository root.
#gitfs_root: somefolder/otherfolder

# Pillar settings

# Salt Pillars allow for the building of global data that can be made selectively
# available to different minions based on minion grain filtering. The Salt
# Pillar is laid out in the same fashion as the file server, with environments,
# a top file and sls files. However, pillar data does not need to be in the
# highstate format, and is generally just key/value pairs.
#pillar_roots:
# base:
# - /srv/pillar
#ext_pillar:
# - hiera: /etc/hiera.yaml
# - cmd_yaml: cat /etc/salt/yaml

# The ext_pillar_first option allows for external pillar sources to populate
# before file system pillar. This allows for targeting file system pillar from
# ext_pillar.
#ext_pillar_first: False

# The external pillars permitted to be used on-demand using pillar.ext
#on_demand_ext_pillar:
# - libvirt
# - virtkey

# The pillar_gitfs_ssl_verify option specifies whether to ignore ssl certificate
# errors when contacting the pillar gitfs backend. You might want to set this to
# false if you're using a git backend that uses a self-signed certificate but
# keep in mind that setting this flag to anything other than the default of True
# is a security concern, you may want to try using the ssh transport.
```
#pillar_gitfs_ssl_verify: True

# The pillar_opts option adds the master configuration file data to a dict in
# the pillar called "master". This is used to set simple configurations in the
# master config file that can then be used on minions.
#pillar_opts: False

# The pillar_safe_render_error option prevents the master from passing pillar
# render errors to the minion. This is set on by default because the error could
# contain templating data which would give that minion information it shouldn't
# have, like a password! When set true the error message will only show:
# Rendering SLS 'my.sls' failed. Please see master log for details.
#pillar_safe_render_error: True

# The pillar_source_merging_strategy option allows you to configure merging strategy
# between different sources. It accepts five values: none, recurse, aggregate, overwrite,
# or smart. None will not do any merging at all. Recurse will merge recursively
# mapping of data. Aggregate instructs aggregation of elements between sources that use the
# !yamlex renderer. Overwrite will overwrite elements according the order in which they are processed. This is
# behavior of the 2014.1 branch and earlier. Smart guesses the best strategy based
# on the "renderer" setting and is the default value.
#pillar_source_merging_strategy: smart

# Recursively merge lists by aggregating them instead of replacing them.
#pillar_lists: False

# Git External Pillar (git_pillar) Configuration Options
#
# Specify the provider to be used for git_pillar. Must be either pygit2 or
# gitpython. If unset, then both will be tried in that same order, and the
# first one with a compatible version installed will be the provider that
# is used.
#git_pillar_provider: pygit2

# If the desired branch matches this value, and the environment is omitted
# from the git_pillar configuration, then the environment for that git_pillar
# remote will be base.
#git_pillar_base: master

# If the branch is omitted from a git_pillar remote, then this branch will
# be used instead
#git_pillar_branch: master

# Environment to use for git_pillar remotes. This is normally derived from
# the branch/tag (or from a per-remote env parameter), but if set this will
# override the process of deriving the env from the branch/tag name.
#git_pillar_env: ''

# Path relative to the root of the repository where the git_pillar top file
# and SLS files are located.
#git_pillar_root: ''

# Specifies whether or not to ignore SSL certificate errors when contacting
# the remote repository.
#git_pillar_ssl_verify: False
When set to False, if there is an update/checkout lock for a git_pillar
remote and the pid written to it is not running on the master, the lock
file will be automatically cleared and a new lock will be obtained.

#git_pillar_global_lock: True

# Git External Pillar Authentication Options
#
# Along with git_pillar_password, is used to authenticate to HTTPS remotes.
#git_pillar_user: ''
#
# Along with git_pillar_user, is used to authenticate to HTTPS remotes.
# This parameter is not required if the repository does not use authentication.
#git_pillar_password: ''
#
# By default, Salt will not authenticate to an HTTP (non-HTTPS) remote.
# This parameter enables authentication over HTTP.
#git_pillar_insecure_auth: False
#
# Along with git_pillar_privkey (and optionally git_pillar_passphrase),
# is used to authenticate to SSH remotes.
#git_pillar_pubkey: ''
#
# Along with git_pillar_pubkey (and optionally git_pillar_passphrase),
# is used to authenticate to SSH remotes.
#git_pillar_privkey: ''
#
# This parameter is optional, required only when the SSH key being used
# to authenticate is protected by a passphrase.
#git_pillar_passphrase: ''
#
# A master can cache pillars locally to bypass the expense of having to render them
# for each minion on every request. This feature should only be enabled in cases
# where pillar rendering time is known to be unsatisfactory and any attendant security
# concerns about storing pillars in a master cache have been addressed.
#
# When enabling this feature, be certain to read through the additional ``pillar_cache_``
# configuration options to fully understand the tunable parameters and their implications.
#
# Note: setting ``pillar_cache: True`` has no effect on targeting Minions with Pillars.
# See https://docs.saltstack.com/en/latest/topics/targeting/pillar.html
#pillar_cache: False
#
# If and only if a master has set ``pillar_cache: True``, the cache TTL controls the amount
# of time, in seconds, before the cache is considered invalid by a master and a fresh
# pillar is recompiled and stored.
#pillar_cache_ttl: 3600
#
# If an only if a master has set ``pillar_cache: True``, one of several storage providers
# can be utilized:
#
# disk: The default storage backend. This caches rendered pillars to the master cache.
# Rendered pillars are serialized and deserialized as `msgpack` structures for speed. Note that pillars are stored UNENCRYPTED. Ensure that the master cache

2.3. Configuration file examples
has permissions set appropriately (sane defaults are provided).

memory: [EXPERIMENTAL] An optional backend for pillar caches which uses a pure-Python
in-memory data structure for maximal performance. There are several caveats,
however. First, because each master worker contains its own in-memory cache,
there is no guarantee of cache consistency between minion requests. This
works best in situations where the pillar rarely if ever changes. Secondly,
and perhaps more importantly, this means that unencrypted pillars will
be accessible to any process which can examine the memory of the `salt-
master`

This may represent a substantial security risk.

pillar_cache_backend: disk

### Syndic settings

The Salt syndic is used to pass commands through a master from a higher
master. Using the syndic is simple. If this is a master that will have
syndic servers(s) below it, then set the "order_masters" setting to True.

If this master that will be running a syndic daemon for passthrough, then
the "syndic_master" setting needs to be set to the location of the master server
to receive commands from.

Set the order_masters setting to True if this master will command lower
masters' syndic interfaces.

order_masters: False

If this master will be running a salt syndic daemon, syndic_master tells
this master where to receive commands from.

syndic_master: masterofmasters

This is the 'ret_port' of the MasterOfMaster:
syndic_ret_port: 4506

PID file of the syndic daemon:
syndic_pidfile: /var/run/salt-syndic.pid

The log file of the salt-syndic daemon:
syndic_log_file: /var/log/salt/syndic

The behaviour of the multi-syndic when connection to a master of masters failed.
Can specify `random` (default) or `ordered`. If set to `random`, masters
will be iterated in random order. If `ordered` is specified, the configured
order will be used.
syndic_failover: random

The number of seconds for the salt client to wait for additional syndics to
check in with their lists of expected minions before giving up.
syndic_wait: 5

### Peer Publish settings

Salt minions can send commands to other minions, but only if the minion is
allowed to. By default "Peer Publication" is disabled, and when enabled it
is enabled for specific minions and specific commands. This allows secure
##### Mine settings ####

# Restrict mine.get access from minions. By default any minion has a full access to get all mine data from master cache. In acl definition below, only pcre matches are allowed.
# mine_get:
#  .*
#  - *
#
# The example below enables minion foo.example.com to get 'network.interfaces' mine data only, minions web* to get all network.* and disk.* mine data and all other minions won't get any mine data.
# mine_get:
#  foo.example.com:
#    - network.interfaces
#  web.*:
#    - network.*
#    - disk.*

##### Logging settings ####

Salt Documentation, Release 2016.3.6
# The location of the master log file
# The master log can be sent to a regular file, local path name, or network
# location. Remote logging works best when configured to use rsyslogd(8) (e.g.:
# `file:///dev/log`), with rsyslogd(8) configured for network logging. The URI
# format is: <file|udp|tcp>://<host|socketpath>:<port-if-required>/<log-facility>
#log_file: /var/log/salt/master
#log_file: file:///dev/log
#log_file: udp://loghost:10514

#log_file: /var/log/salt/master
#key_logfile: /var/log/salt/key

# The level of messages to send to the console.
# One of 'garbage', 'trace', 'debug', 'info', 'warning', 'error', 'critical'.
#log_level: warning
# The level of messages to send to the log file.
# One of 'garbage', 'trace', 'debug', 'info', 'warning', 'error', 'critical'.
# If using 'log_granular_levels' this must be set to the highest desired level.
#log_level_logfile: warning

# The date and time format used in log messages. Allowed date/time formatting
# can be seen here: http://docs.python.org/library/time.html#time.strftime
#log_datefmt: '%H:%M:%S'
#log_datefmt_logfile: '%Y-%m-%d %H:%M:%S'

# The format of the console logging messages. Allowed formatting options can
# be seen here: http://docs.python.org/library/logging.html#logrecord-attributes
#log_fmt_console: '%(colorlevel)s %(colormsg)s'
#log_fmt_console: '[%(levelname)-8s] %(message)s'

#log_fmt_logfile: '%(asctime)s,%(msecs)03.0f [%(name)-17s][%(levelname)-8s] %(message)s'

# This can be used to control logging levels more specifically. This
# example sets the main salt library at the 'warning' level, but sets
# 'salt.modules' to log at the 'debug' level:
#log_granular_levels:
#   'salt': 'warning'
#   'salt.modules': 'debug'
#log_granular_levels: {}}
##### Node Groups ######

Node groups allow for logical groupings of minion nodes. A group consists of a group name and a compound target. Nodegroups can reference other nodegroups with 'N@' classifier. Ensure that you do not have circular references.

```yaml
#nodegroups:
  group1: 'L@foo.domain.com,bar.domain.com,baz.domain.com or bl*.domain.com'
  group2: 'G@os:Debian and foo.domain.com'
  group3: 'G@os:Debian and N@group1'
  group4:
    - 'G@foo:bar'
    - 'or'
    - 'G@foo:baz'
```

##### Range Cluster settings ######

Range server (and optional port) that serves your cluster information.

```yaml
#range_server: range:80
```

##### Windows Software Repo settings ######

Location of the repo on the master:

```yaml
#winrepo_dir_ng: '/srv/salt/win/repo-ng'
```

List of git repositories to include with the local repo:

```yaml
#winrepo_remotes_ng:
  - 'https://github.com/saltstack/salt-winrepo-ng.git'
```

##### Windows Software Repo settings - Pre 2015.8 ######

Legacy repo settings for pre-2015.8 Windows minions.

```yaml
#winrepo_dir: '/srv/salt/win/repo'
#winrepo_mastercachefile: '/srv/salt/win/repo/winrepo.p'
#winrepo_remotes:
  - 'https://github.com/saltstack/salt-winrepo.git'
```

##### Returner settings ######

Which returner(s) will be used for minion's result:

```yaml
#return: mysql
```

##### Miscellaneous settings ######

2.3. Configuration file examples 137
# Default match type for filtering events tags: startswith, endswith, find, regex, fnmatch
#event_match_type: startswith

# Permanently include any available Python 3rd party modules into Salt Thin
# when they are generated for Salt-SSH or other purposes.
# The modules should be named by the names they are actually imported inside the Python.
# The value of the parameters can be either one module or a comma separated list of them.
#thin_extra_mods: foo,bar

## 2.3.2 Example minion configuration file

### Primary configuration settings

# This configuration file is used to manage the behavior of the Salt Minion.
# With the exception of the location of the Salt Master Server, values that are
# commented out but have an empty line after the comment are defaults that need
# not be set in the config. If there is no blank line after the comment, the
# value is presented as an example and is not the default.

# Per default the minion will automatically include all config files
# from minion.d/*.conf (minion.d is a directory in the same directory
# as the main minion config file).
#default_include: minion.d/*.conf

# Set the location of the salt master server. If the master server cannot be
# resolved, then the minion will fail to start.
#master: salt

# Set http proxy information for the minion when doing requests
#proxy_host:
#proxy_port:
#proxy_username:
#proxy_password:

# If multiple masters are specified in the 'master' setting, the default behavior
# is to always try to connect to them in the order they are listed. If random_master is
# set to True, the order will be randomized instead. This can be helpful in distributing
# the load of many minions executing salt-call requests, for example, from a cron job.
# If only one master is listed, this setting is ignored and a warning will be logged.
# NOTE: If master_type is set to failover, use master_shuffle instead.
#random_master: False

# Use if master_type is set to failover.
#master_shuffle: False

# Minions can connect to multiple masters simultaneously (all masters
# are "hot"), or can be configured to failover if a master becomes
# unavailable. Multiple hot masters are configured by setting this
# value to "str". Failover masters can be requested by setting
# to "failover". MAKE SURE TO SET master_alive_interval if you are
# using failover.
#master_type: str

# Poll interval in seconds for checking if the master is still there. Only
# respected if master_type above is "failover". To disable the interval entirely,
# set the value to -1. (This may be necessary on machines which have high numbers
# of TCP connections, such as load balancers.)
# master_alive_interval: 30

# If the minion is in multi-master mode and the master_type configuration option
# is set to "failover", this setting can be set to "True" to force the minion
# to fail back to the first master in the list if the first master is back online.
#master_failback: False

# If the minion is in multi-master mode, the "master_type" configuration is set to
# "failover", and the "master_failback" option is enabled, the master failback
# interval can be set to ping the top master with this interval, in seconds.
#master_failback_interval: 0

# Set whether the minion should connect to the master via IPv6:
#ipv6: False

# Set the number of seconds to wait before attempting to resolve
# the master hostname if name resolution fails. Defaults to 30 seconds.
# Set to zero if the minion should shutdown and not retry.
# retry_dns: 30

# Set the port used by the master reply and authentication server.
#master_port: 4506

# The user to run salt.
#user: root

# The user to run salt remote execution commands as via sudo. If this option is
# enabled then sudo will be used to change the active user executing the remote
# command. If enabled the user will need to be allowed access via the sudoers
# file for the user that the salt minion is configured to run as. The most
# common option would be to use the root user. If this option is set the user
# option should also be set to a non-root user. If migrating from a root minion
# to a non root minion the minion cache should be cleared and the minion pki
# directory will need to be changed to the ownership of the new user.
#sudo_user: root

# Specify the location of the daemon process ID file.
#pidfile: /var/run/salt-minion.pid

# The root directory prepended to these options: pki_dir, cachedir, log_file,
# sock_dir, pidfile.
#root_dir: /

# The path to the minion's configuration file.
#conf_file: /etc/salt/minion

# The directory to store the pki information in
#pki_dir: /etc/salt/pki/minion

# Explicitly declare the id for this minion to use, if left commented the id
# will be the hostname as returned by the python call: socket.getfqdn()
# Since salt uses detached ids it is possible to run multiple minions on the
# same machine but with different ids, this can be useful for salt compute
# clusters.
#id:
# Cache the minion id to a file when the minion's id is not statically defined
# in the minion config. Defaults to "True". This setting prevents potential
# problems when automatic minion id resolution changes, which can cause the
# minion to lose connection with the master. To turn off minion id caching,
# set this config to ``False``.
#minion_id_caching: True

# Append a domain to a hostname in the event that it does not exist. This is
# useful for systems where socket.getfqdn() does not actually result in a
# FQDN (for instance, Solaris).
#append_domain:

# Custom static grains for this minion can be specified here and used in SLS
# files just like all other grains. This example sets 4 custom grains, with
# the 'roles' grain having two values that can be matched against.
#grains:
#  roles:
#    - webserver
#    - memcache
#  deployment: datacenter4
#  cabinet: 13
#  cab_u: 14-15
#
# Where cache data goes.
# This data may contain sensitive data and should be protected accordingly.
#cachedir: /var/cache/salt/minion

# Append minion_id to these directories. Helps with
# multiple proxies and minions running on the same machine.
# Allowed elements in the list: pki_dir, cachedir, extension_modules
# Normally not needed unless running several proxies and/or minions on the same machine
# Defaults to ['cachedir'] for proxies, [] (empty list) for regular minions
#append_minionid_config_dirs:

# Verify and set permissions on configuration directories at startup.
#verify_env: True

# The minion can locally cache the return data from jobs sent to it, this
# can be a good way to keep track of jobs the minion has executed
# (on the minion side). By default this feature is disabled, to enable, set
# cache_jobs to True.
#cache_jobs: False

# Set the directory used to hold unix sockets.
#sock_dir: /var/run/salt/minion

# Set the default outputter used by the salt-call command. The default is
# "nested".
#output: nested
#
# By default output is colored. To disable colored output, set the color value
# to False.
#color: True

# Do not strip off the colored output from nested results and state outputs
# (true by default).
#strip_colors: False
# Backup files that are replaced by file.managed and file.recurse under 'cachedir'/file_backups relative to their original location and appended with a timestamp. The only valid setting is "minion". Disabled by default.

# Alternatively this can be specified for each file in state files:
# /etc/ssh/sshd_config:
# file.managed:
#   - source: salt://ssh/sshd_config
#   - backup: minion
#
#backup_mode: minion

# When waiting for a master to accept the minion's public key, salt will continuously attempt to reconnect until successful. This is the time, in seconds, between those reconnection attempts.
#acceptance_wait_time: 10

# If this is nonzero, the time between reconnection attempts will increase by acceptance_wait_time seconds per iteration, up to this maximum. If this is set to zero, the time between reconnection attempts will stay constant.
#acceptance_wait_time_max: 0

# If the master rejects the minion's public key, retry instead of exiting. Rejected keys will be handled the same as waiting on acceptance.
#rejected_retry: False

# When the master key changes, the minion will try to re-auth itself to receive the new master key. In larger environments this can cause a SYN flood on the master because all minions try to re-auth immediately. To prevent this and have a minion wait for a random amount of time, use this optional parameter. The wait-time will be a random number of seconds between 0 and the defined value.
#random_reauth_delay: 60

# When waiting for a master to accept the minion's public key, salt will continuously attempt to reconnect until successful. This is the timeout value, in seconds, for each individual attempt. After this timeout expires, the minion will wait for acceptance_wait_time seconds before trying again. Unless your master is under unusually heavy load, this should be left at the default.
#auth_timeout: 60

# Number of consecutive SaltReqTimeoutError that are acceptable when trying to authenticate.
#auth_tries: 7

# The number of attempts to connect to a master before giving up. Set this to -1 for unlimited attempts. This allows for a master to have downtime and the minion to reconnect to it later when it comes back up. In 'failover' mode, it is the number of attempts for each set of masters. In this mode, it will cycle through the list of masters for each attempt.
#master_tries: 1
# If authentication fails due to SaltReqTimeoutError during a ping_interval,
# cause sub minion process to restart.
#auth_safemode: False

# Ping Master to ensure connection is alive (minutes).
#ping_interval: 0

# To auto recover minions if master changes IP address (DDNS)
# auth_tries: 10
# auth_safemode: False
# ping_interval: 90
#
# Minions won't know master is missing until a ping fails. After the ping fail,
# the minion will attempt authentication and likely fails out and cause a restart.
# When the minion restarts it will resolve the masters IP and attempt to reconnect.

# If you don't have any problems with syn-floods, don't bother with the
# three recon_* settings described below, just leave the defaults!
#
# The ZeroMQ pull-socket that binds to the masters publishing interface tries
# to reconnect immediately, if the socket is disconnected (for example if
# the master processes are restarted). In large setups this will have all
# minions reconnect immediately which might flood the master (the ZeroMQ-default
# is usually a 100ms delay). To prevent this, these three recon_* settings
# can be used.
# recon_default: the interval in milliseconds that the socket should wait before
# trying to reconnect to the master (1000ms = 1 second)
#
# recon_max: the maximum time a socket should wait. each interval the time to wait
# is calculated by doubling the previous time. if recon_max is reached,
# it starts again at recon_default. Short example:
#
# reconnect 1: the socket will wait 'recon_default' milliseconds
# reconnect 2: 'recon_default' * 2
# reconnect 3: ('recon_default' * 2) * 2
# reconnect 4: value from previous interval * 2
# reconnect 5: value from previous interval * 2
# reconnect x: if value >= recon_max, it starts again with recon_default
#
# recon_randomize: generate a random wait time on minion start. The wait time will
# be a random value between recon_default and recon_default +
# recon_max. Having all minions reconnect with the same recon_default
# and recon_max value kind of defeats the purpose of being able to
# change these settings. If all minions have the same values and your
# setup is quite large (several thousand minions), they will still
# flood the master. The desired behavior is to have timeframe within
# all minions try to reconnect.
#
# Example on how to use these settings. The goal: have all minions reconnect within a
# 60 second timeframe on a disconnect.
# recon_default: 1000
# recon_max: 59000
# recon_randomize: True
#
# Each minion will have a randomized reconnect value between 'recon_default'
# and 'recon_default + recon_max', which in this example means between 1000ms
# 60000ms (or between 1 and 60 seconds). The generated random-value will be
doubled after each attempt to reconnect. Let's say the generated random
value is 11 seconds (or 11000ms).
reconnect 1: wait 11 seconds
reconnect 2: wait 22 seconds
reconnect 3: wait 33 seconds
reconnect 4: wait 44 seconds
reconnect 5: wait 55 seconds
reconnect 6: wait time is bigger than 60 seconds (recon_default + recon_max)
reconnect 7: wait 11 seconds
reconnect 8: wait 22 seconds
reconnect 9: wait 33 seconds
reconnect x: etc.

In a setup with ~6000 thousand hosts these settings would average the reconnects
to about 100 per second and all hosts would be reconnected within 60 seconds.
recon_default: 100
recon_max: 5000
recon_randomize: False

The loop_interval sets how long in seconds the minion will wait between
evaluating the scheduler and running cleanup tasks. This defaults to a
sane 60 seconds, but if the minion scheduler needs to be evaluated more
often lower this value.
#loop_interval: 60

The grains can be merged, instead of overridden, using this option.
This allows custom grains to defined different subvalues of a dictionary
#grains. By default this feature is disabled, to enable set grains_deep_merge
to `True`.
grains_deep_merge: False

The grains_refresh_every setting allows for a minion to periodically check
its grains to see if they have changed and, if so, to inform the master
of the new grains. This operation is moderately expensive, therefore
care should be taken not to set this value too low.
#grains_refresh_every: 1

Cache grains on the minion. Default is False.
grains_cache: False

Cache rendered pillar data on the minion. Default is False.
#minion_pillar_cache: False

Grains cache expiration, in seconds. If the cache file is older than this
number of seconds then the grains cache will be dumped and fully re-populated
with fresh data. Defaults to 5 minutes. Will have no effect if 'grains_cache'
is not enabled.
grains_cache_expiration: 300
# Determines whether or not the salt minion should run scheduled mine updates.
# Defaults to "True". Set to "False" to disable the scheduled mine updates
# (this essentially just does not add the mine update function to the minion's
# scheduler).
#mine_enabled: True

# Determines whether or not scheduled mine updates should be accompanied by a job
# return for the job cache. Defaults to "False". Set to "True" to include job
# returns in the job cache for mine updates.
#mine_return_job: False

# Example functions that can be run via the mine facility
# NO mine functions are established by default.
# Note these can be defined in the minion's pillar as well.
#mine_functions:
#  test.ping: []
#  network.ip_addrs:
#    interface: eth0
#    cidr: '10.0.0.0/8'

# Windows platforms lack posix IPC and must rely on slower TCP based inter-
# process communications. Set ipc_mode to 'tcp' on such systems
#ipc_mode: ipc

# Overwrite the default tcp ports used by the minion when in tcp mode
#tcp_pub_port: 4510
#tcp_pull_port: 4511

# Passing very large events can cause the minion to consume large amounts of
# memory. This value tunes the maximum size of a message allowed onto the
# minion event bus. The value is expressed in bytes.
#max_event_size: 1048576

# To detect failed master(s) and fire events on connect/disconnect, set
# master_alive_interval to the number of seconds to poll the masters for
# connection events.
#
#master_alive_interval: 30

# The minion can include configuration from other files. To enable this,
# pass a list of paths to this option. The paths can be either relative or
# absolute; if relative, they are considered to be relative to the directory
# the main minion configuration file lives in (this file). Paths can make use
# of shell-style globbing. If no files are matched by a path passed to this
# option then the minion will log a warning message.
#
# Include a config file from some other path:
#include: /etc/salt/extra_config
#
# Include config from several files and directories:
#include:
#  - /etc/salt/extra_config
#  - /etc/roles/webserver

# The syndic minion can verify that it is talking to the correct master via the
# key fingerprint of the higher-level master with the "syndic_finger" config.
#syndic_finger: ''
Minion module management

- Disable specific modules. This allows the admin to limit the level of access the master has to the minion.
  
  disable_modules: [cmd, test]
  disable_returners: []

- This is the reverse of disable_modules. The default, like disable_modules, is the empty list, but if this option is set to *anything* then only those modules will load.

- Note that this is a very large hammer and it can be quite difficult to keep the minion working the way you think it should since Salt uses many modules internally itself. At a bare minimum, you need the following enabled or else the minion won't start.

  whitelist_modules:
  - cmdmod
  - test
  - config

- Modules can be loaded from arbitrary paths. This enables the easy deployment of third party modules. Modules for returners and minions can be loaded.

- Specify a list of extra directories to search for minion modules and returners. These paths must be fully qualified!

  module_dirs: []
  returner_dirs: []
  states_dirs: []
  render_dirs: []
  utils_dirs: []

- A module provider can be statically overwritten or extended for the minion via the providers option, in this case the default module will be overwritten by the specified module. In this example the pkg module will be provided by the yumpkg5 module instead of the system default.

  providers:
  - pkg: yumpkg5

- Enable Cython modules searching and loading. (Default: False)

  cython_enable: False

- Specify a max size (in bytes) for modules on import. This feature is currently only supported on *nix operating systems and requires psutil.

  modules_max_memory: -1

State Management Settings

- The state management system executes all of the state templates on the minion to enable more granular control of system state management. The type of template and serialization used for state management needs to be configured on the minion, the default renderer is yaml_jinja. This is a yaml file rendered from a jinja template, the available options are:

  yaml_jinja
  yaml_mako
  yaml_wempy
  json_jinja
# json_mako
# json_wempy
#
#renderer: yaml_jinja
#
# The failhard option tells the minions to stop immediately after the first
# failure detected in the state execution. Defaults to False.
#failhard: False
#
# Reload the modules prior to a highstate run.
#autoload_dynamic_modules: True
#
# clean_dynamic_modules keeps the dynamic modules on the minion in sync with
# the dynamic modules on the master, this means that if a dynamic module is
# not on the master it will be deleted from the minion. By default, this is
# enabled and can be disabled by changing this value to False.
#clean_dynamic_modules: True
#
# Normally, the minion is not isolated to any single environment on the master
# when running states, but the environment can be isolated on the minion side
# by statically setting it. Remember that the recommended way to manage
# environments is to isolate via the top file.
#environment: None
#
# Isolates the pillar environment on the minion side. This functions the same
# as the environment setting, but for pillar instead of states.
#pillarenv: None
#
# If using the local file directory, then the state top file name needs to be
# defined, by default this is top.sls.
#state_top: top.sls
#
# Run states when the minion daemon starts. To enable, set startup_states to:
# 'highstate' -- Execute state.highstate
# 'sls' -- Read in the sls_list option and execute the named sls files
# 'top' -- Read top_file option and execute based on that file on the Master
#startup_states: ''
#
# List of states to run when the minion starts up if startup_states is 'sls':
#sls_list:
# - edit.vim
# - hyper
#
# Top file to execute if startup_states is 'top':
#top_file: ''
#
# Automatically aggregate all states that have support for mod_aggregate by
# setting to True. Or pass a list of state module names to automatically
# aggregate just those types.
#state_aggregate:
# - pkg
#
#state_aggregate: False

##### File Directory Settings #####
##########################################
# The Salt Minion can redirect all file server operations to a local directory,
# this allows for the same state tree that is on the master to be used if
# copied completely onto the minion. This is a literal copy of the settings on
# the master but used to reference a local directory on the minion.

# Set the file client. The client defaults to looking on the master server for
# files, but can be directed to look at the local file directory setting
# defined below by setting it to "local". Setting a local file_client runs the
# minion in masterless mode.
#file_client: remote

# The file directory works on environments passed to the minion, each environment
# can have multiple root directories, the subdirectories in the multiple file
# roots cannot match, otherwise the downloaded files will not be able to be
# reliably ensured. A base environment is required to house the top file.
# Example:
# file_roots:
# base:
# - /srv/salt/
# dev:
# - /srv/salt/dev/services
# - /srv/salt/dev/states
# prod:
# - /srv/salt/prod/services
# - /srv/salt/prod/states
#
#file_roots:
# base:
# - /srv/salt

# Uncomment the line below if you do not want the file_server to follow
# symlinks when walking the filesystem tree. This is set to True
# by default. Currently this only applies to the default roots
# fileserver_backend.
#fileserver_followsymlinks: False
#
# Uncomment the line below if you do not want symlinks to be
# treated as the files they are pointing to. By default this is set to
# False. By uncommenting the line below, any detected symlink while listing
# files on the Master will not be returned to the Minion.
#fileserver_ignoresymlinks: True
#
# By default, the Salt fileserver recurses fully into all defined environments
# to attempt to find files. To limit this behavior so that the fileserver only
# traverses directories with SLS files and special Salt directories like _modules,
# enable the option below. This might be useful for installations where a file root
# has a very large number of files and performance is negatively impacted. Default
# is False.
#fileserver_limit_traversal: False

# The hash_type is the hash to use when discovering the hash of a file in
# the local fileserver. The default is sha256, sha224, sha384 and sha512 are also
# supported.
#
# WARNING: While md5 and sha1 are also supported, do not use it due to the high chance
# of possible collisions and thus security breach.
#
# Warning: Prior to changing this value, the minion should be stopped and all
# Salt caches should be cleared.
hash_type: sha256

# The Salt pillar is searched for locally if file_client is set to local. If
# this is the case, and pillar data is defined, then the pillar_roots need to
# also be configured on the minion:
pillar_roots:
  base:
    - /srv/pillar

# Set a hard-limit on the size of the files that can be pushed to the master.
# It will be interpreted as megabytes. Default: 100
file_recv_max_size: 100

# Security settings
# Enable "open mode", this mode still maintains encryption, but turns off
# authentication, this is only intended for highly secure environments or for
# the situation where your keys end up in a bad state. If you run in open mode
# you do so at your own risk!
open_mode: False

# Enable permissive access to the salt keys. This allows you to run the
# master or minion as root, but have a non-root group be given access to
# your pki_dir. To make the access explicit, root must belong to the group
# you've given access to. This is potentially quite insecure.
permissive_pki_access: False

# The state_verbose and state_output settings can be used to change the way
# state system data is printed to the display. By default all data is printed.
# The state_verbose setting can be set to True or False, when set to False
# all data that has a result of True and no changes will be suppressed.
state_verbose: True

# The state_output setting changes if the output is the full multi line
# output for each changed state if set to 'full', but if set to 'terse'
# the output will be shortened to a single line.
state_output: full

# The state_output_diff setting changes whether or not the output from
# successful states is returned. Useful when even the terse output of these
# states is cluttering the logs. Set it to True to ignore them.
state_output_diff: False

# The state_output_profile setting changes whether profile information
# will be shown for each state run.
state_output_profile: True

# Fingerprint of the master public key to validate the identity of your Salt master
# before the initial key exchange. The master fingerprint can be found by running
# "salt-key -F master" on the Salt master.
master_finger: '

# Thread settings
# Disable multiprocessing support, by default when a minion receives a
# publication a new process is spawned and the command is executed therein.
#multiprocessing: True

##### Logging settings #####
##########################################
# The location of the minion log file
# The minion log can be sent to a regular file, local path name, or network
# location. Remote logging works best when configured to use rsyslogd(8) (e.g.:
# `file:///dev/log``), with rsyslogd(8) configured for network logging. The URI
# format is: <file|udp|tcp://<host|socketpath>:<port-if-required>/<log-facility>
#log_file: /var/log/salt/minion
#log_file: file:///dev/log
#log_file: udp://loghost:10514
#
#log_file: /var/log/salt/minion
#log_file: /var/log/salt/key
#log_file: /var/log/salt/key

# The level of messages to send to the console.
# One of 'garbage', 'trace', 'debug', 'info', 'warning', 'error', 'critical'.
# The following log levels are considered INSECURE and may log sensitive data:
# ['garbage', 'trace', 'debug']
# Default: 'warning'
#log_level: warning

# The level of messages to send to the log file.
# One of 'garbage', 'trace', 'debug', 'info', 'warning', 'error', 'critical'.
# If using 'log_granular_levels' this must be set to the highest desired level.
# Default: 'warning'
#log_level_logfile:

# The date and time format used in log messages. Allowed date/time formatting
# can be seen here: http://docs.python.org/library/time.html#time.strftime
#log_datefmt: '%H:%M:%S'
#log_datefmt_logfile: '%Y-%m-%d %H:%M:%S'

# The format of the console logging messages. Allowed formatting options can
# be seen here: http://docs.python.org/library/logging.html#logrecord-attributes
#
# Console log colors are specified by these additional formatters:
#
# %%(colorlevel)s
# %%(colormsg)s
# %%(colorprocess)s
# %%(colormsg)s
# Since it is desirable to include the surrounding brackets, '[ ' and ' ]', in
# the coloring of the messages, these color formatters also include padding as
# well. Color LogRecord attributes are only available for console logging.
#log_fmt_console: '%(colorlevel)s %%(colormsg)s'
#log_fmt_console: '%(levelname)-8s %%(message)s'

#log_fmt_logfile: '%(asctime)s,%(msecs)03.0f [%(name)-17s][%(levelname)-8s] %%(message)s

# This can be used to control logging levels more specifically. This

2.3. Configuration file examples
# example sets the main salt library at the 'warning' level, but sets
# 'salt.modules' to log at the 'debug' level:
# log_granular_levels:
#   'salt': 'warning'
#   'salt.modules': 'debug'
#
#log_granular_levels: {}

# To diagnose issues with minions disconnecting or missing returns, ZeroMQ
# supports the use of monitor sockets to log connection events. This
# feature requires ZeroMQ 4.0 or higher.
#
# To enable ZeroMQ monitor sockets, set 'zmq_monitor' to 'True' and log at a
# debug level or higher.
#
# A sample log event is as follows:
#
# [DEBUG   ] ZeroMQ event: {'endpoint': 'tcp://127.0.0.1:4505', 'event': 512,
#   'value': 27, 'description': 'EVENT_DISCONNECTED'}
#
# All events logged will include the string 'ZeroMQ event'. A connection event
# should be logged as the minion starts up and initially connects to the
# master. If not, check for debug log level and that the necessary version of
# ZeroMQ is installed.
#
# zmq_monitor: False

######## Module configuration ########

Salt allows for modules to be passed arbitrary configuration data, any data
passed here in valid yaml format will be passed on to the salt minion modules
for use. It is STRONGLY recommended that a naming convention be used in which
the module name is followed by a . and then the value. Also, all top level
data must be applied via the yaml dict construct, some examples:

# You can specify that all modules should run in test mode:
test: True
#
# A simple value for the test module:
test.foo: foo
#
# A list for the test module:
test.bar: [baz,quo]
#
# A dict for the test module:
test.baz: {spam: sausage, cheese: bread}
#
#
######## Update settings ########

Using the features in Esky, a salt minion can both run as a frozen app and
be updated on the fly. These options control how the update process
(saltutil.update()) behaves.

# The url for finding and downloading updates. Disabled by default.
#update_url: False
#
# The list of services to restart after a successful update. Empty by default.
```
#update_restart_services: []

###########  Keepalive settings  ############
############################################
# ZeroMQ now includes support for configuring SO_KEEPALIVE if supported by
# the OS. If connections between the minion and the master pass through
# a state tracking device such as a firewall or VPN gateway, there is
# the risk that it could tear down the connection the master and minion
# without informing either party that their connection has been taken away.
# Enabling TCP Keepalives prevents this from happening.
#
# Overall state of TCP Keepalives, enable (1 or True), disable (0 or False)
# or leave to the OS defaults (-1), on Linux, typically disabled. Default True, enabled.
#tcp_keepalive: True
#
# How long before the first keepalive should be sent in seconds. Default 300
# to send the first keepalive after 5 minutes, OS default (-1) is typically 7200 seconds
# on Linux see /proc/sys/net/ipv4/tcp_keepalive_time.
#tcp_keepalive_idle: 300
#
# How many lost probes are needed to consider the connection lost. Default -1
# to use OS defaults, typically 9 on Linux, see /proc/sys/net/ipv4/tcp_keepalive_probes.
#tcp_keepalive_cnt: -1
#
# How often, in seconds, to send keepalives after the first one. Default -1 to
# use OS defaults, typically 75 seconds on Linux, see
# /proc/sys/net/ipv4/tcp_keepalive_intvl.
#tcp_keepalive_intvl: -1

```
2.4 Minion Blackout Configuration

New in version 2016.3.0.

Salt supports minion blackouts. When a minion is in blackout mode, all remote execution commands are disabled. This allows production minions to be put "on hold", eliminating the risk of an untimely configuration change.

Minion blackouts are configured via a special pillar key, `minion_blackout`. If this key is set to True, then the minion will reject all incoming commands, except for `saltutil.refresh_pillar`. (The exception is important, so minions can be brought out of blackout mode)

Salt also supports an explicit whitelist of additional functions that will be allowed during blackout. This is configured with the special pillar key `minion_blackout_whitelist`, which is formed as a list:

```
minion_blackout_whitelist:
  - test.ping
  - pillar.get
```

2.5 Access Control System

New in version 0.10.4.

Salt maintains a standard system used to open granular control to non administrative users to execute Salt commands. The access control system has been applied to all systems used to configure access to non administrative control interfaces in Salt.

These interfaces include, the `peer` system, the `external auth` system and the `publisher acl` system.

The access control system mandated a standard configuration syntax used in all of the three aforementioned systems. While this adds functionality to the configuration in 0.10.4, it does not negate the old configuration.

Now specific functions can be opened up to specific minions from specific users in the case of external auth and publisher ACLs, and for specific minions in the case of the peer system.

2.5.1 Publisher ACL system

The salt publisher ACL system is a means to allow system users other than root to have access to execute select salt commands on minions from the master.

The publisher ACL system is configured in the master configuration file via the `publisher_acl` configuration option. Under the `publisher_acl` configuration option the users open to send commands are specified and then a list of regular expressions which specify the minion functions which will be made available to specified user. This configuration is much like the `peer` configuration:

```
publisher_acl:
  # Allow thatch to execute anything.
  thatch:
    - *
  # Allow fred to use test and pkg, but only on web* minions.
  fred:
    - web*:
      - test.*
      - pkg.*
```

WARNING: `client_acl` and `client_acl_blacklist` options are deprecated and will be removed in the future releases. Use `publisher_acl` and `publisher_acl_blacklist` instead.
Permission Issues

Directories required for `publisher_acl` must be modified to be readable by the users specified:

```bash
chmod 755 /var/cache/salt /var/cache/salt/master /var/cache/salt/master/jobs /var/run/salt
```

**Note:** In addition to the changes above you will also need to modify the permissions of `/var/log/salt` and the existing log file to be writable by the user(s) which will be running the commands. If you do not wish to do this then you must disable logging or Salt will generate errors as it cannot write to the logs as the system users.

If you are upgrading from earlier versions of salt you must also remove any existing user keys and re-start the Salt master:

```bash
rm /var/cache/salt/.*key
service salt-master restart
```

Whitelist and Blacklist

Salt’s authentication systems can be configured by specifying what is allowed using a whitelist, or by specifying what is disallowed using a blacklist. If you specify a whitelist, only specified operations are allowed. If you specify a blacklist, all operations are allowed except those that are blacklisted.

See `publisher_acl` and `publisher_acl_blacklist`.

2.5.2 External Authentication System

Salt’s External Authentication System (eAuth) allows for Salt to pass through command authorization to any external authentication system, such as PAM or LDAP.

**Note:** eAuth using the PAM external auth system requires salt-master to be run as root as this system needs root access to check authentication.

External Authentication System Configuration

The external authentication system allows for specific users to be granted access to execute specific functions on specific minions. Access is configured in the master configuration file and uses the access control system:

```yaml
external_auth:
  pam:
    thatch:
      - 'web*':
      - test.*
      - network.*
    steve:
      - .*
```

The above configuration allows the user `thatch` to execute functions in the test and network modules on the minions that match the `web*` target. User `steve` is given unrestricted access to minion commands.

Salt respects the current PAM configuration in place, and uses the `login` service to authenticate.
Note: The PAM module does not allow authenticating as root.

Note: state.sls and state.highstate will return "Failed to authenticate!" if the request timeout is reached. Use -t flag to increase the timeout.

To allow access to wheel modules or runner modules the following @ syntax must be used:

```yaml
external_auth:
  pam:
    thatch:
      - '@wheel'  # to allow access to all wheel modules
      - '@runner' # to allow access to all runner modules
      - '@jobs'   # to allow access to the jobs runner and/or wheel module
```

Note: The runner/wheel markup is different, since there are no minions to scope the acl to.

Note: Globs will not match wheel or runners! They must be explicitly allowed with @wheel or @runner.

**Warning:** All users that have external authentication privileges are allowed to run `saltutil.findjob`. Be aware that this could inadvertently expose some data such as minion IDs.

### Matching syntax

The structure of the `external_auth` dictionary can take the following shapes. Function matches are regular expressions; minion matches are compound targets.

**By user:**

```yaml
external_auth:
  <eauth backend>:
    <user or group%>:
      - <regex to match function>
```

**By user, by minion:**

```yaml
external_auth:
  <eauth backend>:
    <user or group%>:
      <minion compound target>:
        - <regex to match function>
```

### Groups

To apply permissions to a group of users in an external authentication system, append a % to the ID:
Limiting by function arguments

Positional arguments or keyword arguments to functions can also be whitelisted.

New in version 2016.3.0.

```yaml
external_auth:
  pam:
    my_user:
      - '*':
        - 'my_mod.*':
          args:
            - 'a.*'
            - 'b.*'
          kwargs:
            'kwa': 'kwa.*'
            'kwb': 'kwb'
```

The rules:

1. The arguments values are matched as regexp.
2. If arguments restrictions are specified the only matched are allowed.
3. If an argument isn’t specified any value is allowed.
4. To skip an arg use "everything" regexp .* I.e. if arg0 and arg2 should be limited but arg1 and other arguments could have any value use:

```yaml
desc:
  - value0
  - .*
  - value2
```

Usage

The external authentication system can then be used from the command-line by any user on the same system as the master with the -a option:

```
$ salt -a pam web\* test.ping
```

The system will ask the user for the credentials required by the authentication system and then publish the command.

Tokens

With external authentication alone, the authentication credentials will be required with every call to Salt. This can be alleviated with Salt tokens.

Tokens are short term authorizations and can be easily created by just adding a -T option when authenticating:
Now a token will be created that has an expiration of 12 hours (by default). This token is stored in a file named `salt_token` in the active user's home directory.

Once the token is created, it is sent with all subsequent communications. User authentication does not need to be entered again until the token expires.

Token expiration time can be set in the Salt master config file.

**LDAP and Active Directory**

---

**Note:** LDAP usage requires that you have installed python-ldap.

Salt supports both user and group authentication for LDAP (and Active Directory accessed via its LDAP interface)

**OpenLDAP and similar systems**

LDAP configuration happens in the Salt master configuration file.

Server configuration values and their defaults:

```bash
# Server to auth against
auth.ldap.server: localhost

# Port to connect via
auth.ldap.port: 389

# Use TLS when connecting
auth.ldap.tls: False

# LDAP scope level, almost always 2
auth.ldap.scope: 2

# Server specified in URI format
auth.ldap.uri: "" # Overrides .ldap.server, .ldap.port, .ldap.tls above

# Verify server's TLS certificate
auth.ldap.no_verify: False

# Bind to LDAP anonymously to determine group membership
# Active Directory does not allow anonymous binds without special configuration
auth.ldap.anonymous: False

# FOR TESTING ONLY, this is a VERY insecure setting.
# If this is True, the LDAP bind password will be ignored and
# access will be determined by group membership alone with
# the group memberships being retrieved via anonymous bind
auth.ldap.auth_by_group_membership_only: False

# Require authenticating user to be part of this Organizational Unit
# This can be blank if your LDAP schema does not use this kind of OU
auth.ldap.groupou: 'Groups'
```
# Object Class for groups. An LDAP search will be done to find all groups of this class to which the authenticating user belongs.

```
auth.ldap.groupclass: 'posixGroup'
```

# Unique ID attribute name for the user

```
auth.ldap.accountattributename: 'memberUid'
```

# These are only for Active Directory

```
auth.ldap.activedirectory: False
auth.ldap.persontype: 'person'
auth.ldap.minion_stripdomains: []
```

There are two phases to LDAP authentication. First, Salt authenticates to search for a user's Distinguished Name and group membership. The user it authenticates as in this phase is often a special LDAP system user with read-only access to the LDAP directory. After Salt searches the directory to determine the actual user's DN and groups, it re-authenticates as the user running the Salt commands.

If you are already aware of the structure of your DNs and permissions in your LDAP store are set such that users can look up their own group memberships, then the first and second users can be the same. To tell Salt this is the case, omit the `auth.ldap.bindpw` parameter. You can template the `binddn` like this:

```
auth.ldap.basedn: dc=saltstack,dc=com
auth.ldap.binddn: uid={{ username }},cn=users,cn=accounts,dc=saltstack,dc=com
```

Salt will use the password entered on the salt command line in place of the bindpw.

To use two separate users, specify the LDAP lookup user in the binddn directive, and include a bindpw like so

```
auth.ldap.binddn: uid=ldaplookup,cn=sysaccounts,cn=etc,dc=saltstack,dc=com
auth.ldap.bindpw: mypassword
```

As mentioned before, Salt uses a filter to find the DN associated with a user. Salt substitutes the `{{ username }}` value for the username when querying LDAP

```
auth.ldap.filter: uid={{ username }}
```

For OpenLDAP, to determine group membership, one can specify an OU that contains group data. This is prepended to the basedn to create a search path. Then the results are filtered against `auth.ldap.groupclass`, default `posixGroup`, and the account's `name` attribute, `memberUid` by default.

```
auth.ldap.groupou: Groups
```

When using the `ldap('DC=domain,DC=com')` eauth operator, sometimes the records returned from LDAP or Active Directory have fully-qualified domain names attached, while minion IDs instead are simple hostnames. The parameter below allows the administrator to strip off a certain set of domain names so the hostnames looked up in the directory service can match the minion IDs.

```
auth.ldap.minion_stripdomains: ['.external.bigcorp.com', '.internal.bigcorp.com']
```

### Active Directory

Active Directory handles group membership differently, and does not utilize the `groupou` configuration variable. AD needs the following options in the master config:
auth.ldap.activedirectory: True
auth.ldap.filter: sAMAccountName={username}
auth.ldap.accountattributename: sAMAccountName
auth.ldap.groupclass: group
auth.ldap.persontype: person

To determine group membership in AD, the username and password that is entered when LDAP is requested as the eAuth mechanism on the command line is used to bind to AD's LDAP interface. If this fails, then it doesn't matter what groups the user belongs to, he or she is denied access. Next, the distinguishedName of the user is looked up with the following LDAP search:

```
(&(<value of auth.ldap.accountattributename>=\{username\})
 (objectClass=<value of auth.ldap.persontype>)
)
```

This should return a distinguishedName that we can use to filter for group membership. Then the following LDAP query is executed:

```
(&\{member=<distinguishedName from search above>\}
 (objectClass=<value of auth.ldap.groupclass>)
)
```

external_auth:
  ldap:
    test_ldap_user:
      - 'x':
        - test.ping

To configure a LDAP group, append a % to the ID:

external_auth:
  ldap:
    test_ldap_group%:
      - 'x':
        - test.echo

In addition, if there are a set of computers in the directory service that should be part of the eAuth definition, they can be specified like this:

external_auth:
  ldap:
    test_ldap_group%
      - ldap('DC=corp,DC=example,DC=com'):
        - test.echo

The string inside ldap() above is any valid LDAP/AD tree limiter. OU= in particular is permitted as long as it would return a list of computer objects.

2.5.3 Peer Communication

Salt 0.9.0 introduced the capability for Salt minions to publish commands. The intent of this feature is not for Salt minions to act as independent brokers one with another, but to allow Salt minions to pass commands to each other.

In Salt 0.10.0 the ability to execute runners from the master was added. This allows for the master to return collective data from runners back to the minions via the peer interface.
The peer interface is configured through two options in the master configuration file. For minions to send commands from the master the peer configuration is used. To allow for minions to execute runners from the master the peer_run configuration is used.

Since this presents a viable security risk by allowing minions access to the master publisher the capability is turned off by default. The minions can be allowed access to the master publisher on a per minion basis based on regular expressions. Minions with specific ids can be allowed access to certain Salt modules and functions.

**Peer Configuration**

The configuration is done under the peer setting in the Salt master configuration file, here are a number of configuration possibilities.

The simplest approach is to enable all communication for all minions, this is only recommended for very secure environments.

```bash
peer:
  .*:
    - .*
```

This configuration will allow minions with IDs ending in example.com access to the test, ps, and pkg module functions.

```bash
peer:
  .*example.com:
    - test.*
    - ps.*
    - pkg.*
```

The configuration logic is simple, a regular expression is passed for matching minion ids, and then a list of expressions matching minion functions is associated with the named minion. For instance, this configuration will also allow minions ending with foo.org access to the publisher.

```bash
peer:
  .*example.com:
    - test.*
    - ps.*
    - pkg.*
  .*foo.org:
    - test.*
    - ps.*
    - pkg.*
```

**Note:** Functions are matched using regular expressions.

**Peer Runner Communication**

Configuration to allow minions to execute runners from the master is done via the peer_run option on the master. The peer_run configuration follows the same logic as the peer option. The only difference is that access is granted to runner modules.

To open up access to all minions to all runners:
Using Peer Communication

The publish module was created to manage peer communication. The publish module comes with a number of functions to execute peer communication in different ways. Currently there are three functions in the publish module. These examples will show how to test the peer system via the salt-call command.

To execute test.ping on all minions:

```bash
# salt-call publish.publish \* test.ping
```

To execute the manage.up runner:

```bash
# salt-call publish.runner manage.up
```

To match minions using other matchers, use `expr_form`:

```bash
# salt-call publish.publish 'webserv* and not G@os:Ubuntu' test.ping expr_form=\~'compound'
```

**Note:** The `expr_form` argument will be renamed to `tgt_type` in the Nitrogen release of Salt.

### 2.5.4 When to Use Each Authentication System

`publisher_acl` is useful for allowing local system users to run Salt commands without giving them root access. If you can log into the Salt master directly, then `publisher_acl` allows you to use Salt without root privileges. If the local system is configured to authenticate against a remote system, like LDAP or Active Directory, then `publisher_acl` will interact with the remote system transparently.

`external_auth` is useful for `salt-api` or for making your own scripts that use Salt's Python API. It can be used at the CLI (with the `-a` flag) but it is more cumbersome as there are more steps involved. The only time it is useful at the CLI is when the local system is not configured to authenticate against an external service but you still want Salt to authenticate against an external service.

### 2.5.5 Examples

The access controls are manifested using matchers in these configurations:
publisher_acl:
  fred:
    - web\*:
      - pkg.list_pkgs
      - test.*
    - apache.*

In the above example, fred is able to send commands only to minions which match the specified glob target. This can be expanded to include other functions for other minions based on standard targets (all matchers are supported except the compound one).

external_auth:
  pam:
    dave:
      - test.ping
      - mongo\*:
        - network.*
      - log\*:
        - network.*
      - pkg.*
      - 'G@os:RedHat':
        - kmod.*
    steve:
      - .*

The above allows for all minions to be hit by test.ping by dave, and adds a few functions that dave can execute on other minions. It also allows steve unrestricted access to salt commands.

Note: Functions are matched using regular expressions.

### 2.6 Job Management

New in version 0.9.7.

Since Salt executes jobs running on many systems, Salt needs to be able to manage jobs running on many systems.

#### 2.6.1 The Minion proc System

Salt Minions maintain a proc directory in the Salt cachedir. The proc directory maintains files named after the executed job ID. These files contain the information about the current running jobs on the minion and allow for jobs to be looked up. This is located in the proc directory under the cachedir, with a default configuration it is under /var/cache/salt/proc.

#### 2.6.2 Functions in the saltutil Module

Salt 0.9.7 introduced a few new functions to the saltutil module for managing jobs. These functions are:

1. running Returns the data of all running jobs that are found in the proc directory.
2. find_job Returns specific data about a certain job based on job id.
3. signal_job Allows for a given jid to be sent a signal.
4. **term_job** Sends a termination signal (SIGTERM, 15) to the process controlling the specified job.

5. **kill_job** Sends a kill signal (SIGKILL, 9) to the process controlling the specified job.

These functions make up the core of the back end used to manage jobs at the minion level.

### 2.6.3 The jobs Runner

A convenience runner front end and reporting system has been added as well. The jobs runner contains functions to make viewing data easier and cleaner.

The jobs runner contains a number of functions...

**active**

The active function runs saltutil.running on all minions and formats the return data about all running jobs in a much more usable and compact format. The active function will also compare jobs that have returned and jobs that are still running, making it easier to see what systems have completed a job and what systems are still being waited on.

```
# salt-run jobs.active
```

**lookup_jid**

When jobs are executed the return data is sent back to the master and cached. By default it is cached for 24 hours, but this can be configured via the `keep_jobs` option in the master configuration. Using the lookup_jid runner will display the same return data that the initial job invocation with the salt command would display.

```
# salt-run jobs.lookup_jid <job id number>
```

**list_jobs**

Before finding a historic job, it may be required to find the job id. `list_jobs` will parse the cached execution data and display all of the job data for jobs that have already, or partially returned.

```
# salt-run jobs.list_jobs
```

### 2.6.4 Scheduling Jobs

Salt's scheduling system allows incremental executions on minions or the master. The schedule system exposes the execution of any execution function on minions or any runner on the master.

Scheduling can be enabled by multiple methods:

- **schedule** option in either the master or minion config files. These require the master or minion application to be restarted in order for the schedule to be implemented.

- Minion pillar data. Schedule is implemented by refreshing the minion's pillar data, for example by using `saltutil.refresh_pillar`.

- The `schedule state` or `schedule module`
Note: The scheduler executes different functions on the master and minions. When running on the master the functions reference runner functions, when running on the minion the functions specify execution functions.

A scheduled run has no output on the minion unless the config is set to info level or higher. Refer to `minion-logging-settings`.

States are executed on the minion, as all states are. You can pass positional arguments and provide a YAML dict of named arguments.

```yaml
schedule:
  job1:
    function: state.sls
    seconds: 3600
    args:
      - httpd
    kwargs:
      test: True
```

This will schedule the command: `state.sls httpd test=True` every 3600 seconds (every hour).

```yaml
schedule:
  job1:
    function: state.sls
    seconds: 3600
    args:
      - httpd
    kwargs:
      test: True
    splay: 15
```

This will schedule the command: `state.sls httpd test=True` every 3600 seconds (every hour) splaying the time between 0 and 15 seconds.

```yaml
schedule:
  job1:
    function: state.sls
    seconds: 3600
    args:
      - httpd
    kwargs:
      test: True
    splay:
      start: 10
      end: 15
```

This will schedule the command: `state.sls httpd test=True` every 3600 seconds (every hour) splaying the time between 10 and 15 seconds.

### Schedule by Date and Time

New in version 2014.7.0.

Frequency of jobs can also be specified using date strings supported by the Python `dateutil` library. This requires the Python `dateutil` library to be installed.
This will schedule the command `state.sls httpd test=True` at 5:00 PM minion localtime.

This will schedule the command `state.sls httpd test=True` at 5:00 PM on Monday, Wednesday and Friday, and 3:00 PM on Tuesday and Thursday.

This will schedule the command `state.sls httpd test=True` every 3600 seconds (every hour) between the hours of 8:00 AM and 5:00 PM. The range parameter must be a dictionary with the date strings using the `dateutil` format.

Using the invert option for range, this will schedule the command `state.sls httpd test=True` every 3600 seconds (every hour) between the hours of 8:00 AM and 5:00 PM.
seconds (every hour) until the current time is between the hours of 8:00 AM and 5:00 PM. The range parameter must be a dictionary with the date strings using the `dateutil` format.

```yaml
schedule:
  job1:
    function: pkg.install
    kwargs:
      pkgs: [{'bar': '>1.2.3'}]
    refresh: true
    once: '2016-01-07T14:30:00'
```

This will schedule the function `pkg.install` to be executed once at the specified time. The schedule entry `job1` will not be removed after the job completes, therefore use `schedule.delete` to manually remove it afterwards.

The schedule date format is ISO 8601 but can be overridden by also specifying the `once_fmt` option, like this:

```yaml
schedule:
  job1:
    function: test.ping
    once: 2015-04-22T20:21:00
    once_fmt: '%Y-%m-%dT%H:%M:%S'
```

### Maximum Parallel Jobs Running

New in version 2014.7.0.

The scheduler also supports ensuring that there are no more than N copies of a particular routine running. Use this for jobs that may be long-running and could step on each other or pile up in case of infrastructure outage.

The default for `maxrunning` is 1.

```yaml
schedule:
  long_running_job:
    function: big_file_transfer
    jid_include: True
    maxrunning: 1
```

### Cron-like Schedule

New in version 2014.7.0.

```yaml
schedule:
  job1:
    function: state.sls
    cron: '/15 * * * *'
    args:
      - httpd
    kwargs:
      test: True
```

The scheduler also supports scheduling jobs using a cron like format. This requires the Python `croniter` library.

### Job Data Return

New in version 2015.5.0.
By default, data about jobs runs from the Salt scheduler is returned to the master. Setting the `return_job` parameter to False will prevent the data from being sent back to the Salt master.

```yaml
schedule:
  job1:
    function: scheduled_job_function
    return_job: False
```

### Job Metadata

New in version 2015.5.0.

It can be useful to include specific data to differentiate a job from other jobs. Using the metadata parameter special values can be associated with a scheduled job. These values are not used in the execution of the job, but can be used to search for specific jobs later if combined with the `return_job` parameter. The metadata parameter must be specified as a dictionary, otherwise it will be ignored.

```yaml
schedule:
  job1:
    function: scheduled_job_function
    metadata:
      foo: bar
```

### Run on Start

New in version 2015.5.0.

By default, any job scheduled based on the startup time of the minion will run the scheduled job when the minion starts up. Sometimes this is not the desired situation. Using the `run_on_start` parameter set to `False` will cause the scheduler to skip this first run and wait until the next scheduled run:

```yaml
schedule:
  job1:
    function: state.sls
    seconds: 3600
    run_on_start: False
    args:
      - httpd
    kwargs:
      test: True
```

### Until and After

New in version 2015.8.0.

```yaml
schedule:
  job1:
    function: state.sls
    seconds: 15
    until: '12/31/2015 11:59pm'
    args:
      - httpd
    kwargs:
      test: True
```
Using the until argument, the Salt scheduler allows you to specify an end time for a scheduled job. If this argument is specified, jobs will not run once the specified time has passed. Time should be specified in a format supported by the dateutil library. This requires the Python dateutil library to be installed.

New in version 2015.8.0.

```yaml
schedule:
  job1:
    function: state.sls
    seconds: 15
    after: '12/31/2015 11:59pm'
    args:
      - httpd
    kwargs:
      test: True
```

Using the after argument, the Salt scheduler allows you to specify an start time for a scheduled job. If this argument is specified, jobs will not run until the specified time has passed. Time should be specified in a format supported by the dateutil library. This requires the Python dateutil library to be installed.

**Scheduling States**

```yaml
schedule:
  log-loadavg:
    function: cmd.run
    seconds: 3660
    args:
      - 'logger -t salt < /proc/loadavg'
    kwargs:
      stateful: False
      shell: /bin/sh
```

**Scheduling Highstates**

To set up a highstate to run on a minion every 60 minutes set this in the minion config or pillar:

```yaml
schedule:
  highstate:
    function: state.highstate
    minutes: 60
```

Time intervals can be specified as seconds, minutes, hours, or days.

**Scheduling Runners**

Runner executions can also be specified on the master within the master configuration file:

```yaml
schedule:
  run_my_orch:
    function: state.orchestrate
    hours: 6
    splay: 600
    args:
      - orchestration.my_orch
```

2.6. Job Management
The above configuration is analogous to running `salt-run state.orch orchestration.my_orch` every 6 hours.

**Scheduler With Returner**

The scheduler is also useful for tasks like gathering monitoring data about a minion, this schedule option will gather status data and send it to a MySQL returner database:

```
schedule:
  uptime:
    function: status.uptime
    seconds: 60
    returner: mysql
  meminfo:
    function: status.meminfo
    minutes: 5
    returner: mysql
```

Since specifying the returner repeatedly can be tiresome, the `schedule_returner` option is available to specify one or a list of global returners to be used by the minions when scheduling.

### 2.7 Managing the Job Cache

The Salt Master maintains a job cache of all job executions which can be queried via the jobs runner. This job cache is called the Default Job Cache.

#### 2.7.1 Default Job Cache

A number of options are available when configuring the job cache. The default caching system uses local storage on the Salt Master and can be found in the job cache directory (on Linux systems this is typically `/var/cache/salt/master/jobs`). The default caching system is suitable for most deployments as it does not typically require any further configuration or management.

The default job cache is a temporary cache and jobs will be stored for 24 hours. If the default cache needs to store jobs for a different period the time can be easily adjusted by changing the `keep_jobs` parameter in the Salt Master configuration file. The value passed in is measured via hours:

```
keep_jobs: 24
```

#### Reducing the Size of the Default Job Cache

The Default Job Cache can sometimes be a burden on larger deployments (over 5000 minions). Disabling the job cache will make previously executed jobs unavailable to the jobs system and is not generally recommended. Normally it is wise to make sure the master has access to a faster IO system or a tmpfs is mounted to the jobs dir.

However, you can disable the `job_cache` by setting it to `False` in the Salt Master configuration file. Setting this value to `False` means that the Salt Master will no longer cache minion returns, but a JID directory and `jid` file for each job will still be created. This JID directory is necessary for checking for and preventing JID collisions.

The default location for the job cache is in the `/var/cache/salt/master/jobs/` directory.
Setting the `job_cache` to `False` in addition to setting the `keep_jobs` option to a smaller value, such as 1, in the Salt Master configuration file will reduce the size of the Default Job Cache, and thus the burden on the Salt Master.

**Note:** Changing the `keep_jobs` option sets the number of hours to keep old job information and defaults to 24 hours. Do not set this value to 0 when trying to make the cache cleaner run more frequently, as this means the cache cleaner will never run.

### 2.7.2 Additional Job Cache Options

Many deployments may wish to use an external database to maintain a long term register of executed jobs. Salt comes with two main mechanisms to do this, the master job cache and the external job cache.

See [*Storing Job Results in an External System*](#).

### 2.8 Storing Job Results in an External System

After a job executes, job results are returned to the Salt Master by each Salt Minion. These results are stored in the Default Job Cache.

In addition to the Default Job Cache, Salt provides two additional mechanisms to send job results to other systems (databases, local syslog, and others):

- External Job Cache
- Master Job Cache

The major difference between these two mechanisms is from where results are returned (from the Salt Master or Salt Minion).

#### 2.8.1 External Job Cache - Minion-Side Returner

When an External Job Cache is configured, data is returned to the Default Job Cache on the Salt Master like usual, and then results are also sent to an External Job Cache using a Salt returner module running on the Salt Minion.
• Advantages: Data is stored without placing additional load on the Salt Master.

• Disadvantages: Each Salt Minion connects to the external job cache, which can result in a large number of connections. Also requires additional configuration to get returner module settings on all Salt Minions.

2.8.2 Master Job Cache - Master-Side Returner

New in version 2014.7.0.

Instead of configuring an External Job Cache on each Salt Minion, you can configure the Master Job Cache to send job results from the Salt Master instead. In this configuration, Salt Minions send data to the Default Job Cache as usual, and then the Salt Master sends the data to the external system using a Salt returner module running on the Salt Master.

• Advantages: A single connection is required to the external system. This is preferred for databases and similar systems.

• Disadvantages: Places additional load on your Salt Master.

2.8.3 Configure an External or Master Job Cache

Step 1: Understand Salt Returners

Before you configure a job cache, it is essential to understand Salt returner modules ('returners'). Returners are pluggable Salt Modules that take the data returned by jobs, and then perform any necessary steps to send the data to an external system. For example, a returner might establish a connection, authenticate, and then format and transfer data.

The Salt Returner system provides the core functionality used by the External and Master Job Cache systems, and the same returners are used by both systems.

Salt currently provides many different returners that let you connect to a wide variety of systems. A complete list is available at all Salt returners. Each returner is configured differently, so make sure you read and follow the instructions linked from that page.

For example, the MySQL returner requires:

• A database created using provided schema (structure is available at MySQL returner)

• A user created with with privileges to the database
• Optional SSL configuration

A simpler returner, such as Slack or HipChat, requires:
• An API key/version
• The target channel/room
• The username that should be used to send the message

Step 2: Configure the Returner

After you understand the configuration and have the external system ready, the configuration requirements must be declared.

External Job Cache

The returner configuration settings can be declared in the Salt Minion configuration file, the Minion’s pillar data, or the Minion’s grains.

If external_job_cache configuration settings are specified in more than one place, the options are retrieved in the following order. The first configuration location that is found is the one that will be used.
• Minion configuration file
• Minion’s grains
• Minion’s pillar data

Master Job Cache

The returner configuration settings for the Master Job Cache should be declared in the Salt Master’s configuration file.

Configuration File Examples

MySQL requires:

```yaml
mysql.host: 'salt'
mysql.user: 'salt'
mysql.pass: 'salt'
mysql.db: 'salt'
mysql.port: 3306
```

Slack requires:

```yaml
slack.channel: 'channel'
slack.api_key: 'key'
slack.from_name: 'name'
```

After you have configured the returner and added settings to the configuration file, you can enable the External or Master Job Cache.
Step 3: Enable the External or Master Job Cache

Configuration is a single line that specifies an already-configured returner to use to send all job data to an external system.

External Job Cache

To enable a returner as the External Job Cache (Minion-side), add the following line to the Salt Master configuration file:

```
ext_job_cache: <returner>
```

For example:

```
ext_job_cache: mysql
```

Note: When configuring an External Job Cache (Minion-side), the returner settings are added to the Minion configuration file, but the External Job Cache setting is configured in the Master configuration file.

Master Job Cache

To enable a returner as a Master Job Cache (Master-side), add the following line to the Salt Master configuration file:

```
master_job_cache: <returner>
```

For example:

```
master_job_cache: mysql
```

Verify that the returner configuration settings are in the Master configuration file, and be sure to restart the salt-master service after you make configuration changes. (service salt-master restart).

2.9 Logging

The salt project tries to get the logging to work for you and help us solve any issues you might find along the way. If you want to get some more information on the nitty-gritty of salt's logging system, please head over to the logging development document, if all you're after is salt's logging configurations, please continue reading.

2.9.1 Log Levels

The log levels are ordered numerically such that setting the log level to a specific level will record all log statements at that level and higher. For example, setting `log_level: error` will log statements at `error`, `critical`, and `quiet` levels, although nothing `should` be logged at `quiet` level.

Most of the logging levels are defined by default in Python's logging library and can be found in the official Python documentation. Salt uses some more levels in addition to the standard levels. All levels available in salt are shown in the table below.
Note: Python dependencies used by salt may define and use additional logging levels. For example, the Python 2 version of the multiprocessing standard Python library uses the levels subwarning, 25 and subdebug, 5.

<table>
<thead>
<tr>
<th>Level</th>
<th>Numeric value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>quiet</td>
<td>1000</td>
<td>Nothing should be logged at this level</td>
</tr>
<tr>
<td>critical</td>
<td>50</td>
<td>Critical errors</td>
</tr>
<tr>
<td>error</td>
<td>40</td>
<td>Errors</td>
</tr>
<tr>
<td>warning</td>
<td>30</td>
<td>Warnings</td>
</tr>
<tr>
<td>info</td>
<td>20</td>
<td>Normal log information</td>
</tr>
<tr>
<td>profile</td>
<td>15</td>
<td>Profiling information on salt performance</td>
</tr>
<tr>
<td>debug</td>
<td>10</td>
<td>Information useful for debugging both salt implementations and salt code</td>
</tr>
<tr>
<td>trace</td>
<td>5</td>
<td>More detailed code debugging information</td>
</tr>
<tr>
<td>garbage</td>
<td>1</td>
<td>Even more debugging information</td>
</tr>
<tr>
<td>all</td>
<td>0</td>
<td>Everything</td>
</tr>
</tbody>
</table>

### 2.9.2 Available Configuration Settings

**log_file**

The log records can be sent to a regular file, local path name, or network location. Remote logging works best when configured to use syslogd(8) (e.g.: file:///dev/log), with syslogd(8) configured for network logging. The format for remote addresses is: `<file|udp|tcp>://<host|socketpath>:<port-if-required>/<log-facility>`. Where log-facility is the symbolic name of a syslog facility as defined in the SysLogHandler documentation. It defaults to LOG_USER.

Default: Dependent of the binary being executed, for example, for salt-master, /var/log/salt/master.

Examples:

```
log_file: /var/log/salt/master
```

```
log_file: /var/log/salt/minion
```

```
log_file: file:///dev/log
```

```
log_file: file:///dev/log/LOG_DAEMON
```

```
log_file: udp://loghost:10514
```

**log_level**

Default: warning

The level of log record messages to send to the console. One of all, garbage, trace, debug, profile, info, warning, error, critical, quiet.

```
log_level: warning
```

Note: Add log_level: quiet in salt configuration file to completely disable logging. In case of running salt in command line use --log-level=quiet instead.
log_level_logfile

Default: info
The level of messages to send to the log file. One of all, garbage, trace, debug, profile, info, warning, error, critical, quiet.

log_level_logfile: warning

log_datefmt

Default: %H:%M:%S
The date and time format used in console log messages. Allowed date/time formatting can be seen on time.strftime.

log_datefmt: '%H:%M:%S'

log_datefmt_logfile

Default: %Y-%m-%d %H:%M:%S
The date and time format used in log file messages. Allowed date/time formatting can be seen on time.strftime.

log_datefmt_logfile: '%Y-%m-%d %H:%M:%S'

log_fmt_console

Default: [%{(levelname)-8s}] %(message)s
The format of the console logging messages. All standard python logging LogRecord attributes can be used. Salt also provides these custom LogRecord attributes to colorize console log output:

'(%(colorlevel)s)'  # log level name colorized by level
'(%(colorname)s)'    # colorized module name
'(%(colorprocess)s)' # colorized process number
'(%(colormsg)s)'     # log message colorized by level

Note: The %(colorlevel)s, %(colormap)s, and %(colorprocess) LogRecord attributes also include padding and enclosing brackets, [ and ] to match the default values of their collateral non-colorized LogRecord attributes.

log_fmt_console: '%{(levelname)-8s}%(message)s'

log_fmt_logfile

Default: %(asctime)s,%(msecs)03.0f [%{name}-17s][%{(levelname)-8s}] %(message)s
The format of the log file logging messages. All standard python logging LogRecord attributes can be used. Salt also provides these custom LogRecord attributes that include padding and enclosing brackets [ and ]:
Salt Documentation, Release 2016.3.6

log_fmt_logfile: '%(asctime)s,%(msecs)03.0f [%(name)-17s][%(levelname)-8s] %(message)s'

log_granular_levels

Default: {}

This can be used to control logging levels more specifically. The example sets the main salt library at the `warning` level, but sets salt.modules to log at the debug level:

```python
log_granular_levels:
    'salt': 'warning'
    'salt.modules': 'debug'
```

External Logging Handlers

Besides the internal logging handlers used by salt, there are some external which can be used, see the external logging handlers document.

2.10 Salt File Server

Salt comes with a simple file server suitable for distributing files to the Salt minions. The file server is a stateless ZeroMQ server that is built into the Salt master.

The main intent of the Salt file server is to present files for use in the Salt state system. With this said, the Salt file server can be used for any general file transfer from the master to the minions.

2.10.1 File Server Backends

In Salt 0.12.0, the modular fileserver was introduced. This feature added the ability for the Salt Master to integrate different file server backends. File server backends allow the Salt file server to act as a transparent bridge to external resources. A good example of this is the git backend, which allows Salt to serve files sourced from one or more git repositories, but there are several others as well. Click here for a full list of Salt’s fileserver backends.

Enabling a Fileserver Backend

Fileserver backends can be enabled with the `fileserver_backend` option.

```python
fileserver_backend:
    - git
```

See the documentation for each backend to find the correct value to add to `fileserver_backend` in order to enable them.
Using Multiple Backends

If `fileserver_backend` is not defined in the Master config file, Salt will use the `roots` backend, but the `fileserver_backend` option supports multiple backends. When more than one backend is in use, the files from the enabled backends are merged into a single virtual filesystem. When a file is requested, the backends will be searched in order for that file, and the first backend to match will be the one which returns the file.

```yaml
fileserver_backend:
  - roots
  - git
```

With this configuration, the environments and files defined in the `file_roots` parameter will be searched first, and if the file is not found then the git repositories defined in `gitfs_remotes` will be searched.

Defining Environments

Just as the order of the values in `fileserver_backend` matters, so too does the order in which different sources are defined within a fileserver environment. For example, given the below `file_roots` configuration, if both `/srv/salt/dev/foo.txt` and `/srv/salt/prod/foo.txt` exist on the Master, then `salt://foo.txt` would point to `/srv/salt/dev/foo.txt` in the `dev` environment, but it would point to `/srv/salt/prod/foo.txt` in the `base` environment.

```yaml
file_roots:
  base:
    - /srv/salt/prod
  qa:
    - /srv/salt/qa
    - /srv/salt/prod
  dev:
    - /srv/salt/dev
    - /srv/salt/qa
    - /srv/salt/prod
```

Similarly, when using the `git` backend, if both repositories defined below have a `hotfix23` branch/tag, and both of them also contain the file `bar.txt` in the root of the repository at that branch/tag, then `salt://bar.txt` in the `hotfix23` environment would be served from the first repository.

```yaml
gitfs_remotes:
  - https://mydomain.tld/repos/first.git
  - https://mydomain.tld/repos/second.git
```

Note: Environments map differently based on the fileserver backend. For instance, the mappings are explicitly defined in the `roots` backend, while in the VCS backends (`git`, `hg`, `svn`) the environments are created from branches/tags/bookmarks/etc. For the `minion` backend, the files are all in a single environment, which is specified by the `minionfs_env` option.

See the documentation for each backend for a more detailed explanation of how environments are mapped.

2.10.2 Dynamic Module Distribution

New in version 0.9.5.

Custom Salt execution, state, and other modules can be distributed to Salt minions using the Salt file server.
Under the root of any environment defined via the `file_roots` option on the master server directories corresponding to the type of module can be used.

The directories are prepended with an underscore:

- `_beacons`
- `_engines`
- `_grains`
- `_modules`
- `_output`
- `_proxy`
- `_renderers`
- `_returners`
- `_states`
- `_utils`

The contents of these directories need to be synced over to the minions after Python modules have been created in them. There are a number of ways to sync the modules.

**Sync Via States**

The minion configuration contains an option `autoload_dynamic_modules` which defaults to `True`. This option makes the state system refresh all dynamic modules when states are run. To disable this behavior set `autoload_dynamic_modules` to `False` in the minion config.

When dynamic modules are autoloaded via states, modules only pertinent to the environments matched in the master's top file are downloaded.

This is important to remember, because modules can be manually loaded from any specific environment that environment specific modules will be loaded when a state run is executed.

**Sync Via the saltutil Module**

The saltutil module has a number of functions that can be used to sync all or specific dynamic modules. The saltutil module function `saltutil.sync_all` will sync all module types over to a minion. For more information see: `salt.modules.saltutil`

**2.10.3 Requesting Files from Specific Environments**

The Salt fileserver supports multiple environments, allowing for SLS files and other files to be isolated for better organization.

For the default backend (called `roots`), environments are defined using the `roots` option. Other backends (such as `gitfs`) define environments in their own ways. For a list of available fileservers, see here.

**Querystring Syntax**

Any `salt://` file URL can specify its fileserver environment using a querystring syntax, like so:
In Reactor configurations, this method must be used to pull files from an environment other than base.

In States

Minions can be instructed which environment to use both globally, and for a single state, and multiple methods for each are available:

Globally

A minion can be pinned to an environment using the `environment` option in the minion config file. Additionally, the environment can be set for a single call to the following functions:

- `state.apply`
- `state.highstate`
- `state.sls`
- `state.top`

Note: When the `saltenv` parameter is used to trigger a `highstate` using either `state.apply` or `state.highstate`, only states from that environment will be applied.

On a Per-State Basis

Within an individual state, there are two ways of specifying the environment. The first is to add a `saltenv` argument to the state. This example will pull the file from the `config` environment:

```
/etc/foo/bar.conf:
  file.managed:
    - source: salt://foo/bar.conf
    - user: foo
    - mode: 600
    - saltenv: config
```

Another way of doing the same thing is to use the `querystring syntax` described above:

```
/etc/foo/bar.conf:
  file.managed:
    - source: salt://foo/bar.conf?saltenv=config
    - user: foo
    - mode: 600
```

Note: Specifying the environment using either of the above methods is only necessary in cases where a state from one environment needs to access files from another environment. If the SLS file containing this state was in the `config` environment, then it would look in that environment by default.
2.10.4 File Server Configuration

The Salt file server is a high performance file server written in ZeroMQ. It manages large files quickly and with little overhead, and has been optimized to handle small files in an extremely efficient manner.

The Salt file server is an environment aware file server. This means that files can be allocated within many root directories and accessed by specifying both the file path and the environment to search. The individual environments can span across multiple directory roots to create overlays and to allow for files to be organized in many flexible ways.

Environments

The Salt file server defaults to the mandatory base environment. This environment MUST be defined and is used to download files when no environment is specified.

Environments allow for files and sls data to be logically separated, but environments are not isolated from each other. This allows for logical isolation of environments by the engineer using Salt, but also allows for information to be used in multiple environments.

Directory Overlay

The environment setting is a list of directories to publish files from. These directories are searched in order to find the specified file and the first file found is returned.

This means that directory data is prioritized based on the order in which they are listed. In the case of this file_roots configuration:

```
file_roots:
  base:
    - /srv/salt/base
    - /srv/salt/failover
```

If a file's URI is salt://httpd/httpd.conf, it will first search for the file at /srv/salt/base/httpd/httpd.conf. If the file is found there it will be returned. If the file is not found there, then /srv/salt/failover/httpd/httpd.conf will be used for the source.

This allows for directories to be overlaid and prioritized based on the order they are defined in the configuration.

It is also possible to have file_roots which supports multiple environments:

```
file_roots:
  base:
    - /srv/salt/base
  dev:
    - /srv/salt/dev
    - /srv/salt/base
  prod:
    - /srv/salt/prod
    - /srv/salt/base
```

This example ensures that each environment will check the associated environment directory for files first. If a file is not found in the appropriate directory, the system will default to using the base directory.

Local File Server

New in version 0.9.8.
The file server can be rerouted to run from the minion. This is primarily to enable running Salt states without a Salt master. To use the local file server interface, copy the file server data to the minion and set the file_roots option on the minion to point to the directories copied from the master. Once the minion file_roots option has been set, change the file_client option to local to make sure that the local file server interface is used.

### 2.10.5 The cp Module

The cp module is the home of minion side file server operations. The cp module is used by the Salt state system, salt-cp, and can be used to distribute files presented by the Salt file server.

#### Escaping Special Characters

The `salt://` url format can potentially contain a query string, for example `salt://dir/file.txt?saltenv=base`. You can prevent the fileclient/fileserver from interpreting ? as the initial token of a query string by referencing the file with `salt://|` rather than `salt:///`.

```
/etc/marathon/conf/?checkpoint:
  file.managed:
    - source: salt://|hw/config/?checkpoint
    - makedirs: True
```

#### Environments

Since the file server is made to work with the Salt state system, it supports environments. The environments are defined in the master config file and when referencing an environment the file specified will be based on the root directory of the environment.

#### get_file

The cp.get_file function can be used on the minion to download a file from the master, the syntax looks like this:

```
# salt '*' cp.get_file salt://vimrc /etc/vimrc
```

This will instruct all Salt minions to download the vimrc file and copy it to /etc/vimrc

Template rendering can be enabled on both the source and destination file names like so:

```
# salt '*' cp.get_file "salt://{{grains.os}}/vimrc" /etc/vimrc template=jinja
```

This example would instruct all Salt minions to download the vimrc from a directory with the same name as their OS grain and copy it to /etc/vimrc

For larger files, the cp.get_file module also supports gzip compression. Because gzip is CPU-intensive, this should only be used in scenarios where the compression ratio is very high (e.g. pretty-printed JSON or YAML files).

To use compression, use the `gzip` named argument. Valid values are integers from 1 to 9, where 1 is the lightest compression and 9 the heaviest. In other words, 1 uses the least CPU on the master (and minion), while 9 uses the most.

```
# salt '*' cp.get_file salt://vimrc /etc/vimrc gzip=5
```

Finally, note that by default `cp.get_file` does not create new destination directories if they do not exist. To change this, use the `makedirs` argument:
In this example, `/etc/vim/` would be created if it didn’t already exist.

### get_dir

The `cp.get_dir` function can be used on the minion to download an entire directory from the master. The syntax is very similar to `get_file`:

```bash
# salt '*' cp.get_dir salt://etc/apache2 /etc
```

cp.get_dir supports template rendering and gzip compression arguments just like `get_file`:

```bash
# salt '*' cp.get_dir salt://etc/{{pillar.webserver}} /etc gzip=5 template=jinja
```

## 2.10.6 File Server Client Instance

A client instance is available which allows for modules and applications to be written which make use of the Salt file server.

The file server uses the same authentication and encryption used by the rest of the Salt system for network communication.

### fileclient Module

The `salt/fileclient.py` module is used to set up the communication from the minion to the master. When creating a client instance using the fileclient module, the minion configuration needs to be passed in. When using the fileclient module from within a minion module the built in `__opts__` data can be passed:

```python
import salt.minion
import salt.fileclient

def get_file(path, dest, env='base'):
    """
    Used to get a single file from the Salt master
    
    CLI Example:
    salt '*' cp.get_file salt://vimrc /etc/vimrc
    
    # Get the fileclient object
    client = salt.fileclient.get_file_client(__opts__)
    # Call get_file
    return client.get_file(path, dest, False, env)
    """

Creating a fileclient instance outside of a minion module where the `__opts__` data is not available, it needs to be generated:

```python
import salt.fileclient
import salt.config

def get_file(path, dest, env='base'):
    """
    Used to get a single file from the Salt master
    """
```
# Get the configuration data
```python
opts = salt.config.minion_config('/etc/salt/minion')
# Get the fileclient object
client = salt.fileclient.get_file_client(opts)
# Call get_file
return client.get_file(path, dest, False, env)
```

## 2.11 Git Fileserver Backend Walkthrough

**Note:** This walkthrough assumes basic knowledge of Salt. To get up to speed, check out the Salt Walkthrough.

The gitfs backend allows Salt to serve files from git repositories. It can be enabled by adding `git` to the `fileserver_backend` list, and configuring one or more repositories in `gitfs_remotes`.

Branches and tags become Salt fileserver environments.

**Note:** Branching and tagging can result in a lot of potentially-conflicting `top files`, for this reason it may be useful to set `top_file_merging_strategy` to `same` in the minions' config files if the top files are being managed in a GitFS repo.

### 2.11.1 Installing Dependencies

Beginning with version 2014.7.0, both `pygit2` and Dulwich are supported as alternatives to GitPython. The desired provider can be configured using the `gitfs_provider` parameter in the master config file.

If `gitfs_provider` is not configured, then Salt will prefer `pygit2` if a suitable version is available, followed by GitPython and Dulwich.

**Note:** It is recommended to always run the most recent version of any the below dependencies. Certain features of gitfs may not be available without the most recent version of the chosen library.

#### pygit2

The minimum supported version of `pygit2` is 0.20.3. Availability for this version of `pygit2` is still limited, though the SaltStack team is working to get compatible versions available for as many platforms as possible.

For the Fedora/EPEL versions which have a new enough version packaged, the following command would be used to install `pygit2`:

```
# yum install python-pygit2
```

Provided a valid version is packaged for Debian/Ubuntu (which is not currently the case), the package name would be the same, and the following command would be used to install it:

```
# apt-get install python-pygit2
```
If pygit2 is not packaged for the platform on which the Master is running, the pygit2 website has installation instructions here. Keep in mind however that following these instructions will install libgit2 and pygit2 without system packages. Additionally, keep in mind that SSH authentication in pygit2 requires libssh2 (not libssh) development libraries to be present before libgit2 is built. On some Debian-based distros pkg-config is also required to link libgit2 with libssh2.

Additionally, version 0.21.0 of pygit2 introduced a dependency on python-cffi, which in turn depends on newer releases of libffi. Upgrading libffi is not advisable as several other applications depend on it, so on older LTS linux releases pygit2 0.20.3 and libgit2 0.20.0 is the recommended combination.

**Warning:** pygit2 is actively developed and frequently makes non-backwards-compatible API changes, even in minor releases. It is not uncommon for pygit2 upgrades to result in errors in Salt. Please take care when upgrading pygit2, and pay close attention to the changelog, keeping an eye out for API changes. Errors can be reported on the SaltStack issue tracker.

### RedHat Pygit2 Issues

The release of RedHat/CentOS 7.3 upgraded both python-cffi and http-parser, both of which are dependencies for pygit2/libgit2. Both pygit2 and libgit2 (which are from the EPEL repository and not managed directly by RedHat) need to be rebuilt against these updated dependencies.

The below errors will show up in the master log if an incompatible python-pygit2 package is installed:

```
2017-02-10 09:07:34,892 [salt.utils.gitfs ][ERROR ][11211] Import pygit2 failed:
  CompileError: command 'gcc' failed with exit status 1
2017-02-10 09:07:34,907 [salt.utils.gitfs ][ERROR ][11211] gitfs is configured but:
  could not be loaded, are pygit2 and libgit2 installed?
2017-02-10 09:07:34,907 [salt.utils.gitfs ][CRITICAL][11211] No suitable gitfs
  provider module is installed.
2017-02-10 09:07:34,912 [salt.master ][CRITICAL][11211] Master failed pre flight:
  checks, exiting
```

The below errors will show up in the master log if an incompatible libgit2 package is installed:

```
2017-02-15 18:04:45,211 [salt.utils.gitfs ][ERROR ][6211] Error occurred fetching:
  gitfs remote 'https://foo.com/bar.git': No Content-Type header in response
```

As of 15 February 2017, python-pygit2 has been rebuilt and is in the stable EPEL repository. However, libgit2 remains broken (a bug report has been filed to get it rebuilt).

In the meantime, you can work around this by downgrading http-parser. To do this, go to this page and download the appropriate http-parser RPM for the OS architecture you are using (x86_64, etc.). Then downgrade using the rpm command. For example:

```
[root@784e8a8c5028 ~]# curl --silent -O https://kojipkgs.fedoraproject.org//packages/http-parser/2.0.5.20121128gitcd01361.el7/x86_64/http-parser-2.0.5.20121128gitcd01361.el7.x86_64.rpm
[root@784e8a8c5028 ~]# rpm --oldpackage http-parser-2.0.5.20121128gitcd01361.el7.x86_64
Preparing... #................................. [100%]

  1:http-parser-2.0.5.20121128gitcd01361.el7.x86_64[100%]
Cleaning up / removing...
  2:http-parser-2.0.5.20121128gitcd01361.el7.x86_64[50%]
```

2.11. Git Fileserver Backend Walkthrough 183
A restart of the salt-master daemon may be required to allow http(s) repositories to continue to be fetched.

**GitPython**

GitPython 0.3.0 or newer is required to use GitPython for gitfs. For RHEL-based Linux distros, a compatible version is available in EPEL, and can be easily installed on the master using yum:

```sh
# yum install GitPython
```

Ubuntu 14.04 LTS and Debian Wheezy (7.x) also have a compatible version packaged:

```sh
# apt-get install python-git
```

If your master is running an older version (such as Ubuntu 12.04 LTS or Debian Squeeze), then you will need to install GitPython using either `pip` or `easy_install` (it is recommended to use pip). Version 0.3.2.RC1 is now marked as the stable release in PyPI, so it should be a simple matter of running `pip install GitPython` or `easy_install GitPython` as root.

**Warning:** Keep in mind that if GitPython has been previously installed on the master using `pip` (even if it was subsequently uninstalled), then it may still exist in the build cache (typically `/tmp/pip-build-root/GitPython`) if the cache is not cleared after installation. The package in the build cache will override any requirement specifiers, so if you try upgrading to version 0.3.2.RC1 by running `pip install 'GitPython==0.3.2.RC1'` then it will ignore this and simply install the version from the cache directory. Therefore, it may be necessary to delete the GitPython directory from the build cache in order to ensure that the specified version is installed.

**Warning:** GitPython 2.0.9 and newer is not compatible with Python 2.6. If installing GitPython using `pip` on a machine running Python 2.6, make sure that a version earlier than 2.0.9 is installed. This can be done on the CLI by running `pip install 'GitPython<2.0.9'`, or in a `pip.installed` state using the following SLS:

```yaml
GitPython:
  pip.installed:
    - name: 'GitPython < 2.0.9'
```

**Dulwich**

Dulwich 0.9.4 or newer is required to use Dulwich as backend for gitfs. Dulwich is available in EPEL, and can be easily installed on the master using yum:

```sh
# yum install python-dulwich
```

For APT-based distros such as Ubuntu and Debian:

```sh
# apt-get install python-dulwich
```

**Important:** If switching to Dulwich from GitPython/pygit2, or switching from GitPython/pygit2 to Dulwich, it is necessary to clear the gitfs cache to avoid unpredictable behavior. This is probably a good idea whenever switching to a new `gitfs_provider`, but it is less important when switching between GitPython and pygit2.

Beginning in version 2015.5.0, the gitfs cache can be easily cleared using the `fileserver.clear_cache` runner.
salt-run fileserver.clear_cache backend=git

If the Master is running an earlier version, then the cache can be cleared by removing the *gitfs* and *file_lists/gitfs* directories (both paths relative to the master cache directory, usually /var/cache/salt/master).

```bash
rm -rf /var/cache/salt/master{,/file_lists}/gitfs
```

### 2.11.2 Simple Configuration

To use the gitfs backend, only two configuration changes are required on the master:

1. Include `git` in the `fileserver_backend` list in the master config file:

   ```yaml
   fileserver_backend:
     - git
   ```

2. Specify one or more `git://`, `https://`, `file://`, or `ssh://` URLs in `gitfs_remotes` to configure which repositories to cache and search for requested files:

   ```yaml
   gitfs_remotes:
     - https://github.com/saltstack-formulas/salt-formula.git
   ```

   SSH remotes can also be configured using scp-like syntax:

   ```yaml
   gitfs_remotes:
     - git@github.com:user/repo.git
     - ssh://user@domain.tld/path/to/repo.git
   ```

   Information on how to authenticate to SSH remotes can be found [here](#).

   **Note:** Dulwich does not recognize `ssh://` URLs, `git+ssh://` must be used instead. Salt version 2015.5.0 and later will automatically add the `git+` to the beginning of these URLs before fetching, but earlier Salt versions will fail to fetch unless the URL is specified using `git+ssh://`.

3. Restart the master to load the new configuration.

   **Note:** In a master/minion setup, files from a gitfs remote are cached once by the master, so minions do not need direct access to the git repository.

### 2.11.3 Multiple Remotes

The `gitfs_remotes` option accepts an ordered list of git remotes to cache and search, in listed order, for requested files.

A simple scenario illustrates this cascading lookup behavior:

If the `gitfs_remotes` option specifies three remotes:
Salt will attempt to lookup the requested file from each gitfs remote repository in the order in which they are defined in the configuration. The `git://github.com/example/first.git` remote will be searched first. If the requested file is found, then it is served and no further searching is executed. For example:

- A request for the file `salt://haproxy/init.sls` will be served from the `https://github.com/example/second.git` git repo.
- A request for the file `salt://haproxy/haproxy.conf` will be served from the `file:///root/third` repo.

Note: This example is purposefully contrived to illustrate the behavior of the gitfs backend. This example should not be read as a recommended way to lay out files and git repos.

The `file://` prefix denotes a git repository in a local directory. However, it will still use the given `file://` URL as a remote, rather than copying the git repo to the salt cache. This means that any refs you want accessible must exist as local refs in the specified repo.

Warning: Salt versions prior to 2014.1.0 are not tolerant of changing the order of remotes or modifying the URI of existing remotes. In those versions, when modifying remotes it is a good idea to remove the gitfs cache directory (`/var/cache/salt/master/gitfs`) before restarting the salt-master service.

### 2.11.4 Per-remote Configuration Parameters

New in version 2014.7.0.

The following master config parameters are global (that is, they apply to all configured gitfs remotes):

- `gitfs_base`
- `gitfs_root`
- `gitfs_mountpoint` (new in 2014.7.0)
- `gitfs_user` (pygit2 only, new in 2014.7.0)
- `gitfs_password` (pygit2 only, new in 2014.7.0)
• `gitfs_insecure_auth` (pygit2 only, new in 2014.7.0)

• `gitfs_pubkey` (pygit2 only, new in 2014.7.0)

• `gitfs_privkey` (pygit2 only, new in 2014.7.0)

• `gitfs_passphrase` (pygit2 only, new in 2014.7.0)

These parameters can now be overridden on a per-remote basis. This allows for a tremendous amount of customization. Here’s some example usage:

```
\begin{verbatim}
gitfs_provider: pygit2

gitfs_base: develop

gitfs_remotes:
  - https://foo.com/foo.git
  - https://foo.com/bar.git:
    - root: salt
    - mountpoint: salt://bar
    - base: salt-base
  - https://foo.com/bar.git:
    - name: second_bar_repo
    - root: other/salt
    - mountpoint: salt://other/bar
    - base: salt-base
  - http://foo.com/baz.git:
    - root: salt/states
    - user: joe
    - password: mysupersecretpassword
    - insecure_auth: True
\end{verbatim}
```

**Important:** There are two important distinctions which should be noted for per-remote configuration:

1. The URL of a remote which has per-remote configuration must be suffixed with a colon.

2. Per-remote configuration parameters are named like the global versions, with the `gitfs_` removed from the beginning. The exception being the `name` parameter which is only available to per-remote configurations.

In the example configuration above, the following is true:

1. The first and fourth `gitfs` remotes will use the `develop` branch/tag as the `base` environment, while the second and third will use the `salt-base` branch/tag as the `base` environment.

2. The first remote will serve all files in the repository. The second remote will only serve files from the `salt` directory (and its subdirectories). The third remote will only serve files from the `other/salt` directory (and its subdirectories), while the fourth remote will only serve files from the `salt/states` directory (and its subdirectories).

3. The first and fourth remotes will have files located under the root of the Salt fileservice namespace (`salt://`). The files from the second remote will be located under `salt://bar`, while the files from the third remote will be located under `salt://other/bar`.

4. The second and third remotes reference the same repository and unique names need to be declared for duplicate `gitfs` remotes.

5. The fourth remote overrides the default behavior of *not authenticating to insecure (non-HTTPS) remotes.*
2.11.5 Serving from a Subdirectory

The `gitfs_root` parameter allows files to be served from a subdirectory within the repository. This allows for only part of a repository to be exposed to the Salt fileserver.

Assume the below layout:

```
.gitignore
README.txt
foo/
  foo/bar/
  foo/bar/one.txt
  foo/bar/two.txt
  foo/bar/three.txt
  foo/baz/
  foo/baz/top.sls
  foo/baz/edit/vim.sls
  foo/baz/edit/vimrc
  foo/baz/nginx/init.sls
```

The below configuration would serve only the files under `foo/baz`, ignoring the other files in the repository:

```
gitfs_remotes:
  - git://mydomain.com/stuff.git

gitfs_root: foo/baz
```

The root can also be configured on a *per-remote basis*.

2.11.6 Mountpoints

New in version 2014.7.0.

The `gitfs_mountpoint` parameter will prepend the specified path to the files served from gitfs. This allows an existing repository to be used, rather than needing to reorganize a repository or design it around the layout of the Salt fileserver.

Before the addition of this feature, if a file being served up via gitfs was deeply nested within the root directory (for example, `salt://webapps/foo/files/foo.conf`), it would be necessary to ensure that the file was properly located in the remote repository, and that all of the parent directories were present (for example, the directories `webapps/foo/files/` would need to exist at the root of the repository).

The below example would allow for a file `foo.conf` at the root of the repository to be served up from the Salt fileserver path `salt://webapps/foo/files/foo.conf`.

```
gitfs_remotes:
  - https://mydomain.com/stuff.git

gitfs_mountpoint: salt://webapps/foo/files
```

Mountpoints can also be configured on a *per-remote basis*.

2.11.7 Using gitfs Alongside Other Backends

Sometimes it may make sense to use multiple backends; for instance, if `sls` files are stored in git but larger files are stored directly on the master.
The cascading lookup logic used for multiple remotes is also used with multiple backends. If the `fileserver_backend` option contains multiple backends:

```yaml
fileserver_backend:
  - roots
  - git
```

Then the `roots` backend (the default backend of files in `/srv/salt`) will be searched first for the requested file; then, if it is not found on the master, each configured git remote will be searched.

### 2.11.8 Branches, Environments, and Top Files

When using the gitfs backend, branches, and tags will be mapped to environments using the branch/tag name as an identifier.

There is one exception to this rule: the `master` branch is implicitly mapped to the `base` environment.

So, for a typical `base, qa, dev` setup, the following branches could be used:

```text
master
qa
dev
```

Top.sls files from different branches will be merged into one at runtime. Since this can lead to overly complex configurations, the recommended setup is to have a separate repository, containing only the `top.sls` file with just one single `master` branch.

To map a branch other than `master` as the `base` environment, use the `gitfs_base` parameter:

```text
gitfs_base: salt-base
```

The base can also be configured on a *per-remote basis*.

### 2.11.9 Environment Whitelist/Blacklist

New in version 2014.7.0.

The `gitfs_env_whitelist` and `gitfs_env_blacklist` parameters allow for greater control over which branches/tags are exposed as fileserver environments. Exact matches, globs, and regular expressions are supported, and are evaluated in that order. If using a regular expression, `^` and `$` must be omitted, and the expression must match the entire branch/tag.

```text
gitfs_env_whitelist:
  - base
  - v1.*
  - 'mybranch\d+'
```

**Note:** `v1.*`, in this example, will match as both a glob and a regular expression (though it will have been matched as a glob, since globs are evaluated before regular expressions).

The behavior of the blacklist/whitelist will differ depending on which combination of the two options is used:

- If only `gitfs_env_whitelist` is used, then only branches/tags which match the whitelist will be available as environments
If only `gitfs_env_blacklist` is used, then the branches/tags which match the blacklist will **not** be available as environments.

If both are used, then the branches/tags which match the whitelist, but do **not** match the blacklist, will be available as environments.

## 2.11.10 Authentication

### pygit2

New in version 2014.7.0.

Both HTTPS and SSH authentication are supported as of version 0.20.3, which is the earliest version of pygit2 supported by Salt for gitfs.

**Note:** The examples below make use of per-remote configuration parameters, a feature new to Salt 2014.7.0. More information on these can be found [here](#).

### HTTPS

For HTTPS repositories which require authentication, the username and password can be provided like so:

```yaml
gitfs_remotes:
  - https://domain.tld/myrepo.git:
    - user: git
    - password: mypassword
```

If the repository is served over HTTP instead of HTTPS, then Salt will by default refuse to authenticate to it. This behavior can be overridden by adding an `insecure_auth` parameter:

```yaml
gitfs_remotes:
  - http://domain.tld/insecure_repo.git:
    - user: git
    - password: mypassword
    - insecure_auth: True
```

### SSH

SSH repositories can be configured using the `ssh://` protocol designation, or using scp-like syntax. So, the following two configurations are equivalent:

- `ssh://git@github.com/user/repo.git`
- `git@github.com:user/repo.git`

Both `gitfs_pubkey` and `gitfs_privkey` (or their *per-remote counterparts*) must be configured in order to authenticate to SSH-based repos. If the private key is protected with a passphrase, it can be configured using `gitfs_passphrase` (or simply `passphrase` if being configured *per-remote*). For example:

```yaml
gitfs_remotes:
  - git@github.com:user/repo.git:
    - pubkey: /root/.ssh/id_rsa.pub
```

---

**Chapter 2. Configuring Salt**

190
Finally, the SSH host key must be _added to the known_hosts file._

**Note:** There is a known issue with public-key SSH authentication to Microsoft Visual Studio (VSTS) with pygit2. This is due to a bug or lack of support for VSTS in older libssh2 releases. Known working releases include libssh2 1.7.0 and later, and known incompatible releases include 1.5.0 and older. At the time of this writing, 1.6.0 has not been tested.

Since upgrading libssh2 would require rebuilding many other packages (curl, etc.), followed by a rebuild of libgit2 and a reinstall of pygit2, an easier workaround for systems with older libssh2 is to use GitPython with a passphraseless key for authentication.

**GitPython**

With **GitPython**, only passphrase-less SSH public key authentication is supported. The auth parameters (pubkey, privkey, etc.) shown in the pygit2 authentication examples above do not work with GitPython.

```plaintext
gitfs_remotes:  
    - ssh://git@github.com/example/salt-states.git
```

Since **GitPython** wraps the git CLI, the private key must be located in `~/.ssh/id_rsa` for the user under which the Master is running, and should have permissions of `0600`. Also, in the absence of a user in the repo URL, **GitPython** will (just as SSH does) attempt to login as the current user (in other words, the user under which the Master is running, usually root).

If a key needs to be used, then `~/.ssh/config` can be configured to use the desired key. Information on how to do this can be found by viewing the manpage for `ssh_config`. Here's an example entry which can be added to the `~/.ssh/config` to use an alternate key for gitfs:

```plaintext
Host github.com
    IdentityFile /root/.ssh/id_rsa_gitfs
    StrictHostKeyChecking no
```

The `Host` parameter should be a hostname (or hostname glob) that matches the domain name of the git repository.

It is also necessary to _add the SSH host key to the known_hosts file_. The exception to this would be if strict host key checking is disabled, which can be done by adding `StrictHostKeyChecking no` to the entry in `~/.ssh/config`:

```plaintext
Host github.com
    IdentityFile /root/.ssh/id_rsa_gitfs
    StrictHostKeyChecking no
```

However, this is generally regarded as insecure, and is not recommended.

**Adding the SSH Host Key to the known_hosts File**

To use SSH authentication, it is necessary to have the remote repository's SSH host key in the `~/.ssh/known_hosts` file. If the master is also a minion, this can be done using the `ssh.set_known_host` function:
If not, then the easiest way to add the key is to su to the user (usually root) under which the salt-master runs and attempt to login to the server via SSH:

```bash
$ su -
Password:
# ssh github.com
Are you sure you want to continue connecting (yes/no)? yes
Warning: Permanently added 'github.com,192.30.252.128' (RSA) to the list of known hosts.
Permission denied (publickey).
```

It doesn’t matter if the login was successful, as answering yes will write the fingerprint to the known_hosts file.

**Verifying the Fingerprint**

To verify that the correct fingerprint was added, it is a good idea to look it up. One way to do this is to use nmap:

```bash
$ nmap -p 22 github.com --script ssh-hostkey
```

Starting Nmap 5.51 ( http://nmap.org ) at 2014-08-18 17:47 CDT
Nmap scan report for github.com (192.30.252.129)
Host is up (0.17s latency).
Not shown: 996 filtered ports
PORT STATE SERVICE
22/tcp open ssh
80/tcp open http
443/tcp open https
9418/tcp open git

Nmap done: 1 IP address (1 host up) scanned in 28.78 seconds
```

Another way is to check one’s own known_hosts file, using this one-liner:
$ ssh-keygen -l -f /dev/stdin <<<'ssh-keyscan github.com 2>/dev/null' | awk '{print $2}'

**Warning**: AWS tracks usage of nmap and may flag it as abuse. On AWS hosts, the `ssh-keygen` method is recommended for host key verification.

**Note**: As of OpenSSH 6.8 the SSH fingerprint is now shown as a base64-encoded SHA256 checksum of the host key. So, instead of the fingerprint looking like 16:27:ac:a5:76:28:2d:36:63:1b:56:4d:eb:df:a6:48, it would look like SHA256:nThbg6kXUpJWGl7E1IGOCspRomTxdCARLviKw6E5SY8.

### 2.11.11 Refreshing gitfs Upon Push

By default, Salt updates the remote filesystem backends every 60 seconds. However, if it is desirable to refresh quicker than that, the Reactor System can be used to signal the master to update the filesystem on each push, provided that the git server is also a Salt minion. There are three steps to this process:

1. On the master, create a file `/srv/reactor/update_fileserver.sls`, with the following contents:

   ```
   update_fileserver:
   runner.fileserver.update
   ```

2. Add the following reactor configuration to the master config file:

   ```
   reactor:
   - 'salt/fileserver/gitfs/update':
     - /srv/reactor/update_fileserver.sls
   ```

3. On the git server, add a post-receive hook

   (a) If the user executing `git push` is the same as the minion user, use the following hook:

   ```
   #!/usr/bin/env sh
   salt-call event.fire_master update salt/fileserver/gitfs/update
   ```

   (a) To enable other git users to run the hook after a push, use `sudo` in the hook script:

   ```
   #!/usr/bin/env sh
   sudo -u root salt-call event.fire_master update salt/fileserver/gitfs/
   ```

2. If using `sudo` in the git hook (above), the policy must be changed to permit all users to fire the event. Add the following policy to the sudoers file on the git server.

   ```
   Cmnd_Alias SALT_GIT_HOOK = /bin/salt-call event.fire_master update salt/
   "fileserver/gitfs/update"
   Defaults!SALT_GIT_HOOK !requiretty
   ALL   ALL=(root) NOPASSWD: SALT_GIT_HOOK
   ```

   The `update` argument right after `event.fire_master` in this example can really be anything, as it represents the data being passed in the event, and the passed data is ignored by this reactor.

   Similarly, the tag name `salt/fileserver/gitfs/update` can be replaced by anything, so long as the usage is consistent.

---

2.11. Git Fileserver Backend Walkthrough
The root user name in the hook script and sudo policy should be changed to match the user under which the minion is running.

### 2.11.12 Using Git as an External Pillar Source

The git external pillar (a.k.a. git_pillar) has been rewritten for the 2015.8.0 release. This rewrite brings with it pygit2 support (allowing for access to authenticated repositories), as well as more granular support for per-remote configuration.

To make use of the new features, changes to the git ext_pillar configuration must be made. The new configuration schema is detailed [here](#).

For Salt releases before 2015.8.0, click [here](#) for documentation.

### 2.11.13 Why aren't my custom modules/states/etc. syncing to my Minions?

In versions 0.16.3 and older, when using the `git filesaver backend`, certain versions of GitPython may generate errors when fetching, which Salt fails to catch. While not fatal to the fetch process, these interrupt the filesaver update that takes place before custom types are synced, and thus interrupt the sync itself. Try disabling the git filesaver backend in the master config, restarting the master, and attempting the sync again.

This issue is worked around in Salt 0.16.4 and newer.

### 2.12 MinionFS Backend Walkthrough

New in version 2014.1.0.

**Note:** This walkthrough assumes basic knowledge of Salt and `cp.push`. To get up to speed, check out the Salt Walkthrough.

Sometimes it is desirable to deploy a file located on one minion to one or more other minions. This is supported in Salt, and can be accomplished in two parts:

1. Minion support for pushing files to the master (using `cp.push`)
2. The `minionfs` filesaver backend

This walkthrough will show how to use both of these features.

#### 2.12.1 Enabling File Push

To set the master to accept files pushed from minions, the `file_recv` option in the master config file must be set to `True` (the default is `False`).

```
file_recv: True
```

**Note:** This change requires a restart of the salt-master service.
2.12.2 Pushing Files

Once this has been done, files can be pushed to the master using the `cp.push` function:

```bash
salt 'minion-id' cp.push /path/to/the/file
```

This command will store the file in a subdirectory named `minions` under the master's `cachedir`. On most masters, this path will be `/var/cache/salt/master/minions`. Within this directory will be one directory for each minion which has pushed a file to the master, and underneath that the full path to the file on the minion. So, for example, if a minion with an ID of `dev1` pushed a file `/var/log/myapp.log` to the master, it would be saved to `/var/cache/salt/master/minions/dev1/var/log/myapp.log`.

2.12.3 Serving Pushed Files Using MinionFS

While it is certainly possible to add `/var/cache/salt/master/minions` to the master's `file_roots` and serve these files, it may only be desirable to expose files pushed from certain minions. Adding `/var/cache/salt/master/minions/<minion-id>` for each minion that needs to be exposed can be cumbersome and prone to errors.

Enter `minionfs`. This fileserver backend will make files pushed using `cp.push` available to the Salt fileserver, and provides an easy mechanism to restrict which minions' pushed files are made available.

Simple Configuration

To use the `minionfs` backend, add `minion` to the list of backends in the `fileserver_backend` configuration option on the master:

```yaml
file_recv: True

fileserver_backend:
  - roots
  - minion
```

**Note:** As described earlier, `file_recv: True` is also needed to enable the master to receive files pushed from minions. As always, changes to the master configuration require a restart of the `salt-master` service.

Files made available via `minionfs` are by default located at `salt://<minion-id>/path/to/file`. Think back to the earlier example, in which `dev1` pushed a file `/var/log/myapp.log` to the master. With `minionfs` enabled, this file would be addressable in Salt at `salt://dev1/var/log/myapp.log`.

If many minions have pushed to the master, this will result in many directories in the root of the Salt fileserver. For this reason, it is recommended to use the `minionfs_mountpoint` config option to organize these files underneath a subdirectory:

```plaintext
minionfs_mountpoint: salt://minionfs
```

Using the above mountpoint, the file in the example would be located at `salt://minionfs/dev1/var/log/myapp.log`.

Restricting Certain Minions' Files from Being Available Via MinionFS

A whitelist and blacklist can be used to restrict the minions whose pushed files are available via `minionfs`. These lists can be managed using the `minionfs_whitelist` and `minionfs_blacklist` config options. Click the
A more complex configuration example, which uses both a whitelist and blacklist, can be found below:

```yaml
file_recv: True
files_server_backend:
  - roots
  - minion
minionfs_mountpoint: salt://minionfs
minionfs_whitelist:
  - host04
  - web*
  - 'mail\d+\..domain\..tld'
minionfs_whitelist:
  - web21
```

**Potential Concerns**

- There is no access control in place to restrict which minions have access to files served up by `minionfs`. All minions will have access to these files.
- Unless the `minionfs_whitelist` and/or `minionfs_blacklist` config options are used, all minions which push files to the master will have their files made available via `minionfs`.

### 2.13 Salt Package Manager

The Salt Package Manager, or *SPM*, enables Salt formulas to be packaged to simplify distribution to Salt masters. The design of SPM was influenced by other existing packaging systems including RPM, Yum, and Pacman.
Note: The previous diagram shows each SPM component as a different system, but this is not required. You can build packages and host the SPM repo on a single Salt master if you’d like.

Packaging System

The packaging system is used to package the state, pillar, file templates, and other files used by your formula into a single file. After a formula package is created, it is copied to the Repository System where it is made available to Salt masters.

See Building SPM Packages

Repo System

The Repo system stores the SPM package and metadata files and makes them available to Salt masters via http(s), ftp, or file URLs. SPM repositories can be hosted on a Salt Master, a Salt Minion, or on another system.

See Distributing SPM Packages

Salt Master

SPM provides Salt master settings that let you configure the URL of one or more SPM repos. You can then quickly install packages that contain entire formulas to your Salt masters using SPM.

See Installing SPM Packages
2.13.1 Building SPM Packages

The first step when using Salt Package Manager is to build packages for each of the formulas that you want to distribute. Packages can be built on any system where you can install Salt.

Package Build Overview

To build a package, all state, pillar, jinja, and file templates used by your formula are assembled into a folder on the build system. These files can be cloned from a Git repository, such as those found at the saltstack-formulas organization on GitHub, or copied directly to the folder.

The following diagram demonstrates a typical formula layout on the build system:

In this example, all formula files are placed in a myapp-formula folder. This is the folder that is targeted by the `spm build` command when this package is built.

Within this folder, pillar data is placed in a pillar.example file at the root, and all state, jinja, and template files are placed within a subfolder that is named after the application being packaged. State files are typically contained within a subfolder, similar to how state files are organized in the state tree. Any non-pillar files in your package that are not contained in a subfolder are placed at the root of the spm state tree.

Additionally, a FORMULA file is created and placed in the root of the folder. This file contains package metadata that is used by SPM.

Package Installation Overview

When building packages, it is useful to know where files are installed on the Salt master. During installation, all files except pillar.example and FORMULA are copied directly to the spm state tree on the Salt master (located at `\srv\spm\salt`).

If a pillar.example file is present in the root, it is renamed to `<formula name>.sls.orig` and placed in the pillar_path.
Note: Even though the pillar data file is copied to the pillar root, you still need to manually assign this pillar data to systems using the pillar top file. This file can also be duplicated and renamed so the .orig version is left intact in case you need to restore it later.

Building an SPM Formula Package

1. Assemble formula files in a folder on the build system.
2. Create a `FORMULA` file and place it in the root of the package folder.
3. Run `spm build <folder name>`. The package is built and placed in the `/srv/spm_build` folder.
   ```bash
   spm build /path/to/salt-packages-source/myapp-formula
   ```
4. Copy the `.spm` file to a folder on the repository system.

Types of Packages

SPM supports different types of packages. The function of each package is denoted by its name. For instance, packages which end in `-formula` are considered to be Salt States (the most common type of formula). Packages which end in `-conf` contain configuration which is to be placed in the `/etc/salt/` directory. Packages which do not contain one of these names are treated as if they have a `-formula` name.

**formula**

By default, most files from this type of package live in the `/srv/spm/salt/` directory. The exception is the pillar.example file, which will be renamed to `<package_name>.sls` and placed in the pillar directory (`/srv/spm/pillar/` by default).

**reactor**

By default, files from this type of package live in the `/srv/spm/reactor/` directory.
conf

The files in this type of package are configuration files for Salt, which normally live in the `/etc/salt/` directory. Configuration files for packages other than Salt can and should be handled with a Salt State (using a formula type of package).

Technical Information

Packages are built using BZ2-compressed tarballs. By default, the package database is stored using the `sqlite3` driver (see Loader Modules below).

Support for these are built into Python, and so no external dependencies are needed.

All other files belonging to SPM use YAML, for portability and ease of use and maintainability.

SPM-Specific Loader Modules

SPM was designed to behave like traditional package managers, which apply files to the filesystem and store package metadata in a local database. However, because modern infrastructures often extend beyond those use cases, certain parts of SPM have been broken out into their own set of modules.

Package Database

By default, the package database is stored using the `sqlite3` module. This module was chosen because support for SQLite3 is built into Python itself.

Please see the SPM Development Guide for information on creating new modules for package database management.

Package Files

By default, package files are installed using the `local` module. This module applies files to the local filesystem, on the machine that the package is installed on.

Please see the SPM Development Guide for information on creating new modules for package file management.

2.13.2 Distributing SPM Packages

SPM packages can be distributed to Salt masters over HTTP(S), FTP, or through the file system. The SPM repo can be hosted on any system where you can install Salt. Salt is installed so you can run the `spm create_repo` command when you update or add a package to the repo. SPM repos do not require the salt-master, salt-minion, or any other process running on the system.

Note: If you are hosting the SPM repo on a system where you can not or do not want to install Salt, you can run the `spm create_repo` command on the build system and then copy the packages and the generated SPM-METADATA file to the repo. You can also install SPM files directly on a Salt master, bypassing the repository completely.
Setting up a Package Repository

After packages are built, the generated SPM files are placed in the `srv/spm_build` folder.

Where you place the built SPM files on your repository server depends on how you plan to make them available to your Salt masters.

You can share the `srv/spm_build` folder on the network, or copy the files to your FTP or Web server.

Adding a Package to the repository

New packages are added by simply copying the SPM file to the repo folder, and then generating repo metadata.

Generate Repo Metadata

Each time you update or add an SPM package to your repository, issue an `spm create_repo` command:

```
spm create_repo /srv/spm_build
```

SPM generates the repository metadata for all of the packages in that directory and places it in an `SPM-METADATA` file at the folder root. This command is used even if repository metadata already exists in that directory.

2.13.3 Installing SPM Packages

SPM packages are installed to your Salt master, where they are available to Salt minions using all of Salt's package management functions.

Configuring Remote Repositories

Before SPM can use a repository, two things need to happen. First, the Salt master needs to know where the repository is through a configuration process. Then it needs to pull down the repository metadata.

Repository Configuration Files

Repositories are configured by adding each of them to the `/etc/salt/spm.repos.d/spm.repo` file on each Salt master. This file contains the name of the repository, and the link to the repository:

```
my_repo:
  url: https://spm.example.com/
```

The URL can use `http`, `https`, `ftp`, or `file`.

```
my_repo:
  url: file:///srv/spm_build
```

Updating Local Repository Metadata

After the repository is configured on the Salt master, repository metadata is downloaded using the `spm update_repo` command:
SPM packages are installed to the `srv/spm/salt` folder on your Salt master. This path needs to be added to the `file_roots` on your Salt master manually.

```yaml
file_roots:
  base:
    1. /srv/salt
    2. /srv/spm/salt
```

Restart the salt-master service after updating the `file_roots` setting.

### Installing Packages

To install a package, use the `spm install` command:

```
spm install apache
```

**Warning:** Currently, SPM does not check to see if files are already in place before installing them. That means that existing files will be overwritten without warning.

### Installing directly from an SPM file

You can also install SPM packages using a local SPM file using the `spm local install` command:

```
spm local install /srv/spm/apache-201506-1.spm
```

An SPM repository is not required when using `spm local install`.

### Pillars

If an installed package includes Pillar data, be sure to target the installed pillar to the necessary systems using the pillar Top file.

### Removing Packages

Packages may be removed after they are installed using the `spm remove` command.

```
spm remove apache
```

If files have been modified, they will not be removed. Empty directories will also be removed.
2.13.4 SPM Configuration

There are a number of options that are specific to SPM. They may be configured in the master configuration file, or in SPM's own spm configuration file (normally located at /etc/salt/spm). If configured in both places, the spm file takes precedence. In general, these values will not need to be changed from the defaults.

**spm_logfile**

Default: /var/log/salt/spm
Where SPM logs messages.

**spm_repos_config**

Default: /etc/salt/spm.repos
SPM repositories are configured with this file. There is also a directory which corresponds to it, which ends in .d. For instance, if the filename is /etc/salt/spm.repos, the directory will be /etc/salt/spm.repos.d/.

**spm_cache_dir**

Default: /var/cache/salt/spm
When SPM updates package repository metadata and downloads packaged, they will be placed in this directory. The package database, normally called packages.db, also lives in this directory.

**spm_db**

Default: /var/cache/salt/spm/packages.db
The location and name of the package database. This database stores the names of all of the SPM packages installed on the system, the files that belong to them, and the metadata for those files.

**spm_build_dir**

Default: /srv/spm
When packages are built, they will be placed in this directory.

**spm_build_exclude**

Default: ['.git']
When SPM builds a package, it normally adds all files in the formula directory to the package. Files listed here will be excluded from that package. This option requires a list to be specified.

```
spm_build_exclude:
    - .git
    - .svn
```
Types of Packages

SPM supports different types of formula packages. The function of each package is denoted by its name. For instance, packages which end in -formula are considered to be Salt States (the most common type of formula). Packages which end in -conf contain configuration which is to be placed in the /etc/salt/ directory. Packages which do not contain one of these names are treated as if they have a -formula name.

**formula**

By default, most files from this type of package live in the /srv/spm/salt/ directory. The exception is the pillar.example file, which will be renamed to <package_name>.sls and placed in the pillar directory (/srv/spm/pillar/ by default).

**reactor**

By default, files from this type of package live in the /srv/spm/reactor/ directory.

**conf**

The files in this type of package are configuration files for Salt, which normally live in the /etc/salt/ directory. Configuration files for packages other than Salt can and should be handled with a Salt State (using a formula type of package).

### 2.13.5 FORMULA File

In addition to the formula itself, a FORMULA file must exist which describes the package. An example of this file is:

```yaml
name: apache
os: RedHat, Debian, Ubuntu, Suse, FreeBSD
os_family: RedHat, Debian, Suse, FreeBSD
version: 201506
release: 2
summary: Formula for installing Apache
description: Formula for installing Apache
```

**Required Fields**

This file must contain at least the following fields:

**name**

The name of the package, as it will appear in the package filename, in the repository metadata, and the package database. Even if the source formula has -formula in its name, this name should probably not include that. For instance, when packaging the apache-formula, the name should be set to apache.

**os**

The value of the os grain that this formula supports. This is used to help users know which operating systems can support this package.
os_family

The value of the `os_family` grain that this formula supports. This is used to help users know which operating system families can support this package.

version

The version of the package. While it is up to the organization that manages this package, it is suggested that this version is specified in a `YYYYMM` format. For instance, if this version was released in June 2015, the package version should be `201506`. If multiple releases are made in a month, the `release` field should be used.

minimum_version

Minimum recommended version of Salt to use this formula. Not currently enforced.

release

This field refers primarily to a release of a version, but also to multiple versions within a month. In general, if a version has been made public, and immediate updates need to be made to it, this field should also be updated.

summary

A one-line description of the package.

description

A more detailed description of the package which can contain more than one line.

Optional Fields

The following fields may also be present.

top_level_dir

This field is optional, but highly recommended. If it is not specified, the package name will be used.

Formula repositories typically do not store `.sls` files in the root of the repository; instead they are stored in a subdirectory. For instance, an `apache-formula` repository would contain a directory called `apache`, which would contain an `init.sls`, plus a number of other related files. In this instance, the `top_level_dir` should be set to `apache`.

Files outside the `top_level_dir`, such as `README.rst`, `FORMULA`, and `LICENSE` will not be installed. The exceptions to this rule are files that are already treated specially, such as `pillar.example` and `_modules/`.
recommended

A list of optional packages that are recommended to be installed with the package. This list is displayed in an informational message when the package is installed to SPM.

Building a Package

Once a FORMULA file has been created, it is placed into the root of the formula that is to be turned into a package. The `spm build` command is used to turn that formula into a package:

```
spm build /path/to/saltstack-formulas/apache-formula
```

The resulting file will be placed in the build directory. By default this directory is located at `/srv/spm/`.

Loader Modules

When an execution module is placed in `<file_roots>/_modules/` on the master, it will automatically be synced to minions, the next time a sync operation takes place. Other modules are also propagated this way: state modules can be placed in `_states/`, and so on.

When SPM detects a file in a package which resides in one of these directories, that directory will be placed in `<file_roots>` instead of in the formula directory with the rest of the files.

Removing Packages

Packages may be removed once they are installed using the `spm remove` command.

```
spm remove apache
```

If files have been modified, they will not be removed. Empty directories will also be removed.

Technical Information

Packages are built using BZ2-compressed tarballs. By default, the package database is stored using the `sqlite3` driver (see Loader Modules below).

Support for these are built into Python, and so no external dependencies are needed.

All other files belonging to SPM use YAML, for portability and ease of use and maintainability.

SPM-Specific Loader Modules

SPM was designed to behave like traditional package managers, which apply files to the filesystem and store package metadata in a local database. However, because modern infrastructures often extend beyond those use cases, certain parts of SPM have been broken out into their own set of modules.
Package Database

By default, the package database is stored using the sqlite3 module. This module was chosen because support for SQLite3 is built into Python itself.

Please see the SPM Development Guide for information on creating new modules for package database management.

Package Files

By default, package files are installed using the local module. This module applies files to the local filesystem, on the machine that the package is installed on.

Please see the SPM Development Guide for information on creating new modules for package file management.

Types of Packages

SPM supports different types of formula packages. The function of each package is denoted by its name. For instance, packages which end in -formula are considered to be Salt States (the most common type of formula). Packages which end in -conf contain configuration which is to be placed in the /etc/salt/ directory. Packages which do not contain one of these names are treated as if they have a -formula name.

formula

By default, most files from this type of package live in the /srv/spm/salt/ directory. The exception is the pillar.example file, which will be renamed to <package_name>.sls and placed in the pillar directory (/srv/spm/pillar/ by default).

reactor

By default, files from this type of package live in the /srv/spm/reactor/ directory.

conf

The files in this type of package are configuration files for Salt, which normally live in the /etc/salt/ directory. Configuration files for packages other than Salt can and should be handled with a Salt State (using a formula type of package).

2.13.6 SPM Development Guide

This document discusses developing additional code for SPM.

SPM-Specific Loader Modules

SPM was designed to behave like traditional package managers, which apply files to the filesystem and store package metadata in a local database. However, because modern infrastructures often extend beyond those use cases, certain parts of SPM have been broken out into their own set of modules.

Each function that accepts arguments has a set of required and optional arguments. Take note that SPM will pass all arguments in, and therefore each function must accept each of those arguments. However, arguments that are
marked as required are crucial to SPM's core functionality, while arguments that are marked as optional are provided as a benefit to the module, if it needs to use them.

**Package Database**

By default, the package database is stored using the `sqlite3` module. This module was chosen because support for SQLite3 is built into Python itself.

Modules for managing the package database are stored in the `salt/spm/pkgdb/` directory. A number of functions must exist to support database management.

**init()**

Get a database connection, and initialize the package database if necessary.

This function accepts no arguments. If a database is used which supports a connection object, then that connection object is returned. For instance, the `sqlite3` module returns a `connect()` object from the `sqlite3` library:

```python
conn = sqlite3.connect(__opts__['spm_db'], isolation_level=None)
...
return conn
```

SPM itself will not use this connection object; it will be passed in as-is to the other functions in the module. Therefore, when you set up this object, make sure to do so in a way that is easily usable throughout the module.

**info()**

Return information for a package. This generally consists of the information that is stored in the FORMULA file in the package.

The arguments that are passed in, in order, are `package` (required) and `conn` (optional).

`package` is the name of the package, as specified in the FORMULA. `conn` is the connection object returned from `init()`.

**list_files()**

Return a list of files for an installed package. Only the filename should be returned, and no other information.

The arguments that are passed in, in order, are `package` (required) and `conn` (optional).

`package` is the name of the package, as specified in the FORMULA. `conn` is the connection object returned from `init()`.

**register_pkg()**

Register a package in the package database. Nothing is expected to be returned from this function.

The arguments that are passed in, in order, are `name` (required), `formula_def` (required), and `conn` (optional).

`name` is the name of the package, as specified in the FORMULA. `formula_def` is the contents of the FORMULA file, as a `dict`. `conn` is the connection object returned from `init()`.
register_file()

Register a file in the package database. Nothing is expected to be returned from this function.

The arguments that are passed in are name (required), member (required), path (required), digest (optional), and conn (optional).

name is the name of the package.
member is a tarfile object for the package file. It is included, because it contains most of the information for the file.
path is the location of the file on the local filesystem.
digest is the SHA1 checksum of the file.
conn is the connection object returned from init().

unregister_pkg()

Unregister a package from the package database. This usually only involves removing the package's record from the database. Nothing is expected to be returned from this function.

The arguments that are passed in, in order, are name (required) and conn (optional).

name is the name of the package, as specified in the FORMULA. conn is the connection object returned from init().

unregister_file()

Unregister a package from the package database. This usually only involves removing the package's record from the database. Nothing is expected to be returned from this function.

The arguments that are passed in, in order, are name (required), pkg (optional) and conn (optional).

name is the path of the file, as it was installed on the filesystem.
pkg is the name of the package that the file belongs to.
conn is the connection object returned from init().

db_exists()

Check to see whether the package database already exists. This is the path to the package database file. This function will return True or False.

The only argument that is expected is db_, which is the package database file.

Package Files

By default, package files are installed using the local module. This module applies files to the local filesystem, on the machine that the package is installed on.

Modules for managing the package database are stored in the salt/spm/pkgfiles/ directory. A number of functions must exist to support file management.
### init()

Initialize the installation location for the package files. Normally these will be directory paths, but other external destinations such as databases can be used. For this reason, this function will return a connection object, which can be a database object. However, in the default `local` module, this object is a dict containing the paths. This object will be passed into all other functions.

Three directories are used for the destinations: `formula_path`, `pillar_path`, and `reactor_path`.

- **formula_path** is the location of most of the files that will be installed. The default is specific to the operating system, but is normally `/srv/salt/`.
- **pillar_path** is the location that the `pillar.example` file will be installed to. The default is specific to the operating system, but is normally `/srv/pillar/`.
- **reactor_path** is the location that reactor files will be installed to. The default is specific to the operating system, but is normally `/srv/reactor/`.

### check_existing()

Check the filesystem for existing files. All files for the package will be checked, and if any are existing, then this function will normally state that SPM will refuse to install the package.

This function returns a list of the files that exist on the system.

The arguments that are passed into this function are, in order: `package` (required), `pkg_files` (required), `formula_def` (formula_def), and `conn` (optional).

- **package** is the name of the package that is to be installed.
- **pkg_files** is a list of the files to be checked.
- **formula_def** is a copy of the information that is stored in the FORMULA file.
- **conn** is the file connection object.

### install_file()

Install a single file to the destination (normally on the filesystem). Nothing is expected to be returned from this function.

This function returns the final location that the file was installed to.

The arguments that are passed into this function are, in order, `package` (required), `formula_tar` (required), `member` (required), `formula_def` (required), and `conn` (optional).

- **package** is the name of the package that is to be installed.
- **formula_tar** is the tarfile object for the package. This is passed in so that the function can call `formula_tar.extract()` for the file.
- **member** is the tarfile object which represents the individual file. This may be modified as necessary, before being passed into `formula_tar.extract()`.
- **formula_def** is a copy of the information from the FORMULA file.
- **conn** is the file connection object.
remove_file()

Remove a single file from file system. Normally this will be little more than an `os.remove()`. Nothing is expected to be returned from this function.

The arguments that are passed into this function are, in order, `path` (required) and `conn` (optional).

`path` is the absolute path to the file to be removed.

`conn` is the file connection object.

hash_file()

Returns the hexdigest hash value of a file.

The arguments that are passed into this function are, in order, `path` (required), `hashobj` (required), and `conn` (optional).

`path` is the absolute path to the file.

`hashobj` is a reference to `hashlib.sha1()`, which is used to pull the `hexdigest()` for the file.

`conn` is the file connection object.

This function will not generally be more complex than:

```python
def hash_file(path, hashobj, conn=None):
    with salt.utils.fopen(path, 'r') as f:
        hashobj.update(f.read())
    return hashobj.hexdigest()
```

path_exists()

Check to see whether the file already exists on the filesystem. Returns `True` or `False`.

This function expects a `path` argument, which is the absolute path to the file to be checked.

path_isdir()

Check to see whether the path specified is a directory. Returns `True` or `False`.

This function expects a `path` argument, which is the absolute path to be checked.

### 2.14 Storing Data in Other Databases

The SDB interface is designed to store and retrieve data that, unlike pillars and grains, is not necessarily minion-specific. The initial design goal was to allow passwords to be stored in a secure database, such as one managed by the keyring package, rather than as plain-text files. However, as a generic database interface, it could conceptually be used for a number of other purposes.

SDB was added to Salt in version 2014.7.0.
2.14.1 SDB Configuration

In order to use the SDB interface, a configuration profile must be set up in either the master or minion configuration file. The configuration stanza includes the name/ID that the profile will be referred to as, a driver setting, and any other arguments that are necessary for the SDB module that will be used. For instance, a profile called mykeyring, which uses the system service in the keyring module would look like:

```
mykeyring:
  driver: keyring
  service: system
```

It is recommended to keep the name of the profile simple, as it is used in the SDB URI as well.

2.14.2 SDB URIs

SDB is designed to make small database queries (hence the name, SDB) using a compact URL. This allows users to reference a database value quickly inside a number of Salt configuration areas, without a lot of overhead. The basic format of an SDB URI is:

```
sdb://<profile>/<args>
```

The profile refers to the configuration profile defined in either the master or the minion configuration file. The args are specific to the module referred to in the profile, but will typically only need to refer to the key of a key/value pair inside the database. This is because the profile itself should define as many other parameters as possible.

For example, a profile might be set up to reference credentials for a specific OpenStack account. The profile might look like:

```
kevinopenstack:
  driver: keyring
  service: salt.cloud.openstack.kevin
```

And the URI used to reference the password might look like:

```
sdb://kevinopenstack/password
```

2.14.3 Getting and Setting SDB Values

Once an SDB driver is configured, you can use the sdb execution module to set and get values from it. There are two functions that will appear in any SDB module: set and get.

Getting a value requires only the SDB URI to be specified. To retrieve a value from the kevinopenstack profile above, you would use:

```
salt-call sdb.get sdb://kevinopenstack/password
```

Some drivers use slightly more complex URIs. For instance, the vault driver requires the full path to where the key is stored, followed by a question mark, followed by the key to be retrieved. If you were using a profile called myvault, you would use a URI that looks like:

```
salt-call sdb.get 'sdb://myvault/secret/salt?saltstack'
```

Setting a value uses the same URI as would be used to retrieve it, followed by the value as another argument. For the above myvault URI, you would set a new value using a command like:
The `sdb.set` and `sdb.get` functions are also available in the runner system:

```
salt-call sdb.set 'sdb://myvault/secret/salt?saltstack' 'super awesome'
salt-run sdb.get 'sdb://myvault/secret/salt?saltstack'
salt-run sdb.set 'sdb://myvault/secret/salt?saltstack' 'super awesome'
```

## 2.14.4 Using SDB URIs in Files

SDB URIs can be used in both configuration files, and files that are processed by the renderer system (jinja, mako, etc.). In a configuration file (such as `/etc/salt/master`, `/etc/salt/minion`, `/etc/salt/cloud`, etc.), make an entry as usual, and set the value to the SDB URI. For instance:

```
mykey: sdb://myetcd/mykey
```

To retrieve this value using a module, the module in question must use the `config.get` function to retrieve configuration values. This would look something like:

```
mykey = __salt__['config.get']('mykey')
```

Templating renderers use a similar construct. To get the `mykey` value from above in Jinja, you would use:

```
{{ salt['config.get']('mykey') }}
```

When retrieving data from configuration files using `config.get`, the SDB URI need only appear in the configuration file itself.

If you would like to retrieve a key directly from SDB, you would call the `sdb.get` function directly, using the SDB URI. For instance, in Jinja:

```
{{ salt['sdb.get']('sdb://myetcd/mykey') }}
```

When writing Salt modules, it is not recommended to call `sdb.get` directly, as it requires the user to provide values in SDB, using a specific URI. Use `config.get` instead.

## 2.14.5 Writing SDB Modules

There is currently one function that MUST exist in any SDB module (get()) and one that SHOULD exist (set()). If using a (set()) function, a `__func_alias__` dictionary MUST be declared in the module as well:

```
__func_alias__ = {
    'set_': 'set',
}
```

This is because `set` is a Python built-in, and therefore functions should not be created which are called `set()`. The `__func_alias__` functionality is provided via Salt's loader interfaces, and allows legally-named functions to be referred to using names that would otherwise be unwise to use.

The `get()` function is required, as it will be called via functions in other areas of the code which make use of the `sdb://` URI. For example, the `config.get` function in the `config` execution module uses this function.

The `set_()` function may be provided, but is not required, as some sources may be read-only, or may be otherwise unwise to access via a URI (for instance, because of SQL injection attacks).

A simple example of an SDB module is `salt/sdb/keyring_db.py`, as it provides basic examples of most, if not all, of the types of functionality that are available not only for SDB modules, but for Salt modules in general.
2.15 Running the Salt Master/Minion as an Unprivileged User

While the default setup runs the master and minion as the root user, some may consider it an extra measure of security to run the master as a non-root user. Keep in mind that doing so does not change the master's capability to access minions as the user they are running as. Due to this many feel that running the master as a non-root user does not grant any real security advantage which is why the master has remained as root by default.

Note: Some of Salt’s operations cannot execute correctly when the master is not running as root, specifically the pam external auth system, as this system needs root access to check authentication.

As of Salt 0.9.10 it is possible to run Salt as a non-root user. This can be done by setting the `user` parameter in the master configuration file and restarting the `salt-master` service. The minion has its own `user` parameter as well, but running the minion as an unprivileged user will keep it from making changes to things like users, installed packages, etc. unless access controls (sudo, etc.) are setup on the minion to permit the non-root user to make the needed changes.

In order to allow Salt to successfully run as a non-root user, ownership, and permissions need to be set such that the desired user can read from and write to the following directories (and their subdirectories, where applicable):

- `/etc/salt`
- `/var/cache/salt`
- `/var/log/salt`
- `/var/run/salt`

Ownership can be easily changed with `chown`, like so:

```
# chown -R user /etc/salt /var/cache/salt /var/log/salt /var/run/salt
```

**Warning:** Running either the master or minion with the `root_dir` parameter specified will affect these paths, as will setting options like `pki_dir`, `cachedir`, `log_file`, and other options that normally live in the above directories.

2.16 Using cron with Salt

The Salt Minion can initiate its own highstate using the `salt-call` command.

```
$ salt-call state.apply
```

This will cause the minion to check in with the master and ensure it is in the correct `state`.

2.17 Use cron to initiate a highstate

If you would like the Salt Minion to regularly check in with the master you can use cron to run the `salt-call` command:

```
0 0 * * * salt-call state.apply
```
The above cron entry will run a highstate every day at midnight.

Note: When executing Salt using cron, keep in mind that the default PATH for cron may not include the path for any scripts or commands used by Salt, and it may be necessary to set the PATH accordingly in the crontab:

```
PATH=/bin:/sbin:/usr/bin:/usr/sbin:/usr/local/bin:/usr/local/sbin:/opt/bin
0 0 * * * salt-call state.apply
```

## 2.18 Hardening Salt

This topic contains tips you can use to secure and harden your Salt environment. How you best secure and harden your Salt environment depends heavily on how you use Salt, where you use Salt, how your team is structured, where you get data from, and what kinds of access (internal and external) you require.

### 2.18.1 General hardening tips

- Restrict who can directly log into your Salt master system.
- Use SSH keys secured with a passphrase to gain access to the Salt master system.
- Track and secure SSH keys and any other login credentials you and your team need to gain access to the Salt master system.
- Use a hardened bastion server or a VPN to restrict direct access to the Salt master from the internet.
- Don’t expose the Salt master any more than what is required.
- Harden the system as you would with any high-priority target.
- Keep the system patched and up-to-date.
- Use tight firewall rules.

### 2.18.2 Salt hardening tips

- Subscribe to salt-users or salt-announce so you know when new Salt releases are available. Keep your systems up-to-date with the latest patches.
- Use Salt’s Client ACL system to avoid having to give out root access in order to run Salt commands.
- Use Salt’s Client ACL system to restrict which users can run what commands.
- Use external Pillar to pull data into Salt from external sources so that non-sysadmins (other teams, junior admins, developers, etc) can provide configuration data without needing access to the Salt master.
- Make heavy use of SLS files that are version-controlled and go through a peer-review/code-review process before they’re deployed and run in production. This is good advice even for “one-off” CLI commands because it helps mitigate typos and mistakes.
- Use salt-api, SSL, and restrict authentication with the external auth system if you need to expose your Salt master to external services.
- Make use of Salt’s event system and reactor to allow minions to signal the Salt master without requiring direct access.
• Run the salt-master daemon as non-root.
• Disable which modules are loaded onto minions with the `disable_modules` setting. (For example, disable the `cmd` module if it makes sense in your environment.)
• Look through the fully-commented sample `master` and `minion` config files. There are many options for securing an installation.
• Run `masterless-mode` minions on particularly sensitive minions. There is also Salt SSH or the modules `sudo` if you need to further restrict a minion.

2.19.1 Security response procedure

SaltStack takes security and the trust of our customers and users very seriously. Our disclosure policy is intended to resolve security issues as quickly and safely as is possible.

1. A security report sent to security@saltstack.com is assigned to a team member. This person is the primary contact for questions and will coordinate the fix, release, and announcement.

2. The reported issue is reproduced and confirmed. A list of affected projects and releases is made.

3. Fixes are implemented for all affected projects and releases that are actively supported. Back-ports of the fix are made to any old releases that are actively supported.

4. Packagers are notified via the salt-packagers mailing list that an issue was reported and resolved, and that an announcement is incoming.

5. A new release is created and pushed to all affected repositories. The release documentation provides a full description of the issue, plus any upgrade instructions or other relevant details.

6. An announcement is made to the salt-users and salt-announce mailing lists. The announcement contains a description of the issue and a link to the full release documentation and download locations.

2.19.2 Receiving security announcements

The fastest place to receive security announcements is via the salt-announce mailing list. This list is low-traffic.

2.20 Salt Transport

One of fundamental features of Salt is remote execution. Salt has two basic "channels" for communicating with minions. Each channel requires a client (minion) and a server (master) implementation to work within Salt. These pairs of channels will work together to implement the specific message passing required by the channel interface.
2.20.1 Pub Channel

The pub channel, or publish channel, is how a master sends a job (payload) to a minion. This is a basic pub/sub paradigm, which has specific targeting semantics. All data which goes across the publish system should be encrypted such that only members of the Salt cluster can decrypt the publishes.

2.20.2 Req Channel

The req channel is how the minions send data to the master. This interface is primarily used for fetching files and returning job returns. The req channels have two basic interfaces when talking to the master. send is the basic method that guarantees the message is encrypted at least so that only minions attached to the same master can read it-- but no guarantee of minion-master confidentiality, whereas the crypted_transfer_decode_dictentry method does guarantee minion-master confidentiality.

Zeromq Transport

Note: Zeromq is the current default transport within Salt

Zeromq is a messaging library with bindings into many languages. Zeromq implements a socket interface for message passing, with specific semantics for the socket type.

Pub Channel

The pub channel is implemented using zeromq's pub/sub sockets. By default we don't use zeromq's filtering, which means that all publish jobs are sent to all minions and filtered minion side. Zeromq does have publisher side filtering which can be enabled in salt using zmq_filtering.

Req Channel

The req channel is implemented using zeromq's req/rep sockets. These sockets enforce a send/recv pattern, which forces salt to serialize messages through these socket pairs. This means that although the interface is asynchronous on the minion we cannot send a second message until we have received the reply of the first message.

TCP Transport

The tcp transport is an implementation of Salt's channels using raw tcp sockets. Since this isn't using a pre-defined messaging library we will describe the wire protocol, message semantics, etc. in this document.

The tcp transport is enabled by changing the transport setting to tcp on each Salt minion and Salt master.

wire_protocol: tcp

Wire Protocol

This implementation over TCP focuses on flexibility over absolute efficiency. This means we are okay to spend a couple of bytes of wire space for flexibility in the future. That being said, the wire framing is quite efficient and looks like:
Since msgpack is an iterably parsed serialization, we can simply write the serialized payload to the wire. Within that payload we have two items "head" and "body". Head contains header information (such as "message id"). The Body contains the actual message that we are sending. With this flexible wire protocol we can implement any message semantics that we'd like-- including multiplexed message passing on a single socket.

**Crypto**

The current implementation uses the same crypto as the zeromq transport.

**Pub Channel**

For the pub channel we send messages without "message ids" which the remote end interprets as a one-way send.

---

**Note:** As of today we send all publishes to all minions and rely on minion-side filtering.

**Req Channel**

For the req channel we send messages with a "message id". This "message id" allows us to multiplex messages across the socket.

**The RAET Transport**

---

**Note:** The RAET transport is in very early development, it is functional but no promises are yet made as to its reliability or security. As for reliability and security, the encryption used has been audited and our tests show that raet is reliable. With this said we are still conducting more security audits and pushing the reliability. This document outlines the encryption used in RAET

New in version 2014.7.0.

The Reliable Asynchronous Event Transport, or RAET, is an alternative transport medium developed specifically with Salt in mind. It has been developed to allow queuing to happen up on the application layer and comes with socket layer encryption. It also abstracts a great deal of control over the socket layer and makes it easy to bubble up errors and exceptions.

RAET also offers very powerful message routing capabilities, allowing for messages to be routed between processes on a single machine all the way up to processes on multiple machines. Messages can also be restricted, allowing processes to be sent messages of specific types from specific sources allowing for trust to be established.

**Using RAET in Salt**

Using RAET in Salt is easy, the main difference is that the core dependencies change, instead of needing pycrypto, M2Crypto, ZeroMQ, and PYZMQ, the packages libsodium, libnacl, ioflo, and raet are required. Encryption is handled very cleanly by libnacl, while the queueing and flow control is handled by ioflo. Distribution packages are forthcoming, but libsodium can be easily installed from source, or many distributions do ship packages for it. The libnacl and ioflo packages can be easily installed from pypi, distribution packages are in the works.
Once the new deps are installed the 2014.7 release or higher of Salt needs to be installed.

Once installed, modify the configuration files for the minion and master to set the transport to raet:

/etc/salt/master:

```
transport: raet
```

/etc/salt/minion:

```
transport: raet
```

Now start salt as it would normally be started, the minion will connect to the master and share long term keys, which can then in turn be managed via salt-key. Remote execution and salt states will function in the same way as with Salt over ZeroMQ.

**Limitations**

The 2014.7 release of RAET is not complete! The Syndic and Multi Master have not been completed yet and these are slated for completion in the 2015.5.0 release.

Also, Salt-Raet allows for more control over the client but these hooks have not been implemented yet, therefore the client still uses the same system as the ZeroMQ client. This means that the extra reliability that RAET exposes has not yet been implemented in the CLI client.

**Why?**

**Customer and User Request**

Why make an alternative transport for Salt? There are many reasons, but the primary motivation came from customer requests, many large companies came with requests to run Salt over an alternative transport, the reasoning was varied, from performance and scaling improvements to licensing concerns. These customers have partnered with SaltStack to make RAET a reality.

**More Capabilities**

RAET has been designed to allow salt to have greater communication capabilities. It has been designed to allow for development into features which out ZeroMQ topologies can’t match.

Many of the proposed features are still under development and will be announced as they enter proof of concept phases, but these features include `salt-fuse` - a filesystem over salt, `salt-vr` - a parallel api driven shell over the salt transport and many others.

**RAET Reliability**

RAET is reliable, hence the name (Reliable Asynchronous Event Transport).

The concern posed by some over RAET reliability is based on the fact that RAET uses UDP instead of TCP and UDP does not have built in reliability.

RAET itself implements the needed reliability layers that are not natively present in UDP, this allows RAET to dynamically optimize packet delivery in a way that keeps it both reliable and asynchronous.
RAET and ZeroMQ

When using RAET, ZeroMQ is not required. RAET is a complete networking replacement. It is noteworthy that RAET is not a ZeroMQ replacement in a general sense, the ZeroMQ constructs are not reproduced in RAET, but they are instead implemented in such a way that is specific to Salt's needs.

RAET is primarily an async communication layer over truly async connections, defaulting to UDP. ZeroMQ is over TCP and abstracts async constructs within the socket layer.

Salt is not dropping ZeroMQ support and has no immediate plans to do so.

Encryption

RAET uses Dan Bernstein's NACL encryption libraries and CurveCP handshake. The libnacl python binding binds to both libsodium and tweetnacl to execute the underlying cryptography. This allows us to completely rely on an externally developed cryptography system.

Programming Intro

Intro to RAET Programming

Note: This page is still under construction

The first thing to cover is that RAET does not present a socket api, it presents, and queueing api, all messages in RAET are made available to via queues. This is the single most differentiating factor with RAET vs other networking libraries, instead of making a socket, a stack is created. Instead of calling send() or recv(), messages are placed on the stack to be sent and messages that are received appear on the stack.

Different kinds of stacks are also available, currently two stacks exist, the UDP stack, and the UXD stack. The UDP stack is used to communicate over udp sockets, and the UXD stack is used to communicate over Unix Domain Sockets.

The UDP stack runs a context for communicating over networks, while the UXD stack has contexts for communicating between processes.

UDP Stack Messages

To create a UDP stack in RAET, simply create the stack, manage the queues, and process messages:

```python
from salt.transport.road.raet import stacking
from salt.transport.road.raet import estating

udp_stack = stacking.StackUdp(ha=('127.0.0.1', 7870))
r_estate = estating.Estate(stack=udp_stack, name='foo', ha=('192.168.42.42', 7870))
msg = {'hello': 'world'}
udp_stack.transmit(msg, udp_stack.estates[r_estate.name])
udp_stack.serviceAll()
```
2.21 Master Tops System

In 0.10.4 the external_nodes system was upgraded to allow for modular subsystems to be used to generate the top file data for a highstate run on the master.

The old external_nodes option has been removed. The master tops system provides a pluggable and extendable replacement for it, allowing for multiple different subsystems to provide top file data.

Using the new master_tops option is simple:

```yaml
master_tops:
  ext_nodes: cobbler-external-nodes
```

for Cobbler or:

```yaml
master_tops:
  reclass:
    inventory_base_uri: /etc/reclass
    classes_uri: roles
```

for Reclass.

It's also possible to create custom master_tops modules. Simply place them into salt://_tops in the Salt file-server and use the saltutil.sync_tops runner to sync them. If this runner function is not available, they can manually be placed into extmods/tops, relative to the master cachedir (in most cases the full path will be /var/cache/salt/master/extmods/tops).

Custom tops modules are written like any other execution module, see the source for the two modules above for examples of fully functional ones. Below is a bare-bones example:

```bash
/etc/salt/master:
master_tops:
  customtop: True

customtop.py: (custom master_tops module)

```import logging
import sys
# Define the module's virtual name
__virtualname__ = 'customtop'

log = logging.getLogger(__name__)

def __virtual__():
    return __virtualname__

def top(**kwargs):
    log.debug('Calling top in customtop')
    return {'base': ['test']}
```

salt minion state.show_top should then display something like:

```
$ salt minion state.show_top
minion
```

---

Chapter 2. Configuring Salt
base:
  - test

Note: If a master_tops module returns top file data for a given minion, it will be added to the states configured in the top file. It will not replace it altogether. The Oxygen release adds additional functionality allowing a minion to treat master_tops as the single source of truth, irrespective of the top file.

## 2.22 Returners

By default the return values of the commands sent to the Salt minions are returned to the Salt master, however anything at all can be done with the results data.

By using a Salt returner, results data can be redirected to external data-stores for analysis and archival.

Returners pull their configuration values from the Salt minions. Returners are only configured once, which is generally at load time.

The returner interface allows the return data to be sent to any system that can receive data. This means that return data can be sent to a Redis server, a MongoDB server, a MySQL server, or any system.

See also:
- [Full list of builtin returners](#)

### 2.22.1 Using Returners

All Salt commands will return the command data back to the master. Specifying returners will ensure that the data is also sent to the specified returner interfaces.

Specifying what returners to use is done when the command is invoked:

```
salt '*' test.ping --return redis_return
```

This command will ensure that the redis_return returner is used.

It is also possible to specify multiple returners:

```
salt '*' test.ping --return mongo_return,redis_return,cassandra_return
```

In this scenario all three returners will be called and the data from the test.ping command will be sent out to the three named returners.

### 2.22.2 Writing a Returner

A returner is a Python module containing at minimum a returner function. Other optional functions can be included to add support for master_job_cache, external_job_cache, and Event Returners.

**returner** The returner function must accept a single argument. The argument contains return data from the called minion function. If the minion function test.ping is called, the value of the argument will be a dictionary. Run the following command from a Salt master to get a sample of the dictionary:

```
salt-call --local --metadata test.ping --out=pprint
```
import redis
import json

def returner(ret):
    '''
    Return information to a redis server
    '''
    # Get a redis connection
    serv = redis.Redis(
        host='redis-serv.example.com',
        port=6379,
        db=0)
    serv.sadd("%(id)s:jobs" % ret, ret['jid'])
    serv.set("%(jid)s:%(id)s" % ret, json.dumps(ret['return']))
    serv.sadd('jobs', ret['jid'])
    serv.sadd(ret['jid'], ret['id'])

The above example of a returner set to send the data to a Redis server serializes the data as JSON and sets it in redis.

Master Job Cache Support

master_job_cache, external_job_cache, and Event Returners. Salt’s master_job_cache allows returners to be used as a pluggable replacement for the Default Job Cache. In order to do so, a returner must implement the following functions:

**Note:** The code samples contained in this section were taken from the cassandra_cql returner.

**prep_jid** Ensures that job ids (jid) don’t collide, unless passed_jid is provided.

nocache is an optional boolean that indicates if return data should be cached. passed_jid is a caller provided jid which should be returned unconditionally.

```python
def prep_jid(nocache, passed_jid=None):  # pylint: disable=unused-argument
    '''
    Do any work necessary to prepare a JID, including sending a custom id
    '''
    return passed_jid if passed_jid is not None else salt.utils.jid.gen_jid()
```

**save_load** Save job information. The jid is generated by prep_jid and should be considered a unique identifier for the job. The jid, for example, could be used as the primary/unique key in a database. The load is what is returned to a Salt master by a minion. The following code example stores the load as a JSON string in the salt.jids table.

```python
def save_load(jid, load):
    '''
    Save the load to the specified jid id
    '''
    query = '''INSERT INTO salt.jids (jid, load)
        VALUES ('{0}', '{1}');'''.format(jid, json.dumps(load))
    # cassandra_cql.cql_query may raise a CommandExecutionError
    try:
```
get_load must accept a job id (jid) and return the job load stored by save_load, or an empty dictionary when not found.

```python
def get_load(jid):
    '''
    Return the load data that marks a specified jid
    '''
    query = '''SELECT load FROM salt.jids WHERE jid = '{0}';'''.format(jid)
    ret = {}
    # cassandra_cql.cql_query may raise a CommandExecutionError
    try:
        data = __salt__['cassandra_cql.cql_query'](query)
        if data:
            load = data[0].get('load')
            if load:
                ret = json.loads(load)
    except CommandExecutionError:
        log.critical('Could not get load from jids table.')
        raise
    except Exception as e:
        log.critical('''Unexpected error while getting load from
jids: {0}'''.format(str(e)))
        raise
    return ret
```

**External Job Cache Support**

Salt's external_job_cache extends the master_job_cache. External Job Cache support requires the following functions in addition to what is required for Master Job Cache support:

**get_jid** Return a dictionary containing the information (load) returned by each minion when the specified job id was executed.

Sample:

```
{
    "local": {
        "master_minion": {
            "fun_args": [],
            "jid": "20150330121011408195",
            "return": "true",
            "retcode": 0,
            "success": "true",
            "cmd": "_return",
            "_stamp": "2015-03-30T12:10:12.708663",
```
get_fun Return a dictionary of minions that called a given Salt function as their last function call.

Sample:

```json
{
    "local": {
        "minion1": "test.ping",
        "minion3": "test.ping",
        "minion2": "test.ping"
    }
}
```

get_jids Return a list of all job ids.

Sample:

```json
{
    "local": [
        "20150330121011408195",
        "20150330195922139916"
    ]
}
```

get_minions Returns a list of minions

Sample:

```json
{
    "local": [
        "minion3",
        "minion2",
        "minion1",
        "master_minion"
    ]
}
```

Please refer to one or more of the existing returners (i.e. mysql, cassandra_cql) if you need further clarification.

**Event Support**

An event_return function must be added to the returner module to allow events to be logged from a master via the returner. A list of events are passed to the function by the master.

The following example was taken from the MySQL returner. In this example, each event is inserted into the salt_events table keyed on the event tag. The tag contains the jid and therefore is guaranteed to be unique.

```python
def event_return(events):
    """
    Return event to mysql server
    
    Requires that configuration be enabled via 'event_return'
    option in master config.
    """
```
'with _get_serv(events, commit=True) as cur:
    for event in events:
        tag = event.get('tag', '')
        data = event.get('data', '')
        sql = '"""INSERT INTO `salt_events` (`tag`, `data`, `master_id`) VALUES (%s, %s, %s)"""
        cur.execute(sql, (tag, json.dumps(data), __opts__['id']))

Custom Returners

Place custom returners in a _returners directory within the file_roots specified by the master config file. Custom returners are distributed when any of the following are called:

- state.apply
- saltutil.sync_returners
- saltutil.sync_all

Any custom returners which have been synced to a minion that are named the same as one of Salt's default set of returners will take the place of the default returner with the same name.

Naming the Returner

Note that a returner's default name is its filename (i.e. foo.py becomes returner foo), but that its name can be overridden by using a __virtual__ function. A good example of this can be found in the redis returner, which is named redis_return.py but is loaded as simply redis:

```
try:
    import redis
    HAS_REDIS = True
except ImportError:
    HAS_REDIS = False

__virtualname__ = 'redis'

def __virtual__():
    if not HAS_REDIS:
        return False
    return __virtualname__
```

Testing the Returner

The returner, prep_jid, save_load, get_load, and event_return functions can be tested by configuring the master_job_cache and Event Returners in the master config file and submitting a job to test.ping each minion from the master.

Once you have successfully exercised the Master Job Cache functions, test the External Job Cache functions using the ret execution module.

```
salt-call ret.get_jids cassandra_cql --output=json
salt-call ret.get_fun cassandra_cql test.ping --output=json
salt-call ret.get_minions cassandra_cql --output=json
salt-call ret.get_jid cassandra_cql 20150330121011408195 --output=json
```
2.22.3 Event Returners

For maximum visibility into the history of events across a Salt infrastructure, all events seen by a salt master may be logged to a returner.

To enable event logging, set the `event_return` configuration option in the master config to returner which should be designated as the handler for event returns.

**Note:** Not all returners support event returns. Verify a returner has an `event_return()` function before using.

**Note:** On larger installations, many hundreds of events may be generated on a busy master every second. Be certain to closely monitor the storage of a given returner as Salt can easily overwhelm an underpowered server with thousands of returns.

2.22.4 Full List of Returners

**returner modules**

</table>

**salt.returners.carbon_return**

Take data from salt and "return" it into a carbon receiver.

Add the following configuration to the minion configuration file:

```yaml
carbon.host: <server ip address>
carbon.port: 2003
```

Errors when trying to convert data to numbers may be ignored by setting `carbon.skip_on_error` to `True`:

```yaml
carbon.skip_on_error: True
```

By default, data will be sent to carbon using the plaintext protocol. To use the pickle protocol, set `carbon.mode` to `pickle`:

```yaml
carbon.mode: pickle
```

You can also specify the pattern used for the metric base path (except for virt modules metrics):

```
carbon.metric_base_pattern: carbon.[minion_id].[module].[function]
```

**These tokens can used**: `[module]`: salt module `[function]`: salt function `[minion_id]`: minion id

**Default is**: `carbon.metric_base_pattern: [module].[function].[minion_id]`

Carbon settings may also be configured as:

```yaml
carbon:
    host: <server IP or hostname>
    port: <carbon port>
    skip_on_error: True
    mode: (pickle|text)
    metric_base_pattern: <pattern> | [module].[function].[minion_id]
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```yaml
alternative.carbon:
    host: <server IP or hostname>
    port: <carbon port>
    skip_on_error: True
    mode: (pickle|text)
```

To use the carbon returner, append `--return carbon` to the salt command.

```
salt '*' test.ping --return carbon
```
To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return carbon --return_config alternative
```

To override individual configuration items, append `--return_kwargs '{``key``: ``value``}'` to the salt command.

New in version 2016.3.0.

```
salt '*' test.ping --return carbon --return_kwargs '{"skip_on_error": False}'
```

```
salt.returners.carbon_return.event_return(events)
    Return event data to remote carbon server
    Provide a list of events to be stored in carbon
```

```
salt.returners.carbon_return.prep_jid(nocache=False, passed_jid=None)
    Do any work necessary to prepare a JID, including sending a custom id
```

```
salt.returners.carbon_return.returner(ret)
    Return data to a remote carbon server using the text metric protocol
    Each metric will look like:
    ```
    [module].[function].[minion_id].[metric path [...]].[metric name]
    ```
```

```
salt.returners.cassandra_cql_return
```

Return data to a cassandra server

New in version 2015.5.0.

**maintainer** Corin Kochenower<ckochenower@saltstack.com>

**maturity** new as of 2015.2

**depends** salt.modules.cassandra_cql

**depends** DataStax Python Driver for Apache Cassandra https://github.com/datastax/python-driver pip install cassandra-driver

**platform** all

**configuration** To enable this returner, the minion will need the DataStax Python Driver for Apache Cassandra (https://github.com/datastax/python-driver) installed and the following values configured in the minion or master config. The list of cluster IPs must include at least one cassandra node IP address. No assumption or default will be used for the cluster IPs. The cluster IPs will be tried in the order listed. The port, username, and password values shown below will be the assumed defaults if you do not provide values:

```yaml
[cassandra]
    cluster:
        - 192.168.50.11
        - 192.168.50.12
        - 192.168.50.13
    port: 9042
    username: salt
    password: salt
```
Use the following cassandra database schema:

```
CREATE KEYSPACE IF NOT EXISTS salt
  WITH replication = {'class': 'SimpleStrategy', 'replication_factor': 1};

CREATE USER IF NOT EXISTS salt WITH PASSWORD 'salt' NOSUPERUSER;

GRANT ALL ON KEYSPACE salt TO salt;

USE salt;

CREATE TABLE IF NOT EXISTS salt.salt_returns (
  jid text,
  minion_id text,
  fun text,
  alter_time timestamp,
  full_ret text,
  return text,
  success boolean,
  PRIMARY KEY (jid, minion_id, fun)
) WITH CLUSTERING ORDER BY (minion_id ASC, fun ASC);

CREATE INDEX IF NOT EXISTS salt_returns_minion_id ON salt.salt_returns (minion_id);

CREATE INDEX IF NOT EXISTS salt_returns_fun ON salt.salt_returns (fun);

CREATE TABLE IF NOT EXISTS salt.jids (jid text PRIMARY KEY, load text);

CREATE TABLE IF NOT EXISTS salt.minions (minion_id text PRIMARY KEY, last_fun text);

CREATE TABLE IF NOT EXISTS salt.salt_events (id timeuuid, tag text, alter_time timestamp, data text, master_id text, PRIMARY KEY (id, tag)) WITH CLUSTERING ORDER BY (tag ASC);

CREATE INDEX tag ON salt.salt_events (tag);
```

Required python modules: cassandra-driver

To use the cassandra returner, append `--return_cql cassandra` to the salt command. ex:

```
salt '*' test.ping --return_cql cassandra
```

Note: if your Cassandra instance has not been tuned much you may benefit from altering some timeouts in cassandra.yaml like so:

```
# How long the coordinator should wait for read operations to complete
read_request_timeout_in_ms: 5000

# How long the coordinator should wait for seq or index scans to complete
```
As always, your mileage may vary and your Cassandra cluster may have different needs. SaltStack has seen situations where these timeouts can resolve some stacktraces that appear to come from the Datastax Python driver.

```python
salt.returners.cassandra_cql_return.event_return(events)
    Return event to one of potentially many clustered cassandra nodes
    Requires that configuration be enabled via `event_return' option in master config.

    Cassandra does not support an auto-increment feature due to the highly inefficient nature of creating a monotonically increasing number across all nodes in a distributed database. Each event will be assigned a uuid by the connecting client.

salt.returners.cassandra_cql_return.get_fun(fun)
    Return a dict of the last function called for all minions

salt.returners.cassandra_cql_return.get_jid(jid)
    Return the information returned when the specified job id was executed

salt.returners.cassandra_cql_return.get_jids()
    Return a list of all job ids

salt.returners.cassandra_cql_return.get_load(jid)
    Return the load data that marks a specified jid

salt.returners.cassandra_cql_return.get_minions()
    Return a list of minions

salt.returners.cassandra_cql_return.prep_jid(nocache, passed_jid=None)
    Do any work necessary to prepare a JID, including sending a custom id

salt.returners.cassandra_cql_return.returner(ret)
    Return data to one of potentially many clustered cassandra nodes

salt.returners.cassandra_cql_return.save_load(jid, load, minions=None)
    Save the load to the specified jid id
```

**salt.returners.cassandra_cql_return**

Return data to a Cassandra ColumnFamily

Here's an example Keyspace / ColumnFamily setup that works with this returner:

```sql
create keyspace salt;
use salt;
create column family returns
```
**Required python modules:** pycassa

To use the cassandra returner, append `--return cassandra` to the salt command. ex:
```
salt '*' test.ping --return cassandra
```

```python
with key_validation_class='UTF8Type'
    and comparator='UTF8Type'
    and default_validation_class='UTF8Type';
```

**salt.returners.cassandra_return.prep_jid**

- `nocache=False`
- `passed_jid=None`

Do any work necessary to prepare a JID, including sending a custom id

```python
salt.returners.cassandra_return.returner(ret)
```

Return data to a Cassandra ColumnFamily

**salt.returners.couchbase_return**

Simple returner for Couchbase. Optional configuration settings are listed below, along with sane defaults.

```python
couchbase.host: 'salt'
couchbase.port: 8091
couchbase.bucket: 'salt'
couchbase.ttl: 24

couchbase.password: 'password'
couchbase.skip_verify_views: False
```

To use the couchbase returner, append `--return couchbase` to the salt command. ex:
```
salt '*' test.ping --return couchbase
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.
```
salt '*' test.ping --return couchbase --return_config alternative
```

To override individual configuration items, append `--return_kwargs '{``key:''value''}'` to the salt command.
New in version 2016.3.0.
```
salt '*' test.ping --return couchbase --return_kwargs '{"bucket": "another-salt"}'
```

All of the return data will be stored in documents as follows:

**JID**

- `load`: load obj
- `tgt_minions`: list of minions targeted
- `nocache`: should we not cache the return data

**JID/MINION_ID**

- `return`: return_data
- `full_ret`: full load of job return

```python
salt.returners.couchbase_return.get_jid(jid)
```

Return the information returned when the specified job id was executed

---

2.22. Returners

233
salt.returners.couchbase_return.get_jids()
    Return a list of all job ids
salt.returners.couchbase_return.get_load(jid)
    Return the load data that marks a specified jid
salt.returners.couchbase_return.prep_jid(nocache=False, passed_jid=None)
    Return a job id and prepare the job id directory. This is the function responsible for making sure jids don't
    collide (unless its passed a jid). So do what you have to do to make sure that stays the case
salt.returners.couchbase_return.returner(load)
    Return data to couchbase bucket
salt.returners.couchbase_return.save_load(jid, clear_load, minion=None)
    Save the load to the specified jid
salt.returners.couchbase_return.save_minions(jid, minions, syndic_id=None)
    Save/update the minion list for a given jid. The syndic_id argument is included for API compatibility only.

salt.returners.couchdb_return

Simple returner for CouchDB. Optional configuration settings are listed below, along with sane defaults:

couchdb.db: 'salt'
couchdb.url: 'http://salt:5984/'

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative
configuration will be pulled from the default location:

alternative.couchdb.db: 'salt'
alternative.couchdb.url: 'http://salt:5984/'

To use the couchdb returner, append --return couchdb to the salt command. Example:

salt '*' test.ping --return couchdb

To use the alternative configuration, append --return_config alternative to the salt command.
New in version 2015.5.0.

salt '*' test.ping --return couchdb --return_config alternative

To override individual configuration items, append --return_kwargs '{"key": "value"}' to the salt command.
New in version 2016.3.0.

salt '*' test.ping --return couchdb --return_kwargs '{"db": "another-salt"}''

On concurrent database access

As this returner creates a couchdb document with the salt job id as document id and as only one document with
a given id can exist in a given couchdb database, it is advised for most setups that every minion be configured to
write to it own database (the value of couchdb.db may be suffixed with the minion id), otherwise multi-minion
targeting can lead to losing output:

- the first returning minion is able to create a document in the database
- other minions fail with {'error': 'HTTP Error 409: Conflict'}
salt.returners.couchdb_return.\texttt{ensure_views()}
This function makes sure that all the views that should exist in the design document do exist.

salt.returners.couchdb_return.\texttt{get_fun(fun)}
Return a dict with key being minion and value being the job details of the last run of function 'fun'.

salt.returners.couchdb_return.\texttt{get_jid(jid)}
Get the document with a given JID.

salt.returners.couchdb_return.\texttt{get_jids()}
List all the jobs that we have.

salt.returners.couchdb_return.\texttt{get_minions()}
Return a list of minion identifiers from a request of the view.

salt.returners.couchdb_return.\texttt{get_valid_salt_views()}
Returns a dict object of views that should be part of the salt design document.

salt.returners.couchdb_return.\texttt{prep_jid(nocache=False, passed_jid=None)}
Do any work necessary to prepare a JID, including sending a custom ID

salt.returners.couchdb_return.\texttt{returner(ret)}
Take in the return and shove it into the couchdb database.

salt.returners.couchdb_return.\texttt{set_salt_view()}
Helper function that sets the salt design document. Uses get_valid_salt_views and some hardcoded values.

salt.returners.django_return
A returner that will inform a Django system that returns are available using Django's signal system.
https://docs.djangoproject.com/en/dev/topics/signals/

It is up to the Django developer to register necessary handlers with the signals provided by this returner and process returns as necessary.

The easiest way to use signals is to import them from this returner directly and then use a decorator to register them.

An example Django module that registers a function called 'returner_callback' with this module's 'returner' function:

```python
import salt.returners.django_return
from django.dispatch import receiver

@receiver(salt.returners.django_return, sender=returner)
def returner_callback(sender, ret):
    print('I received {0} from {1}'.format(ret, sender))
```

salt.returners.django_return.\texttt{prep_jid(nocache=False, passed_jid=None)}
Do any work necessary to prepare a JID, including sending a custom ID

salt.returners.django_return.\texttt{returner(ret)}
Signal a Django server that a return is available

salt.returners.django_return.\texttt{save_load(jid, load, minions=None)}
Save the load to the specified jid

salt.returners.elasticsearch_return
Return data to an elasticsearch server for indexing.
To enable this returner the elasticsearch python client must be installed on the desired minions (all or some subset).

Please see documentation of elasticsearch execution module for a valid connection configuration.

**Warning:** The index that you wish to store documents will be created by Elasticsearch automatically if doesn't exist yet. It is highly recommended to create predefined index templates with appropriate mapping(s) that will be used by Elasticsearch upon index creation. Otherwise you will have problems as described in #20826.

To use the returner per salt call:

```
salt '*' test.ping --return elasticsearch
```

In order to have the returner apply to all minions:

```
ext_job_cache: elasticsearch
```

```
salt.returners.elasticsearch_return.get_load(jid)
   Return the load data that marks a specified jid

salt.returners.elasticsearch_return.prep_jid(nocache=False, passed_jid=None)
   Do any work necessary to prepare a JID, including sending a custom id

salt.returners.elasticsearch_return.returner(ret)
   Process the return from Salt

salt.returners.elasticsearch_return.save_load(jid, load, minions=None)
   Save the load to the specified jid id
```

**salt.returners.etcd_return**

Return data to an etcd server or cluster

**depends**

- python-etcd

In order to return to an etcd server, a profile should be created in the master configuration file:

```
my_etcd_config:
etcd.host: 127.0.0.1
etcd.port: 4001
```

It is technically possible to configure etcd without using a profile, but this is not considered to be a best practice, especially when multiple etcd servers or clusters are available.
etcd.host: 127.0.0.1  
etcd.port: 4001

Additionally, two more options must be specified in the top-level configuration in order to use the etcd returner:

```
etcd.returner: my_etcd_config
etcd.returner_root: /salt/return
```

The `etcd.returner` option specifies which configuration profile to use. The `etcd.returner_root` option specifies the path inside etcd to use as the root of the returner system.

Once the etcd options are configured, the returner may be used:

CLI Example:

```
salt '*' test.ping --return etcd
```

A username and password can be set:

```
etcd.username: larry  # Optional; requires etcd.password to be set
etcd.password: 123pass # Optional; requires etcd.username to be set
```

You can also set a TTL (time to live) value for the returner:

```
etcd.ttl: 5
```

Authentication with username and password, and ttl, currently requires the master branch of python-etcd.

You may also specify different roles for read and write operations. First, create the profiles as specified above. Then add:

```
etcd.returner_read_profile: my_etcd_read
etcd.returner_write_profile: my_etcd_write
```

salt.returners.etcd_return.get_fun()  
Return a dict of the last function called for all minions

salt.returners.etcd_return.get_jid(jid)  
Return the information returned when the specified job id was executed

salt.returners.etcd_return.get_jids()  
Return a list of all job ids

salt.returners.etcd_return.get_load(jid)  
Return the load data that marks a specified jid

salt.returners.etcd_return.get_minions()  
Return a list of minions

salt.returners.etcd_return.prep_jid(nocache=False, passed_jid=None)  
Do any work necessary to prepare a JID, including sending a custom id

salt.returners.etcd_return.returner(ret)  
Return data to an etcd server or cluster

salt.returners.etcd_return.save_load(jid, load, minions=None)  
Save the load to the specified jid
salt.returners.hipchat_return

Return salt data via hipchat.

New in version 2015.5.0.

The following fields can be set in the minion conf file:

```
hipchat.room_id (required)
hipchat.api_key (required)
hipchat.api_version (required)
hipchat.from_name (required)
hipchat.color (optional)
hipchat.notify (optional)
hipchat.profile (optional)
hipchat.url (optional)
```

**Note:** When using Hipchat's API v2, `api_key` needs to be assigned to the room with the `Label` set to what you would have been set in the `hipchat.from_name` field. The v2 API disregards the `from_name` in the data sent for the room notification and uses the Label assigned through the Hipchat control panel.

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
hipchat.room_id
hipchat.api_key
hipchat.api_version
hipchat.from_name
```

Hipchat settings may also be configured as:

```
hipchat:
  room_id: RoomName
  api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  api_version: v1
  from_name: user@email.com

alternative.hipchat:
  room_id: RoomName
  api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  api_version: v1
  from_name: user@email.com

hipchat_profile:
  hipchat.api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  hipchat.api_version: v1
  hipchat.from_name: user@email.com

hipchat:
  profile: hipchat_profile
  room_id: RoomName

alternative.hipchat:
  profile: hipchat_profile
  room_id: RoomName
```

```
To use the HipChat returner, append `--return hipchat' to the salt command.

```
salt '*' test.ping --return hipchat
```

To use the alternative configuration, append `--return_config alternative' to the salt command.
New in version 2015.5.0.

```
salt '*' test.ping --return hipchat --return_config alternative
```

To override individual configuration items, append `--return_kwargs `{``key``: ``value``}`' to the salt command.
New in version 2016.3.0.

```
salt '*' test.ping --return hipchat --return_kwargs '{"room_id": "another-room"}'
```

```
salt.returners.hipchat_return.event_return(events)
   Return event data to hipchat

salt.returners.hipchat_return.returner(ret)
   Send an hipchat message with the return data from a job
```

```
salt.returners.influxdb_return
```

Return data to an influxdb server.
New in version 2015.8.0.

To enable this returner the minion will need the python client for influxdb installed and the following values configured in the minion or master config, these are the defaults:

```
influxdb.db: 'salt'
influxdb.user: 'salt'
influxdb.password: 'salt'
influxdb.host: 'localhost'
influxdb.port: 8086
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
alternative.influxdb.db: 'salt'
alternative.influxdb.user: 'salt'
alternative.influxdb.password: 'salt'
alternative.influxdb.host: 'localhost'
alternative.influxdb.port: 6379
```

To use the influxdb returner, append `--return influxdb' to the salt command.

```
salt '*' test.ping --return influxdb
```

To use the alternative configuration, append `--return_config alternative' to the salt command.
salt '*' test.ping --return influxdb --return_config alternative

To override individual configuration items, append --return_kwargs '{key: value}' to the salt command.

New in version 2016.3.0.

```bash
salt '*' test.ping --return influxdb --return_kwargs '{"db": "another-salt"}'
```

```python
salt.returners.influxdb_return.get_fun(fun)
   Return a dict of the last function called for all minions
salt.returners.influxdb_return.get_jid(jid)
   Return the information returned when the specified job id was executed
salt.returners.influxdb_return.get_jids()
   Return a list of all job ids
salt.returners.influxdb_return.get_load(jid)
   Return the load data that marks a specified jid
salt.returners.influxdb_return.get_minions()
   Return a list of minions
salt.returners.influxdb_return.prep_jid(nocache=False, passed_jid=None)
   Do any work necessary to prepare a JID, including sending a custom id
salt.returners.influxdb_return.returner(ret)
   Return data to a influxdb data store
salt.returners.influxdb_return.save_load(jid, load, minions=None)
   Save the load to the specified jid
```

**salt.returners.kafka_return**

Return data to a Kafka server

- **maintainer** Christer Edwards (christer.edwards@gmail.com)
- **maturity** 0.1
- **depends** kafka-python
- **platform** all

To enable this returner install kafka-python and enable the following settings in the minion config:

```ini
retainer.kafka.hostnames:
   - `server1`
   - `server2`
   - `server3`
retainer.kafka.topic: `topic`
```

To use the kafka returner, append `--return kafka` to the Salt command, eg:

```bash
salt '*' test.ping --return kafka
```

```python
salt.returners.kafka_return.returner(ret)
   Return information to a Kafka server
```
The local returner is used to test the returner interface, it just prints the return data to the console to verify that it is being passed properly.

To use the local returner, append `--return local` to the salt command. ex:
```
salt '*' test.ping --return local
```

---

**salt.returners.local**

**event_return**

Description:
Print event return data to the terminal to verify functionality

**retuner**

Description:
Print the return data to the terminal to verify functionality

---

**salt.returners.local_cache**

Return data to local job cache

**clean_old_jobs**

Clean out the old jobs from the job cache

**get_endtime**

Description:
Retrieve the stored endtime for a given job
Returns False if no endtime is present

**get_jid**

Description:
Return the information returned when the specified job id was executed

**get_jids**

Return a dict mapping all job ids to job information

**get_jids_filter**

Description:
Return a list of all jobs information filtered by the given criteria. :param int count: show not more than the count of most recent jobs :param bool filter_find_jobs: filter out `saltutil.find_job` jobs

**get_load**

Description:
Return the load data that marks a specified jid

**prep_jid**

Description:
Return a job id and prepare the job id directory.
This is the function responsible for making sure jids don’t collide (unless it is passed a jid). So do what you have to do to make sure that stays the case

**returner**

Description:
Return data to the local job cache

**save_load**

Description:
Save the load to the specified jid

**save_minions**

Description:
Save/update the serialized list of minions for a given job

**update_endtime**

Description:
Update (or store) the end time for a given job
Endtime is stored as a plain text string
salt.returners.memcache_return

Return data to a memcache server

To enable this returner the minion will need the python client for memcache installed and the following values configured in the minion or master config, these are the defaults.

```
memcache.host: 'localhost'
memcache.port: '11211'
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location.

```
alternative.memcache.host: 'localhost'
alternative.memcache.port: '11211'
```

python2-memcache uses `localhost' and `11211' as syntax on connection.

To use the memcache returner, append `--return memcache' to the salt command.

```
salt '*' test.ping --return memcache
```

To use the alternative configuration, append `--return_config alternative' to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return memcache --return_config alternative
```

To override individual configuration items, append --return_kwargs '{'key': 'value'}' to the salt command.

New in version 2016.3.0.

```
salt '*' test.ping --return memcache --return_kwargs '{"host": "hostname.domain.com"}'
```

salt.returners.memcache_return.get_fun(fun)
Return a dict of the last function called for all minions

salt.returners.memcache_return.get_jid(jid)
Return the information returned when the specified job id was executed

salt.returners.memcache_return.get_jids()
Return a list of all job ids

salt.returners.memcache_return.get_load(jid)
Return the load data that marks a specified jid

salt.returners.memcache_return.get_minions()
Return a list of minions

salt.returners.memcache_return.prep_jid(nocache=False, passed_jid=None)
Do any work necessary to prepare a JID, including sending a custom id

salt.returners.memcache_return.returner(ret)
Return data to a memcache data store

salt.returners.memcache_return.save_load(jid, load, minions=None)
Save the load to the specified jid
salt.returners.mongo_future_return

Return data to a mongodb server

Required python modules: pymongo

This returner will send data from the minions to a MongoDB server. To configure the settings for your MongoDB server, add the following lines to the minion config files:

```
mongo.db: <database name>
mongo.host: <server ip address>
mongo.user: <MongoDB username>
mongo.password: <MongoDB user password>
mongo.port: 27017
```

You can also ask for indexes creation on the most common used fields, which should greatly improve performance. Indexes are not created by default.

```
mongo.indexes: true
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
alternative.mongo.db: <database name>
alternative.mongo.host: <server ip address>
alternative.mongo.user: <MongoDB username>
alternative.mongo.password: <MongoDB user password>
alternative.mongo.port: 27017
```

This mongo returner is being developed to replace the default mongodb returner in the future and should not be considered API stable yet.

To use the mongo returner, append `--return mongo` to the salt command.

```
salt '*' test.ping --return mongo
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return mongo --return_config alternative
```

To override individual configuration items, append `--return_kwargs `{``key:`: ``value''}` to the salt command.

New in version 2016.3.0.

```
salt '*' test.ping --return mongo --return_kwargs '{"db": "another-salt"}'}
```

salt.returners.mongo_future_return.get_fun(fun)
    Return the most recent jobs that have executed the named function

salt.returners.mongo_future_return.get_jid(jid)
    Return the return information associated with a jid

salt.returners.mongo_future_return.get_jids()
    Return a list of job ids

salt.returners.mongo_future_return.get_load(jid)
    Return the load associated with a given job id
Salt Documentation, Release 2016.3.6

salt.returners.mongo_future_return.get_minions()
    Return a list of minions

salt.returners.mongo_future_return.prep_jid(nocache=False, passed_jid=None)
    Do any work necessary to prepare a JID, including sending a custom id

salt.returners.mongo_future_return.returner(ret)
    Return data to a mongodb server

salt.returners.mongo_future_return.save_load(jid, load, minions=None)
    Save the load for a given job id

salt.returners.mongo_return

Return data to a mongodb server

Required python modules: pymongo

This returner will send data from the minions to a MongoDB server. To configure the settings for your MongoDB server, add the following lines to the minion config files.

```
mongo.db: <database name>
mongo.host: <server ip address>
mongo.user: <MongoDB username>
mongo.password: <MongoDB user password>
mongo.port: 27017
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location.

```
alternative.mongo.db: <database name>
alternative.mongo.host: <server ip address>
alternative.mongo.user: <MongoDB username>
alternative.mongo.password: <MongoDB user password>
alternative.mongo.port: 27017
```

To use the mongo returner, append `--return mongo` to the salt command.

```
salt '*' test.ping --return mongo_return
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return mongo_return --return_config alternative
```

To override individual configuration items, append `--return_kwargs '{"key": "value"}'` to the salt command.

New in version 2016.3.0.

```
salt '*' test.ping --return mongo --return_kwargs '{"db": "another-salt"}'
```

To override individual configuration items, append `--return_kwargs '{"key": "value"}'` to the salt command.

New in version 2016.3.0.

```
salt '*' test.ping --return mongo --return_kwargs '{"db": "another-salt"}'
```

salt.returners.mongo_return.get_fun(fun)
    Return the most recent jobs that have executed the named function
salt.returners.mongo_return.get_jid(jid)
   Return the return information associated with a jid

salt.returners.mongo_return.prep_jid(nocache=False, passed_jid=None)
   Do any work necessary to prepare a JID, including sending a custom id

salt.returners.mongo_return.returner(ret)
   Return data to a mongodb server

salt.returners.multi_returner

Read/Write multiple returners

salt.returners.multi_returner.clean_old_jobs()
   Clean out the old jobs from all returners (if you have it)

salt.returners.multi_returner.get_jid(jid)
   Merge the return data from all returners

salt.returners.multi_returner.get_jids()
   Return all job data from all returners

salt.returners.multi_returner.get_load(jid)
   Merge the load data from all returners

salt.returners.multi_returner.prep_jid(nocache=False, passed_jid=None)
   Call both with prep_jid on all returners in multi_returner

   TODO: finish this, what do do when you get different jids from 2 returners... since our jids are time based, this
   make this problem hard, because they aren’t unique, meaning that we have to make sure that no one else got
   the jid and if they did we spin to get a new one, which means ”locking” the jid in 2 returners is non-trivial

salt.returners.multi_returner.returner(load)
   Write return to all returners in multi_returner

salt.returners.multi_returner.save_load(jid, clear_load, minions=None)
   Write load to all returners in multi_returner

salt.returners.mysql

Return data to a mysql server

  maintainer  Dave Boucha <dave@saltstack.com>, Seth House <shouse@saltstack.com>
  maturity    new
  depends     python-mysqldb
  platform    all

To enable this returner, the minion will need the python client for mysql installed and the following values configured
in the minion or master config. These are the defaults:

mysql.host: 'salt'
mysql.user: 'salt'
mysql.pass: 'salt'
mysql.db: 'salt'
mysql.port: 3306
SSL is optional. The defaults are set to None. If you do not want to use SSL, either exclude these options or set them to None.

```bash
mysql.ssl_ca: None
mysql.ssl_cert: None
mysql.ssl_key: None
```

Alternative configuration values can be used by prefacing the configuration with `alternative`. Any values not found in the alternative configuration will be pulled from the default location. As stated above, SSL configuration is optional. The following ssl options are simply for illustration purposes:

```bash
alternative.mysql.host: 'salt'
alternative.mysql.user: 'salt'
alternative.mysql.pass: 'salt'
alternative.mysql.db: 'salt'
alternative.mysql.port: 3306
alternative.mysql.ssl_ca: '/etc/pki/mysql/certs/localhost.pem'
alternative.mysql.ssl_cert: '/etc/pki/mysql/certs/localhost.crt'
alternative.mysql.ssl_key: '/etc/pki/mysql/certs/localhost.key'
```

Use the following mysql database schema:

```sql
CREATE DATABASE `salt`
 DEFAULT CHARACTER SET utf8
 DEFAULT COLLATE utf8_general_ci;

USE `salt`;
--
-- Table structure for table `jids`
--

DROP TABLE IF EXISTS `jids`;
CREATE TABLE `jids` (  `jid` varchar(255) NOT NULL,  `load` mediumtext NOT NULL,  UNIQUE KEY `jid` (`jid`) ) ENGINE=InnoDB DEFAULT CHARSET=utf8;
CREATE INDEX jid ON jids(jid) USING BTREE;
--
-- Table structure for table `salt_returns`
--

DROP TABLE IF EXISTS `salt_returns`;
CREATE TABLE `salt_returns` (  `fun` varchar(50) NOT NULL,  `jid` varchar(255) NOT NULL,  `return` mediumtext NOT NULL,  `id` varchar(255) NOT NULL,  `success` varchar(10) NOT NULL,  `full_ret` mediumtext NOT NULL,  `alter_time` TIMESTAMP DEFAULT CURRENT_TIMESTAMP,  KEY `id` (`id`),  KEY `jid` (`jid`),  KEY `fun` (`fun`) ) ENGINE=InnoDB DEFAULT CHARSET=utf8;
```
DROP TABLE IF EXISTS `salt_events`;
CREATE TABLE `salt_events`(
    `id` BIGINT NOT NULL AUTO_INCREMENT,
    `tag` varchar(255) NOT NULL,
    `data` mediumtext NOT NULL,
    `alter_time` TIMESTAMP DEFAULT CURRENT_TIMESTAMP,
    `master_id` varchar(255) NOT NULL,
    PRIMARY KEY (`id`),
    KEY `tag` (`tag`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8;

Required python modules: MySQLdb

To use the mysql returner, append `--return mysql' to the salt command.

```
salt '*' test.ping --return mysql
```

To use the alternative configuration, append `--return_config alternative' to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return mysql --return_config alternative
```

To override individual configuration items, append `--return_kwargs `{``key':'': ``value''}' to the salt command.

New in version 2016.3.0.

```
salt '*' test.ping --return mysql --return_kwargs '{"db": "another-salt"}'
```

salt.returners.mysql.event_return(events)
  Return event to mysql server
    Requires that configuration be enabled via `event_return' option in master config.

salt.returners.mysql.get_fun(fun)
  Return a dict of the last function called for all minions

salt.returners.mysql.get_jid(jid)
  Return the information returned when the specified job id was executed

salt.returners.mysql.get_jids()
  Return a list of all job ids

salt.returners.mysql.get_jids_filter(count, filter_find_job=True)
  Return a list of all job ids :param int count: show not more than the count of most recent jobs :param bool filter_find_jobs: filter out `saltutil.find_job' jobs

salt.returners.mysql.get_load(jid)
  Return the load data that marks a specified jid

salt.returners.mysql.get_minions()
  Return a list of minions

salt.returners.mysql.prep_jid(nocache=False, passed_jid=None)
  Do any work necessary to prepare a JID, including sending a custom id
salt.returners.mysql.returner(ret)
   Return data to a mysql server

salt.returners.mysql.save_load(jid, load, minions=None)
   Save the load to the specified jid id

salt.returners.nagios_return

Return salt data to Nagios

The following fields can be set in the minion conf file:

- **nagios.url** (required)
- **nagios.token** (required)
- **nagios.service** (optional)
- **nagios.check_type** (optional)

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

- **nagios.url**
- **nagios.token**
- **nagios.service**

Nagios settings may also be configured as:

- **nagios:**
  - **url**: http://localhost/nrdp
  - **token**: r4nd0mt0k3n
  - **service**: service-check

- **alternative.nagios:**
  - **url**: http://localhost/nrdp
  - **token**: r4nd0mt0k3n
  - **service**: another-service-check

To use the Nagios returner, append ```--return nagios``` to the salt command. ex:

```
.. code-block:: bash

   salt '*' test.ping --return nagios
```

To use the alternative configuration, append ```--return_config alternative``` to the salt command. ex:

```
   salt '*' test.ping --return nagios --return_config alternative
```

To override individual configuration items, append --return_kwargs `{{"key": "value"}}` to the salt command.

New in version 2016.3.0.

```
   salt '*' test.ping --return nagios --return_kwargs {{"service": "service-name"}}
```

salt.returners.nagios_return.returner(ret)
   Send a message to Nagios with the data
salt.returners.odbc

Return data to an ODBC compliant server. This driver was developed with Microsoft SQL Server in mind, but theoretically could be used to return data to any compliant ODBC database as long as there is a working ODBC driver for it on your minion platform.

maintainer

3. (a) Oldham (cr@saltstack.com)

maturity New

depends unixodbc, pyodbc, freetds (for SQL Server)

platform all

To enable this returner the minion will need

On Linux:

unixodbc (http://www.unixodbc.org) pyodbc (pip install pyodbc) The FreeTDS ODBC driver for SQL Server (http://www.freetds.org) or another compatible ODBC driver

On Windows:

TBD

unixODBC and FreeTDS need to be configured via /etc/odbcinst.ini and /etc/odbc.ini.

/etc/odbcinst.ini:

```
[TDS]
Description=TDS
Driver=/usr/lib/x86_64-linux-gnu/odbc/libtdsodbc.so
```

(Note the above Driver line needs to point to the location of the FreeTDS shared library. This example is for Ubuntu 14.04.)

/etc/odbc.ini:

```
[TS]
Description = "Salt Returner"
Driver=TDS
Server = <your server ip or fqdn>
Port = 1433
Database = salt
Trace = No
```

Also you need the following values configured in the minion or master config. Configure as you see fit:

```
returner.odbc.dsn: 'TS'
returner.odbc.user: 'salt'
returner.odbc.passwd: 'salt'
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
alternative.returner.odbc.dsn: 'TS'
alternative.returner.odbc.user: 'salt'
alternative.returner.odbc.passwd: 'salt'
```
Running the following commands against Microsoft SQL Server in the desired database as the appropriate user should create the database tables correctly. Replace with equivalent SQL for other ODBC-compliant servers.

```sql
-- Table structure for table 'jids'

if OBJECT_ID('dbo.jids', 'U') is not null
    DROP TABLE dbo.jids

CREATE TABLE dbo.jids (jid varchar(255) PRIMARY KEY, load varchar(MAX) NOT NULL);

-- Table structure for table 'salt_returns'

IF OBJECT_ID('dbo.salt_returns', 'U') IS NOT NULL
    DROP TABLE dbo.salt_returns;

CREATE TABLE dbo.salt_returns (added datetime not null default (getdate()), fun varchar(100) NOT NULL, jid varchar(255) NOT NULL, retval varchar(MAX) NOT NULL, id varchar(255) NOT NULL, success bit default(0) NOT NULL, full_ret varchar(MAX));

CREATE INDEX salt_returns_added on dbo.salt_returns(added);
CREATE INDEX salt_returns_id on dbo.salt_returns(id);
CREATE INDEX salt_returns_jid on dbo.salt_returns(jid);
CREATE INDEX salt_returns_fun on dbo.salt_returns(fun);

To use this returner, append ' --return odbc' to the salt command.

.. code-block:: bash

    salt '*' status.diskusage --return odbc

To use the alternative configuration, append ' --return_config alternative' to the salt command.

.. versionadded:: 2015.5.0

To override individual configuration items, append --return_kwargs '{"key": "value"}' to the salt command.

New in version 2016.3.0.

salt '*' test.ping --return odbc --return_config alternative

salt.returners.odbc.get_fun(fun)

    Return a dict of the last function called for all minions
salt.returners.odbc.get_jid(jid)
   Return the information returned when the specified job id was executed
	salt.returners.odbc.get_jids()
   Return a list of all job ids
	salt.returners.odbc.get_load(jid)
   Return the load data that marks a specified jid
	salt.returners.odbc.get_minions()
   Return a list of minions
	salt.returners.odbc.prep_jid(nocache=False, passed_jid=None)
   Do any work necessary to prepare a JID, including sending a custom id
	salt.returners.odbc.returner(ret)
   Return data to an odbc server
	salt.returners.odbc.save_load(jid, load, minions=None)
   Save the load to the specified jid id

salt.returners.pgjsonb

Return data to a PostgreSQL server with json data stored in Pg's jsonb data type

   maintainer  Dave Boucha <dave@saltstack.com>, Seth House <shouse@saltstack.com>, C. R. Oldham <cr@saltstack.com>

   maturity  Stable

   depends  python-psycopg2

   platform  all

Note: There are three PostgreSQL returners. Any can function as an external master job cache, but each has different features. SaltStack recommends returners.pgjsonb if you are working with a version of PostgreSQL that has the appropriate native binary JSON types. Otherwise, review returners.postgres and returners.postgres_local_cache to see which module best suits your particular needs.

To enable this returner, the minion will need the python client for PostgreSQL installed and the following values configured in the minion or master config. These are the defaults:

```
returner.pgjsonb.host: 'salt'
returner.pgjsonb.user: 'salt'
returner.pgjsonb.pass: 'salt'
returner.pgjsonb.db: 'salt'
returner.pgjsonb.port: 5432
```

SSL is optional. The defaults are set to None. If you do not want to use SSL, either exclude these options or set them to None.

```
returner.pgjsonb.ssl_ca: None
returner.pgjsonb.ssl_cert: None
returner.pgjsonb.ssl_key: None
```

Alternative configuration values can be used by prefacing the configuration with alternative. Any values not found in the alternative configuration will be pulled from the default location. As stated above, SSL configuration is optional. The following ssl options are simply for illustration purposes:
Use the following Pg database schema:

```sql
CREATE DATABASE salt
    WITH ENCODING 'utf-8';

-- Table structure for table `jids`
DROP TABLE IF EXISTS jids;
CREATE TABLE jids (
    jid varchar(255) NOT NULL primary key,
    load jsonb NOT NULL
);
CREATE INDEX idx_jids_jsonb on jids
    USING gin (load)
    WITH (fastupdate=on);

-- Table structure for table `salt_returns`
DROP TABLE IF EXISTS salt_returns;
CREATE TABLE salt_returns (  
    fun varchar(50) NOT NULL,  
    jid varchar(255) NOT NULL,  
    return jsonb NOT NULL,  
    id varchar(255) NOT NULL,  
    success varchar(10) NOT NULL,  
    full_ret jsonb NOT NULL,  
    alter_time TIMESTAMP WITH TIME ZONE DEFAULT NOW());
CREATE INDEX idx_salt_returns_id ON salt_returns (id);
CREATE INDEX idx_salt_returns_jid ON salt_returns (jid);
CREATE INDEX idx_salt_returns_fun ON salt_returns (fun);
CREATE INDEX idx_salt_returns_return ON salt_returns
    USING gin (return) with (fastupdate=on);
CREATE INDEX idx_salt_returns_full_ret ON salt_returns
    USING gin (full_ret) with (fastupdate=on);

-- Table structure for table `salt_events`
DROP TABLE IF EXISTS salt_events;
DROP SEQUENCE IF EXISTS seq_salt_events_id;
CREATE SEQUENCE seq_salt_events_id;
CREATE TABLE salt_events (  
    id BIGINT NOT NULL UNIQUE DEFAULT nextval('seq_salt_events_id'),  
    tag varchar(255) NOT NULL,
```
```
data jsonb NOT NULL,
alter_time TIMESTAMP WITH TIME ZONE DEFAULT NOW(),
master_id varchar(255) NOT NULL);

CREATE INDEX idx_salt_events_tag on
  salt_events (tag);
CREATE INDEX idx_salt_events_data ON salt_events
  USING gin (data) with (fastupdate=on);
```

Required python modules: Psycopg2

To use this returner, append `--return pgjsonb' to the salt command.

```
salt '*' test.ping --return pgjsonb
```

To use the alternative configuration, append `--return_config alternative' to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return pgjsonb --return_config alternative
```

To override individual configuration items, append `--return_kwargs` '{``key:'': ``value''}' to the salt command.

New in version 2016.3.0.

```
salt '*' test.ping --return pgjsonb --return_kwargs '{"db": "another-salt"}'
```

```
salt.returners.pgjsonb.event_return(events)
    Return event to Pg server
        Requires that configuration be enabled via `event_return' option in master config.

salt.returners.pgjsonb.get_fun(fun)
    Return a dict of the last function called for all minions

salt.returners.pgjsonb.get_jid(jid)
    Return the information returned when the specified job id was executed

salt.returners.pgjsonb.get_jids()
    Return a list of all job ids

salt.returners.pgjsonb.get_load(jid)
    Return the load data that marks a specified jid

salt.returners.pgjsonb.get_minions()
    Return a list of minions

salt.returners.pgjsonb.prep_jid(nocache=False, passed_jid=None)
    Do any work necessary to prepare a JID, including sending a custom id

salt.returners.pgjsonb.returner(ret)
    Return data to a Pg server

salt.returners.pgjsonb.save_load(jid, load, minions=None)
    Save the load to the specified jid id
```

salt.returners.postgres

Return data to a postgresql server

2.22. Returners
Note: There are three PostgreSQL returners. Any can function as an external *master job cache*, but each has different features. SaltStack recommends `returners.pgjsonb` if you are working with a version of PostgreSQL that has the appropriate native binary JSON types. Otherwise, review `returners.postgres` and `returners.postgres_local_cache` to see which module best suits your particular needs.

**maintainer** None  
**maturity** New  
**depends** psycopg2  
**platform** all

To enable this returner the minion will need the psycopg2 installed and the following values configured in the minion or master config:

```
returner.postgres.host: 'salt'
returner.postgres.user: 'salt'
returner.postgres.passwd: 'salt'
returner.postgres.db: 'salt'
returner.postgres.port: 5432
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
alternative.returner.postgres.host: 'salt'
alternative.returner.postgres.user: 'salt'
alternative.returner.postgres.passwd: 'salt'
alternative.returner.postgres.db: 'salt'
alternative.returner.postgres.port: 5432
```

Running the following commands as the postgres user should create the database correctly:

```
psql << EOF
CREATE ROLE salt WITH PASSWORD 'salt';
CREATE DATABASE salt WITH OWNER salt;
EOF

psql -h localhost -U salt << EOF
-- Table structure for table 'jids'
--
DROP TABLE IF EXISTS jids;
CREATE TABLE jids (  
jid    varchar(20) PRIMARY KEY,
load   text NOT NULL  
);  
--
-- Table structure for table 'salt_returns'
--
DROP TABLE IF EXISTS salt_returns;
CREATE TABLE salt_returns (  
added TIMESTAMP WITH TIME ZONE DEFAULT now(),
fun     text NOT NULL,
jid     varchar(20) NOT NULL,
EOF
```
```
return text NOT NULL,
id text NOT NULL,
success boolean
);
CREATE INDEX ON salt_returns (added);
CREATE INDEX ON salt_returns (id);
CREATE INDEX ON salt_returns (jid);
CREATE INDEX ON salt_returns (fun);
EOF
```

Required python modules: psycopg2

To use the postgres returner, append `--return postgres` to the salt command.

```
salt '*' test.ping --return postgres
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return postgres --return_config alternative
```

To override individual configuration items, append `--return_kwargs `{``key:'': ``value''}' to the salt command.

New in version 2016.3.0.

```
salt '*' test.ping --return postgres --return_kwargs '{"db": "another-salt"}'
```

salt.returners.postgres.get_fun(fun)

Return a dict of the last function called for all minions

salt.returners.postgres.get_jid(jid)

Return the information returned when the specified job id was executed

salt.returners.postgres.get_jids()

Return a list of all job ids

salt.returners.postgres.get_load(jid)

Return the load data that marks a specified jid

salt.returners.postgres.get_minions()

Return a list of minions

salt.returners.postgres.prep_jid(nocache=False, passed_jid=None)

Do any work necessary to prepare a JID, including sending a custom id

salt.returners.postgres.returner(ret)

Return data to a postgres server

salt.returners.postgres.save_load(jid, load, minions=None)

Save the load to the specified jid id

salt.returners.postgres_local_cache

Use a postgresql server for the master job cache. This helps the job cache to cope with scale.

Note: There are three PostgreSQL returners. Any can function as an external master job cache, but each has different features. SaltStack recommends `returners.pgjsonb` if you are working with a version of PostgreSQL
that has the appropriate native binary JSON types. Otherwise, review `returners.postgres` and `returners.postgres_local_cache` to see which module best suits your particular needs.

maintainer gjredelinghuys@gmail.com
maturity Stable
depends psycopg2
platform all

To enable this returner the minion will need the psycopg2 installed and the following values configured in the master config:

```
master_job_cache: postgres_local_cache
master_job_cache.postgres.host: 'salt'
master_job_cache.postgres.user: 'salt'
master_job_cache.postgres.passwd: 'salt'
master_job_cache.postgres.db: 'salt'
master_job_cache.postgres.port: 5432
```

Running the following command as the postgres user should create the database correctly:

```
psql << EOF
CREATE ROLE salt WITH PASSWORD 'salt';
CREATE DATABASE salt WITH OWNER salt;
EOF
```

In case the postgres database is a remote host, you'll need this command also:

```
ALTER ROLE salt WITH LOGIN;
```

and then:

```
psql -h localhost -U salt << EOF
-- Table structure for table 'jids'
--
DROP TABLE IF EXISTS jids;
CREATE TABLE jids (jid varchar(20) PRIMARY KEY, started TIMESTAMP WITH TIME ZONE DEFAULT now(), tgt_type text NOT NULL, cmd text NOT NULL, tgt text NOT NULL, kwargs text NOT NULL, ret text NOT NULL, username text NOT NULL, arg text NOT NULL, fun text NOT NULL);
--
-- Table structure for table 'salt_returns'
--
-- note that 'success' must not have NOT NULL constraint, since
-- some functions don't provide it.
```

256 Chapter 2. Configuring Salt
DROP TABLE IF EXISTS salt_returns;
CREATE TABLE salt_returns ( 
    added TIMESTAMP WITH TIME ZONE DEFAULT now(),
    fun text NOT NULL,
    jid varchar(20) NOT NULL,
    return text NOT NULL,
    id text NOT NULL,
    success boolean
);
CREATE INDEX ON salt_returns (added);
CREATE INDEX ON salt_returns (id);
CREATE INDEX ON salt_returns (jid);
CREATE INDEX ON salt_returns (fun);

DROP TABLE IF EXISTS salt_events;
CREATE TABLE salt_events ( 
    id SERIAL,
    tag text NOT NULL,
    data text NOT NULL,
    alter_time TIMESTAMP WITH TIME ZONE DEFAULT now(),
    master_id text NOT NULL
);
CREATE INDEX ON salt_events (tag);
CREATE INDEX ON salt_events (data);
CREATE INDEX ON salt_events (id);
CREATE INDEX ON salt_events (master_id);

Required python modules: psycopg2

salt.returners.postgres_local_cache.clean_old_jobs()  
Clean out the old jobs from the job cache

salt.returners.postgres_local_cache.event_return(events)  
Return event to a postgres server

  Require that configuration be enabled via `event_return' option in master config.

salt.returners.postgres_local_cache.get_jid(jid)  
Return the information returned when the specified job id was executed

salt.returners.postgres_local_cache.get_jids()  
Return a list of all job ids For master job cache this also formats the output and returns a string

salt.returners.postgres_local_cache.get_load(jid)  
Return the load data that marks a specified jid

salt.returners.postgres_local_cache.prep_jid(nocache=False, passed_jid=None)  
Return a job id and prepare the job id directory This is the function responsible for making sure jids don't collide (unless its passed a jid). So do what you have to do to make sure that stays the case

salt.returners.postgres_local_cache.returner(load)  
Return data to a postgres server

salt.returners.postgres_local_cache.save_load(jid, clear_load, minions=None)  
Save the load to the specified jid id
salt.returners.pushover_returner

Return salt data via pushover (http://www.pushover.net)

New in version 2016.3.0.

The following fields can be set in the minion conf file:

- pushover.user (required)
- pushover.token (required)
- pushover.title (optional)
- pushover.device (optional)
- pushover.priority (optional)
- pushover.expire (optional)
- pushover.retry (optional)
- pushover.profile (optional)

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

- alternative.pushover.user
- alternative.pushover.token
- alternative.pushover.title
- alternative.pushover.device
- alternative.pushover.priority
- alternative.pushover.expire
- alternative.pushover.retry

PushOver settings may also be configured as:

```plaintext
pushover:
  user: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  token: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  title: Salt Returner
  device: phone
  priority: -1
  expire: 3600
  retry: 5

alternative.pushover:
  user: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  token: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  title: Salt Returner
  device: phone
  priority: 1
  expire: 4800
  retry: 2

pushover_profile:
  pushover.token: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

pushover:
  user: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  profile: pushover_profile

alternative.pushover:
  user: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  profile: pushover_profile
```
To use the PushOver returner, append `--return pushover` to the salt command. ex:
```
.. code-block:: bash
   salt '*' test.ping --return pushover
```

To use the alternative configuration, append `--return_config alternative` to the salt command. ex:
```
salt '*' test.ping --return pushover --return_config alternative
```

To override individual configuration items, append `--return_kwargs {"key": "value"}` to the salt command.
```
salt '*' test.ping --return pushover --return_kwargs "{"title": "Salt is awesome!"}"
```

```{.python}
salt.returners.pushover_returner.returner(ret)
Send an PushOver message with the data
```

**salt.returners.redis_return**

Return data to a redis server

To enable this returner the minion will need the python client for redis installed and the following values configured in the minion or master config, these are the defaults:

```{.ini}
redis.db: 0
redis.host: 'salt'
redis.port: 6379
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```{.ini}
alternative.redis.db: 0
alternative.redis.host: 'salt'
alternative.redis.port: 6379
```

To use the redis returner, append `--return redis` to the salt command.
```
salt '*' test.ping --return redis
```

To use the alternative configuration, append `--return_config alternative` to the salt command.
New in version 2015.5.0.
```
salt '*' test.ping --return redis --return_config alternative
```

To override individual configuration items, append `--return_kwargs {'key': 'value'}` to the salt command.
New in version 2016.3.0.
```
salt '*' test.ping --return redis --return_kwargs {'db': 'another-salt'}
```

```{.python}
salt.returners.redis_return.clean_old_jobs()
Clean out minions's return data for old jobs.
```

Normally, hset 'ret:<jid>' are saved with a TTL, and will eventually get cleaned by redis. But for jobs with some very late minion return, the corresponding hset's TTL will be refreshed to a too late timestamp, we'll do manually cleaning here.

2.22. Returners
salt.returners.redis_return.get_fun(fun)

Return a dict of the last function called for all minions

salt.returners.redis_return.get_jid(jid)

Return the information returned when the specified job id was executed

salt.returners.redis_return.get_jids()

Return a dict mapping all job ids to job information

salt.returners.redis_return.get_load(jid)

Return the load data that marks a specified jid

salt.returners.redis_return.get_minions()

Return a list of minions

salt.returners.redis_return.prep_jid(nocache=False, passed_jid=None)

Do any work necessary to prepare a JID, including sending a custom id

salt.returners.redis_return.returner(ret)

Return data to a redis data store

salt.returners.redis_return.save_load(jid, load, minions=None)

Save the load to the specified jid

salt.returners.sentry_return

Salt returner that reports execution results back to sentry. The returner will inspect the payload to identify errors and flag them as such.

Pillar needs something like:

```yaml
raven:
  servers:
    - http://192.168.1.1
    - https://sentry.example.com
  public_key: deadbeefdeadbeefdeadbeefdeadbeef
  secret_key: beefdeadbeefdeadbeefdeadbeefdead
  project: 1
  tags:
    - os
    - master
    - saltversion
    - cpuarch
```

and https://pypi.python.org/pypi/raven installed

The tags list (optional) specifies grains items that will be used as sentry tags, allowing tagging of events in the sentry ui.

salt.returners.sentry_return.prep_jid(nocache=False, passed_jid=None)

Do any work necessary to prepare a JID, including sending a custom id

salt.returners.sentry_return.returner(ret)

Log outcome to sentry. The returner tries to identify errors and report them as such. All other messages will be reported at info level.

salt.returners.slack_returner

Return salt data via slack
New in version 2015.5.0.

The following fields can be set in the minion conf file:

```yaml
slack.channel (required) slack.api_key (required) slack.username (required) slack.as_user (required to see the profile picture of your bot) slack.profile (optional) slack.changes(optional, only show changes and failed states) slack.yaml_format(optional, format the json in yaml format)
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```python
slack.channel
slack.api_key
slack.username
slack.as_user
```

Slack settings may also be configured as:

```python
slack:
  channel: RoomName
  api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  username: user
  as_user: true

alternative.slack:
  room_id: RoomName
  api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  from_name: user@email.com

slack_profile:
  slack.api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  slack.from_name: user@email.com

slack:
  profile: slack_profile
  channel: RoomName

alternative.slack:
  profile: slack_profile
  channel: RoomName
```

To use the Slack returner, append `--return slack` to the salt command.

```
salt '*' test.ping --return slack
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

```
salt '*' test.ping --return slack --return_config alternative
```

To override individual configuration items, append `--return_kwargs `{"key": "value"}` to the salt command.

New in version 2016.3.0.

```
salt '*' test.ping --return slack --return_kwargs '{"channel": "+random"}'
```

```
salt.returners.slack_returner.returner(ret)
  Send an slack message with the data
```
salt.returners.sms_return

Return data by SMS.
New in version 2015.5.0.

maintainer Damian Myerscough
maturity new
depends twilio
platform all

To enable this returner the minion will need the python twilio library installed and the following values configured in the minion or master config:

```
twilio.sid: 'XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
twilio.token: 'XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
twilio.to: '+1415XXXXXXX'
twilio.from: '+1650XXXXXXX'
```

To use the sms returner, append `--return sms` to the salt command.

```
salt '*' test.ping --return sms
```

salt.returners.sms_return.returner(ret)
Return a response in an SMS message

salt.returners.smtp_return

Return salt data via email
The following fields can be set in the minion conf file. Fields are optional unless noted otherwise.

- **from** (required) The name/address of the email sender.
- **to** (required) The name/address of the email recipient.
- **host** (required) The SMTP server hostname or address.
- **port** The SMTP server port; defaults to 25.
- **username** The username used to authenticate to the server. If specified a password is also required. It is recommended but not required to also use TLS with this option.
- **password** The password used to authenticate to the server.
- **tls** Whether to secure the connection using TLS; defaults to False
- **subject** The email subject line.
- **fields** Which fields from the returned data to include in the subject line of the email; comma-delimited. For example: id, fun. Please note, the subject line is not encrypted.
- **gpgowner** A user’s ~/.gpg directory. This must contain a gpg public key matching the address the mail is sent to. If left unset, no encryption will be used. Requires python-gnupg to be installed.
- **template** The path to a file to be used as a template for the email body.
- **renderer** A Salt renderer, or render-pipe, to use to render the email template. Default jinja.

Below is an example of the above settings in a Salt Minion configuration file:
Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location. For example:

```python
alternative.smtp.username: saltdev
alternative.smtp.password: saltdev
alternative.smtp.tls: True
```

To use the SMTP returner, append `--return smtp` to the salt command.

```
salt '* test.ping --return smtp
```

To use the alternative configuration, append `--return_config alternative` to the salt command.
New in version 2015.5.0.

```
salt '* test.ping --return smtp --return_config alternative
```

To override individual configuration items, append `--return_kwargs` to the salt command. New in version 2016.3.0.

```
salt '* test.ping --return smtp --return_kwargs \{"to": "user@domain.com"\}
```

An easy way to test the SMTP returner is to use the development SMTP server built into Python. The command below will start a single-threaded SMTP server that prints any email it receives to the console.

```
python -m smtpd -n -c DebuggingServer localhost:1025
```

```
salt.returners.smtp_return.prep_jid(nocache=False, passed_jid=None)
```
Do any work necessary to prepare a JID, including sending a custom id

```
salt.returners.smtp_return.returner(ret)
```
Send an email with the data

```
salt.returners.sqlite3
```
Insert minion return data into a sqlite3 database

- **maintainer** Mickey Malone `<mickey.malone@gmail.com>`
- **maturity** New
- **depends** None
- **platform** All

Sqlite3 is a serverless database that lives in a single file. In order to use this returner the database file must exist, have the appropriate schema defined, and be accessible to the user whom the minion process is running as. This returner requires the following values configured in the master or minion config:

```
sqlite3.database: /usr/lib/salt/salt.db
sqlite3.timeout: 5.0
```
Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```yaml
alternative.sqlite3.database: /usr/lib/salt/salt.db
alternative.sqlite3.timeout: 5.0
```

Use the commands to create the sqlite3 database and tables:

```sql
sqlite3 /usr/lib/salt/salt.db << EOF
-- Table structure for table 'jids'
CREATE TABLE jids (jid TEXT PRIMARY KEY, load TEXT NOT NULL );

-- Table structure for table 'salt_returns'
CREATE TABLE salt_returns (fun TEXT KEY, jid TEXT KEY, id TEXT KEY, fun_args TEXT, date TEXT NOT NULL, full_ret TEXT NOT NULL, success TEXT NOT NULL );
EOF
```

To use the sqlite returner, append `--return sqlite3' to the salt command.

```bash
salt '*' test.ping --return sqlite3
```

To use the alternative configuration, append `--return_config alternative' to the salt command.

New in version 2015.5.0.

```bash
salt '*' test.ping --return sqlite3 --return_config alternative
```

To override individual configuration items, append `--return_kwargs {"key":"value"}' to the salt command.

New in version 2016.3.0.

```bash
salt '*' test.ping --return sqlite3 --return_kwargs {"db": "/var/lib/salt/another-salt.db"}
```

*Salt.returners.sqlite3_return.*

- `get_fun(fun)`
  Return a dict of the last function called for all minions

- `get_jid(jid)`
  Return the information returned from a specified jid

- `get_jids()`
  Return a list of all job ids
salt.returners.sqlite3_return.get_load(jid)
    Return the load from a specified jid
salt.returners.sqlite3_return.get_minions()
    Return a list of minions
salt.returners.sqlite3_return.prep_jid(nocache=False, passed_jid=None)
    Do any work necessary to prepare a JID, including sending a custom id
salt.returners.sqlite3_return.returner(ret)
    Insert minion return data into the sqlite3 database
salt.returners.sqlite3_return.save_load(jid, load, minions=None)
    Save the load to the specified jid

salt.returners.syslog_return

Return data to the host operating system's syslog facility

Required python modules: syslog, json

The syslog returner simply reuses the operating system's syslog facility to log return data

To use the syslog returner, append `--return syslog` to the salt command.

```
salt '*' test.ping --return syslog
```

Note: Syslog server implementations may have limits on the maximum record size received by the client. This may lead to job return data being truncated in the syslog server's logs. For example, for rsyslog on RHEL-based systems, the default maximum record size is approximately 2KB (which return data can easily exceed). This is configurable in rsyslog.conf via the $MaxMessageSize config parameter. Please consult your syslog implementation's documentation to determine how to adjust this limit.

salt.returners.syslog_return.prep_jid(nocache=False, passed_jid=None)
    Do any work necessary to prepare a JID, including sending a custom id
salt.returners.syslog_return.returner(ret)
    Return data to the local syslog

salt.returners.xmpp_return

Return salt data via xmpp

    depends sleekxmpp >= 1.3.1

The following fields can be set in the minion conf file:

```
xmpp.jid (required)
xmpp.password (required)
xmpp.recipient (required)
xmpp.profile (optional)
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location.

2.22. Returners
XMPP settings may also be configured as:

```python
xmpp:
    jid: user@xmpp.domain.com/resource
    password: password
    recipient: user@xmpp.example.com

alternative.xmpp:
    jid: user@xmpp.domain.com/resource
    password: password
    recipient: someone@xmpp.example.com

xmpp_profile:
    xmpp.jid: user@xmpp.domain.com/resource
    xmpp.password: password

xmpp:
    profile: xmpp_profile
    recipient: user@xmpp.example.com

alternative.xmpp:
    profile: xmpp_profile
    recipient: someone-else@xmpp.example.com
```

To use the XMPP returner, append `--return xmpp` to the salt command.

```
salt '*' test.ping --return xmpp
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return xmpp --return_config alternative
```

To override individual configuration items, append `--return_kwargs '{"key": "value"}'` to the salt command.

New in version 2016.3.0.

```
salt '*' test.ping --return xmpp --return_kwargs '{"recipient": "someone-else@xmpp.example.com"}''
```

```python
class salt.returners.xmpp_return.SendMessageBot(jid, password, recipient, msg)

    start(event)

salt.returners.xmpp_return.returner(ret)
    Send an xmpp message with the data
```
2.23 Renderers

The Salt state system operates by gathering information from common data types such as lists, dictionaries, and strings that would be familiar to any developer.

SLS files are translated from whatever data templating format they are written in back into Python data types to be consumed by Salt.

By default SLS files are rendered as Jinja templates and then parsed as YAML documents. But since the only thing the state system cares about is raw data, the SLS files can be any structured format that can be dreamed up.

Currently there is support for Jinja + YAML, Mako + YAML, Wempy + YAML, Jinja + json, Mako + json, and Wempy + json.

Renderers can be written to support any template type. This means that the Salt states could be managed by XML files, HTML files, Puppet files, or any format that can be translated into the Pythonic data structure used by the state system.

2.23.1 Multiple Renderers

A default renderer is selected in the master configuration file by providing a value to the renderer key.

When evaluating an SLS, more than one renderer can be used.

When rendering SLS files, Salt checks for the presence of a Salt-specific shebang line.

The shebang line directly calls the name of the renderer as it is specified within Salt. One of the most common reasons to use multiple renderers is to use the Python or py renderer.

Below, the first line is a shebang that references the py renderer.

```
#!/py

def run():
    '''
    Install the python-mako package
    '''
    return {'include': ['python'],
            'python-mako': {'pkg': ['installed']}}
```

2.23.2 Composing Renderers

A renderer can be composed from other renderers by connecting them in a series of pipes().

In fact, the default Jinja + YAML renderer is implemented by connecting a YAML renderer to a Jinja renderer. Such renderer configuration is specified as: jinja | yaml.

Other renderer combinations are possible:

- **yaml** i.e., just YAML, no templating.
- **mako | yaml** pass the input to the mako renderer, whose output is then fed into the yaml renderer.
- **jinja | mako | yaml** This one allows you to use both jinja and mako templating syntax in the input and then parse the final rendered output as YAML.

The following is a contrived example SLS file using the jinja | mako | yaml renderer:
An Example:

```yaml
cmd.run:
  - name: |
      echo "Using Salt ${grains['saltversion']}" \
        "from path {{grains['saltpath']}}." \
  - cwd: /

<%doc> ${...} is Mako's notation, and so is this comment. </%doc>
{# Similarly, {{...}} is Jinja's notation, and so is this comment. #}
```

For backward compatibility, `jinja | yaml` can also be written as `yaml_jinja`, and similarly, the `yaml_mako`, `yaml_wempy`, `json_jinja`, `json_mako`, and `json_wempy` renderers are all supported.

Keep in mind that not all renderers can be used alone or with any other renderers. For example, the template renderers shouldn't be used alone as their outputs are just strings, which still need to be parsed by another renderer to turn them into highstate data structures.

For example, it doesn't make sense to specify `yaml | jinja` because the output of the YAML renderer is a highstate data structure (a dict in Python), which cannot be used as the input to a template renderer. Therefore, when combining renderers, you should know what each renderer accepts as input and what it returns as output.

### 2.23.3 Writing Renderers

A custom renderer must be a Python module placed in the renderers directory and the module implement the `render` function.

The `render` function will be passed the path of the SLS file as an argument.

The purpose of the `render` function is to parse the passed file and to return the Python data structure derived from the file.

Custom renderers must be placed in a `_renderers` directory within the `file_roots` specified by the master configuration.

Custom renderers are distributed when any of the following are run:

- `state.apply`
- `saltutil.sync_renderers`
- `saltutil.sync_all`

Any custom renderers which have been synced to a minion, that are named the same as one of Salt’s default set of renderers, will take the place of the default renderer with the same name.

### 2.23.4 Examples

The best place to find examples of renderers is in the Salt source code.

Documentation for renderers included with Salt can be found here:

[https://github.com/saltstack/salt/blob/develop/salt/renderers](https://github.com/saltstack/salt/blob/develop/salt/renderers)

Here is a simple YAML renderer example:
import yaml

def render(yaml_data, env='', sls='', **kws):
    if not isinstance(yaml_data, basestring):
        yaml_data = yaml_data.read()
    data = yaml.load(yaml_data)
    return data if data else {}
salt.renderers.gpg

Renderer that will decrypt GPG ciphers

Any key in the SLS file can be a GPG cipher, and this renderer will decrypt it before passing it off to Salt. This allows you to safely store secrets in source control, in such a way that only your Salt master can decrypt them and distribute them only to the minions that need them.

The typical use-case would be to use ciphers in your pillar data, and keep a secret key on your master. You can put the public key in source control so that developers can add new secrets quickly and easily.

This renderer requires the `gpg` binary. No python libraries are required as of the 2015.8.0 release.

Setup

To set things up, first generate a keypair. On the master, run the following:

```
# mkdir -p /etc/salt/gpgkeys
# chmod 0700 /etc/salt/gpgkeys
# gpg --gen-key --homedir /etc/salt/gpgkeys
```

Do not supply a password for the keypair, and use a name that makes sense for your application. Be sure to back up the `gpgkeys` directory someplace safe!

Note: Unfortunately, there are some scenarios - for example, on virtual machines which don’t have real hardware - where insufficient entropy causes key generation to be extremely slow. In these cases, there are usually means of increasing the system entropy. On virtualised Linux systems, this can often be achieved by installing the `rng-tools` package.

Export the Public Key

```
# gpg --homedir /etc/salt/gpgkeys --armor --export <KEY-NAME> > exported_pubkey.gpg
```

Import the Public Key

To encrypt secrets, copy the public key to your local machine and run:

```
$ gpg --import exported_pubkey.gpg
```

To generate a cipher from a secret:

```
$ echo -n "supersecret" | gpg --armor --batch --trust-model always --encrypt -r <KEY-NAME>
```

To apply the renderer on a file-by-file basis add the following line to the top of any pillar with gpg data in it:

```
#!yaml|gpg
```

Now with your renderer configured, you can include your ciphers in your pillar data like so:
Encrypted CLI Pillar Data

New in version 2016.3.0.

Functions like `state.highstate` and `state.sls` allow for pillar data to be passed on the CLI.

```
salt myminion state.highstate pillar="{'mypillar': 'foo'}"
```

Starting with the 2016.3.0 release of Salt, it is now possible for this pillar data to be GPG-encrypted, and to use the GPG renderer to decrypt it.

Replacing Newlines

To pass encrypted pillar data on the CLI, the ciphertext must have its newlines replaced with a literal backslash-n (`\n`), as newlines are not supported within Salt CLI arguments. There are a number of ways to do this:

With awk or Perl:

```
# awk
ciphertext=`echo -n "supersecret" | gpg --armor --batch --trust-model always --encrypt\n--r user@domain.com | awk '{printf "%s\n",$0} END {print "\n"}'`
# Perl
ciphertext=`echo -n "supersecret" | gpg --armor --batch --trust-model always --encrypt\n--r user@domain.com | perl -pe 's/'s/\n/\n/g'`
```

With Python:

```
import subprocess

secret, stderr = subprocess.Popen(  
[  
'gpg',  
'--armor',  
'--batch',  
'--trust-model',  
'always',  
'--encrypt',  
'--r',  
'user@domain.com'  
],  
stdin=subprocess.PIPE,  
stdout=subprocess.PIPE,  
stderr=subprocess.PIPE).communicate(input='supersecret')

if secret:
    print(secret.replace('\n', 'r\n'))
```
else:
    raise ValueError('No ciphertext found: {0}'.format(stderr))

ciphertext='python /path/to/script.py'

The ciphertext can be included in the CLI pillar data like so:

salt myminion state.sls secretstuff pillar_enc=gpg pillar="{secret_pillar: '${ciphertext}'"

The pillar_enc=gpg argument tells Salt that there is GPG-encrypted pillar data, so that the CLI pillar data is passed through the GPG renderer, which will iterate recursively though the CLI pillar dictionary to decrypt any encrypted values.

Encrypting the Entire CLI Pillar Dictionary

If several values need to be encrypted, it may be more convenient to encrypt the entire CLI pillar dictionary. Again, this can be done in several ways:

With awk or Perl:

```bash
# awk
$ciphertext='echo -n "{'secret_a': 'CorrectHorseBatteryStaple', 'secret_b': 'GPG is fun!'}" | gpg --armor --batch --trust-model always --encrypt -r user@domain.com | awk '{printf "%s\\n",$0} END {print "}"}
# Perl
$ciphertext='echo -n "{'secret_a': 'CorrectHorseBatteryStaple', 'secret_b': 'GPG is fun!'}" | gpg --armor --batch --trust-model always --encrypt -r user@domain.com | perl -pe 's/
/\n/g'
```

With Python:

```python
import subprocess

pillar_data = {'secret_a': 'CorrectHorseBatteryStaple', 'secret_b': 'GPG is fun!'}

secret, stderr = subprocess.Popen(['gpg', '--armor', '--batch', '--trust-model', 'always', '--encrypt', '-r', 'user@domain.com'], stdin=subprocess.PIPE, stdout=subprocess.PIPE, stderr=subprocess.PIPE).communicate(input=repr(pillar_data))

if secret:
    print(secret.replace('
', r'
'))
else:
    raise ValueError('No ciphertext found: {0}'.format(stderr))

ciphertext='python /path/to/script.py'

With the entire pillar dictionary now encrypted, it can be included in the CLI pillar data like so:

```bash
salt myminion state.sls secretstuff pillar_enc=gpg pillar="${ciphertext}"
```
salt.renderers.gpg.render(gpg_data, saltenv='base', sls='`, argline='`, **kwargs)

Create a gpg object given a gpg_keydir, and then use it to try to decrypt the data to be rendered.

salt.renderers.hjson

Hjson Renderer for Salt  http://laktak.github.io/hjson/
salt.renderers.hjson.render(hjson_data, saltenv='base', sls='`, **kw)

Accepts HJSON as a string or as a file object and runs it through the HJSON parser.

Return type  A Python data structure

salt.renderers.jinja

Jinja loading util to enable a more powerful backend for jinja templates

For Jinja usage information see Understanding Jinja.

salt.renderers.jinja.render(template_file, saltenv='base', sls='`, argline='`, context=None, tmplpath=None, **kw)

Render the template_file, passing the functions and grains into the Jinja rendering system.

Return type  string

class salt.utils.jinja.SerializerExtension(environment)

Yaml and Json manipulation.

Format filters

Allows jsonifying or yamlifying any data structure. For example, this dataset:

data = {
    'foo': True,
    'bar': 42,
    'baz': [1, 2, 3],
    'qux': 2.0
}

yaml = {{ data|yaml }}
json = {{ data|json }}
python = {{ data|python }}

will be rendered as:

yaml = {"bar": 42, "baz": [1, 2, 3], "foo": true, "qux": 2.0}
json = {"baz": [1, 2, 3], "foo": true, "bar": 42, "qux": 2.0}
python = {'bar': 42, 'baz': [1, 2, 3], 'foo': True, 'qux': 2.0}

The yaml filter takes an optional flow_style parameter to control the default-flow-style parameter of the YAML dumper.

{{ data|yaml(False) }}

will be rendered as:

bar: 42
baz:
  - 1
Load filters

Strings and variables can be deserialized with `load_yaml` and `load_json` tags and filters. It allows one to manipulate data directly in templates, easily:

```yaml
{% set yaml_src = "{foo: it works}"|load_yaml %}
{% set json_src = '{"bar": "for real"}"|load_json %}
Dude, {{ yaml_src.foo }} {{ json_src.bar }}!
```

will be rendered as:

Dude, it works for real!

Load tags

Salt implements `load_yaml` and `load_json` tags. They work like the `import` tag, except that the document is also deserialized.

Syntaxes are `{% load_yaml as [VARIABLE] %}[YOUR DATA]{% endload %} and `{% load_json as [VARIABLE] %}[YOUR DATA]{% endload %}

For example:

```yaml
{% load_yaml as yaml_src %}
foo: it works
{% endload %}
{% load_json as json_src %}
{
   "bar": "for real"
}
{% endload %}
Dude, {{ yaml_src.foo }} {{ json_src.bar }}!
```

will be rendered as:

Dude, it works for real!

Import tags

External files can be imported and made available as a Jinja variable.

```yaml
{% import_yaml "myfile.yml" as myfile %}
{% import_json "defaults.json" as defaults %}
{% import_text "completeworksofshakespeare.txt" as poems %}
```

Catalog

`import_*` and `load_*` tags will automatically expose their target variable to import. This feature makes catalog of data to handle.

for example:

```yaml
# doc1.sls
{% load_yaml as var1 %}
foo: it works
```
salt.renderers.json

JSON Renderer for Salt

salt.renderers.json.render(json_data, saltenv='base', sls='`, **kws)

Accepts JSON as a string or as a file object and runs it through the JSON parser.

Return type  A Python data structure

salt.renderers.json5

JSON5 Renderer for Salt

New in version 2016.3.0.

JSON5 is an unofficial extension to JSON. See http://json5.org/ for more information.

This renderer requires the json5 python bindings, installable via pip.

salt.renderers.json5.render(json_data, saltenv='base', sls='`, **kws)

Accepts JSON as a string or as a file object and runs it through the JSON parser.

Return type  A Python data structure

salt.renderers.mako

Mako Renderer for Salt

salt.renderers.mako.render(template_file, saltenv='base', sls='`, context=None, tmplpath=None, **kws)

Render the template_file, passing the functions and grains into the Mako rendering system.

Return type  string

salt.renderers.msgpack

salt.renderers.msgpack.render(msgpack_data, saltenv='base', sls='`, **kws)

Accepts a message pack string or a file object, renders said data back to a python dict.

Return type  A Python data structure
salt.renderers.py

Pure python state renderer

The SLS file should contain a function called `run` which returns high state data.

In this module, a few objects are defined for you, giving access to Salt's execution functions, grains, pillar, etc. They are:

- `__salt__` - Execution functions (i.e. `__salt__['test.echo']('foo')`)
- `__grains__` - Grains (i.e. `__grains__['os']`)
- `__pillar__` - Pillar data (i.e. `__pillar__['foo']`)
- `__opts__` - Minion configuration options
- `__env__` - The effective salt fileserver environment (i.e. base). Also referred to as a `saltenv`. `__env__` should not be modified in a pure python SLS file. To use a different environment, the environment should be set when executing the state. This can be done in a couple different ways:
  - Using the `saltenv` argument on the salt CLI (i.e. `salt '*' state.sls foo.bar.baz saltenv=env_name`).
  - By adding a `saltenv` argument to an individual state within the SLS file. In other words, adding a line like this to the state's data structure: `{ 'saltenv': 'env_name' }`
- `__sls__` - The SLS path of the file. For example, if the root of the base environment is `/srv/salt`, and the SLS file is `/srv/salt/foo/bar/baz.sls`, then `__sls__` in that file will be `foo.bar.baz`.

```python
#!/py

def run():
    config = {}

    if __grains__['os'] == 'Ubuntu':
        user = 'ubuntu'
        group = 'ubuntu'
        home = '/home/{0}'.format(user)
    else:
        user = 'root'
        group = 'root'
        home = '/root/

    config['s3cmd'] = {
        'pkg': [  
            'installed',  
            { 'name': 's3cmd' },  
        ],
    }

    config[home + '/.s3cfg'] = {
        'file.managed': [  
            {'source': 'salt://s3cfg/templates/s3cfg'},  
            {'template': 'jinja'},  
            {'user': user},  
            {'group': group},  
            {'mode': 600},  
            {'context': {  
                'aws_key': __pillar__['AWS_ACCESS_KEY_ID'],  
                'aws_secret_key': __pillar__['AWS_SECRET_ACCESS_KEY'],  
            }},
        ],
    }
```
32 }},
33 },
34 }
35 }
36 }
37 } return config

salt.renderers.py.render(template, saltenv='base', sls='', tmplpath=None, **kws)

Render the python module's components

Return type string

salt.renderers.pydsl

A Python-based DSL

maintainer Jack Kuan <kjkuan@gmail.com>
maturity new
platform all

The pydsl renderer allows one to author salt formulas (.sls files) in pure Python using a DSL that's easy to write and easy to read. Here's an example:

```python
#!pydsl
apache = state('apache')
apache.pkg.installed()
apache.service.running()
state('/var/www/index.html') |
   .file('managed',
      source='salt://webserver/index.html') |
   .require(pkg='apache')
```

Notice that any Python code is allow in the file as it's really a Python module, so you have the full power of Python at your disposal. In this module, a few objects are defined for you, including the usual (with __ added) __salt__ dictionary, __grains__, __pillar__, __opts__, __env__, and __sls__, plus a few more:

__file__
local file system path to the sls module.

__pydsl__
Salt PyDSL object, useful for configuring DSL behavior per sls rendering.

include
Salt PyDSL function for creating Include declaration's.

extend
Salt PyDSL function for creating Extend declaration's.

state
Salt PyDSL function for creating ID declaration's.

A state ID declaration is created with a state(id) function call. Subsequent state(id) call with the same id returns the same object. This singleton access pattern applies to all declaration objects created with the DSL.

2.23. Renderers 277
state('example')
assert state('example') is state('example')
assert state('example').cmd is state('example').cmd
assert state('example').cmd.running is state('example').cmd.running

The *id* argument is optional. If omitted, an UUID will be generated and used as the *id*.

state(id) returns an object under which you can create a *State declaration* object by accessing an attribute named after any state module available in Salt.

state('example').cmd
state('example').file
state('example').pkg
...

Then, a *Function declaration* object can be created from a *State declaration* object by one of the following two ways:

1. by calling a method named after the state function on the *State declaration* object.

   state('example').file.managed(...)

2. by directly calling the attribute named for the *State declaration*, and supplying the state function name as the first argument.

   state('example').file('managed', ...)

With either way of creating a *Function declaration* object, any *Function arg declaration*’s can be passed as keyword arguments to the call. Subsequent calls of a *Function declaration* will update the arg declarations.

state('example').file('managed', source='salt://webserver/index.html')
state('example').file.managed(source='salt://webserver/index.html')

As a shortcut, the special *name* argument can also be passed as the first or second positional argument depending on the first or second way of calling the *State declaration* object. In the following two examples *ls -la* is the *name* argument.

state('example').cmd.run('ls -la', cwd='/')
state('example').cmd('run', 'ls -la', cwd='/')

Finally, a *Requisite declaration* object with its *Requisite reference*’s can be created by invoking one of the requisite methods (see *State Requisites*) on either a *Function declaration* object or a *State declaration* object. The return value of a requisite call is also a *Function declaration* object, so you can chain several requisite calls together.

Arguments to a requisite call can be a list of *State declaration* objects and/or a set of keyword arguments whose names are state modules and values are IDs of *ID declaration*’s or names of *Name declaration*’s.

```
apache2 = state('apache2')
apache2.pkg.installed()
state('libapache2-mod-wsgi').pkg.installed()

# you can call requisites on function declaration
apache2.service.running() |
  .require(apache2.pkg,  
    pkg='libapache2-mod-wsgi') |
  .watch(file=':/etc/apache2/httpd.conf')

# or you can call requisites on state declaration.
# this actually creates an anonymous function declaration object
```
# to add the requisites.
apache2.service.require(state('libapache2-mod-wsgi').pkg,
pkg='apache2') \
.watch(file='/etc/apache2/httpd.conf')

# we still need to set the name of the function declaration.
apache2.service.running()

Include declaration objects can be created with the `include` function, while Extend declaration objects can be created with the `extend` function, whose arguments are just Function declaration objects.

```python
include('edit.vim', 'http.server')
extend(state('apache2').service.watch(file='/etc/httpd/httpd.conf'))
```

The `include` function, by default, causes the included sls file to be rendered as soon as the `include` function is called. It returns a list of rendered module objects; sls files not rendered with the pydsl renderer return `None`'s. This behavior creates no Include declaration's in the resulting high state data structure.

```python
# including multiple sls returns a list.
_, mod = include('a-non-pydsl-sls', 'a-pydsl-sls')

assert _ is None
assert isinstance(slsmods[1], types.ModuleType)

# including a single sls returns a single object
mod = include('a-pydsl-sls')

# myfunc is a function that calls state(...) to create more states.
mod.myfunc(1, 2, "three")
```

Notice how you can define a reusable function in your pydsl sls module and then call it via the module returned by `include`.

It's still possible to do late includes by passing the `delayed=True` keyword argument to `include`.

```python
include('edit.vim', 'http.server', delayed=True)
```

Above will just create a Include declaration in the rendered result, and such call always returns `None`.

Special integration with the cmd state

Taking advantage of rendering a Python module, PyDSL allows you to declare a state that calls a pre-defined Python function when the state is executed.

```python
greeting = "hello world"
def helper(something, *args, **kws):
    print greeting  # hello world
    print something, args, kws  # test123 ['a', 'b', 'c'] {'x': 1, 'y': 2}
state().cmd.call(helper, "test123", 'a', 'b', 'c', x=1, y=2)
```

The `cmd.call` state function takes care of calling our `helper` function with the arguments we specified in the states, and translates the return value of our function into a structure expected by the state system. See `salt.states.cmd.call()` for more information.
Implicit ordering of states

Salt states are explicitly ordered via Requisite declaration’s. However, with pydsl it’s possible to let the renderer track the order of creation for Function declaration objects, and implicitly add require requisites for your states to enforce the ordering. This feature is enabled by setting the ordered option on __pydsl__.

Note: this feature is only available if your minions are using Python >= 2.7.

```python
include('some.sls.file')
A = state('A').cmd.run(cwd='/var/tmp')
extend(A)
__pydsl__.set(ordered=True)
for i in range(10):
    i = str(i)
    state(i).cmd.run('echo '+i, cwd='/')
state('1').cmd.run('echo one')
state('2').cmd.run(name='echo two')
```

Notice that the ordered option needs to be set after any extend calls. This is to prevent pydsl from tracking the creation of a state function that's passed to an extend call.

Above example should create states from 0 to 9 that will output 0, one, two, 3, ... 9, in that order.

It’s important to know that pydsl tracks the creations of Function declaration objects, and automatically adds a require requisite to a Function declaration object that requires the last Function declaration object created before it in the sls file.

This means later calls (perhaps to update the function's Function arg declaration) to a previously created function declaration will not change the order.

Render time state execution

When Salt processes a salt formula file, the file is rendered to salt's high state data representation by a renderer before the states can be executed. In the case of the pydsl renderer, the .sls file is executed as a python module as it is being rendered which makes it easy to execute a state at render time. In pydsl, executing one or more states at render time can be done by calling a configured ID declaration object.

```python
#!pydsl
s = state() # save for later invocation
# configure it
s.cmd.run('echo at render time', cwd='/')
s.file.managed('target.txt', source='salt://source.txt')
s() # execute the two states now
```

Once an ID declaration is called at render time it is detached from the sls module as if it was never defined.
Note: If implicit ordering is enabled (i.e., via `__pydsl__.set(ordered=True)`) then the first invocation of a ID declaration object must be done before a new Function declaration is created.

Integration with the stateconf renderer

The `salt.renderers.stateconf` renderer offers a few interesting features that can be leveraged by the `pydsl` renderer. In particular, when using with the `pydsl` renderer, we are interested in `stateconf`’s sls namespaces feature (via dot-prefixed id declarations), as well as, the automatic `start` and `goal` states generation.

Now you can use `pydsl` with `stateconf` like this:

```#!pydsl|stateconf -ps
include('xxx', 'yyy')
#
# ensure that states in xxx run BEFORE states in this file.
# extend(state('.'start').stateconf.require(stateconf='xxx::goal'))
#
# ensure that states in yyy run AFTER states in this file.
# extend(state('.'goal').stateconf.require_in(stateconf='yyy::start'))
__pydsl__.set(ordered=True)
...
```

`-s` enables the generation of a stateconf `start` state, and `-p` lets us pipe high state data rendered by `pydsl` to `stateconf`. This example shows that by require-ing or require_in-ing the included sls’ `start` or `goal` states, it’s possible to ensure that the included sls files can be made to execute before or after a state in the including sls file.

Importing custom Python modules

To use a custom Python module inside a PyDSL state, place the module somewhere that it can be loaded by the Salt loader, such as `_modules` in the `/srv/salt` directory.

Then, copy it to any minions as necessary by using `saltutil.sync_modules`.

To import into a PyDSL SLS, one must bypass the Python importer and insert it manually by getting a reference from Python’s `sys.modules` dictionary.

For example:

```#!pydsl|stateconf -ps
def main():
  my_mod = sys.modules['salt.loaded.ext.module.my_mod']

salt.renderers.pydsl.render(template, saltenv='base', sls='...', tmplpath=None, rendered_sls=None, **kws)

salt.renderers.pyobjects
```

Python renderer that includes a Pythonic Object based interface
Let’s take a look at how you use pyobjects in a state file. Here’s a quick example that ensures the /tmp directory is in the correct state.

```python
#!pyobjects
File.managed("/tmp", user='root', group='root', mode='1777')
```

Nice and Pythonic!

By using the ``shebang'' syntax to switch to the pyobjects renderer we can now write our state data using an object based interface that should feel at home to python developers. You can import any module and do anything that you’d like (with caution, importing SQLAlchemy, Django or other large frameworks has not been tested yet). Using the pyobjects renderer is exactly the same as using the built-in Python renderer with the exception that pyobjects provides you with an object based interface for generating state data.

Creating state data

Pyobjects takes care of creating an object for each of the available states on the minion. Each state is represented by an object that is the CamelCase version of its name (i.e. File, Service, User, etc), and these objects expose all of their available state functions (i.e. File.managed, Service.running, etc).

The name of the state is split based upon underscores (_), then each part is capitalized and finally the parts are joined back together.

Some examples:

- `postgres_user` becomes `PostgresUser`
- `ssh_known_hosts` becomes `SshKnownHosts`

Context Managers and requisites

How about something a little more complex. Here we’re going to get into the core of how to use pyobjects to write states.

```python
#!pyobjects
with Pkg.installed("nginx"):
    Service.running("nginx", enable=True)
    with Service("nginx", "watch_in"):
        File.managed("/etc/nginx/conf.d/mysite.conf",
                    owner='root', group='root', mode='0444',
                    source='salt://nginx/mysite.conf')
```

The objects that are returned from each of the magic method calls are setup to be used a Python context managers (with) and when you use them as such all declarations made within the scope will automatically use the enclosing state as a requisite!

The above could have also been written use direct requisite statements as.

```python
#!pyobjects
Pkg.installed("nginx")
    Service.running("nginx", enable=True, require=Pkg("nginx"))
```
You can use the direct requisite statement for referencing states that are generated outside of the current file.

```python
#!pyobjects
# some-other-package is defined in some other state file
Pkg.installed("nginx", require=Pkg("some-other-package"))
```

The last thing that direct requisites provide is the ability to select which of the SaltStack requisites you want to use (require, require_in, watch, watch_in, use & use_in) when using the requisite as a context manager.

```python
#!pyobjects
with Service("my-service", "watch_in"):
...
```

The above example would cause all declarations inside the scope of the context manager to automatically have their `watch_in` set to `Service("my-service")`.

**Including and Extending**

To include other states use the `include()` function. It takes one name per state to include.

To extend another state use the `extend()` function on the name when creating a state.

```python
#!pyobjects
include('http', 'ssh')
Service.running(extend('apache'),
    watch=[File('/etc/httpd/extra/httpd-vhosts.conf')])
```

**Importing from other state files**

Like any Python project that grows you will likely reach a point where you want to create reusability in your state tree and share objects between state files, Map Data (described below) is a perfect example of this. To facilitate this Python's `import` statement has been augmented to allow for a special case when working with a Salt state tree. If you specify a Salt url (`salt://...`) as the target for importing from then the pyobjects renderer will take care of fetching the file for you, parsing it with all of the pyobjects features available and then place the requested objects in the global scope of the template being rendered.

This works for all types of import statements; `import X`, `from X import Y`, and `from X import Y as Z`.

```python
#!pyobjects
import salt://myfile.sls
from salt://something/data.sls import Object
from salt://something/data.sls import Object as Other
```
See the Map Data section for a more practical use.

Caveats:
- Imported objects are ALWAYS put into the global scope of your template, regardless of where your import statement is.

Salt object

In the spirit of the object interface for creating state data pyobjects also provides a simple object interface to the __salt__ object.
A function named salt exists in scope for your sls files and will dispatch its attributes to the __salt__ dictionary.

The following lines are functionally equivalent:

```python
#!pyobjects
ret = salt.cmd.run(bar)
ret = __salt__['cmd.run'](bar)
```

Pillar, grain, mine & config data

Pyobjects provides shortcut functions for calling pillar.get, grains.get, mine.get & config.get on the __salt__ object. This helps maintain the readability of your state files.

Each type of data can be access by a function of the same name: pillar(), grains(), mine() and config().

The following pairs of lines are functionally equivalent:

```python
#!pyobjects
value = pillar('foo:bar:baz', 'qux')
value = __salt__['pillar.get']('foo:bar:baz', 'qux')
value = grains('pkg:apache')
value = __salt__['grains.get']('pkg:apache')
value = mine('os:Fedora', 'network.interfaces', 'grain')
value = __salt__['mine.get']('os:Fedora', 'network.interfaces', 'grain')
value = config('foo:bar:baz', 'qux')
value = __salt__['config.get']('foo:bar:baz', 'qux')
```

Map Data

When building complex states or formulas you often need a way of building up a map of data based on grain data. The most common use of this is tracking the package and service name differences between distributions.

To build map data using pyobjects we provide a class named Map that you use to build your own classes with inner classes for each set of values for the different grain matches.

```python
#!pyobjects
class Samba(Map):
    merge = 'samba:lookup'
```
To use this new data you can import it into your state file and then access your attributes. To access the data in the map you simply access the attribute name on the base class that is extending Map. Assuming the above Map was in the file `samba/map.sls`, you could do the following.

```python
#!pyobjects
from salt://samba/map.sls import Samba

with Pkg.installed("samba", names=[Samba.server, Samba.client]):
    Service.running("samba", name=Samba.service)
```

**TODO**

- Interface for working with reactor files

```python
class salt.renderers.pyobjects.PyobjectsModule(name, attrs)
    This provides a wrapper for bare imports.

class salt.renderers.pyobjects.load_states()
    This loads our states into the salt __context__

class salt.renderers.pyobjects.render(template, saltenv='base', sls='', salt_data=True, **kwargs)
```

**salt.renderers.stateconf**

```python
    maintainer Jack Kuan <kjkuan@gmail.com>
    maturity new
    platform all
```

This module provides a custom renderer that processes a salt file with a specified templating engine (e.g. Jinja) and a chosen data renderer (e.g. YAML), extracts arguments for any `stateconf.set` state, and provides the extracted arguments (including Salt-specific args, such as `require`, etc) as template context. The goal is to make writing reusable/configurable/parameterized salt files easier and cleaner.

To use this renderer, either set it as the default renderer via the `renderer` option in master/minion's config, or use the shebang line in each individual `sls` file, like so: `#!stateconf`. Note, due to the way this renderer works, it must be specified as the first renderer in a render pipeline. That is, you cannot specify `#!mako|yaml|stateconf`, for example. Instead, you specify them as renderer arguments: `#!stateconf mako . yaml`.

Here’s a list of features enabled by this renderer.
• Prefixes any state id (declaration or reference) that starts with a dot (.) to avoid duplicated state ids when the salt file is included by other salt files.

For example, in the `salt://some/file.sls`, a state id such as `.sls_params` will be turned into `some.file::sls_params`. Example:

```yaml
#!stateconf yaml . jinja
.vim:
  pkg.installed
```

Above will be translated into:

```yaml
some.file::vim:
  pkg.installed:
    - name: vim
```

Notice how that if a state under a dot-prefixed state id has no `name` argument then one will be added automatically by using the state id with the leading dot stripped off.

The leading dot trick can be used with extending state ids as well, so you can include relatively and extend relatively. For example, when extending a state in `salt://some/other_file.sls`, e.g.:

```yaml
#!stateconf yaml . jinja
include:
  - .file
extend:
  .file::sls_params:
    stateconf.set:
      - name1: something
```

Above will be pre-processed into:

```yaml
include:
  - some.file
extend:
  some.file::sls_params:
    stateconf.set:
      - name1: something
```

• Adds a `sls_dir` context variable that expands to the directory containing the rendering salt file. So, you can write `salt://{{sls_dir}}/...` to reference templates files used by your salt file.

• Recognizes the special state function, `stateconf.set`, that configures a default list of named arguments usable within the template context of the salt file. Example:

```yaml
#!stateconf yaml . jinja
.sls_params:
  stateconf.set:
    - name1: value1
    - name2: value2
    - name3:
      - value1
      - value2
      - value3
```
- require_in:
  - cmd: output

# --- end of state config ---
.output:
  cmd.run:
    - name: |
      echo 'name1={{sls_params.name1}}
      name2={{sls_params.name2}}
      name3[1]={{sls_params.name3[1]}}

This even works with include + extend so that you can override the default configured arguments by including the salt file and then extend the stateconf.set states that come from the included salt file. (IMPORTANT: Both the included and the extending sls files must use the stateconf renderer for this `extend` to work!)

Notice that the end of configuration marker (# ---end of state config --) is needed to separate the use of `stateconf.set` form the rest of your salt file. The regex that matches such marker can be configured via the stateconf_end_marker option in your master or minion config file.

Sometimes, it is desirable to set a default argument value that’s based on earlier arguments in the same stateconf.set. For example, it may be tempting to do something like this:

```yaml
#!stateconf yaml . jinja
.apache:
  stateconf.set:
    - host: localhost
    - port: 1234
    - url: 'http://{{host}}:{{port}}/

# --- end of state config ---
# {{ apache.setdefault('url', "http://%(host)s:%(port)s/" % apache) }}
.test:
  cmd.run:
    - name: echo '{{apache.url}}'
    - cwd: /
```

However, this won’t work. It can however be worked around like so:

```yaml
#!stateconf yaml . jinja
.apache:
  stateconf.set:
    - host: localhost
    - port: 1234
    [ # - url: 'http://{{host}}:{{port}}/' #]

# --- end of state config ---
# {{ apache.setdefault('url', "http://%(host)s:%(port)s/" % apache) }}
.test:
  cmd.run:
    - name: echo '{{apache.url}}'
    - cwd: /
```
• Adds support for relative include and exclude of .sls files. Example:

```yaml
#!stateconf yaml . jinja
include:
- .apache
- .db.mysql
- ..app.django

exclude:
- sls: .users
```

If the above is written in a salt file at `salt://some/where.sls` then it will include `salt://some/apache.sls`, `salt://some/db/mysql.sls` and `salt://app/django.sls`, and exclude `salt://some/users.ssl`. Actually, it does that by rewriting the above `include` and `exclude` into:

```yaml
include:
- some.apache
- some.db.mysql
- app.django

exclude:
- sls: some.users
```

• Optionally (enabled by default, `disable` via the `-G` renderer option, e.g. in the shebang line: `#!stateconf -G`), generates a `stateconf.set` goal state (state id named as `.goal` by default, configurable via the master/minion config option, `stateconf_goal_state`) that requires all other states in the salt file. Note, the `.goal` state id is subject to dot-prefix rename rule mentioned earlier.

Such goal state is intended to be required by some state in an including salt file. For example, in your webapp salt file, if you include a sls file that is supposed to setup Tomcat, you might want to make sure that all states in the Tomcat sls file will be executed before some state in the webapp sls file.

• Optionally (enable via the `-o` renderer option, e.g. in the shebang line: `#!stateconf -o`), orders the states in a sls file by adding a `require` requisite to each state such that every state requires the state defined just before it. The order of the states here is the order they are defined in the sls file. (Note: this feature is only available if your minions are using Python >= 2.7. For Python2.6, it should also work if you install the `ordereddict` module from PyPI)

By enabling this feature, you are basically agreeing to author your sls files in a way that gives up the explicit (or implicit?) ordering imposed by the use of `require`, `watch`, `require_in` or `watch_in` requisites, and instead, you rely on the order of states you define in the sls files. This may or may not be a better way for you. However, if there are many states defined in a sls file, then it tends to be easier to see the order they will be executed with this feature.

You are still allowed to use all the requisites, with a few restrictions. You cannot `require` or `watch` a state defined `after` the current state. Similarly, in a state, you cannot `require_in` or `watch_in` a state defined `before` it. Breaking any of the two restrictions above will result in a state loop. The renderer will check for such incorrect uses if this feature is enabled.

Additionally, `names` declarations cannot be used with this feature because the way they are compiled into low states make it impossible to guarantee the order in which they will be executed. This is also checked by the renderer. As a workaround for not being able to use `names`, you can achieve the same effect, by generate your states with the template engine available within your sls file.

Finally, with the use of this feature, it becomes possible to easily make an included sls file execute all its states `after` some state (say, with id X) in the including sls file. All you have to do is to make state, X, `require_in` the first state defined in the included sls file.
When writing sls files with this renderer, one should avoid using what can be defined in a `name` argument of a state as the state's id. That is, avoid writing states like this:

```
/path/to/some/file:
  file.managed:
    - source: salt://some/file

cp /path/to/some/file file2:
  cmd.run:
    - cwd: /  
    - require:
      - file: /path/to/some/file
```

Instead, define the state id and the `name` argument separately for each state. Also, the ID should be something meaningful and easy to reference within a requisite (which is a good habit anyway, and such extra indirection would also makes the sls file easier to modify later). Thus, the above states should be written like this:

```
add-some-file:
  file.managed:
    - name: /path/to/some/file
    - source: salt://some/file

copy-files:
  cmd.run:
    - name: cp /path/to/some/file file2
    - cwd: /  
    - require:
      - file: add-some-file
```

Moreover, when referencing a state from a requisite, you should reference the state's id plus the state name rather than the state name plus its `name` argument. (Yes, in the above example, you can actually require the `file: /path/to/some/file`, instead of the `file: add-some-file`). The reason is that this renderer will re-write or rename state id's and their references for state id's prefixed with .. So, if you reference `name` then there's no way to reliably rewrite such reference.

```
salt.renderers.wempy

salt.renderers.wempy.render(template_file, saltenv='base', sls='`, argline='`, context=None, **kws)

Render the data passing the functions and grains into the rendering system

Return type string
```

```
salt.renderers.yamlex

YAMLEX renderer is a replacement of the YAML renderer. It's 100% YAML with a pinch of Salt magic:
- All mappings are automatically OrderedDict
- All strings are automatically str obj
- data aggregation with !aggregation yaml tag, based on the salt.utils.aggregation module.
- data aggregation over documents for pillar

Instructed aggregation within the !aggregation and the !reset tags:
```

2.23. Renderers
#!yamlex
foo: !aggregate first
foo: !aggregate second
bar: !aggregate {first: foo}
bar: !aggregate {second: bar}
baz: !aggregate 42
qux: !aggregate default
!reset qux: !aggregate my custom data

is roughly equivalent to

foo: [first, second]
bar: {first: foo, second: bar}
baz: [42]
qux: [my custom data]

Reference

salt.renderers.yamlex.render(sls_data, saltenv='base', sls='...', **kws)

Accepts YAML_EX as a string or as a file object and runs it through the YAML_EX parser.

Return type A Python data structure
This section describes the fundamental components and concepts that you need to understand to use Salt.

3.1 Grains

Salt comes with an interface to derive information about the underlying system. This is called the grains interface, because it presents salt with grains of information. Grains are collected for the operating system, domain name, IP address, kernel, OS type, memory, and many other system properties.

The grains interface is made available to Salt modules and components so that the right salt minion commands are automatically available on the right systems.

Grain data is relatively static, though if system information changes (for example, if network settings are changed), or if a new value is assigned to a custom grain, grain data is refreshed.

Note: Grains resolve to lowercase letters. For example, FOO, and foo target the same grain.

3.1.1 Listing Grains

Available grains can be listed by using the `grains.ls` module:

```bash
salt '*' grains.ls
```

Grains data can be listed by using the `grains.items` module:

```bash
salt '*' grains.items
```

3.1.2 Grains in the Minion Config

Grains can also be statically assigned within the minion configuration file. Just add the option `grains` and pass options to it:

```yaml
grains:
  roles:
    - webserver
    - memcache
  deployment: datacenter4
```
Then status data specific to your servers can be retrieved via Salt, or used inside of the State system for matching. It also makes targeting, in the case of the example above, simply based on specific data about your deployment.

### 3.1.3 Grains in /etc/salt/grains

If you do not want to place your custom static grains in the minion config file, you can also put them in `/etc/salt/grains` on the minion. They are configured in the same way as in the above example, only without a top-level `grains: key:

```yaml
roles:
  - webserver
  - memcache
deployment: datacenter4
cabinet: 13
cab_u: 14-15
```

### 3.1.4 Matching Grains in the Top File

With correctly configured grains on the Minion, the top file used in Pillar or during Highstate can be made very efficient. For example, consider the following configuration:

```yaml
'node_type:webserver':
  - match: grain
  - webserver

'node_type:postgres':
  - match: grain
  - postgres

'node_type:redis':
  - match: grain
  - redis

'node_type:lb':
  - match: grain
  - lb
```

For this example to work, you would need to have defined the grain `node_type` for the minions you wish to match. This simple example is nice, but too much of the code is similar. To go one step further, Jinja templating can be used to simplify the top file.

```python
{% set the_node_type = salt['grains.get']('node_type', '') %}
{% if the_node_type %}
  'node_type:{{ the_node_type }}':
    - match: grain
    - {{ the_node_type }}
{% endif %}
```

Using Jinja templating, only one match entry needs to be defined.
Note: The example above uses the grains.get function to account for minions which do not have the node_type grain set.

3.1.5 Writing Grains

The grains are derived by executing all of the “public” functions (i.e. those which do not begin with an underscore) found in the modules located in the Salt’s core grains code, followed by those in any custom grains modules. The functions in a grains module must return a Python dict, where the dictionary keys are the names of grains, and each key's value is that value for that grain.

Custom grains modules should be placed in a subdirectory named _grains located under the file_roots specified by the master config file. The default path would be /srv/salt/_grains. Custom grains modules will be distributed to the minions when state.highstate is run, or by executing the saltutil.sync_grains or saltutil.sync_all functions.

Grains modules are easy to write, and (as noted above) only need to return a dictionary. For example:

```python
def yourfunction():
    # initialize a grains dictionary
    grains = {}
    # Some code for logic that sets grains like
    grains['yourcustomgrain'] = True
    grains['anothergrain'] = 'somevalue'
    return grains
```

The name of the function does not matter and will not factor into the grains data at all; only the keys/values returned become part of the grains.

When to Use a Custom Grain

Before adding new grains, consider what the data is and remember that grains should (for the most part) be static data.

If the data is something that is likely to change, consider using Pillar or an execution module instead. If it’s a simple set of key/value pairs, pillar is a good match. If compiling the information requires that system commands be run, then putting this information in an execution module is likely a better idea.

Good candidates for grains are data that is useful for targeting minions in the top file or the Salt CLI. The name and data structure of the grain should be designed to support many platforms, operating systems or applications. Also, keep in mind that Jinja templating in Salt supports referencing pillar data as well as invoking functions from execution modules, so there’s no need to place information in grains to make it available to Jinja templates. For example:

```plaintext
... ... 
{{ salt['module.function_name']('argument_1', 'argument_2') }}
{{ pillar['my_pillar_key'] }}
... ... 
```
Warning: Custom grains will not be available in the top file until after the first highstate. To make custom grains available on a minion's first highstate, it is recommended to use this example to ensure that the custom grains are synced when the minion starts.

Loading Custom Grains

If you have multiple functions specifying grains that are called from a main function, be sure to prepend grain function names with an underscore. This prevents Salt from including the loaded grains from the grain functions in the final grain data structure. For example, consider this custom grain file:

```python
#!/usr/bin/env python

def _my_custom_grain():
    my_grain = {'foo': 'bar', 'hello': 'world'}
    return my_grain

def main():
    # initialize a grains dictionary
    grains = {}
    grains['my_grains'] = _my_custom_grain()
    return grains
```

The output of this example renders like so:

```
# salt-call --local grains.items
local:
    ---------
    <Snipped for brevity>
    my_grains:
    ---------
    foo:
    bar
    hello:
    world
```

However, if you don't prepend the my_custom_grain function with an underscore, the function will be rendered twice by Salt in the items output: once for the my_custom_grain call itself, and again when it is called in the main function:

```
# salt-call --local grains.items
local:
    ---------
    <Snipped for brevity>
    foo:
        bar
    <Snipped for brevity>
    hello:
        world
    <Snipped for brevity>
    my_grains:
    ---------
    foo:
        bar
    hello:
        world
```
3.1.6 Precedence

Core grains can be overridden by custom grains. As there are several ways of defining custom grains, there is an order of precedence which should be kept in mind when defining them. The order of evaluation is as follows:

1. Core grains.
2. Custom grains in /etc/salt/grains.
3. Custom grains in /etc/salt/minion.
4. Custom grain modules in _grains directory, synced to minions.

Each successive evaluation overrides the previous ones, so any grains defined by custom grains modules synced to minions that have the same name as a core grain will override that core grain. Similarly, grains from /etc/salt/minion override both core grains and custom grain modules, and grains in _grains will override any grains of the same name.

3.1.7 Examples of Grains

The core module in the grains package is where the main grains are loaded by the Salt minion and provides the principal example of how to write grains:

https://github.com/saltstack/salt/blob/develop/salt/grains/core.py

3.1.8 Syncing Grains

Syncing grains can be done a number of ways, they are automatically synced when state.highstate is called, or (as noted above) the grains can be manually synced and reloaded by calling the saltutil.sync_grains or saltutil.sync_all functions.

3.2 Storing Static Data in the Pillar

Pillar is an interface for Salt designed to offer global values that can be distributed to all minions. Pillar data is managed in a similar way as the Salt State Tree.

Pillar was added to Salt in version 0.9.8

---

**Note:** Storing sensitive data

Pillar data is compiled on the master. Additionally, pillar data for a given minion is only accessible by the minion for which it is targeted in the pillar configuration. This makes pillar useful for storing sensitive data specific to a particular minion.

---

3.2.1 Declaring the Master Pillar

The Salt Master server maintains a pillar_roots setup that matches the structure of the file_roots used in the Salt file server. Like file_roots, the pillar_roots option mapps environments to directories. The pillar data is then mapped to minions based on matchers in a top file which is laid out in the same way as the state top file. Salt pillars can use the same matcher types as the standard top file.

conf_master:pillar_roots is configured just like file_roots. For example:
pillar_roots:
  base:
    - /srv/pillar

This example configuration declares that the base environment will be located in the /srv/pillar directory. It must not be in a subdirectory of the state tree.

The top file used matches the name of the top file used for States, and has the same structure:
/srv/pillar/top.sls

base:
  '*':
    - packages

In the above top file, it is declared that in the base environment, the glob matching all minions will have the pillar data found in the packages pillar available to it. Assuming the pillar_roots value of /srv/pillar taken from above, the packages pillar would be located at /srv/pillar/packages.sls.

Any number of matchers can be added to the base environment. For example, here is an expanded version of the Pillar top file stated above:
/srv/pillar/top.sls:

base:
  '*':
    - packages
  'web*':
    - vim

In this expanded top file, minions that match web* will have access to the /srv/pillar/pacakges.sls file, as well as the /srv/pillar/vim.sls file.

Another example shows how to use other standard top matching types to deliver specific salt pillar data to minions with different properties.

Here is an example using the grains matcher to target pillars to minions by their os grain:
/dev:
  'os:Debian':
    - match:  grain
    - servers

/srv/pillar/packages.sls

{% if grains['os'] == 'RedHat' %}
apache:  httpd
git:  git
{% endif %}

{% elif grains['os'] == 'Debian' %}
apache:  apache2
git:  git-core
{% endif %}

company:  Foo Industries

Important:  See Is Targeting using Grain Data Secure? for important security information.
The above pillar sets two key/value pairs. If a minion is running RedHat, then the `apache` key is set to `httpd` and the `git` key is set to the value of `git`. If the minion is running Debian, those values are changed to `apache2` and `git-core` respectively. All minions that have this pillar targeting to them via a top file will have the key of `company` with a value of `Foo Industries`.

Consequently this data can be used from within modules, renderers, State SLS files, and more via the shared pillar dict:

```yaml
apache:
  pkg.installed:
    - name: {{ pillar['apache'] }}

git:
  pkg.installed:
    - name: {{ pillar['git'] }}
```

Finally, the above states can utilize the values provided to them via Pillar. All pillar values targeted to a minion are available via the `pillar` dictionary. As seen in the above example, Jinja substitution can then be utilized to access the keys and values in the Pillar dictionary.

Note that you cannot just list key/value-information in `top.sls`. Instead, target a minion to a pillar file and then list the keys and values in the pillar. Here is an example top file that illustrates this point:

```yaml
base:
  '*':
    - common_pillar
```

And the actual pillar file at `/srv/pillar/common_pillar.sls`:

```yaml
foo: bar
boo: baz
```

### 3.2.2 Pillar Namespace Flattening

The separate pillar SLS files all merge down into a single dictionary of key-value pairs. When the same key is defined in multiple SLS files, this can result in unexpected behavior if care is not taken to how the pillar SLS files are laid out.

For example, given a `top.sls` containing the following:

```yaml
base:
  '*':
    - packages
    - services
```

with `packages.sls` containing:

```yaml
bind: bind9
```

and `services.sls` containing:

```yaml
bind: named
```

Then a request for the `bind` pillar key will only return `named`. The `bind9` value will be lost, because `services.sls` was evaluated later.
Note: Pillar files are applied in the order they are listed in the top file. Therefore conflicting keys will be overwritten in a 'last one wins' manner! For example, in the above scenario conflicting key values in `services` will overwrite those in `packages` because it’s at the bottom of the list.

It can be better to structure your pillar files with more hierarchy. For example the `package.sls` file could be configured like so:

```yaml
packages:
    bind: bind9
```

This would make the `packages` pillar key a nested dictionary containing a `bind` key.

### 3.2.3 Pillar Dictionary Merging

If the same pillar key is defined in multiple pillar SLS files, and the keys in both files refer to nested dictionaries, then the content from these dictionaries will be recursively merged.

For example, keeping the `top.sls` the same, assume the following modifications to the pillar SLS files:

**packages.sls**:

```yaml
bind:
    package-name: bind9
    version: 9.9.5
```

**services.sls**:

```yaml
bind:
    port: 53
    listen-on: any
```

The resulting pillar dictionary will be:

```
$ salt-call pillar.get bind
local:
    listen-on: any
    package-name: bind9
    port: 53
    version: 9.9.5
```

Since both pillar SLS files contained a `bind` key which contained a nested dictionary, the pillar dictionary's `bind` key contains the combined contents of both SLS files' `bind` keys.

### 3.2.4 Including Other Pillars

New in version 0.16.0.

Pillar SLS files may include other pillar files, similar to State files. Two syntaxes are available for this purpose. The simple form simply includes the additional pillar as if it were part of the same file:
include:
  - users

The full include form allows two additional options -- passing default values to the templating engine for the included pillar file as well as an optional key under which to nest the results of the included pillar:

```yaml
include:
  - users:
      defaults:
        sudo: ['bob', 'paul']
      key: users
```

With this form, the included file (users.sls) will be nested within the `users' key of the compiled pillar. Additionally, the `sudo' value will be available as a template variable to users.sls.

### 3.2.5 In-Memory Pillar Data vs. On-Demand Pillar Data

Since compiling pillar data is computationally expensive, the minion will maintain a copy of the pillar data in memory to avoid needing to ask the master to recompile and send it a copy of the pillar data each time pillar data is requested. This in-memory pillar data is what is returned by the `pillar.item`, `pillar.get`, and `pillar.raw` functions.

Also, for those writing custom execution modules, or contributing to Salt's existing execution modules, the in-memory pillar data is available as the `__pillar__` dunder dictionary.

The in-memory pillar data is generated on minion start, and can be refreshed using the `saltutil.refresh_pillar` function:

```
salt '*' saltutil.refresh_pillar
```

This function triggers the minion to asynchronously refresh the in-memory pillar data and will always return `None`. In contrast to in-memory pillar data, certain actions trigger pillar data to be compiled to ensure that the most up-to-date pillar data is available. These actions include:

- Running states
- Running `pillar.items`

Performing these actions will not refresh the in-memory pillar data. So, if pillar data is modified, and then states are run, the states will see the updated pillar data, but `pillar.item`, `pillar.get`, and `pillar.raw` will not see this data unless refreshed using `saltutil.refresh_pillar`.

### 3.2.6 How Pillar Environments Are Handled

When multiple pillar environments are used, the default behavior is for the pillar data from all environments to be merged together. The pillar dictionary will therefore contain keys from all configured environments.

The `pillarenv` minion config option can be used to force the minion to only consider pillar configuration from a single environment. This can be useful in cases where one needs to run states with alternate pillar data, either in a testing/QA environment or to test changes to the pillar data before pushing them live.

For example, assume that the following is set in the minion config file:

```
pillarenv: base
```
This would cause that minion to ignore all other pillar environments besides base when compiling the in-memory pillar data. Then, when running states, the pillarenv CLI argument can be used to override the minion's pillarenv config value:

```sh
salt '*' state.apply mystates pillarenv=testing
```

The above command will run the states with pillar data sourced exclusively from the testing environment, without modifying the in-memory pillar data.

**Note:** When running states, the pillarenv CLI option does not require a pillarenv option to be set in the minion config file. When pillarenv is left unset, as mentioned above all configured environments will be combined. Running states with pillarenv=testing in this case would still restrict the states' pillar data to just that of the testing pillar environment.

### 3.2.7 Viewing Pillar Data

To view pillar data, use the pillar execution module. This module includes several functions, each of them with their own use. These functions include:

- **pillar.item** - Retrieves the value of one or more keys from the in-memory pillar data.
- **pillar.items** - Compiles a fresh pillar dictionary and returns it, leaving the in-memory pillar data untouched. If pillar keys are passed to this function however, this function acts like pillar.item and returns their values from the in-memory pillar data.
- **pillar.raw** - Like pillar.items, it returns the entire pillar dictionary, but from the in-memory pillar data instead of compiling fresh pillar data.
- **pillar.get** - Described in detail below.

### 3.2.8 The pillar.get Function

New in version 0.14.0.

The pillar.get function works much in the same way as the get method in a python dict, but with an enhancement: nested dictionaries can be traversed using a colon as a delimiter.

If a structure like this is in pillar:

```ini
foo:
    bar:
        baz: qux
```

Extracting it from the raw pillar in an sls formula or file template is done this way:

```sh
{{ pillar['foo']['bar']['baz'] }}
```

Now, with the new pillar.get function the data can be safely gathered and a default can be set, allowing the template to fall back if the value is not available:

```sh
{{ salt['pillar.get']('foo:bar:baz', 'qux') }}
```

This makes handling nested structures much easier.

**Note:** pillar.get() vs salt['pillar.get']()
Salt Documentation, Release 2016.3.6

It should be noted that within templating, the pillar variable is just a dictionary.
is means
that calling pillar.get() inside of a template will just use the default dictionary .get() function
which does not include the extra : delimiter functionality. It must be called using the above syntax
(salt['pillar.get']('foo:bar:baz','qux')) to get the salt function, instead of the default dictionary
behavior.

3.2.9 Seing Pillar Data at the Command Line
Pillar data can be set at the command line like the following example:
salt '*' state.apply pillar='{"cheese": "spam"}'

is will add a pillar key of cheese with its value set to spam.
Note: Be aware that when sending sensitive data via pillar on the command-line that the publication containing
that data will be received by all minions and will not be restricted to the targeted minions. is may represent a
security concern in some cases.

3.2.10 Master Config in Pillar
For convenience the data stored in the master conﬁguration ﬁle can be made available in all minion's pillars. is
makes global conﬁguration of services and systems very easy but may not be desired if sensitive data is stored in the
master conﬁguration. is option is disabled by default.
To enable the master conﬁg from being added to the pillar set pillar_opts to True in the minion conﬁg ﬁle:
pillar_opts: True

3.2.11 Minion Config in Pillar
Minion conﬁguration options can be set on pillars. Any option that you want to modify, should be in the ﬁrst level
of the pillars, in the same way you set the options in the conﬁg ﬁle. For example, to conﬁgure the MySQL root
password to be used by MySQL Salt execution module, set the following pillar variable:
mysql.pass: hardtoguesspassword

3.2.12 Master Provided Pillar Error
By default if there is an error rendering a pillar, the detailed error is hidden and replaced with:
Rendering SLS 'my.sls' failed. Please see master log for details.

e error is protected because it's possible to contain templating data which would give that minion information it
shouldn't know, like a password!
To have the master provide the detailed error that could potentially carry protected data set pillar_safe_render_error to False:

3.2. Storing Static Data in the Pillar

301


Pillar Walkthrough

Note: This walkthrough assumes that the reader has already completed the initial Salt walkthrough.

Pillars are tree-like structures of data defined on the Salt Master and passed through to minions. They allow confidential, targeted data to be securely sent only to the relevant minion.

Note: Grains and Pillar are sometimes confused, just remember that Grains are data about a minion which is stored or generated from the minion. This is why information like the OS and CPU type are found in Grains. Pillar is information about a minion or many minions stored or generated on the Salt Master.

Pillar data is useful for:

**Highly Sensitive Data:** Information transferred via pillar is guaranteed to only be presented to the minions that are targeted, making Pillar suitable for managing security information, such as cryptographic keys and passwords.

**Minion Configuration:** Minion modules such as the execution modules, states, and returners can often be configured via data stored in pillar.

**Variables:** Variables which need to be assigned to specific minions or groups of minions can be defined in pillar and then accessed inside sls formulas and template files.

**Arbitrary Data:** Pillar can contain any basic data structure in dictionary format, so a key/value store can be defined making it easy to iterate over a group of values in sls formulas.

Pillar is therefore one of the most important systems when using Salt. This walkthrough is designed to get a simple Pillar up and running in a few minutes and then to dive into the capabilities of Pillar and where the data is available.

Setting Up Pillar

The pillar is already running in Salt by default. To see the minion's pillar data:

```
salt '*' pillar.items
```

Note: Prior to version 0.16.2, this function is named `pillar.data`. This function name is still supported for backwards compatibility.

By default, the contents of the master configuration file are not loaded into pillar for all minions. This default is stored in the `pillar_opts` setting, which defaults to `False`.

The contents of the master configuration file can be made available to minion pillar files. This makes global configuration of services and systems very easy, but note that this may not be desired or appropriate if sensitive data is stored in the master's configuration file. To enable the master configuration file to be available to a minion's pillar files, set `pillar_opts` to `True` in the minion configuration file.

Similar to the state tree, the pillar is comprised of sls files and has a top file. The default location for the pillar is in `/srv/pillar`. 
Note: The pillar location can be configured via the `pillar_roots` option inside the master configuration file. It must not be in a subdirectory of the state tree or `file_roots`. If the pillar is under `file_roots`, any pillar targeting can be bypassed by minions.

To start setting up the pillar, the `/srv/pillar` directory needs to be present:

```bash
mkdir /srv/pillar
```

Now create a simple top file, following the same format as the top file used for states:

```bash
/srv/pillar/top.sls:
```

```yaml
base:
  '*':
    - data
```

This top file associates the data.sls file to all minions. Now the `/srv/pillar/data.sls` file needs to be populated:

```bash
/srv/pillar/data.sls:
```

```yaml
info: some data
```

To ensure that the minions have the new pillar data, issue a command to them asking that they fetch their pillars from the master:

```bash
salt '*' saltutil.refresh_pillar
```

Now that the minions have the new pillar, it can be retrieved:

```bash
salt '*' pillar.items
```

The key `info` should now appear in the returned pillar data.

**More Complex Data**

Unlike states, pillar files do not need to define formulas. This example sets up user data with a UID:

```bash
/srv/pillar/users/init.sls:
```

```yaml
users:
  thatch: 1000
  shouse: 1001
  utahdave: 1002
  redbeard: 1003
```

Note: The same directory lookups that exist in states exist in pillar, so the file `users/init.sls` can be referenced with `users` in the top file.

The top file will need to be updated to include this sls file:

```bash
/srv/pillar/top.sls:
```

3.2. Storing Static Data in the Pillar 303
Now the data will be available to the minions. To use the pillar data in a state, you can use Jinja:

```
/srv/salt/users/init.sls

{% for user, uid in pillar.get('users', {}).items() %}
  user.present:
    - uid: {{uid}}
{% endfor %}
```

This approach allows for users to be safely defined in a pillar and then the user data is applied in an sls file.

### Parameterizing States With Pillar

Pillar data can be accessed in state files to customise behavior for each minion. All pillar (and grain) data applicable to each minion is substituted into the state files through templating before being run. Typical uses include setting directories appropriate for the minion and skipping states that don't apply.

A simple example is to set up a mapping of package names in pillar for separate Linux distributions:

```
/srv/pillar/pkg/init.sls:

pkgs:
  {% if grains['os_family'] == 'RedHat' %}
    apache: httpd
    vim: vim-enhanced
  {% elif grains['os_family'] == 'Debian' %}
    apache: apache2
    vim: vim
  {% elif grains['os'] == 'Arch' %}
    apache: apache
    vim: vim
  {% endif %}
```

The new pkg sls needs to be added to the top file:

```
/srv/pillar/top.sls:

base:
  '*':
    - data
    - users
    - pkg
```

Now the minions will auto map values based on respective operating systems inside of the pillar, so sls files can be safely parameterized:

```
/srv/salt/apache/init.sls:

apache:
  pkg.installed:
    - name: {{ pillar['pkgs']['apache'] }}
```
Or, if no pillar is available a default can be set as well:

Note: The function pillar.get used in this example was added to Salt in version 0.14.0

```
/srv/salt/apache/init.sls:
apache:
  pkg.installed:
    - name: {{ salt['pillar.get']('pkgs:apache', 'httpd') }}
```

In the above example, if the pillar value pillar['pkgs']['apache'] is not set in the minion's pillar, then the default of httpd will be used.

Note: Under the hood, pillar is just a Python dict, so Python dict methods such as get and items can be used.

**Pillar Makes Simple States Grow Easily**

One of the design goals of pillar is to make simple sls formulas easily grow into more flexible formulas without refactoring or complicating the states.

A simple formula:

```
/srv/salt/edit/vim.sls:
```

```
vim:
  pkg.installed: []
/etc/vimrc:
  file.managed:
    - source: salt://edit/vimrc
    - mode: 644
    - user: root
    - group: root
    - require:
      - pkg: vim
```

Can be easily transformed into a powerful, parameterized formula:

```
/srv/salt/edit/vim.sls:
```

```
vim:
  pkg.installed:
    - name: {{ pillar['pkgs']['vim'] }}
/etc/vimrc:
  file.managed:
    - source: {{ pillar['vimrc'] }}
    - mode: 644
    - user: root
    - group: root
    - require:
      - pkg: vim
```

Where the vimrc source location can now be changed via pillar:

### 3.2. Storing Static Data in the Pillar
Salt Documentation, Release 2016.3.6

/srv/pillar/edit/vim.sls:
{% if grains['id'].startswith('dev') %}
vimrc: salt://edit/dev_vimrc
{% elif grains['id'].startswith('qa') %}
vimrc: salt://edit/qa_vimrc
{% else %}
vimrc: salt://edit/vimrc
{% endif %}

Ensuring that the right vimrc is sent out to the correct minions.
Seing Pillar Data on the Command Line
Pillar data can be set on the command line when running state.apply <salt.modules.state.apply_()
like so:
salt '*' state.apply pillar='{"foo": "bar"}'
salt '*' state.apply my_sls_file pillar='{"hello": "world"}'

Nested pillar values can also be set via the command line:
salt '*' state.sls my_sls_file pillar='{"foo": {"bar": "baz"}}'

Note: If a key is passed on the command line that already exists on the minion, the key that is passed in will
overwrite the entire value of that key, rather than merging only the speciﬁed value set via the command line.
e example below will swap the value for vim with telnet in the previously speciﬁed list, notice the nested pillar
dict:
salt '*' state.apply edit.vim pillar='{"pkgs": {"vim": "telnet"}}'

is will aempt to install telnet on your minions, feel free to uninstall the package or replace telnet value with
anything else.
Note: Be aware that when sending sensitive data via pillar on the command-line that the publication containing
that data will be received by all minions and will not be restricted to the targeted minions. is may represent a
security concern in some cases.

More On Pillar
Pillar data is generated on the Salt master and securely distributed to minions. Salt is not restricted to the pillar sls
ﬁles when deﬁning the pillar but can retrieve data from external sources. is can be useful when information about
an infrastructure is stored in a separate location.
Reference information on pillar and the external pillar interface can be found in the Salt documentation:
Pillar

306

Chapter 3. Using Salt


Minion Config in Pillar

Minion configuration options can be set on pillars. Any option that you want to modify, should be in the first level of the pillars, in the same way you set the options in the config file. For example, to configure the MySQL root password to be used by MySQL Salt execution module:

```
mysql.pass: hardtoguesspassword
```

This is very convenient when you need some dynamic configuration change that you want to be applied on the fly. For example, there is a chicken and the egg problem if you do this:

```
mysql-admin-passwd:
  mysql_user.present:
    - name: root
    - password: somepasswd

mydb:
  mysql_db.present
```

The second state will fail, because you changed the root password and the minion didn't notice it. Setting `mysql.pass` in the pillar, will help to sort out the issue. But always change the root admin password in the first place.

This is very helpful for any module that needs credentials to apply state changes: mysql, keystone, etc.

### 3.3 Targeting Minions

Targeting minions is specifying which minions should run a command or execute a state by matching against hostnames, or system information, or defined groups, or even combinations thereof.

For example the command `salt web1 apache.signal restart` to restart the Apache httpd server specifies the machine `web1` as the target and the command will only be run on that one minion.

Similarly when using States, the following top file specifies that only the `web1` minion should execute the contents of `webserver.sls`:

```
base:
  'web1':
    - webserver
```

The simple target specifications, glob, regex, and list will cover many use cases, and for some will cover all use cases, but more powerful options exist.

#### 3.3.1 Targeting with Grains

The Grains interface was built into Salt to allow minions to be targeted by system properties. So minions running on a particular operating system can be called to execute a function, or a specific kernel.

Calling via a grain is done by passing the `-G` option to salt, specifying a grain and a glob expression to match the value of the grain. The syntax for the target is the grain key followed by a glob expression: ```os:Arch```.

```
salt -G 'os:Fedora' test.ping
```

Will return True from all of the minions running Fedora.

To discover what grains are available and what the values are, execute the grains.item salt function:
3.3.2 Compound Targeting

New in version 0.9.5.

Multiple target interfaces can be used in conjunction to determine the command targets. These targets can then be combined using and or or statements. This is well defined with an example:

```
salt -C 'G@os:Debian and webser* or E@db.*' test.ping
```

In this example any minion who's id starts with `webser` and is running Debian, or any minion who's id starts with `db` will be matched.

The type of matcher defaults to glob, but can be specified with the corresponding letter followed by the @ symbol. In the above example a grain is used with `G@` as well as a regular expression with `E@`. The `webser*` target does not need to be prefaced with a target type specifier because it is a glob.

more info on using compound targeting can be found [here](#).

3.3.3 Node Group Targeting

New in version 0.9.5.

For certain cases, it can be convenient to have a predefined group of minions on which to execute commands. This can be accomplished using what are called nodegroups. Nodegroups allow for predefined compound targets to be declared in the master configuration file, as a sort of shorthand for having to type out complicated compound expressions.

```
nodegroups:
  group1: 'L@foo.domain.com,bar.domain.com,baz.domain.com and bl*.domain.com'
  group2: 'G@os:Debian and foo.domain.com'
  group3: 'G@os:Debian and N@group1'
```

There are many ways to target individual minions or groups of minions in Salt:

Matching the minion id

Each minion needs a unique identifier. By default when a minion starts for the first time it chooses its FQDN (fully qualified domain name) as that identifier. The minion id can be overridden via the minion's `id` configuration setting.

Tip: minion id and minion keys

The minion id is used to generate the minion's public/private keys and if it ever changes the master must then accept the new key as though the minion was a new host.

Globbing

The default matching that Salt utilizes is shell-style globbing around the minion id. This also works for states in the top file.
Note: You must wrap `salt` calls that use globbing in single-quotes to prevent the shell from expanding the globs before Salt is invoked.

Match all minions:

```
salt '*' test.ping
```

Match all minions in the example.net domain or any of the example domains:

```
salt '*.example.net' test.ping
salt '*.example.*' test.ping
```

Match all the webN minions in the example.net domain (web1.example.net, web2.example.net ... webN.example.net):

```
salt 'web?.example.net' test.ping
```

Match the web1 through web5 minions:

```
salt 'web[1-5]' test.ping
```

Match the web1 and web3 minions:

```
salt 'web[1,3]' test.ping
```

Match the web-x, web-y, and web-z minions:

```
salt 'web-[x-z]' test.ping
```

Note: For additional targeting methods please review the `compound matchers` documentation.

**Regular Expressions**

Minions can be matched using Perl-compatible regular expressions (which is globbing on steroids and a ton of caffeine).

Match both `web1-prod` and `web1-devel` minions:

```
salt -E 'web1-(prod|devel)' test.ping
```

When using regular expressions in a State's top file, you must specify the matcher as the first option. The following example executes the contents of `webserver.sls` on the above-mentioned minions.

```
base:
  'web1-(prod|devel)':
  - match: pcre
  - webserver
```

**Lists**

At the most basic level, you can specify a flat list of minion IDs:
Targeting using Grains

Grain data can be used when targeting minions.

For example, the following matches all CentOS minions:

```
salt -G 'os:CentOS' test.ping
```

Match all minions with 64-bit CPUs, and return number of CPU cores for each matching minion:

```
salt -G 'cpuarch:x86_64' grains.item num_cpus
```

Additionally, globs can be used in grain matches, and grains that are nested in a dictionary can be matched by adding a colon for each level that is traversed. For example, the following will match hosts that have a grain called `ec2_tags`, which itself is a dict with a key named `environment`, which has a value that contains the word `production`:

```
salt -G 'ec2_tags:environment:*production*'
```

**Important:** See Is Targeting using Grain Data Secure? for important security information.

Targeting using Pillar

Pillar data can be used when targeting minions. This allows for ultimate control and flexibility when targeting minions.

**Note:** To start using Pillar targeting it is required to make a Pillar data cache on Salt Master for each Minion via following commands: `salt '*' saltutil.refresh_pillar` or `salt '*' saltutil.sync_all`. Also Pillar data cache will be populated during the `highstate` run. Once Pillar data changes, you must refresh the cache by running above commands for this targeting method to work correctly.

Example:

```
salt -I 'somekey:specialvalue' test.ping
```

Like with Grains, it is possible to use globbing as well as match nested values in Pillar, by adding colons for each level that is being traversed. The below example would match minions with a pillar named `foo`, which is a dict containing a key `bar`, with a value beginning with `baz`:

```
salt -I 'foo:bar:baz*' test.ping
```

Subnet/IP Address Matching

Minions can easily be matched based on IP address, or by subnet (using CIDR notation).

```
salt -S 192.168.40.20 test.ping
salt -S 2001:db8::/64 test.ping
```
Ipclidr matching can also be used in compound matches

```bash
salt -C 'S@10.0.0.0/24 and G@os:Debian' test.ping
```

It is also possible to use in both pillar and state-matching

```bash
['172.16.0.0/12']:
- match: ipclidr
- internal
```

## Compound matchers

Compound matchers allow very granular minion targeting using any of Salt's matchers. The default matcher is a glob match, just as with CLI and top file matching. To match using anything other than a glob, prefix the match string with the appropriate letter from the table below, followed by an @ sign.

<table>
<thead>
<tr>
<th>Letter</th>
<th>Match Type</th>
<th>Example</th>
<th>Alt Delimiter?</th>
</tr>
</thead>
<tbody>
<tr>
<td>G</td>
<td>Grains glob</td>
<td>G@os:Ubuntu</td>
<td>Yes</td>
</tr>
<tr>
<td>E</td>
<td>PCRE Minion ID</td>
<td>E@web\d+.(dev</td>
<td>qa</td>
</tr>
<tr>
<td>P</td>
<td>Grains PCRE</td>
<td>P@os:(RedHat</td>
<td>Fedora</td>
</tr>
<tr>
<td>L</td>
<td>List of minions</td>
<td><a href="mailto:L@minion1.example.com">L@minion1.example.com</a>, minion3.domain.com or bl*.domain.com</td>
<td>No</td>
</tr>
<tr>
<td>I</td>
<td>Pillar glob</td>
<td>I@pdata:foobar</td>
<td>Yes</td>
</tr>
<tr>
<td>J</td>
<td>Pillar PCRE</td>
<td>J@pdata:^(foo</td>
<td>bar)$</td>
</tr>
<tr>
<td>S</td>
<td>Subnet/IP address</td>
<td>S@192.168.1.0/24 or S@192.168.1.100</td>
<td>No</td>
</tr>
<tr>
<td>R</td>
<td>Range cluster</td>
<td>R@%foo.bar</td>
<td>No</td>
</tr>
</tbody>
</table>

Matchers can be joined using boolean and, or, and not operators.

For example, the following string matches all Debian minions with a hostname that begins with `webserv`, as well as any minions that have a hostname which matches the regular expression `web-dc1-srv.*`:

```bash
salt -C 'webserv* and G@os:Debian or E@web-dc1-srv.*' test.ping
```

That same example expressed in a top file looks like the following:

```yaml
base:
  'webserv* and G@os:Debian or E@web-dc1-srv.*':
    - match: compound
    - webserver
```

New in version 2015.8.0.

Excluding a minion based on its ID is also possible:

```bash
salt -C 'not web-dc1-srv' test.ping
```

Versions prior to 2015.8.0 a leading not was not supported in compound matches. Instead, something like the following was required:

```bash
salt -C '* and not G@kernel:Daruin' test.ping
```

Excluding a minion based on its ID was also possible:
Precedence Matching

Matchers can be grouped together with parentheses to explicitly declare precedence amongst groups.

```
salt -C "( ms-1 or G@id:ms-3 ) and G@id:ms-3" test.ping
```

Note: Be certain to note that spaces are required between the parentheses and targets. Failing to obey this rule may result in incorrect targeting!

Alternate Delimiters

New in version 2015.8.0.

Matchers that target based on a key value pair use a colon (:) as a delimiter. Matchers with a Yes in the Alt Delimiters column in the previous table support specifying an alternate delimiter character. This is done by specifying an alternate delimiter character between the leading matcher character and the @ pattern separator character. This avoids incorrect interpretation of the pattern in the case that : is part of the grain or pillar data structure traversal.

```
salt -C "J|@foo|bar|^foo:bar$ or J!@gitrepo!https://github.com:example/project.git" test.ping
```

Node groups

Nodegroups are declared using a compound target specification. The compound target documentation can be found here.

The nodegroups master config file parameter is used to define nodegroups. Here's an example nodegroup configuration within /etc/salt/master:

```yaml
nodegroups:
    group1: 'L@foo.domain.com,bar.domain.com,baz.domain.com or bl*.domain.com'
    group2: 'G@os:Debian and foo.domain.com'
    group3: 'G@os:Debian and N@group1'
    group4:
        - 'G@foo:bar'
        - 'or'
        - 'G@foo:baz'
```

Note: The L within group1 is matching a list of minions, while the G in group2 is matching specific grains. See the compound matchers documentation for more details.

New in version 2015.8.0.
Note: Nodgroups can reference other nodgroups as seen in `group3`. Ensure that you do not have circular references. Circular references will be detected and cause partial expansion with a logged error message.

New in version 2015.8.0.

Compound nodgroups can be either string values or lists of string values. When the nodgroup is a string value will be tokenized by splitting on whitespace. This may be a problem if whitespace is necessary as part of a pattern. When a nodgroup is a list of strings then tokenization will happen for each list element as a whole.

To match a nodgroup on the CLI, use the `-N` command-line option:

```
salt -N group1 test.ping
```

Note: The `N@` classifier cannot be used in compound matches within the CLI or top file, it is only recognized in the `nodegroups` master config file parameter.

To match a nodgroup in your top file, make sure to put `-match: nodegroup` on the line directly following the nodgroup name.

```
base:
  group1:
    - match: nodegroup
    - webserver
```

Note: When adding or modifying nodgroups to a master configuration file, the master must be restarted for those changes to be fully recognized.

A limited amount of functionality, such as targeting with `-N` from the command-line may be available without a restart.

**Using Nodegroups in SLS files**

To use Nodegroups in Jinja logic for SLS files, the `pillar_opts` option in `/etc/salt/master` must be set to `True`. This will pass the master's configuration as Pillar data to each minion.

Note: If the master's configuration contains any sensitive data, this will be passed to each minion. Do not enable this option if you have any configuration data that you do not want to get on your minions.

Also, if you make changes to your nodgroups, you might need to run `salt '*' saltutil.refresh_pillar` after restarting the master.

Once `pillar_opts` is enabled, you can find the nodgroups under the `master` pillar. To make sure that only the correct minions are targeted, you should use each matcher for the nodgroup definition. For example, to check if a minion is in the `webserver` nodgroup:

```
nodegroups:
  webserver: 'G@os:Debian and L@minion1,minion2'
```
Note: If you do not include all of the matchers used to define a nodegroup, Salt might incorrectly target minions that meet some of the nodegroup requirements, but not all of them.

**Batch Size**

The `-b` (or `--batch-size`) option allows commands to be executed on only a specified number of minions at a time. Both percentages and finite numbers are supported.

```
salt '*' -b 10 test.ping
salt -G 'os:RedHat' --batch-size 25% apache.signal restart
```

This will only run `test.ping` on 10 of the targeted minions at a time and then restart `apache` on 25% of the minions matching `os:RedHat` at a time and work through them all until the task is complete. This makes jobs like rolling web server restarts behind a load balancer or doing maintenance on BSD firewalls using carp much easier with salt.

The batch system maintains a window of running minions, so, if there are a total of 150 minions targeted and the batch size is 10, then the command is sent to 10 minions, when one minion returns then the command is sent to one additional minion, so that the job is constantly running on 10 minions.

New in version 2016.3.

The `--batch-wait` argument can be used to specify a number of seconds to wait after a minion returns, before sending the command to a new minion.

**SECO Range**

SECO range is a cluster-based metadata store developed and maintained by Yahoo!

The Range project is hosted here:

https://github.com/ytoolshed/range

Learn more about range here:

https://github.com/ytoolshed/range/wiki/

**Prerequisites**

To utilize range support in Salt, a range server is required. Setting up a range server is outside the scope of this document. Apache modules are included in the range distribution.

With a working range server, cluster files must be defined. These files are written in YAML and define hosts contained inside a cluster. Full documentation on writing YAML range files is here:

https://github.com/ytoolshed/range/wiki/%22yamlfile%22-module-file-spec

Additionally, the Python seco range libraries must be installed on the salt master. One can verify that they have been installed correctly via the following command:
python -c 'import seco.range'

If no errors are returned, range is installed successfully on the salt master.

Preparing Salt

Range support must be enabled on the salt master by setting the hostname and port of the range server inside the master configuration file:

```
range_server: my.range.server.com:80
```

Following this, the master must be restarted for the change to have an effect.

Targeting with Range

Once a cluster has been defined, it can be targeted with a salt command by using the `-R` or `--range` flags.

For example, given the following range YAML file being served from a range server:

```yaml
$ cat /etc/range/test.yaml
CLUSTER: host1..100.test.com
APPS:
  - frontend
  - backend
  - mysql
```

One might target host1 through host100 in the test.com domain with Salt as follows:

```
salt --range %test:CLUSTER test.ping
```

The following salt command would target three hosts: `frontend`, `backend`, and `mysql`:

```
salt --range %test:APPS test.ping
```

3.4 The Salt Mine

The Salt Mine is used to collect arbitrary data from Minions and store it on the Master. This data is then made available to all Minions via the `salt.modules.mine` module.

Mine data is gathered on the Minion and sent back to the Master where only the most recent data is maintained (if long term data is required use returners or the external job cache).

3.4.1 Mine vs Grains

Mine data is designed to be much more up-to-date than grain data. Grains are refreshed on a very limited basis and are largely static data. Mines are designed to replace slow peer publishing calls when Minions need data from other Minions. Rather than having a Minion reach out to all the other Minions for a piece of data, the Salt Mine, running on the Master, can collect it from all the Minions every mine-interval, resulting in almost fresh data at any given time, with much less overhead.
3.4.2 Mine Functions

To enable the Salt Mine the `mine_functions` option needs to be applied to a Minion. This option can be applied via the Minion’s configuration file, or the Minion’s Pillar. The `mine_functions` option dictates what functions are being executed and allows for arguments to be passed in. If no arguments are passed, an empty list must be added:

```yaml
mine_functions:
  test.ping: []
  network.ip_addrs:
    interface: eth0
    cidr: '10.0.0.0/8'
```

Mine Functions Aliases

Function aliases can be used to provide friendly names, usage intentions or to allow multiple calls of the same function with different arguments. There is a different syntax for passing positional and key-value arguments. Mixing positional and key-value arguments is not supported.

New in version 2014.7.0.

```yaml
mine_functions:
  network.ip_addrs: [eth0]
  networkplus.internal_ip_addrs: []
  internal_ip_addrs:
    mine_function: network.ip_addrs
    cidr: 192.168.0.0/16
  ip_list:
    - mine_function: grains.get
    - ip_interfaces
```

3.4.3 Mine Interval

The Salt Mine functions are executed when the Minion starts and at a given interval by the scheduler. The default interval is every 60 minutes and can be adjusted for the Minion via the `mine_interval` option:

```yaml
mine_interval: 60
```

3.4.4 Mine in Salt-SSH

As of the 2015.5.0 release of salt, salt-ssh supports `mine.get`.

Because the Minions cannot provide their own `mine_functions` configuration, we retrieve the args for specified mine functions in one of three places, searched in the following order:

1. Roster data
2. Pillar
3. Master config

The `mine_functions` are formatted exactly the same as in normal salt, just stored in a different location. Here is an example of a flat roster containing `mine_functions`:
test:
  host: 104.237.131.248
  user: root
  mine_functions:
    cmd.run: ['echo "hello!"']
    network.ip_addrs:
      - interface: eth0

Note: Because of the differences in the architecture of salt-ssh, `mine.get` calls are somewhat inefficient. Salt must make a new salt-ssh call to each of the Minions in question to retrieve the requested data, much like a publish call. However, unlike publish, it must run the requested function as a wrapper function, so we can retrieve the function args from the pillar of the Minion in question. This results in a non-trivial delay in retrieving the requested data.

### 3.4.5 Minions Targeting with Mine

The `mine.get` function supports various methods of Minions targeting to fetch Mine data from particular hosts, such as glob or regular expression matching on Minion id (name), grains, pillars and compound matches. See the `salt.modules.mine` module documentation for the reference.

Note: Pillar data needs to be cached on Master for pillar targeting to work with Mine. Read the note in relevant section.

### 3.4.6 Example

One way to use data from Salt Mine is in a State. The values can be retrieved via Jinja and used in the SLS file. The following example is a partial HAProxy configuration file and pulls IP addresses from all Minions with the "web" grain to add them to the pool of load balanced servers.

/srv/pillar/top.sls:

```yaml
base:
  'G@roles:web':
    - web
```

/srv/pillar/web.sls:

```yaml
mine_functions:
  - network.ip_addrs: [eth0]
```

/etc/salt/minion.d/mine.conf:

```yaml
mine_interval: 5
```

/srv/salt/haproxy.sls:

```yaml
haproxy_config:
  file.managed:
    - name: /etc/haproxy/config
    - source: salt://haproxy_config
    - template: jinja
```
/srv/salt/haproxy_config:

```python
{% for server, addrs in salt['mine.get']('roles:web', 'network.ip_addrs', expr_form= →'grain') | dictsort() %}
server {{ server }} {{ addrs[0] }}:80 check
{% endfor %}
```

Note: The expr_form argument will be renamed to tgt_type in the Nitrogen release of Salt.

## 3.5 Runners

Salt runners are convenience applications executed with the salt-run command.

Salt runners work similarly to Salt execution modules however they execute on the Salt master itself instead of remote Salt minions.

A Salt runner can be a simple client call or a complex application.

See also:
*The full list of runners*

### 3.5.1 Writing Salt Runners

A Salt runner is written in a similar manner to a Salt execution module. Both are Python modules which contain functions and each public function is a runner which may be executed via the `salt-run` command.

For example, if a Python module named `test.py` is created in the runners directory and contains a function called `foo`, the `test` runner could be invoked with the following command:

```
# salt-run test.foo
```

Runners have several options for controlling output.

Any `print` statement in a runner is automatically also fired onto the master event bus where. For example:

```python
def a_runner(outputter=None, display_progress=False):
    print('Hello world')
    ...
```

The above would result in an event fired as follows:

```
Event fired at Tue Jan 13 15:26:45 2015
****************************
Tag: salt/run/20150113152644070246/print
Data:
{'_stamp': '2015-01-13T15:26:45.078707',
 'data': 'hello',
 'outputter': 'pprint'}
```
A runner may also send a progress event, which is displayed to the user during runner execution and is also passed across the event bus if the `display_progress` argument to a runner is set to True.

A custom runner may send its own progress event by using the `__jid_event__.fire_event()` method as shown here:

```python
if display_progress:
    __jid_event__.fire_event({'message': 'A progress message'}, 'progress')
```

The above would produce output on the console reading: A progress message as well as an event on the event similar to:

```
Event fired at Tue Jan 13 15:21:20 2015
*************************
Tag: salt/run/20150113152118341421/progress
Data:
'message': "A progress message"}
```

A runner could use the same approach to send an event with a customized tag onto the event bus by replacing the second argument (`progress`) with whatever tag is desired. However, this will not be shown on the command-line and will only be fired onto the event bus.

### 3.5.2 Synchronous vs. Asynchronous

A runner may be fired asynchronously which will immediately return control. In this case, no output will be display to the user if `salt-run` is being used from the command-line. If used programmatically, no results will be returned. If results are desired, they must be gathered either by firing events on the bus from the runner and then watching for them or by some other means.

**Note:** When running a runner in asynchronous mode, the `--progress` flag will not deliver output to the salt-run CLI. However, progress events will still be fired on the bus.

In synchronous mode, which is the default, control will not be returned until the runner has finished executing. To add custom runners, put them in a directory and add it to `runner_dirs` in the master configuration file.

### 3.5.3 Examples

Examples of runners can be found in the Salt distribution:

https://github.com/saltstack/salt/blob/develop/salt/runners

A simple runner that returns a well-formatted list of the minions that are responding to Salt calls could look like this:

```python
# Import salt modules
import salt.client

def up():
    '''
    Print a list of all of the minions that are up
    '''
    client = salt.client.LocalClient(__opts__['conf_file'])
    minions = client.cmd('x', 'test.ping', timeout=1)
```

## 3.5. Runners
3.6 Salt Engines

New in version 2015.8.0.

Salt Engines are long-running, external system processes that leverage Salt.

- Engines have access to Salt configuration, execution modules, and runners (\_\_opts\_\_, \_\_salt\_\_, and \_\_runners\_\_).
- Engines are executed in a separate process that is monitored by Salt. If a Salt engine stops, it is restarted automatically.
- Engines can run on the Salt master and on Salt minions.

Salt engines enhance and replace the external processes functionality.

3.6.1 Configuration

Salt engines are configured under an engines top-level section in your Salt master or Salt minion configuration. Provide a list of engines and parameters under this section.

```python
engines:
  - logstash:
      host: log.my_network.com
      port: 5959
```

Salt engines must be in the Salt path, or you can add the engines_dirs option in your Salt master configuration with a list of directories under which Salt attempts to find Salt engines.

3.6.2 Writing an Engine

An example Salt engine, https://github.com/saltstack/salt/blob/develop/salt/engines/test.py, is available in the Salt source. To develop an engine, the only requirement is that your module implement the start() function.

3.7 Understanding YAML

The default renderer for SLS files is the YAML renderer. YAML is a markup language with many powerful features. However, Salt uses a small subset of YAML that maps over very commonly used data structures, like lists and dictionaries. It is the job of the YAML renderer to take the YAML data structure and compile it into a Python data structure for use by Salt.

Though YAML syntax may seem daunting and terse at first, there are only three very simple rules to remember when writing YAML for SLS files.

3.7.1 Rule One: Indentation

YAML uses a fixed indentation scheme to represent relationships between data layers. Salt requires that the indentation for each level consists of exactly two spaces. Do not use tabs.
3.7.2 Rule Two: Colons

Python dictionaries are, of course, simply key-value pairs. Users from other languages may recognize this data type as hashes or associative arrays.

Dictionary keys are represented in YAML as strings terminated by a trailing colon. Values are represented by either a string following the colon, separated by a space:

```
my_key: my_value
```

In Python, the above maps to:

```
{my_key: 'my_value'}
```

Alternatively, a value can be associated with a key through indentation.

```
my_key:
  my_value
```

**Note:** The above syntax is valid YAML but is uncommon in SLS files because most often, the value for a key is not singular but instead is a list of values.

```
In Python, the above maps to:

{my_key: 'my_value'}
```

Dictionaries can be nested:

```
first_level_dict_key:
  second_level_dict_key: value_in_second_level_dict
```

And in Python:

```
{
  first_level_dict_key: {
    second_level_dict_key: 'value_in_second_level_dict'
  }
}
```

3.7.3 Rule Three: Dashes

To represent lists of items, a single dash followed by a space is used. Multiple items are a part of the same list as a function of their having the same level of indentation.

```
- list_value_one
- list_value_two
- list_value_three
```

Lists can be the value of a key-value pair. This is quite common in Salt:

```
my_dictionary:
  - list_value_one
  - list_value_two
  - list_value_three
```
In Python, the above maps to:

```python
{'my_dictionary': ['list_value_one', 'list_value_two', 'list_value_three']}
```

### 3.7.4 Learning More

One easy way to learn more about how YAML gets rendered into Python data structures is to use an online YAML parser to see the Python output.

One excellent choice for experimenting with YAML parsing is: [http://yaml-online-parser.appspot.com/](http://yaml-online-parser.appspot.com/)

### 3.7.5 Templating

Jinja statements and expressions are allowed by default in SLS files. See Understanding Jinja.

### 3.8 Understanding Jinja

Jinja is the default templating language in SLS files.

#### 3.8.1 Jinja in States

Jinja is evaluated before YAML, which means it is evaluated before the States are run.

The most basic usage of Jinja in state files is using control structures to wrap conditional or redundant state elements:

```jinja
{% if grains['os'] != 'FreeBSD' %}
tcsh:
    pkg:
        - installed
{% endif %}

motd:
    file.managed:
        {% if grains['os'] == 'FreeBSD' %}
            - name: /etc/motd
        {% elif grains['os'] == 'Debian' %}
            - name: /etc/motd.tail
        {% endif %}
        - source: salt://motd
```

In this example, the first if block will only be evaluated on minions that aren't running FreeBSD, and the second block changes the file name based on the os grain.

Writing if-else blocks can lead to very redundant state files however. In this case, using pillars, or using a previously defined variable might be easier:

```jinja
{% set motd = ['/etc/motd'] %}
{% if grains['os'] == 'Debian' %}
    {% set motd = ['/etc/motd.tail', '/var/run/motd'] %}
{% endif %}

{% for motdfile in motd %}
{{ motdfile }}:
{% endfor %}
```
file.managed:
    - source: salt://motd
{% endfor %}

Using a variable set by the template, the for loop will iterate over the list of MOTD files to update, adding a state block for each file.

The filter_by function can also be used to set variables based on grains:

{% set auditd = salt['grains.filter_by']({'
    'RedHat': { 'package': 'audit' },
    'Debian': { 'package': 'auditd' },
}) %}

### 3.8.2 Include and Import

Includes and imports can be used to share common, reusable state configuration between state files and between files.

{% from 'lib.sls' import test %}

This would import the test template variable or macro, not the test state element, from the file lib.sls. In the case that the included file performs checks again grains, or something else that requires context, passing the context into the included file is required:

{% from 'lib.sls' import test with context %}

**Including Context During Include/Import**

By adding with context to the include/import directive, the current context can be passed to an included/imported template.

{% import 'openssl/vars.sls' as ssl with context %}

### 3.8.3 Macros

Macros are helpful for eliminating redundant code. Macros are most useful as mini-templates to repeat blocks of strings with a few parameterized variables. Be aware that stripping whitespace from the template block, as well as contained blocks, may be necessary to emulate a variable return from the macro.

```
# init.sls
{% from 'lib.sls' import pythonpkg with context %}

python-virtualenv:
    pkg.installed:
        - name: {{ pythonpkg('virtualenv') }}

python-fabric:
    pkg.installed:
        - name: {{ pythonpkg('fabric') }}
```

3.8. Understanding Jinja
This would define a macro that would return a string of the full package name, depending on the packaging system's naming convention. The whitespace of the macro was eliminated, so that the macro would return a string without line breaks, using whitespace control.

### 3.8.5 Filters

Saltstack extends builtin filters with these custom filters:

**strftime** Converts any time related object into a time based string. It requires a valid strftime directives. An exhaustive list can be found in the official Python documentation.

```python
{% set curtime = None | strftime() %}
```

Fuzzy dates require the timelib Python module is installed.

```python
{{ "2002/12/25"|strftime("%Y") }}
{{ "1040814000"|strftime("%Y-%m-%d") }}
{{ "2016-12-01 00:00:00"|strftime("%Y-%m-%d") }}
{{ "tomorrow"|strftime %}}
```

**sequence** Ensure that parsed data is a sequence.

**yaml_encode** Serializes a single object into a YAML scalar with any necessary handling for escaping special characters. This will work for any scalar YAML data type: ints, floats, timestamps, booleans, strings, unicode. It will not work for multi-objects such as sequences or maps.

```python
{% set bar = 7 %}
{% set baz = none %}
{% set zip = true %}
{% set zap = 'The word of the day is "salty"' %}

{% load_yaml as foo %}
bar: {{ bar|yaml_encode }}
baz: {{ baz|yaml_encode }}
zip: {{ zip|yaml_encode }}
zap: {{ zap|yaml_encode }}
{% endload %}
```

In the above case {{ bar }} and {{ foo.bar }} should be identical and {{ baz }} and {{ foo.baz }} should be identical.
yaml_dquote Serializes a string into a properly-escaped YAML double-quoted string. This is useful when the contents of a string are unknown and may contain quotes or unicode that needs to be preserved. The resulting string will be emitted with opening and closing double quotes.

```yaml
{%- set bar = '"The quick brown fox . . ."!' %}
{%- set baz = 'The word of the day is "salty".' %}

{%- load_yaml as foo %}
bar: {{ bar|yaml_dquote }}
baz: {{ baz|yaml_dquote }}
{%- endload %}
```

In the above case `{{ bar }}` and `{{ foo.bar }}` should be identical and `{{ baz }}` and `{{ foo.baz }}` should be identical. If variable contents are not guaranteed to be a string then it is better to use `yaml_encode` which handles all YAML scalar types.

yaml_squote Similar to the yaml_dquote filter but with single quotes. Note that YAML only allows special escapes inside double quotes so `yaml_squote` is not nearly as useful (viz. you likely want to use `yaml_encode` or `yaml_dquote`).

### 3.8.6 Jinja in Files

Jinja_ can be used in the same way in managed files:

```
# redis.sls
/etc/redis/redis.conf:
  file.managed:
    - source: salt://redis.conf
    - template: jinja
    - context:
      bind: 127.0.0.1
```

```
# lib.sls
{% set port = 6379 %}
```

```
# redis.conf
{% from 'lib.sls' import port with context %}
port {{ port }}
bind {{ bind }}
```

As an example, configuration was pulled from the file context and from an external template file.

**Note:** Macros and variables can be shared across templates. They should not be starting with one or more underscores, and should be managed by one of the following tags: `macro`, `set`, `load_yaml`, `load_json`, `import_yaml` and `import_json`.

### 3.8.7 Escaping Jinja

Occasionally, it may be necessary to escape Jinja syntax. There are two ways to do this in Jinja. One is escaping individual variables or strings and the other is to escape entire blocks.

To escape a string commonly used in Jinja syntax such as `{`, you can use the following syntax:
For larger blocks that contain Jinja syntax that needs to be escaped, you can use raw blocks:

```jinja
{% raw %}
    some text that contains jinja characters that need to be escaped
{% endraw %}
```

See the Escaping section of Jinja's documentation to learn more.

A real-world example of needing to use raw tags to escape a larger block of code is when using `file.managed` with the `contents_pillar` option to manage files that contain something like consul-template, which shares a syntax subset with Jinja. Raw blocks are necessary here because the Jinja in the pillar would be rendered before the file.managed is ever called, so the Jinja syntax must be escaped:

```jinja
{% raw %}
- contents_pillar: |
  job "example-job" {
  <snipped>
  task "example" {
    driver = "docker"
    config {
      image = "docker-registry.service.consul:5000/example-job:{{key "nomad/jobs/example-job/version"}}"
    <snipped>
  }{% endraw %}
```

### 3.8.8 Calling Salt Functions

The Jinja renderer provides a shorthand lookup syntax for the `salt` dictionary of execution function.

New in version 2014.7.0.

```jinja
# The following two function calls are equivalent.
{{ salt['cmd.run']('whoami') }}
{{ salt.cmd.run('whoami') }}
```

### 3.8.9 Debugging

The `show_full_context` function can be used to output all variables present in the current Jinja context.

New in version 2014.7.0.

```jinja
Context is: {{ show_full_context() }}
```

### 3.8.10 Custom Execution Modules

Custom execution modules can be used to supplement or replace complex Jinja. Many tasks that require complex looping and logic are trivial when using Python in a Salt execution module. Salt execution modules are easy to write and distribute to Salt minions.

Functions in custom execution modules are available in the Salt execution module dictionary just like the built-in execution modules:
{{ salt['my_custom_module.my_custom_function']() }}

- How to Convert Jinja Logic to an Execution Module
- Writing Execution Modules

3.10 Troubleshooting

The intent of the troubleshooting section is to introduce solutions to a number of common issues encountered by users and the tools that are available to aid in developing States and Salt code.

3.10.1 Troubleshooting the Salt Master

If your Salt master is having issues such as minions not returning data, slow execution times, or a variety of other issues, the following links contain details on troubleshooting the most common issues encountered:

Troubleshooting the Salt Master

Running in the Foreground

A great deal of information is available via the debug logging system, if you are having issues with minions connecting or not starting run the master in the foreground:

```
# salt-master -l debug
```

Anyone wanting to run Salt daemons via a process supervisor such as monit, runit, or supervisord, should omit the -d argument to the daemons and run them in the foreground.

What Ports does the Master Need Open?

For the master, TCP ports 4505 and 4506 need to be open. If you’ve put both your Salt master and minion in debug mode and don’t see an acknowledgment that your minion has connected, it could very well be a firewall interfering with the connection. See our firewall configuration page for help opening the firewall on various platforms.

If you’ve opened the correct TCP ports and still aren’t seeing connections, check that no additional access control system such as SELinux or AppArmor is blocking Salt.

Too many open files

The salt-master needs at least 2 sockets per host that connects to it, one for the Publisher and one for response port. Thus, large installations may, upon scaling up the number of minions accessing a given master, encounter:

```
12:45:29,289 [salt.master ][INFO ] Starting Salt worker process 38
Too many open files
sock != -1 (tcp_listener.cpp:335)
```

The solution to this would be to check the number of files allowed to be opened by the user running salt-master (root by default):

```
[root@salt-master ~]# ulimit -n
1024
```
If this value is not equal to at least twice the number of minions, then it will need to be raised. For example, in an environment with 1800 minions, the `nofile` limit should be set to no less than 3600. This can be done by creating the file `/etc/security/limits.d/99-salt.conf`, with the following contents:

<table>
<thead>
<tr>
<th>user</th>
<th>type</th>
<th>limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>root</td>
<td>hard</td>
<td>nofile</td>
</tr>
<tr>
<td>root</td>
<td>soft</td>
<td>nofile</td>
</tr>
</tbody>
</table>

Replace `root` with the user under which the master runs, if different.

If your master does not have an `/etc/security/limits.d` directory, the lines can simply be appended to `/etc/security/limits.conf`.

As with any change to resource limits, it is best to stay logged into your current shell and open another shell to run `ulimit -n` again and verify that the changes were applied correctly. Additionally, if your master is running upstart, it may be necessary to specify the `nofile` limit in `/etc/default/salt-master` if upstart isn’t respecting your resource limits:

```
limit nofile 4096 4096
```

**Note:** The above is simply an example of how to set these values, and you may wish to increase them even further if your Salt master is doing more than just running Salt.

### Salt Master Stops Responding

There are known bugs with ZeroMQ versions less than 2.1.11 which can cause the Salt master to not respond properly. If you’re running a ZeroMQ version greater than or equal to 2.1.9, you can work around the bug by setting the sysctls `net.core.rmem_max` and `net.core.wmem_max` to 16777216. Next, set the third field in `net.ipv4.tcp_rmem` and `net.ipv4.tcp_wmem` to at least 16777216.

You can do it manually with something like:

```
# echo 16777216 > /proc/sys/net/core/rmem_max
# echo 16777216 > /proc/sys/net/core/wmem_max
# echo "4096 87380 16777216" > /proc/sys/net/ipv4/tcp_rmem
# echo "4096 87380 16777216" > /proc/sys/net/ipv4/tcp_wmem
```

Or with the following Salt state:

```bash
net.core.rmem_max:
  sysctl:
    - present
    - value: 16777216

net.core.wmem_max:
  sysctl:
    - present
    - value: 16777216

net.ipv4.tcp_rmem:
  sysctl:
    - present
    - value: 4096 87380 16777216

net.ipv4.tcp_wmem:
  sysctl:
```

3.10. Troubleshooting
Live Python Debug Output

If the master seems to be unresponsive, a SIGUSR1 can be passed to the salt-master threads to display what piece of code is executing. This debug information can be invaluable in tracking down bugs.

To pass a SIGUSR1 to the master, first make sure the minion is running in the foreground. Stop the service if it is running as a daemon, and start it in the foreground like so:

```
# salt-master -l debug
```

Then pass the signal to the master when it seems to be unresponsive:

```
# killall -SIGUSR1 salt-master
```

When filing an issue or sending questions to the mailing list for a problem with an unresponsive daemon, be sure to include this information if possible.

Live Salt-Master Profiling

When faced with performance problems one can turn on master process profiling by sending it SIGUSR2.

```
# killall -SIGUSR2 salt-master
```

This will activate yappi profiler inside salt-master code, then after some time one must send SIGUSR2 again to stop profiling and save results to file. If run in foreground salt-master will report filename for the results, which are usually located under /tmp on Unix-based OSes and c:\temp on windows.

Results can then be analyzed with kcachegrind or similar tool.

Commands Time Out or Do Not Return Output

Depending on your OS (this is most common on Ubuntu due to apt-get) you may sometimes encounter times where a state.apply, or other long running commands do not return output.

By default the timeout is set to 5 seconds. The timeout value can easily be increased by modifying the timeout line within your /etc/salt/master configuration file.

Having keys accepted for Salt minions that no longer exist or are not reachable also increases the possibility of timeouts, since the Salt master waits for those systems to return command results.

Passing the -c Option to Salt Returns a Permissions Error

Using the -c option with the Salt command modifies the configuration directory. When the configuration file is read it will still base data off of the root_dir setting. This can result in unintended behavior if you are expecting files such as /etc/salt/pki to be pulled from the location specified with -c. Modify the root_dir setting to address this behavior.
Salt Master Doesn’t Return Anything While Running jobs

When a command being run via Salt takes a very long time to return (package installations, certain scripts, etc.) the master may drop you back to the shell. In most situations the job is still running but Salt has exceeded the set timeout before returning. Querying the job queue will provide the data of the job but is inconvenient. This can be resolved by either manually using the `-t` option to set a longer timeout when running commands (by default it is 5 seconds) or by modifying the master configuration file: `/etc/salt/master` and setting the `timeout` value to change the default timeout for all commands, and then restarting the salt-master service.

Salt Master Auth Flooding

In large installations, care must be taken not to overwhelm the master with authentication requests. Several options can be set on the master which mitigate the chances of an authentication flood from causing an interruption in service.

**Note:** recon_default:

The average number of seconds to wait between reconnection attempts.

**recon_max:** The maximum number of seconds to wait between reconnection attempts.

**recon_randomize:** A flag to indicate whether the recon_default value should be randomized.

**acceptance_wait_time:** The number of seconds to wait for a reply to each authentication request.

**random_reauth_delay:** The range of seconds across which the minions should attempt to randomize authentication attempts.

**auth_timeout:** The total time to wait for the authentication process to complete, regardless of the number of attempts.

Running state locally

To debug the states, you can use `call` locally.

```
salt-call -l trace --local state.highstate
```

The top.sls file is used to map what SLS modules get loaded onto what minions via the state system.

It is located in the file defined in the `file_roots` variable of the salt master configuration file which is defined by found in `CONFIG_DIR/master`, normally `/etc/salt/master`.

The default configuration for the `file_roots` is:

```
file_roots:
  base:
    - /srv/salt
```

So the top file is defaulted to the location `/srv/salt/top.sls`

Salt Master Umask

The salt master uses a cache to track jobs as they are published and returns come back. The recommended umask for a salt-master is 022, which is the default for most users on a system. Incorrect umasks can result in permission-denied
errors when the master tries to access files in its cache.

3.10.2 Troubleshooting the Salt Minion

In the event that your Salt minion is having issues, a variety of solutions and suggestions are available. Please refer to the following links for more information:

Troubleshooting the Salt Minion

Running in the Foreground

A great deal of information is available via the debug logging system, if you are having issues with minions connecting or not starting run the minion in the foreground:

```
# salt-minion -l debug
```

Anyone wanting to run Salt daemons via a process supervisor such as monit, runit, or supervisord, should omit the -d argument to the daemons and run them in the foreground.

What Ports does the Minion Need Open?

No ports need to be opened on the minion, as it makes outbound connections to the master. If you’ve put both your Salt master and minion in debug mode and don’t see an acknowledgment that your minion has connected, it could very well be a firewall interfering with the connection. See our firewall configuration page for help opening the firewall on various platforms.

If you have netcat installed, you can check port connectivity from the minion with the nc command:

```
$ nc -v -z salt.master.ip.addr 4505
Connection to salt.master.ip.addr 4505 port [tcp/unknown] succeeded!
$ nc -v -z salt.master.ip.addr 4506
Connection to salt.master.ip.addr 4506 port [tcp/unknown] succeeded!
```

The Nmap utility can also be used to check if these ports are open:

```
# nmap -sS -q -p 4505-4506 salt.master.ip.addr
Starting Nmap 6.40 (http://nmap.org) at 2013-12-29 19:44 CST
Nmap scan report for salt.master.ip.addr (10.0.0.10)
Host is up (0.0026s latency).
PORT     STATE     SERVICE
4505/tcp open unknown
4506/tcp open unknown
MAC Address: 00:11:22:AA:BB:CC (Intel)
Nmap done: 1 IP address (1 host up) scanned in 1.64 seconds
```

If you’ve opened the correct TCP ports and still aren’t seeing connections, check that no additional access control system such as SELinux or AppArmor is blocking Salt.
Using salt-call

The `salt-call` command was originally developed for aiding in the development of new Salt modules. Since then, many applications have been developed for running any Salt module locally on a minion. These range from the original intent of `salt-call` (development assistance), to gathering more verbose output from calls like `state.apply`.

When initially creating your state tree, it is generally recommended to invoke highstates by running `state.apply` directly from the minion with `salt-call`, rather than remotely from the master. This displays far more information about the execution than calling it remotely. For even more verbosity, increase the loglevel using the `-l` argument:

```bash
# salt-call -l debug state.apply
```

The main difference between using `salt` and using `salt-call` is that `salt-call` is run from the minion, and it only runs the selected function on that minion. By contrast, `salt` is run from the master, and requires you to specify the minions on which to run the command using salt's targeting system.

Live Python Debug Output

If the minion seems to be unresponsive, a SIGUSR1 can be passed to the process to display what piece of code is executing. This debug information can be invaluable in tracking down bugs.

To pass a SIGUSR1 to the minion, first make sure the minion is running in the foreground. Stop the service if it is running as a daemon, and start it in the foreground like so:

```bash
# salt-minion -l debug
```

Then pass the signal to the minion when it seems to be unresponsive:

```bash
# killall -SIGUSR1 salt-minion
```

When filing an issue or sending questions to the mailing list for a problem with an unresponsive daemon, be sure to include this information if possible.

Multiprocessing in Execution Modules

As is outlined in github issue #6300, Salt cannot use python's multiprocessing pipes and queues from execution modules. Multiprocessing from the execution modules is perfectly viable, it is just necessary to use Salt's event system to communicate back with the process.

The reason for this difficulty is that python attempts to pickle all objects in memory when communicating, and it cannot pickle function objects. Since the Salt loader system creates and manages function objects this causes the pickle operation to fail.

Salt Minion Doesn't Return Anything While Running Jobs Locally

When a command being run via Salt takes a very long time to return (package installations, certain scripts, etc.) the minion may drop you back to the shell. In most situations the job is still running but Salt has exceeded the set timeout before returning. Querying the job queue will provide the data of the job but is inconvenient. This can be resolved by either manually using the `-t` option to set a longer timeout when running commands (by default it is 5 seconds) or by modifying the minion configuration file: `/etc/salt/minion` and setting the `timeout` value to change the default timeout for all commands, and then restarting the salt-minion service.
Note: Modifying the minion timeout value is not required when running commands from a Salt Master. It is only required when running commands locally on the minion.

3.10.3 Running in the Foreground

A great deal of information is available via the debug logging system, if you are having issues with minions connecting or not starting run the minion and/or master in the foreground:

```
salt-master -l debug
salt-minion -l debug
```

Anyone wanting to run Salt daemons via a process supervisor such as monit, runit, or supervisord, should omit the `-d` argument to the daemons and run them in the foreground.

3.10.4 What Ports do the Master and Minion Need Open?

No ports need to be opened up on each minion. For the master, TCP ports 4505 and 4506 need to be open. If you've put both your Salt master and minion in debug mode and don't see an acknowledgment that your minion has connected, it could very well be a firewall.

You can check port connectivity from the minion with the `nc` command:

```
nc -v -z salt.master.ip 4505
nc -v -z salt.master.ip 4506
```

There is also a firewall configuration document that might help as well.

If you’ve enabled the right TCP ports on your operating system or Linux distribution’s firewall and still aren’t seeing connections, check that no additional access control system such as SELinux or AppArmor is blocking Salt.

3.10.5 Using salt-call

The `salt-call` command was originally developed for aiding in the development of new Salt modules. Since then, many applications have been developed for running any Salt module locally on a minion. These range from the original intent of `salt-call`, development assistance, to gathering more verbose output from calls like `state.apply`.

When initially creating your state tree, it is generally recommended to invoke `state.apply` directly from the minion with `salt-call`, rather than remotely from the master. This displays far more information about the execution than calling it remotely. For even more verbosity, increase the loglevel using the `-l` argument:

```
salt-call -l debug state.apply
```

The main difference between using `salt` and using `salt-call` is that `salt-call` is run from the minion, and it only runs the selected function on that minion. By contrast, `salt` is run from the master, and requires you to specify the minions on which to run the command using salt's targeting system.

3.10.6 Too many open files

The salt-master needs at least 2 sockets per host that connects to it, one for the Publisher and one for response port. Thus, large installations may, upon scaling up the number of minions accessing a given master, encounter:
The solution to this would be to check the number of files allowed to be opened by the user running salt-master (root by default):

```
[root@salt-master ~]# ulimit -n
1024
```

And modify that value to be at least equal to the number of minions x 2. This setting can be changed in limits.conf as the nofile value(s), and activated upon new a login of the specified user.

So, an environment with 1800 minions, would need 1800 x 2 = 3600 as a minimum.

### 3.10.7 Salt Master Stops Responding

There are known bugs with ZeroMQ versions less than 2.1.11 which can cause the Salt master to not respond properly. If you’re running a ZeroMQ version greater than or equal to 2.1.9, you can work around the bug by setting the sysctls `net.core.rmem_max` and `net.core.wmem_max` to `16777216`. Next, set the third field in `net.ipv4.tcp_rmem` and `net.ipv4.tcp_wmem` to at least `16777216`.

You can do it manually with something like:

```
# echo 16777216 > /proc/sys/net/core/rmem_max
# echo 16777216 > /proc/sys/net/core/wmem_max
# echo "4096 87380 16777216" > /proc/sys/net/ipv4/tcp_rmem
# echo "4096 87380 16777216" > /proc/sys/net/ipv4/tcp_wmem
```

Or with the following Salt state:

```
net.core.rmem_max:
  syscall:
    - present
    - value: 16777216

net.core.wmem_max:
  syscall:
    - present
    - value: 16777216

net.ipv4.tcp_rmem:
  syscall:
    - present
    - value: 4096 87380 16777216

net.ipv4.tcp_wmem:
  syscall:
    - present
    - value: 4096 87380 16777216
```

### 3.10.8 Salt and SELinux

Currently there are no SELinux policies for Salt. For the most part Salt runs without issue when SELinux is running in Enforcing mode. This is because when the minion executes as a daemon the type context is changed to `initrc_t`.

---

**3.10. Troubleshooting** 335
The problem with SELinux arises when using salt-call or running the minion in the foreground, since the type context stays unconfined_t.

This problem is generally manifest in the rpm install scripts when using the pkg module. Until a full SELinux Policy is available for Salt the solution to this issue is to set the execution context of salt-call and salt-minion to rpm_exec_t:

```
# CentOS 5 and RHEL 5:
chcon -t system_u:system_r:rpm_exec_t:s0 /usr/bin/salt-minion
chcon -t system_u:system_r:rpm_exec_t:s0 /usr/bin/salt-call

# CentOS 6 and RHEL 6:
chcon system_u:object_r:rpm_exec_t:s0 /usr/bin/salt-minion
chcon system_u:object_r:rpm_exec_t:s0 /usr/bin/salt-call
```

This works well, because the rpm_exec_t context has very broad control over other types.

### 3.10.9 Red Hat Enterprise Linux 5

Salt requires Python 2.6 or 2.7. Red Hat Enterprise Linux 5 and its variants come with Python 2.4 installed by default. When installing on RHEL 5 from the EPEL repository this is handled for you. But, if you run Salt from git, be advised that its dependencies need to be installed from EPEL and that Salt needs to be run with the python26 executable.

### 3.10.10 Common YAML Gotchas

An extensive list of YAML idiosyncrasies has been compiled:

**YAML Idiosyncrasies**

One of Salt’s strengths, the use of existing serialization systems for representing SLS data, can also backfire. YAML is a general purpose system and there are a number of things that would seem to make sense in an sls file that cause YAML issues. It is wise to be aware of these issues. While reports or running into them are generally rare they can still crop up at unexpected times.

**Spaces vs Tabs**

YAML uses spaces, period. Do not use tabs in your SLS files! If strange errors are coming up in rendering SLS files, make sure to check that no tabs have crept in! In Vim, after enabling search highlighting with: `:set hlsearch`, you can check with the following key sequence in normal mode(you can hit ESC twice to be sure): `/`, `Ctrl-v`, `Tab`, then hit `Enter`. Also, you can convert tabs to 2 spaces by these commands in Vim: `:set tabstop=2` `expandtab` and then `:retab`.

**Indentation**

The suggested syntax for YAML files is to use 2 spaces for indentation, but YAML will follow whatever indentation system that the individual file uses. Indentation of two spaces works very well for SLS files given the fact that the data is uniform and not deeply nested.
Nested Dictionaries

When `dicts` are nested within other data structures (particularly lists), the indentation logic sometimes changes. Examples of where this might happen include `context` and `defaults` options from the `file.managed` state:

```
/etc/http/conf/http.conf:
  file:
    - managed
    - source: salt://apache/http.conf
    - user: root
    - group: root
    - mode: 644
    - template: jinja
    - context:
      custom_var: "override"
    - defaults:
      custom_var: "default value"
      other_var: 123
```

Notice that while the indentation is two spaces per level, for the values under the `context` and `defaults` options there is a four-space indent. If only two spaces are used to indent, then those keys will be considered part of the same dictionary that contains the `context` key, and so the data will not be loaded correctly. If using a double indent is not desirable, then a deeply-nested dict can be declared with curly braces:

```
/etc/http/conf/http.conf:
  file:
    - managed
    - source: salt://apache/http.conf
    - user: root
    - group: root
    - mode: 644
    - template: jinja
    - context: {
      custom_var: "override"
    }
    - defaults: {
      custom_var: "default value",
      other_var: 123
    }
```

Here is a more concrete example of how YAML actually handles these indentations, using the Python interpreter on the command line:

```
>>> import yaml
>>> yaml.safe_load('"mystate:
...   file.managed:
...     - context:
...       some: var''')
{'mystate': {'file.managed': [{'context': {'some': 'var'}}]}}
>>> yaml.safe_load('"mystate:
...   file.managed:
...     - context:
...       some: var'''}
{'mystate': {'file.managed': [{'some': 'var', 'context': None}]}}
```

Note that in the second example, `some` is added as another key in the same dictionary, whereas in the first example, it's the start of a new dictionary. That's the distinction. `context` is a common example because it is a keyword arg for many functions, and should contain a dictionary.
True/False, Yes/No, On/Off

PyYAML will load these values as boolean True or False. Un-capitalized versions will also be loaded as booleans (true, false, yes, no, on, and off). This can be especially problematic when constructing Pillar data. Make sure that your Pillars which need to use the string versions of these values are enclosed in quotes. Pillars will be parsed twice by salt, so you’ll need to wrap your values in multiple quotes, for example ```false```

The `%` Sign

The % symbol has a special meaning in YAML, it needs to be passed as a string literal:

```yaml
cheese:
  ssh_auth.present:
    - user: tborcels
    - source: salt://ssh_keys/cheese.pub
    - config: %h/.ssh/authorized_keys
```

Time Expressions

PyYAML will load a time expression as the integer value of that, assuming HH:MM. So for example, 12:00 is loaded by PyYAML as 720. An excellent explanation for why can be found here.

To keep time expressions like this from being loaded as integers, always quote them.

Note: When using a jinja load_yaml map, items must be quoted twice. For example:

```yaml
{% load_yaml as wsus_schedule %}

FRI_10:
  time: "23:00"
  day: 6 - Every Friday
SAT_10:
  time: "06:00"
  day: 7 - Every Saturday
SAT_20:
  time: "14:00"
  day: 7 - Every Saturday
SAT_30:
  time: "22:00"
  day: 7 - Every Saturday
SUN_10:
  time: "06:00"
  day: 1 - Every Sunday
{% endload %}
```

YAML does not like ```Double Short Decs```

If I can find a way to make YAML accept ```Double Short Decs``` then I will, since I think that double short decs would be awesome. So what is a ```Double Short Dec```? It is when you declare a multiple short decs in one ID. Here is a standard short dec, it works great:
vim:
  pkg.installed

The short dec means that there are no arguments to pass, so it is not required to add any arguments, and it can save space.

YAML though, gets upset when declaring multiple short decs, for the record...

THIS DOES NOT WORK:

vim:
  pkg.installed
  user.present

Similarly declaring a short dec in the same ID dec as a standard dec does not work either...

ALSO DOES NOT WORK:

fred:
  user.present
  ssh_auth.present:
    - name: AAAAB3NzaC...
    - user: fred
    - enc: ssh-dss
    - require:
      - user: fred

The correct way is to define them like this:

vim:
  pkg.installed: []
  user.present: []

fred:
  user.present: []
  ssh_auth.present:
    - name: AAAAB3NzaC...
    - user: fred
    - enc: ssh-dss
    - require:
      - user: fred

Alternatively, they can be defined the "old way", or with multiple "full decs":

vim:
  pkg:
    - installed
  user:
    - present

fred:
  user:
    - present
  ssh_auth:
    - present
    - name: AAAAB3NzaC...
    - user: fred
    - enc: ssh-dss
Salt Documentation, Release 2016.3.6

- require:
- user: fred

YAML support only plain ASCII
According to YAML speciﬁcation, only ASCII characters can be used.
Within double-quotes, special characters may be represented with C-style escape sequences starting with a backslash
( \ ).
Examples:
-

micro: "\u00b5"
copyright: "\u00A9"
A: "\x41"
alpha: "\u0251"
Alef: "\u05d0"

List of usable Unicode characters will help you to identify correct numbers.
Python can also be used to discover the Unicode number for a character:
repr(u"Text with wrong characters i need to figure out")

is shell command can ﬁnd wrong characters in your SLS ﬁles:
find . -name '*.sls'

-exec

grep --color='auto' -P -n '[^\x00-\x7F]' \{} \;

Alternatively you can toggle the yaml_utf8 seing in your master conﬁguration ﬁle. is is still an experimental
seing but it should manage the right encoding conversion in salt aer yaml states compilations.
Underscores stripped in Integer Definitions
If a deﬁnition only includes numbers and underscores, it is parsed by YAML as an integer and all underscores are
stripped. To ensure the object becomes a string, it should be surrounded by quotes. More information here.
Here's an example:
>>> import yaml
>>> yaml.safe_load('2013_05_10')
20130510
>>> yaml.safe_load('"2013_05_10"')
'2013_05_10'

Automatic datetime conversion
If there is a value in a YAML ﬁle formaed 2014-01-20 14:23:23 or similar, YAML will automatically convert
this to a Python datetime object. ese objects are not msgpack serializable, and so may break core salt functionality. If values such as these are needed in a salt YAML ﬁle (speciﬁcally a conﬁguration ﬁle), they should be
formaed with surrounding strings to force YAML to serialize them as strings:

340

Chapter 3. Using Salt


```
>>> import yaml
>>> yaml.safe_load('2014-01-20 14:23:23')
datetime.datetime(2014, 1, 20, 14, 23, 23)
>>> yaml.safe_load('"2014-01-20 14:23:23"')
'2014-01-20 14:23:23'
```

Additionally, numbers formatted like XXXX-XX-XX will also be converted (or YAML will attempt to convert them, and error out if it doesn’t think the date is a real one). Thus, for example, if a minion were to have an ID of 4017-16-20 the minion would not start because YAML would complain that the date was out of range. The workaround is the same, surround the offending string with quotes:

```
>>> import yaml
>>> yaml.safe_load('4017-16-20')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "/usr/local/lib/python2.7/site-packages/yaml/__init__.py", line 93, in safe_load
    return load(stream, SafeLoader)
  File "/usr/local/lib/python2.7/site-packages/yaml/__init__.py", line 71, in load

    data = self.construct_object(node)
  File "/usr/local/lib/python2.7/site-packages/yaml/constructor.py", line 88, in construct_object
    data = constructor(self, node)
  File "/usr/local/lib/python2.7/site-packages/yaml/constructor.py", line 312, in construct_yaml_timestamp
    return datetime.date(year, month, day)
ValueError: month must be in 1..12
>>> yaml.safe_load('"4017-16-20"')
'4017-16-20'
```

### Keys Limited to 1024 Characters

Simple keys are limited to a single line and cannot be longer than 1024 characters. This is a limitation from PyYaml, as seen in a comment in PyYAML’s code, and applies to anything parsed by YAML in Salt.

### 3.10.11 Live Python Debug Output

If the minion or master seems to be unresponsive, a SIGUSR1 can be passed to the processes to display where in the code they are running. If encountering a situation like this, this debug information can be invaluable. First make sure the master of minion are running in the foreground:

```
salt-master -l debug
salt-minion -l debug
```

Then pass the signal to the master or minion when it seems to be unresponsive:

```
nkillall -SIGUSR1 salt-master
nkillall -SIGUSR1 salt-minion
```
Also under BSD and Mac OS X in addition to SIGUSR1 signal, debug subroutine set up for SIGINFO which has an advantage of being sent by Ctrl+T shortcut.

When filing an issue or sending questions to the mailing list for a problem with an unresponsive daemon this information can be invaluable.

### 3.10.12 Salt 0.16.x minions cannot communicate with a 0.17.x master

As of release 0.17.1 you can no longer run different versions of Salt on your Master and Minion servers. This is due to a protocol change for security purposes. The Salt team will continue to attempt to ensure versions are as backwards compatible as possible.

### 3.10.13 Debugging the Master and Minion

A list of common master and minion troubleshooting steps provide a starting point for resolving issues you may encounter.

### 3.11 Frequently Asked Questions

#### FAQ

- Frequently Asked Questions
  - Is Salt open-core?
  - I think I found a bug! What should I do?
  - What ports should I open on my firewall?
  - I'm seeing weird behavior (including but not limited to packages not installing their users properly)
  - My script runs every time I run a state.apply. Why?
  - When I run test.ping, why don't the Minions that aren't responding return anything? Returning False would be helpful.
  - How does Salt determine the Minion's id?
  - I'm trying to manage packages/services but I get an error saying that the state is not available. Why?
  - Why aren't my custom modules/states/etc. available on my Minions?
  - Module X isn't available, even though the shell command it uses is installed. Why?
  - Can I run different versions of Salt on my Master and Minion?
  - Does Salt support backing up managed files?
  - Is it possible to deploy a file to a specific minion, without other minions having access to it?
  - What is the best way to restart a Salt daemon using Salt?
    - Linux/Unix
    - Windows
    - Salting the Salt Master
3.11.1 Is Salt open-core?

No. Salt is 100% committed to being open-source, including all of our APIs. It is developed under the Apache 2.0 license, allowing it to be used in both open and proprietary projects.

To expand on this a little:

There is much argument over the actual definition of "open core". From our standpoint, Salt is open source because

1. It is a standalone product that anyone is free to use.
2. It is developed in the open with contributions accepted from the community for the good of the project.
3. There are no features of Salt itself that are restricted to separate proprietary products distributed by SaltStack, Inc.
4. Because of our Apache 2.0 license, Salt can be used as the foundation for a project or even a proprietary tool.
5. Our APIs are open and documented (any lack of documentation is an oversight as opposed to an intentional decision by SaltStack the company) and available for use by anyone.

SaltStack the company does make proprietary products which use Salt and its libraries, like company is free to do, but we do so via the APIs, NOT by forking Salt and creating a different, closed-source version of it for paying customers.

3.11.2 I think I found a bug! What should I do?

The salt-users mailing list as well as the salt IRC channel can both be helpful resources to confirm if others are seeing the issue and to assist with immediate debugging.

To report a bug to the Salt project, please follow the instructions in reporting a bug.

3.11.3 What ports should I open on my firewall?

Minions need to be able to connect to the Master on TCP ports 4505 and 4506. Minions do not need any inbound ports open. More detailed information on firewall settings can be found here.

3.11.4 I’m seeing weird behavior (including but not limited to packages not installing their users properly)

This is often caused by SELinux. Try disabling SELinux or putting it in permissive mode and see if the weird behavior goes away.

3.11.5 My script runs every time I run a state.apply. Why?

You are probably using cmd.run rather than cmd.wait. A cmd.wait state will only run when there has been a change in a state that it is watching.

A cmd.run state will run the corresponding command every time (unless it is prevented from running by the unless or onlyif arguments).

More details can be found in the documentation for the cmd states.
3.11.6 When I run test.ping, why don't the Minions that aren't responding return anything? Returning False would be helpful.

When you run test.ping the Master tells Minions to run commands/functions, and listens for the return data, printing it to the screen when it is received. If it doesn't receive anything back, it doesn't have anything to display for that Minion.

There are a couple options for getting information on Minions that are not responding. One is to use the verbose (-v) option when you run salt commands, as it will display ``Minion did not return`` for any Minions which time out.

```bash
salt -v '*' pkg.install zsh
```

Another option is to use the manage.down runner:

```bash
salt-run manage.down
```

Also, if the Master is under heavy load, it is possible that the CLI will exit without displaying return data for all targeted Minions. However, this doesn't mean that the Minions did not return; this only means that the Salt CLI timed out waiting for a response. Minions will still send their return data back to the Master once the job completes. If any expected Minions are missing from the CLI output, the jobs.list_jobs runner can be used to show the job IDs of the jobs that have been run, and the jobs.lookup_jid runner can be used to get the return data for that job.

```bash
salt-run jobs.list_jobs
salt-run jobs.lookup_jid 20130916125524463507
```

If you find that you are often missing Minion return data on the CLI, only to find it with the jobs runners, then this may be a sign that the worker_threads value may need to be increased in the master config file. Additionally, running your Salt CLI commands with the -t option will make Salt wait longer for the return data before the CLI command exits. For instance, the below command will wait up to 60 seconds for the Minions to return:

```bash
salt -t 60 '*' test.ping
```

3.11.7 How does Salt determine the Minion's id?

If the Minion id is not configured explicitly (using the id parameter), Salt will determine the id based on the hostname. Exactly how this is determined varies a little between operating systems and is described in detail here.

3.11.8 I'm trying to manage packages/services but I get an error saying that the state is not available. Why?

Salt detects the Minion's operating system and assigns the correct package or service management module based on what is detected. However, for certain custom spins and OS derivatives this detection fails. In cases like this, an issue should be opened on our tracker, with the following information:

1. The output of the following command:
   
   ```bash
   salt <minion_id> grains.items | grep os
   ```

2. The contents of /etc/lsb-release, if present on the Minion.
3.11.9 Why aren’t my custom modules/states/etc. available on my Minions?

Custom modules are synced to Minions when `saltutil.sync_modules` or `saltutil.sync_all` is run. Custom modules are also synced by `state.apply` when run without any arguments.

Similarly, custom states are synced to Minions when `state.apply`, `saltutil.sync_states`, or `saltutil.sync_all` is run.

Custom states are also synced by `state.apply` when run without any arguments.

Other custom types (renderers, outputters, etc.) have similar behavior, see the documentation for the `saltutil` module for more information.

*This reactor example* can be used to automatically sync custom types when the minion connects to the master, to help with this chicken-and-egg issue.

3.11.10 Module X isn’t available, even though the shell command it uses is installed. Why?

This is most likely a PATH issue. Did you custom-compile the software which the module requires? RHEL/CentOS/etc. in particular override the root user’s path in `/etc/init.d/functions`, setting it to `/sbin:/usr/sbin:/bin:/usr/bin`, making software installed into `/usr/local/bin` unavailable to Salt when the Minion is started using the initscript. In version 2014.1.0, Salt will have a better solution for these sort of PATH-related issues, but recompiling the software to install it into a location within the PATH should resolve the issue in the meantime. Alternatively, you can create a symbolic link within the PATH using a `file.symlink` state.

```
/usr/bin/foo:
  file.symlink:
    - target: /usr/local/bin/foo
```

3.11.11 Can I run different versions of Salt on my Master and Minion?

This depends on the versions. In general, it is recommended that Master and Minion versions match.

When upgrading Salt, the master(s) should always be upgraded first. Backwards compatibility for minions running newer versions of salt than their masters is not guaranteed.

Whenever possible, backwards compatibility between new masters and old minions will be preserved. Generally, the only exception to this policy is in case of a security vulnerability.

Recent examples of backwards compatibility breakage include the 0.17.1 release (where all backwards compatibility was broken due to a security fix), and the 2014.1.0 release (which retained compatibility between 2014.1.0 masters and 0.17 minions, but broke compatibility for 2014.1.0 minions and older masters).

3.11.12 Does Salt support backing up managed files?

Yes. Salt provides an easy to use addition to your file.managed states that allow you to back up files via `backup_mode`, `backup_mode` can be configured on a per state basis, or in the minion config (note that if set in the minion config this would simply be the default method to use, you still need to specify that the file should be backed up!).
3.11.13 Is it possible to deploy a file to a specific minion, without other minions having access to it?

The Salt fileserver does not yet support access control, but it is still possible to do this. As of Salt 2015.5.0, the `file_tree` external pillar is available, and allows the contents of a file to be loaded as Pillar data. This external pillar is capable of assigning Pillar values both to individual minions, and to `nodegroups`. See the documentation for details on how to set this up.

Once the external pillar has been set up, the data can be pushed to a minion via a `file.managed` state, using the `contents_pillar` argument:

```yaml
/etc/my_super_secret_file:
  file.managed:
    - user: secret
    - group: secret
    - mode: 600
    - contents_pillar: secret_files:my_super_secret_file
```

In this example, the source file would be located in a directory called `secret_files` underneath the file_tree path for the minion. The syntax for specifying the pillar variable is the same one used for `pillar.get`, with a colon representing a nested dictionary.

**Warning:** Deploying binary contents using the `file.managed` state is only supported in Salt 2015.8.4 and newer.

3.11.14 What is the best way to restart a Salt daemon using Salt?

Updating the salt-minion package requires a restart of the salt-minion service. But restarting the service while in the middle of a state run interrupts the process of the minion running states and sending results back to the master. It’s a tricky problem to solve, and we’re working on it, but in the meantime one way of handling this (on Linux and UNIX-based operating systems) is to use `at` (a job scheduler which predates cron) to schedule a restart of the service. `at` is not installed by default on most distros, and requires a service to be running (usually called `atd`) in order to schedule jobs. Here’s an example of how to upgrade the salt-minion package at the end of a Salt run, and schedule a service restart for one minute after the package update completes.

**Linux/Unix**

```yaml
salt-minion:
  pkg.installed:
    - name: salt-minion
      - version: 2014.1.7-3.el6
      - order: last
    service.running:
      - name: salt-minion
        require:
          - pkg: salt-minion
    cmd.run:
      - name: echo service salt-minion restart | at now + 1 minute
      - onchanges:
        - pkg: salt-minion
```

To ensure that `at` is installed and `atd` is running, the following states can be used (be sure to double-check the package name and service name for the distro the minion is running, in case they differ from the example below.)
An alternative to using the `atd` daemon is to fork and disown the process.

```yaml
restart_minion:
  cmd.run:
    - name: |
      exec 0<&- # close stdin
eexec 1<&- # close stdout
eexec 2<&- # close stderr
      nohup /bin/sh -c 'sleep 10 && salt-call --local service.restart salt-minion' &
    - python_shell: True
    - order: last
```

**Windows**

For Windows machines, restarting the minion can be accomplished using the following state:

```yaml
schedule-start:
  cmd.run:
    - name: 'start powershell "Restart-Service -Name salt-minion"'
    - order: last
```

or running immediately from the command line:

```bash
salt -G kernel:Windows cmd.run 'start powershell "Restart-Service -Name salt-minion"'
```

### 3.11.15 Salting the Salt Master

In order to configure a master server via states, the Salt master can also be ``salted`` in order to enforce state on the Salt master as well as the Salt minions. Salting the Salt master requires a Salt minion to be installed on the same machine as the Salt master. Once the Salt minion is installed, the minion configuration file must be pointed to the local Salt master:

```
master: 127.0.0.1
```

Once the Salt master has been ``salted`` with a Salt minion, it can be targeted just like any other minion. If the minion on the salted master is running, the minion can be targeted via any usual `salt` command. Additionally, the `salt-call` command can execute operations to enforce state on the salted master without requiring the minion to be running.

More information about salting the Salt master can be found in the salt-formula for salt itself:

https://github.com/saltstack-formulas/salt-formula

### 3.11.16 Is Targeting using Grain Data Secure?

Because grains can be set by users that have access to the minion configuration files on the local system, grains are considered less secure than other identifiers in Salt. Use caution when targeting sensitive operations or setting pillar...
values based on grain data.

When possible, you should target sensitive operations and data using the Minion ID. If the Minion ID of a system changes, the Salt Minion's public key must be re-accepted by an administrator on the Salt Master, making it less vulnerable to impersonation attacks.

### 3.11.17 Why Did the Value for a Grain Change on Its Own?

This is usually the result of an upstream change in an OS distribution that replaces or removes something that Salt was using to detect the grain. Fortunately, when this occurs, you can use Salt to fix it with a command similar to the following:

```
salt -G 'grain:ChangedValue' grains.setvals "{'grain': 'OldValue'}"
```

(Replacing `grain`, `ChangedValue`, and `OldValue` with the grain and values that you want to change / set.)

You should also file an issue describing the change so it can be fixed in Salt.

### 3.12 Salt Best Practices

Salt's extreme flexibility leads to many questions concerning the structure of configuration files. This document exists to clarify these points through examples and code.

#### 3.12.1 General rules

1. Modularity and clarity should be emphasized whenever possible.
2. Create clear relations between pillars and states.
3. Use variables when it makes sense but don't overuse them.
4. Store sensitive data in pillar.
5. Don't use grains for matching in your pillar top file for any sensitive pillars.

#### 3.12.2 Structuring States and Formulas

When structuring Salt States and Formulas it is important to begin with the directory structure. A proper directory structure clearly defines the functionality of each state to the user via visual inspection of the state's name.

Reviewing the **MySQL Salt Formula** it is clear to see the benefits to the end-user when reviewing a sample of the available states:

```
/srv/salt/mysql/files/
/srv/salt/mysql/client.sls
/srv/salt/mysql/map.jinja
/srv/salt/mysql/python.sls
/srv/salt/mysql/server.sls
```

This directory structure would lead to these states being referenced in a top file in the following way:
This clear definition ensures that the user is properly informed of what each state will do.

Another example comes from the vim-formula:

```bash
/srv/salt/vim/files/
/srv/salt/vim/absent.sls
/srv/salt/vim/init.sls
/srv/salt/vim/map.jinja
/srv/salt/vim/nerdtree.sls
/srv/salt/vim/pyflakes.sls
/srv/salt/vim/salt.sls
```

Once again viewing how this would look in a top file:

```bash
/srv/salt/top.sls:
```

```bash
base:
  'web*':
    - vim
    - vim.nerdtree
    - vim.pyflakes
    - vim.salt
  'db*':
    - vim.absent
```

The usage of a clear top-level directory as well as properly named states reduces the overall complexity and leads a user to both understand what will be included at a glance and where it is located.

In addition Formulas should be used as often as possible.

---

**Note:** Formulas repositories on the saltstack-formulas GitHub organization should not be pointed to directly from systems that automatically fetch new updates such as GitFS or similar tooling. Instead formulas repositories should be forked on GitHub or cloned locally, where unintended, automatic changes will not take place.

### 3.12.3 Structuring Pillar Files

*Pillars* are used to store secure and insecure data pertaining to minions. When designing the structure of the /srv/pillar directory, the pillars contained within should once again be focused on clear and concise data which users can easily review, modify, and understand.

The /srv/pillar/ directory is primarily controlled by top.sls. It should be noted that the pillar top.sls is not used as a location to declare variables and their values. The top.sls is used as a way to include other pillar files and organize the way they are matched based on environments or grains.

An example top.sls may be as simple as the following:

```bash
/srv/pillar/top.sls:
```
Any number of matchers can be added to the base environment. For example, here is an expanded version of the Pillar top file stated above:

```
/srv/pillar/top.sls:
```

```
base: '*
  - packages
```

Or an even more complicated example, using a variety of matchers in numerous environments:

```
/srv/pillar/top.sls:
```

```
base: '*
  - packages
  'web*':
    - apache
    - vim
```

It is clear to see through these examples how the top file provides users with power but when used incorrectly it can lead to confusing configurations. This is why it is important to understand that the top file for pillar is not used for variable definitions.

Each SLS file within the `/srv/pillar/` directory should correspond to the states which it matches.

This would mean that the `apache` pillar file should contain data relevant to Apache. Structuring files in this way once again ensures modularity, and creates a consistent understanding throughout our Salt environment. Users can expect that pillar variables found in an Apache state will live inside of an Apache pillar:

```
/srv/pillar/apache.sls:
```

```
apache:
  lookup:
    name: httpd
  config:
    tmpl: /etc/httpd/httpd.conf
```

While this pillar file is simple, it shows how a pillar file explicitly relates to the state it is associated with.

### 3.12.4 Variable Flexibility

Salt allows users to define variables in SLS files. When creating a state variables should provide users with as much flexibility as possible. This means that variables should be clearly defined and easy to manipulate, and that sane defaults should exist in the event a variable is not properly defined. Looking at several examples shows how these different items can lead to extensive flexibility.
Although it is possible to set variables locally, this is generally not preferred:

```yaml
/srv/salt/apache/conf.sls:

{% set name = 'httpd' %}
{% set tmpl = 'salt://apache/files/httpd.conf' %}

include:
  - apache

apache_conf:
  file.managed:
    - name: {{ name }}
    - source: {{ tmpl }}
    - template: jinja
    - user: root
    - watch_in:
      - service: apache
```

When generating this information it can be easily transitioned to the pillar where data can be overwritten, modified, and applied to multiple states, or locations within a single state:

```yaml
/srv/pillar/apache.sls:

apache:
  lookup:
    name: httpd
  config:
    tmpl: salt://apache/files/httpd.conf
```

```yaml
/srv/salt/apache/conf.sls:

{% from "apache/map.jinja" import apache with context %}

include:
  - apache

apache_conf:
  file.managed:
    - name: {{ salt['pillar.get']('apache:lookup:name') }}
    - source: {{ salt['pillar.get']('apache:lookup:config:tmpl') }}
    - template: jinja
    - user: root
    - watch_in:
      - service: apache
```

This flexibility provides users with a centralized location to modify variables, which is extremely important as an environment grows.

### 3.12.5 Modularity Within States

Ensuring that states are modular is one of the key concepts to understand within Salt. When creating a state a user must consider how many times the state could be re-used, and what it relies on to operate. Below are several examples which will iteratively explain how a user can go from a state which is not very modular to one that is:

```yaml
/srv/salt/apache/init.sls:
```

3.12. Salt Best Practices
The example above is probably the worst-case scenario when writing a state. There is a clear lack of focus by naming both the pkg/service, and managed file directly as the state ID. This would lead to changing multiple requires within this state, as well as others that may depend upon the state.

Imagine if a require was used for the `httpd` package in another state, and then suddenly it’s a custom package. Now changes need to be made in multiple locations which increases the complexity and leads to a more error prone configuration.

There is also the issue of having the configuration file located in the init, as a user would be unable to simply install the service and use the default conf file.

Our second revision begins to address the referencing by using `-name`, as opposed to direct ID references:

```
srv/salt/apache/init.sls:
apache:
  pkg.installed:
   - name: httpd
  service.running:
   - name: httpd
   - enable: True

apache_conf:
  file.managed:
   - name: /etc/httpd/httpd.conf
   - source: salt://apache/files/httpd.conf
   - template: jinja
   - watch_in:
     - service: apache
```

The above init file is better than our original, yet it has several issues which lead to a lack of modularity. The first of these problems is the usage of static values for items such as the name of the service, the name of the managed file, and the source of the managed file. When these items are hard coded they become difficult to modify and the opportunity to make mistakes arises. It also leads to multiple edits that need to occur when changing these items (imagine if there were dozens of these occurrences throughout the state!). There is also still the concern of the configuration file data living in the same state as the service and package.

In the next example steps will be taken to begin addressing these issues. Starting with the addition of a map.jinja file (as noted in the [Formula documentation](http://saltstack.com/docs/chapter17-formula.html)), and modification of static values:

```
srv/salt/apache/map.jinja:
{% set apache = salt['grains.filter_by']({
  'Debian': {
    'server': 'apache2',
    'service': 'apache2',
    'conf': '/etc/apache2/apache.conf',
  }
})
```
The changes to this state now allow us to easily identify the location of the variables, as well as ensuring they are flexible and easy to modify. While this takes another step in the right direction, it is not yet complete. Suppose the user did not want to use the provided conf file, or even their own configuration file, but the default apache conf. With the current state setup this is not possible. To attain this level of modularity this state will need to be broken into two states.

```jinja
{# from "apache/map.jinja" import apache with context #}

apache:
  pkg.installed:
    - name: {{ apache.server }}
  service.running:
    - name: {{ apache.service }}
    - enable: True

apache_conf:
  file.managed:
    - name: {{ apache.conf }}
    - source: {{ salt['pillar.get'](apache:lookup:config:tmpl) }}
    - template: jinja
    - user: root
    - watch_in:
      - service: apache
```

The changes to this state now allow us to easily identify the location of the variables, as well as ensuring they are flexible and easy to modify. While this takes another step in the right direction, it is not yet complete. Suppose the user did not want to use the provided conf file, or even their own configuration file, but the default apache conf. With the current state setup this is not possible. To attain this level of modularity this state will need to be broken into two states.
This new structure now allows users to choose whether they only wish to install the default Apache, or if they wish, overwrite the default package, service, configuration file location, or the configuration file itself. In addition to this the data has been broken between multiple files allowing for users to identify where they need to change the associated data.

### 3.12.6 Storing Secure Data

Secure data refers to any information that you would not wish to share with anyone accessing a server. This could include data such as passwords, keys, or other information.

As all data within a state is accessible by EVERY server that is connected it is important to store secure data within pillar. This will ensure that only those servers which require this secure data have access to it. In this example a use can go from an insecure configuration to one which is only accessible by the appropriate hosts:

```
/srv/salt/mysql/testerdb.sls:

testdb:
  mysql_database.present:
    - name: testerdb
```

```
/srv/salt/mysql/user.sls:

include:
  - mysql.testerdb
```
Many users would review this state and see that the password is there in plain text, which is quite problematic. It results in several issues which may not be immediately visible.

The first of these issues is clear to most users -- the password being visible in this state. This means that any minion will have a copy of this, and therefore the password which is a major security concern as minions may not be locked down as tightly as the master server.

The other issue that can be encountered is access by users on the master. If everyone has access to the states (or their repository), then they are able to review this password. Keeping your password data accessible by only a few users is critical for both security and peace of mind.

There is also the issue of portability. When a state is configured this way it results in multiple changes needing to be made. This was discussed in the sections above but it is a critical idea to drive home. If states are not portable it may result in more work later!

Fixing this issue is relatively simple, the content just needs to be moved to the associated pillar:

```
/srv/pillar/mysql.sls:

mysql:
    lookup:
        name: testerdb
        password: test3rdb
        user: frank
        host: localhost
```

```
/srv/salt/mysql/testerdb.sls:

testdb:
    mysql_database.present:
        - name: {{ salt['pillar.get']('mysql:lookup:name') }}
```

```
/srv/salt/mysql/user.sls:

include:
    - mysql.testerdb

testdb_user:
    mysql_user.present:
        - name: {{ salt['pillar.get']('mysql:lookup:user') }}
        - password: {{ salt['pillar.get']('mysql:lookup:password') }}
        - host: {{ salt['pillar.get']('mysql:lookup:host') }}
        - require:
            - sls: mysql.testerdb
```

Now that the database details have been moved to the associated pillar file, only machines which are targeted via pillar will have access to these details. Access to users who should not be able to review these details can also be prevented while ensuring that they are still able to write states which take advantage of this information.
Remote Execution

Running pre-defined or arbitrary commands on remote hosts, also known as remote execution, is the core function of Salt. The following links explore modules and returners, which are two key elements of remote execution.

Salt Execution Modules

Salt execution modules are called by the remote execution system to perform a wide variety of tasks. These modules provide functionality such as installing packages, restarting a service, running a remote command, transferring files, and so on.

- Full list of execution modules Contains: a list of core modules that ship with Salt.
- Writing execution modules Contains: a guide on how to write Salt modules.

4.1 Remote execution tutorial

Before continuing make sure you have a working Salt installation by following the Installation and the configuration instructions.

Stuck?

There are many ways to get help from the Salt community including our mailing list and our IRC channel #salt.

4.1.1 Order your minions around

Now that you have a master and at least one minion communicating with each other you can perform commands on the minion via the salt command. Salt calls are comprised of three main components:

```
salt '<target>' <function> [arguments]
```

See also:

- salt manpage

**target**

The target component allows you to filter which minions should run the following function. The default filter is a glob on the minion id. For example:
Targets can be based on minion system information using the Grains system:

```
salt -G 'os:Ubuntu' test.ping
```

See also:

*Grains system*

Targets can be filtered by regular expression:

```
salt -E 'virtmach[0-9]' test.ping
```

Targets can be explicitly specified in a list:

```
salt -L 'foo,bar,baz,quo' test.ping
```

Or Multiple target types can be combined in one command:

```
salt -C 'G@os:Ubuntu and webser* or E@database.*' test.ping
```

**function**

A function is some functionality provided by a module. Salt ships with a large collection of available functions. List all available functions on your minions:

```
salt '*' sys.doc
```

Here are some examples:

Show all currently available minions:

```
salt '*' test.ping
```

Run an arbitrary shell command:

```
salt '*' cmd.run 'uname -a'
```

See also:

*the full list of modules*

**arguments**

Space-delimited arguments to the function:

```
salt '*' cmd.exec_code python 'import sys; print sys.version'
```

Optional, keyword arguments are also supported:

```
salt '*' pip.install salt timeout=5 upgrade=True
```

They are always in the form of `kwarg=argument`. 
4.2 Running Commands on Salt Minions

Salt can be controlled by a command line client by the root user on the Salt master. The Salt command line client uses the Salt client API to communicate with the Salt master server. The Salt client is straightforward and simple to use.

Using the Salt client commands can be easily sent to the minions.

Each of these commands accepts an explicit \--config option to point to either the master or minion configuration file. If this option is not provided and the default configuration file does not exist then Salt falls back to use the environment variables SALT_MASTER_CONFIG and SALT_MINION_CONFIG.

See also:

Configuration

4.2.1 Using the Salt Command

The Salt command needs a few components to send information to the Salt minions. The target minions need to be defined, the function to call and any arguments the function requires.

Defining the Target Minions

The first argument passed to salt, defines the target minions, the target minions are accessed via their hostname. The default target type is a bash glob:

```
salt '*foo.com' sys.doc
```

Salt can also define the target minions with regular expressions:

```
salt -E '.*cmd.run 'ls -l | grep foo''
```

Or to explicitly list hosts, salt can take a list:

```
salt -L foo.bar.baz,quo.qux cmd.run 'ps aux | grep foo'
```

More Powerful Targets

See Targeting.

Calling the Function

The function to call on the specified target is placed after the target specification.

New in version 0.9.8.

Functions may also accept arguments, space-delimited:

```
salt '*cmd.exec_code python 'import sys; print sys.version''
```

Optional, keyword arguments are also supported:

```
salt '*pip.install salt timeout=5 upgrade=True'
```
They are always in the form of `kwarg=argument`.

Arguments are formatted as YAML:

```python
salt '*' cmd.run 'echo "Hello: $FIRST_NAME"' env='\{FIRST_NAME: "Joe"\}'
```

Note: dictionaries must have curly braces around them (like the `env` keyword argument above). This was changed in 0.15.1: in the above example, the first argument used to be parsed as the dictionary `{"echo "Hello": "$FIRST_NAME"}`. This was generally not the expected behavior.

If you want to test what parameters are actually passed to a module, use the `test.arg_repr` command:

```python
salt '*' test.arg_repr 'echo "Hello: $FIRST_NAME"' env='\{FIRST_NAME: "Joe"\}'
```

### Finding available minion functions

The Salt functions are self documenting, all of the function documentation can be retrieved from the minions via the `sys.doc()` function:

```python
salt '*' sys.doc
```

### Compound Command Execution

If a series of commands needs to be sent to a single target specification then the commands can be sent in a single publish. This can make gathering groups of information faster, and lowers the stress on the network for repeated commands.

Compound command execution works by sending a list of functions and arguments instead of sending a single function and argument. The functions are executed on the minion in the order they are defined on the command line, and then the data from all of the commands are returned in a dictionary. This means that the set of commands are called in a predictable way, and the returned data can be easily interpreted.

Executing compound commands if done by passing a comma delimited list of functions, followed by a comma delimited list of arguments:

```python
salt '*' cmd.run,test.ping,test.echo 'cat /proc/cpuinfo',,,foo
```

The trick to look out for here, is that if a function is being passed no arguments, then there needs to be a placeholder for the absent arguments. This is why in the above example, there are two commas right next to each other. `test.ping` takes no arguments, so we need to add another comma, otherwise Salt would attempt to pass `"foo"` to `test.ping`.

If you need to pass arguments that include commas, then make sure you add spaces around the commas that separate arguments. For example:

```python
salt '*' cmd.run,test.ping,test.echo 'echo "1,2,3"' , , foo
```

You may change the arguments separator using the `--args-separator` option:

```bash
salt --args-separator=:: '*X' some.fun,test.echo params with , comma :: foo
```

### 4.2.2 CLI Completion

Shell completion scripts for the Salt CLI are available in the `pkg Salt` source directory.
4.3 Writing Execution Modules

Salt execution modules are the functions called by the `salt` command.

4.3.1 Modules Are Easy to Write!

Writing Salt execution modules is straightforward.

A Salt execution module is a Python or Cython module placed in a directory called `_modules/` within the `file_roots` as specified by the master config file. By default this is `/srv/salt/_modules` on Linux systems.

Modules placed in `_modules/` will be synced to the minions when any of the following Salt functions are called:

- `state.apply`
- `saltutil.sync_modules`
- `saltutil.sync_all`

Note that a module's default name is its filename (i.e. `foo.py` becomes module `foo`), but that its name can be overridden by using a `__virtual__` function.

If a Salt module has errors and cannot be imported, the Salt minion will continue to load without issue and the module with errors will simply be omitted.

If adding a Cython module the file must be named `<modulename>.pyx` so that the loader knows that the module needs to be imported as a Cython module. The compilation of the Cython module is automatic and happens when the minion starts, so only the `*.pyx` file is required.

4.3.2 Zip Archives as Modules

Python 2.3 and higher allows developers to directly import zip archives containing Python code. By setting `enable_zip_modules` to `True` in the minion config, the Salt loader will be able to import `.zip` files in this fashion.

This allows Salt module developers to package dependencies with their modules for ease of deployment, isolation, etc.

For a user, Zip Archive modules behave just like other modules. When executing a function from a module provided as the file `my_module.zip`, a user would call a function within that module as `my_module.<function>`.

Creating a Zip Archive Module

A Zip Archive module is structured similarly to a simple Python package. The `.zip` file contains a single directory with the same name as the module. The module code traditionally in `<module_name>.py` goes in `<module_name>/__init__.py`. The dependency packages are subdirectories of `<module_name>/`.

Here is an example directory structure for the `lumberjack` module, which has two library dependencies (`sleep` and `work`) to be included.

```
modules $ ls -R lumberjack
__init__.py  sleep  work
lumberjack/sleep:  __init__.py
lumberjack/work:  __init__.py
```
The contents of `lumberjack/__init__.py` show how to import and use these included libraries.

```
# Libraries included in lumberjack.zip
from lumberjack import sleep, work

def is_ok(person):
    ''' Checks whether a person is really a lumberjack '''
    return sleep.all_night(person) and work.all_day(person)
```

Then, create the zip:

```
modules $ zip -r lumberjack lumberjack
  adding: lumberjack/ (stored 0%)
  adding: lumberjack/__init__.py (deflated 39%)
  adding: lumberjack/sleep/ (stored 0%)
  adding: lumberjack/sleep/__init__.py (deflated 7%)
  adding: lumberjack/work/ (stored 0%)
  adding: lumberjack/work/__init__.py (deflated 7%)
modules $ unzip -l lumberjack.zip
Archive: lumberjack.zip
  Length Date  Time    Name
  ------  ----  ----    ----
     0 08-21-15 20:08  lumberjack/
    348 08-21-15 20:08  lumberjack/__init__.py
     0 08-21-15 19:53  lumberjack/sleep/
     83 08-21-15 19:53  lumberjack/sleep/__init__.py
     0 08-21-15 19:53  lumberjack/work/
     81 08-21-15 19:21  lumberjack/work/__init__.py
  ------  ------
     512 6 files
```

Once placed in `file_roots`, Salt users can distribute and use `lumberjack.zip` like any other module.

```
$ sudo salt minion1 saltutil.sync_modules
minion1:
  - modules.lumberjack
$ sudo salt minion1 lumberjack.is_ok 'Michael Palin'
minion1: True
```

### 4.3.3 Cross Calling Execution Modules

All of the Salt execution modules are available to each other and modules can call functions available in other execution modules.

The variable `__salt__` is packed into the modules after they are loaded into the Salt minion.

The `__salt__` variable is a Python dictionary containing all of the Salt functions. Dictionary keys are strings representing the names of the modules and the values are the functions themselves.

Salt modules can be cross-called by accessing the value in the `__salt__` dict:

```
def foo(bar):
    return __salt__['cmd.run'](bar)
```

This code will call the `run` function in the `cmd` module and pass the argument `bar` to it.
4.3.4 Preloaded Execution Module Data

When interacting with execution modules often it is nice to be able to read information dynamically about the minion or to load in configuration parameters for a module.

Salt allows for different types of data to be loaded into the modules by the minion.

Grains Data

The values detected by the Salt Grains on the minion are available in a dict named `__grains__` and can be accessed from within callable objects in the Python modules.

To see the contents of the grains dictionary for a given system in your deployment run the `grains.items()` function:

```
salt 'hostname' grains.items --output=pprint
```

Any value in a grains dictionary can be accessed as any other Python dictionary. For example, the grain representing the minion ID is stored in the `id` key and from an execution module, the value would be stored in `__grains__['id']`.

Module Configuration

Since parameters for configuring a module may be desired, Salt allows for configuration information from the minion configuration file to be passed to execution modules.

Since the minion configuration file is a YAML document, arbitrary configuration data can be passed in the minion config that is read by the modules. It is therefore strongly recommended that the values passed in the configuration file match the module name. A value intended for the `test` execution module should be named `test.<value>`.

The test execution module contains usage of the module configuration and the default configuration file for the minion contains the information and format used to pass data to the modules. `salt.modules.test.conf/minion`.

4.3.5 Printout Configuration

Since execution module functions can return different data, and the way the data is printed can greatly change the presentation, Salt has a printout configuration.

When writing a module the `__outputter__` dictionary can be declared in the module. The `__outputter__` dictionary contains a mapping of function name to Salt Outputter.

```
__outputter__ = {
    'run': 'txt'
}
```

This will ensure that the text outputter is used.

4.3.6 Virtual Modules

Virtual modules let you override the name of a module in order to use the same name to refer to one of several similar modules. The specific module that is loaded for a virtual name is selected based on the current platform or environment.
For example, packages are managed across platforms using the `pkg` module. `pkg` is a virtual module name that is an alias for the specific package manager module that is loaded on a specific system (for example, `yumpkg` on RHEL/CentOS systems, and `aptpkg` on Ubuntu).

Virtual module names are set using the `__virtual__` function and the `virtual name`.

### 4.3.7 __virtual__ Function

The `__virtual__` function returns either a `string`, `True`, `False`, or `False` with an `error string`. If a string is returned then the module is loaded using the name of the string as the virtual name. If `True` is returned the module is loaded using the current module name. If `False` is returned the module is not loaded. `False` lets the module perform system checks and prevent loading if dependencies are not met.

Since `__virtual__` is called before the module is loaded, `__salt__` will be unavailable as it will not have been packed into the module at this point in time.

**Note:** Modules which return a string from `__virtual__` that is already used by a module that ships with Salt will _override_ the stock module.

#### Returning Error Information from __virtual__

Optionally, Salt plugin modules, such as execution, state, returner, beacon, etc. modules may additionally return a string containing the reason that a module could not be loaded. For example, an execution module called `cheese` and a corresponding state module also called `cheese`, both depending on a utility called `enzymes` should have `__virtual__` functions that handle the case when the dependency is unavailable.

```python
try:
    import enzymes
    HAS_ENZYMES = True
except ImportError:
    HAS_ENZYMES = False

def __virtual__():
    """
    only load cheese if enzymes are available
    """
    if HAS_ENZYMES:
        return 'cheese'
    else:
        return False, 'The cheese execution module cannot be loaded: enzymes unavailable.'

def __virtual__():
    """
    Cheese state module
    """
    return 'cheese'

```
# predicate loading of the cheese state on the corresponding execution module
if 'cheese.slice' in __salt__:
    return 'cheese'
else:
    return False, 'The cheese state module cannot be loaded: enzymes unavailable.'

Examples

The package manager modules are among the best examples of using the __virtual__ function. A table of all the virtual pkg modules can be found here.

Overriding Virtual Module Providers

Salt often uses OS grains (os, osrelease, os_family, etc.) to determine which module should be loaded as the virtual module for pkg, service, etc. Sometimes this OS detection is incomplete, with new distros popping up, existing distros changing init systems, etc. The virtual modules likely to be affected by this are in the list below (click each item for more information):

- pkg
- service
- user
- shadow
- group

If Salt is using the wrong module for one of these, first of all, please report it on the issue tracker, so that this issue can be resolved for a future release. To make it easier to troubleshoot, please also provide the grains.items output, taking care to redact any sensitive information.

Then, while waiting for the SaltStack development team to fix the issue, Salt can be made to use the correct module using the providers option in the minion config file:

```python
providers:
    service: systemd
    pkg: aptpkg
```

The above example will force the minion to use the systemd module to provide service management, and the aptpkg module to provide package management.

4.3.8 __virtualname__

__virtualname__ is a variable that is used by the documentation build system to know the virtual name of a module without calling the __virtual__ function. Modules that return a string from the __virtual__ function must also set the __virtualname__ variable.

To avoid setting the virtual name string twice, you can implement __virtual__ to return the value set for __virtualname__ using a pattern similar to the following:

```python
# Define the module’s virtual name
__virtualname__ = 'pkg'

def __virtual__():
```

4.3. Writing Execution Modules
Confine this module to Mac OS with Homebrew.

```python
if salt.utils.which('brew') and __grains__['os'] == 'MacOS':
    return __virtualname__
return False
```

### 4.3.9 Documentation

Salt execution modules are documented. The `sys.doc()` function will return the documentation for all available modules:

```bash
salt '*' sys.doc
```

The `sys.doc` function simply prints out the docstrings found in the modules; when writing Salt execution modules, please follow the formatting conventions for docstrings as they appear in the other modules.

#### Adding Documentation to Salt Modules

It is strongly suggested that all Salt modules have documentation added.

To add documentation add a **Python docstring** to the function.

```python
def spam(eggs):
    '''
    A function to make some spam with eggs!
    
    CLI Example:::
    
    salt '*' test.spam eggs
    '''
    return eggs
```

Now when the `sys.doc` call is executed the docstring will be cleanly returned to the calling terminal.

Documentation added to execution modules in docstrings will automatically be added to the online web-based documentation.

#### Add Execution Module Metadata

When writing a Python docstring for an execution module, add information about the module using the following field lists:

```
:maintainer: Thomas Hatch <thatch@saltstack.com, Seth House <shouse@saltstack.com>
:maturity: new
:depends: python-mysqld
:platform: all
```

The maintainer field is a comma-delimited list of developers who help maintain this module.

The maturity field indicates the level of quality and testing for this module. Standard labels will be determined.

The depends field is a comma-delimited list of modules that this module depends on.

The platform field is a comma-delimited list of platforms that this module is known to run on.
4.3.10 Log Output

You can call the logger from custom modules to write messages to the minion logs. The following code snippet demonstrates writing log messages:

```python
import logging

log = logging.getLogger(__name__)

log.info('Here is Some Information')
log.warning('You Should Not Do That')
log.error('It Is Busted')
```

4.3.11 Aliasing Functions

Sometimes one wishes to use a function name that would shadow a python built-in. A common example would be `set()`. To support this, append an underscore to the function definition, `def set_()`, and use the `__func_alias__` feature to provide an alias to the function.

`__func_alias__` is a dictionary where each key is the name of a function in the module, and each value is a string representing the alias for that function. When calling an aliased function from a different execution module, state module, or from the cli, the alias name should be used.

```python
__func_alias__ = {
    'set_': 'set',
    'list_': 'list',
}
```

4.3.12 Private Functions

In Salt, Python callable objects contained within an execution module are made available to the Salt minion for use. The only exception to this rule is a callable object with a name starting with an underscore `_`.

**Objects Loaded Into the Salt Minion**

```python
def foo(bar):
    return bar
class baz:
    def __init__(self, quo):
        pass
```

**Objects NOT Loaded into the Salt Minion**

```python
def _foobar(baz): # Preceded with an _
    return baz
cheese = {} # Not a callable Python object
```
4.3.13 Useful Decorators for Modules

Depends Decorator

When writing execution modules there are many times where some of the module will work on all hosts but some functions have an external dependency, such as a service that needs to be installed or a binary that needs to be present on the system.

Instead of trying to wrap much of the code in large try/except blocks, a decorator can be used.

If the dependencies passed to the decorator don't exist, then the salt minion will remove those functions from the module on that host.

If a `fallback_function` is defined, it will replace the function instead of removing it

```python
import logging

from salt.utils.decorators import depends

log = logging.getLogger(__name__)

try:
    import dependency_that_sometimes_exists
except ImportError as e:
    log.trace('Failed to import dependency_that_sometimes_exists: {0}'.format(e))

@depends('dependency_that_sometimes_exists')
def foo():
    '''
    Function with a dependency on the "dependency_that_sometimes_exists" module,
    if the "dependency_that_sometimes_exists" is missing this function will not exist
    '''
    return True

def _fallback():
    '''
    Fallback function for the depends decorator to replace a function with
    '''
    return '"dependency_that_sometimes_exists" needs to be installed for this function to exist'

@depends('dependency_that_sometimes_exists', fallback_function=_fallback)
def foo():
    '''
    Function with a dependency on the "dependency_that_sometimes_exists" module.
    If the "dependency_that_sometimes_exists" is missing this function will be replaced with "_fallback"
    '''
    return True
```

In addition to global dependencies the depends decorator also supports raw booleans.

```python
from salt.utils.decorators import depends

HAS_DEP = False
try:
    import dependency_that_sometimes_exists
    HAS_DEP = True
except ImportError:
```

368 Chapter 4. Remote Execution
```python
pass
@depends(HAS_DEP)
def foo():
    return True
```
CHAPTER 5

Configuration Management

Salt contains a robust and flexible configuration management framework, which is built on the remote execution core. This framework executes on the minions, allowing effortless, simultaneous configuration of tens of thousands of hosts, by rendering language specific state files. The following links provide resources to learn more about state and renderers.

**States**  Express the state of a host using small, easy to read, easy to understand configuration files. *No programming required.*

- **Full list of states**  Contains: list of install packages, create users, transfer files, start services, and so on.
- **Pillar System**  Contains: description of Salt’s Pillar system.
- **Highstate data structure**  Contains: a dry vocabulary and technical representation of the configuration format that states represent.
- **Writing states**  Contains: a guide on how to write Salt state modules, easily extending Salt to directly manage more software.

**Note:**  Salt execution modules are different from state modules and cannot be called directly within state files. You must use the `module` state module to call execution modules within state runs.

**Renderers**  Renderers use state configuration files written in a variety of languages, templating engines, or files. Salt’s configuration management system is, under the hood, language agnostic.

- **Full list of renderers**  Contains: a list of renderers. YAML is one choice, but many systems are available, from alternative templating engines to the PyDSL language for rendering sls formulas.
- **Renderers**  Contains: more information about renderers. Salt states are only concerned with the ultimate highstate data structure, not how the data structure was created.

5.1 **How Do I Use Salt States?**

Simplicity, Simplicity, Simplicity

Many of the most powerful and useful engineering solutions are founded on simple principles. Salt States strive to do just that: K.I.S.S. (Keep It Stupidly Simple)

The core of the Salt State system is the SLS, or Salt State file. The SLS is a representation of the state in which a system should be in, and is set up to contain this data in a simple format. This is often called configuration management.
5.1.1 It is All Just Data

Before delving into the particulars, it will help to understand that the SLS file is just a data structure under the hood. While understanding that the SLS is just a data structure isn't critical for understanding and making use of Salt States, it should help bolster knowledge of where the real power is.

SLS files are therefore, in reality, just dictionaries, lists, strings, and numbers. By using this approach Salt can be much more flexible. As one writes more state files, it becomes clearer exactly what is being written. The result is a system that is easy to understand, yet grows with the needs of the admin or developer.

5.1.2 The Top File

The example SLS files in the below sections can be assigned to hosts using a file called top.sls. This file is described in-depth here.

5.1.3 Default Data - YAML

By default Salt represents the SLS data in what is one of the simplest serialization formats available - YAML.

A typical SLS file will often look like this in YAML:

```yaml
Note: These demos use some generic service and package names, different distributions often use different names for packages and services. For instance apache should be replaced with httpd on a Red Hat system. Salt uses the name of the init script, systemd name, upstart name etc. based on what the underlying service management for the platform. To get a list of the available service names on a platform execute the service.get_all salt function.
Information on how to make states work with multiple distributions is later in the tutorial.

apache:
  pkg.installed: []
  service.running:
    - require:
      - pkg: apache

This SLS data will ensure that the package named apache is installed, and that the apache service is running. The components can be explained in a simple way.

The first line is the ID for a set of data, and it is called the ID Declaration. This ID sets the name of the thing that needs to be manipulated.

The second and third lines contain the state module function to be run, in the format <state_module>..<function>. The pkg.installed state module function ensures that a software package is installed via the system's native package manager. The service.running state module function ensures that a given system daemon is running.

Finally, on line five, is the word require. This is called a Requisite Statement, and it makes sure that the Apache service is only started after a successful installation of the apache package.

372 Chapter 5. Configuration Management
5.1.4 Adding Configs and Users

When setting up a service like an Apache web server, many more components may need to be added. The Apache configuration file will most likely be managed, and a user and group may need to be set up.

```yaml
apache:
  pkg.installed: []
  service.running:
    - watch:
      - pkg: apache
      - file: /etc/httpd/conf/httpd.conf
      - user: apache
  user.present:
    - uid: 87
    - gid: 87
    - home: /var/www/html
    - shell: /bin/nologin
    - require:
      - group: apache
  group.present:
    - gid: 87
    - require:
      - pkg: apache

/etc/httpd/conf/httpd.conf:
  file.managed:
    - source: salt://apache/httpd.conf
    - user: root
    - group: root
    - mode: 644
```

This SLS data greatly extends the first example, and includes a config file, a user, a group and new requisite statement: `watch`.

Adding more states is easy, since the new user and group states are under the Apache ID, the user and group will be the Apache user and group. The `require` statements will make sure that the user will only be made after the group, and that the group will be made only after the Apache package is installed.

Next, the `require` statement under service was changed to `watch`, and is now watching 3 states instead of just one. The `watch` statement does the same thing as `require`, making sure that the other states run before running the state with a `watch`, but it adds an extra component. The `watch` statement will run the state’s watcher function for any changes to the watched states. So if the package was updated, the config file changed, or the user uid modified, then the service state’s watcher will be run. The service state’s watcher just restarts the service, so in this case, a change in the config file will also trigger a restart of the respective service.

5.1.5 Moving Beyond a Single SLS

When setting up Salt States in a scalable manner, more than one SLS will need to be used. The above examples were in a single SLS file, but two or more SLS files can be combined to build out a State Tree. The above example also references a file with a strange source - `salt://apache/httpd.conf`. That file will need to be available as well.

The SLS files are laid out in a directory structure on the Salt master; an SLS is just a file and files to download are just files.

The Apache example would be laid out in the root of the Salt file server like this:
So the httpd.conf is just a file in the apache directory, and is referenced directly.

**Do not use dots in SLS file names or their directories**

The initial implementation of *top.sls* and *Include declaration* followed the python import model where a slash is represented as a period. This means that a SLS file with a period in the name (besides the suffix period) cannot be referenced. For example, *webserver_1.0.sls* is not referenceable because *webserver_1.0* would refer to the directory/file *webserver_1/0.sls*

The same applies for any subdirectories, this is especially `tricky` when git repos are created. Another command that typically can't render it's output is `state.show_sls` of a file in a path that contains a dot.

But when using more than one single SLS file, more components can be added to the toolkit. Consider this SSH example:

```yaml
ssh/init.sls:
  openssh-client:
    pkg.installed

  /etc/ssh/ssh_config:
    file.managed:
      - user: root
      - group: root
      - mode: 644
      - source: salt://ssh/ssh_config
      - require:
        - pkg: openssh-client

ssh/server.sls:

  include:
    - ssh

  openssh-server:
    pkg.installed

  sshd:
    service.running:
      - require:
        - pkg: openssh-client
        - pkg: openssh-server
        - file: /etc/ssh/banner
        - file: /etc/ssh/sshd_config

  /etc/ssh/sshd_config:
    file.managed:
      - user: root
      - group: root
      - mode: 644
      - source: salt://ssh/sshd_config
      - require:
        - pkg: openssh-server
```
/etc/ssh/banner:
  file:
  - managed
  - user: root
  - group: root
  - mode: 644
  - source: salt://ssh/banner
  - require:
    - pkg: openssh-server

Note: Notice that we use two similar ways of denoting that a file is managed by Salt. In the /etc/ssh/sshd_config state section above, we use the `file.managed` state declaration whereas with the /etc/ssh/banner state section, we use the `file` state declaration and add a `managed` attribute to that state declaration. Both ways produce an identical result; the first way -- using `file.managed` -- is merely a shortcut.

Now our State Tree looks like this:

```
apache/init.sls
apache/httpd.conf
ssh/init.sls
ssh/server.sls
ssh/banner
ssh/sshd_config
```

This example now introduces the `include` statement. The include statement includes another SLS file so that components found in it can be required, watched or as will soon be demonstrated - extended.

The include statement allows for states to be cross linked. When an SLS has an include statement it is literally extended to include the contents of the included SLS files.

Note that some of the SLS files are called init.sls, while others are not. More info on what this means can be found in the States Tutorial.

### 5.1.6 Extending Included SLS Data

Sometimes SLS data needs to be extended. Perhaps the apache service needs to watch additional resources, or under certain circumstances a different file needs to be placed.

In these examples, the first will add a custom banner to ssh and the second will add more watchers to apache to include mod_python.

**ssh/custom-server.sls:**

```
include:
  - ssh.server

extend:
  /etc/ssh/banner:
    file:
      - source: salt://ssh/custom-banner
```

**python/mod_python.sls:**

```
```
The custom-server.sls file uses the extend statement to overwrite where the banner is being downloaded from, and therefore changing what file is being used to configure the banner.

In the new mod_python SLS the mod_python package is added, but more importantly the apache service was extended to also watch the mod_python package.

### Using extend with require or watch

The `extend` statement works differently for `require` or `watch`. It appends to, rather than replacing the requisite component.

### 5.1.7 Understanding the Render System

Since SLS data is simply that (data), it does not need to be represented with YAML. Salt defaults to YAML because it is very straightforward and easy to learn and use. But the SLS files can be rendered from almost any imaginable medium, so long as a renderer module is provided.

The default rendering system is the `yaml_jinja` renderer. The `yaml_jinja` renderer will first pass the template through the Jinja2 templating system, and then through the YAML parser. The benefit here is that full programming constructs are available when creating SLS files.

Other renderers available are `yaml_mako` and `yaml_wempy` which each use the Mako or Wempy templating system respectively rather than the jinja templating system, and more notably, the pure Python or `py`, `pydsl` & `pyobjects` renderers. The `py` renderer allows for SLS files to be written in pure Python, allowing for the utmost level of flexibility and power when preparing SLS data; while the `pydsl` renderer provides a flexible, domain-specific language for authoring SLS data in Python; and the `pyobjects` renderer gives you a "Pythonic" interface to building state data.

Note: The templating engines described above aren't just available in SLS files. They can also be used in `file.managed` states, making file management much more dynamic and flexible. Some examples for using templates in managed files can be found in the documentation for the file state, as well as the MooseFS example below.

### Getting to Know the Default - yaml_jinja

The default renderer - `yaml_jinja`, allows for use of the jinja templating system. A guide to the Jinja templating system can be found here: [http://jinja.pocoo.org/docs](http://jinja.pocoo.org/docs)

When working with renderers a few very useful bits of data are passed in. In the case of templating engine based renderers, three critical components are available, `salt`, `grains`, and `pillar`. The `salt` object allows for any
Salt function to be called from within the template, and grains allows for the Grains to be accessed from within the template. A few examples:

apache/init.sls:

```yaml
apache:
  pkg.installed:
    - {% if grains['os'] == 'RedHat' %}
      name: httpd
    {%- endif %}
  service.running:
    - {%- if grains['os'] == 'RedHat' %}
      name: httpd
    {%- endif %}
    - watch:
      - pkg: apache
      - file: /etc/httpd/conf/httpd.conf
      - user: apache
  user.present:
    - uid: 87
    - gid: 87
    - home: /var/www/html
    - shell: /bin/nologin
    - require:
      - group: apache
  group.present:
    - gid: 87
    - require:
      - pkg: apache

/etc/httpd/conf/httpd.conf:
  file.managed:
    - source: salt://apache/httpd.conf
    - user: root
    - group: root
    - mode: 644
```

This example is simple. If the os grain states that the operating system is Red Hat, then the name of the Apache package and service needs to be httpd. A more aggressive way to use Jinja can be found here, in a module to set up a MooseFS distributed filesystem chunkserver:

moosefs/chunk.sls:

```yaml
include:
  - moosefs

{% for mnt in salt['cmd.run']('ls /dev/data/moose*').split() %}
/mnt/moose{{ mnt[-1] }}:
  mount.mounted:
    - device: {{ mnt }}
    - fstype: xfs
    - mkmnt: True
  file.directory:
    - user: mfs
    - group: mfs
    - require:
      - user: mfs
      - group: mfs
{% endfor %}
```
/etc/mfshdd.cfg:
  file.managed:
    - source: salt://moosefs/mfshdd.cfg
    - user: root
    - group: root
    - mode: 644
    - template: jinja
    - require:
      - pkg: mfs-chunkserver

/etc/mfschunkserver.cfg:
  file.managed:
    - source: salt://moosefs/mfschunkserver.cfg
    - user: root
    - group: root
    - mode: 644
    - template: jinja
    - require:
      - pkg: mfs-chunkserver

mfs-chunkserver:
  pkg.installed: []
mfschunkserver:
  service.running:
    - require:
      {% for mnt in salt['cmd.run']('ls /dev/data/moose*') %}
        - mount: /mnt/moose{{ mnt[-1] }}
        - file: /mnt/moose{{ mnt[-1] }}
      {% endfor %}
      - file: /etc/mfschunkserver.cfg
      - file: /etc/mfshdd.cfg
      - file: /var/lib/mfs

This example shows much more of the available power of Jinja. Multiple for loops are used to dynamically detect available hard drives and set them up to be mounted, and the salt object is used multiple times to call shell commands to gather data.

**Introducing the Python, PyDSL, and the Pyobjects Renderers**

Sometimes the chosen default renderer might not have enough logical power to accomplish the needed task. When this happens, the Python renderer can be used. Normally a YAML renderer should be used for the majority of SLS files, but an SLS file set to use another renderer can be easily added to the tree.

This example shows a very basic Python SLS file:

```
# py/django.sls:

def run():
  '''
  Install the django package
  '''
  return {'include': ['python'],
          'django': {'pkg': ['installed']}}
```
This is a very simple example; the first line has an SLS shebang that tells Salt to not use the default renderer, but to use the py renderer. Then the run function is defined, the return value from the run function must be a Salt friendly data structure, or better known as a Salt HighState data structure.

Alternatively, using the pydsl renderer, the above example can be written more succinctly as:

```pydsl
#include('python', delayed=True)
state('django').pkg.installed()
```

The pyobjects renderer provides an "Pythonic" object based approach for building the state data. The above example could be written as:

```pyobjects
#include('python')
Pkg.installed("django")
```

These Python examples would look like this if they were written in YAML:

```yaml
include:  
  - python
django:  
  pkg.installed
```

This example clearly illustrates that; one, using the YAML renderer by default is a wise decision and two, unbridled power can be obtained where needed by using a pure Python SLS.

Running and Debugging Salt States

Once the rules in an SLS are ready, they should be tested to ensure they work properly. To invoke these rules, simply execute `salt '*' state.apply` on the command line. If you get back only hostnames with a : after, but no return, chances are there is a problem with one or more of the sls files. On the minion, use the `salt-call` command to examine the output for errors:

```
salt-call state.apply -l debug
```

This should help troubleshoot the issue. The minion can also be started in the foreground in debug mode by running `salt-minion -l debug`.

5.1.8 Next Reading

With an understanding of states, the next recommendation is to become familiar with Salt’s pillar interface:

Pillar Walkthrough

5.2 States tutorial, part 1 - Basic Usage

The purpose of this tutorial is to demonstrate how quickly you can configure a system to be managed by Salt States. For detailed information about the state system please refer to the full states reference.
This tutorial will walk you through using Salt to configure a minion to run the Apache HTTP server and to ensure the server is running.

**Before continuing** make sure you have a working Salt installation by following the *Installation* and the *configuration* instructions.

---

**Stuck?**

There are many ways to get help from the Salt community including our mailing list and our IRC channel #salt.

---

### 5.2.1 Setting up the Salt State Tree

States are stored in text files on the master and transferred to the minions on demand via the master's File Server. The collection of state files make up the **State Tree**.

To start using a central state system in Salt, the Salt File Server must first be set up. Edit the master config file (*file_roots*) and uncomment the following lines:

```bash
file_roots:
  base:
    - /srv/salt
```

**Note:** If you are deploying on FreeBSD via ports, the `file_roots` path defaults to `/usr/local/etc/salt/states`.

Restart the Salt master in order to pick up this change:

```bash
pkill salt-master
salt-master -d
```

### 5.2.2 Preparing the Top File

On the master, in the directory uncommented in the previous step, (/srv/salt by default), create a new file called `top.sls` and add the following:

```bash
base:
  '*':
    - webserver
```

The **top file** is separated into environments (discussed later). The default environment is `base`. Under the `base` environment a collection of minion matches is defined; for now simply specify all hosts (`*`).

**Targeting minions**

The expressions can use any of the targeting mechanisms used by Salt — minions can be matched by glob, PCRE regular expression, or by *grains*. For example:

```bash
base:
  'G@os:Fedora':
    - match: grain
    - webserver
```
5.2.3 Create an sls file

In the same directory as the top file, create a file named webserver.sls, containing the following:

```
apache:
  # ID declaration
pkg:
  # state declaration
- installed
  # function declaration
```

The first line, called the **ID declaration**, is an arbitrary identifier. In this case it defines the name of the package to be installed.

**Note:** The package name for the Apache httpd web server may differ depending on OS or distro — for example, on Fedora it is httpd but on Debian/Ubuntu it is apache2.

The second line, called the **State declaration**, defines which of the Salt States we are using. In this example, we are using the `pkg state` to ensure that a given package is installed.

The third line, called the **Function declaration**, defines which function in the `pkg state` module to call.

**Renderers**

States sls files can be written in many formats. Salt requires only a simple data structure and is not concerned with how that data structure is built. Templating languages and DSLs are a dime-a-dozen and everyone has a favorite.

Building the expected data structure is the job of Salt *Renderers* and they are dead-simple to write.

In this tutorial we will be using YAML in Jinja2 templates, which is the default format. The default can be changed by editing `renderer` in the master configuration file.

5.2.4 Install the package

Next, let’s run the state we created. Open a terminal on the master and run:

```
salt '*' state.apply
```

Our master is instructing all targeted minions to run `state.apply`. When this function is executed without any SLS targets, a minion will download the top file and attempt to match the expressions within it. When the minion does match an expression the modules listed for it will be downloaded, compiled, and executed.

**Note:** This action is referred to as a ”highstate”, and can be run using the `state.highstate` function. However, to make the usage easier to understand (“highstate” is not necessarily an intuitive name), a `state.apply` function was added in version 2015.5.0, which when invoked without any SLS names will trigger a highstate. `state.highstate` still exists and can be used, but the documentation (as can be seen above) has been updated to reference `state.apply`, so keep the following in mind as you read the documentation:

- `state.apply` invoked without any SLS names will run `state.highstate`
- `state.apply` invoked with SLS names will run `state.sls`

Once completed, the minion will report back with a summary of all actions taken and all changes made.
Warning: If you have created custom grain modules, they will not be available in the top file until after the first highstate. To make custom grains available on a minion’s first highstate, it is recommended to use this example to ensure that the custom grains are synced when the minion starts.

SLS File Namespace

Note that in the example above, the SLS file `webserver.sls` was referred to simply as `webserver`. The namespace for SLS files when referenced in `top.sls` or an `Include declaration` follows a few simple rules:

1. The `.sls` is discarded (i.e. `webserver.sls` becomes `webserver`).
2. Subdirectories can be used for better organization.
   - Each subdirectory is represented with a dot (following the Python import model) in Salt states and on the command line. `webserver/dev.sls` on the filesystem is referred to as `webserver.dev` in Salt.
   - Because slashes are represented as dots, SLS files cannot contain dots in the name (other than the dot for the SLS suffix). The SLS file `webserver_1.0.sls` can not be matched, and `webserver_1/0.sls` would match the directory/file `webserver_1/0.sls`.
3. A file called `init.sls` in a subdirectory is referred to by the path of the directory. So, `webserver/init.sls` is referred to as `webserver`.
4. If both `webserver.sls` and `webserver/init.sls` happen to exist, `webserver/init.sls` will be ignored and `webserver.sls` will be the file referred to as `webserver`.

Troubleshooting Salt

If the expected output isn’t seen, the following tips can help to narrow down the problem.

Turn up logging  Salt can be quite chatty when you change the logging setting to `debug`:

```
salt-minion -l debug
```

Run the minion in the foreground  By not starting the minion in daemon mode (`-d`) one can view any output from the minion as it works:

```
salt-minion
```

Increase the default timeout value when running `salt`. For example, to change the default timeout to 60 seconds:

```
salt -t 60
```

For best results, combine all three:

```
salt-minion -l debug  # On the minion
salt '*' state.apply -t 60  # On the master
```

5.2.5 Next steps

This tutorial focused on getting a simple Salt States configuration working. Part 2 will build on this example to cover more advanced SLS syntax and will explore more of the states that ship with Salt.
5.3 States tutorial, part 2 - More Complex States, Requisites

Note: This tutorial builds on topics covered in part 1. It is recommended that you begin there.

In the last part of the Salt States tutorial we covered the basics of installing a package. We will now modify our webserver.sls file to have requirements, and use even more Salt States.

5.3.1 Call multiple States

You can specify multiple State declaration under an ID declaration. For example, a quick modification to our webserver.sls to also start Apache if it is not running:

```bash
apache:
  pkg.installed: []
  service.running:
    - require:
      - pkg: apache
```

Try stopping Apache before running state.apply once again and observe the output.

Note: For those running RedhatOS derivatives (Centos, AWS), you will want to specify the service name to be httpd. More on state service here, service state. With the example above, just add `- name: httpd` above the require line and with the same spacing.

5.3.2 Require other states

We now have a working installation of Apache so let’s add an HTML file to customize our website. It isn’t exactly useful to have a website without a webserver so we don’t want Salt to install our HTML file until Apache is installed and running. Include the following at the bottom of your webserver/init.sls file:

```bash
apache:
  pkg.installed: []
  service.running:
    - require:
      - pkg: apache

/var/www/index.html:
  file:
    - managed
    - source: salt://webserver/index.html
    - require:
      - pkg: apache
```

Line 7 is the ID declaration. In this example it is the location we want to install our custom HTML file. (Note: the default location that Apache serves may differ from the above on your OS or distro. /srv/www could also be a likely place to look.)

Line 8 the State declaration. This example uses the Salt file state.

Line 9 is the Function declaration. The managed function will download a file from the master and install it in the location specified.
Line 10 is a Function arg declaration which, in this example, passes the source argument to the managed function.

Line 11 is a Requisite declaration.

Line 12 is a Requisite reference which refers to a state and an ID. In this example, it is referring to the ID declaration from our example in part 1. This declaration tells Salt not to install the HTML file until Apache is installed.

Next, create the index.html file and save it in the webserver directory:

```html
<!DOCTYPE html>
<html>
  <head><title>Salt rocks</title></head>
  <body>
    <h1>This file brought to you by Salt</h1>
  </body>
</html>
```

Last, call state.apply again and the minion will fetch and execute the highstate as well as our HTML file from the master using Salt's File Server:

```
salt '*' state.apply
```

Verify that Apache is now serving your custom HTML.

**require vs. watch**

There are two Requisite declaration, "require", and "watch". Not every state supports "watch". The service state does support "watch" and will restart a service based on the watch condition.

For example, if you use Salt to install an Apache virtual host configuration file and want to restart Apache whenever that file is changed you could modify our Apache example from earlier as follows:

```
/etc/httpd/extra/httpd-vhosts.conf:
  file.managed:
    - source: salt://webserver/httpd-vhosts.conf

apache:
  pkg.installed: []
  service.running:
    - watch:
      - file: /etc/httpd/extra/httpd-vhosts.conf
      - require:
        - pkg: apache
```

If the pkg and service names differ on your OS or distro of choice you can specify each one separately using a Name declaration which explained in Part 3.

**5.3.3 Next steps**

In part 3 we will discuss how to use includes, extends, and templating to make a more complete State Tree configuration.

**5.4 States tutorial, part 3 - Templating, Includes, Extends**
This tutorial builds on topics covered in part 1 and part 2. It is recommended that you begin there.

This part of the tutorial will cover more advanced templating and configuration techniques for SLS files.

### 5.4.1 Templating SLS modules

SLS modules may require programming logic or inline execution. This is accomplished with module templating. The default module templating system used is Jinja2 and may be configured by changing the `renderer` value in the master config.

All states are passed through a templating system when they are initially read. To make use of the templating system, simply add some templating markup. An example of an sls module with templating markup may look like this:

```python
{% for usr in ['moe', 'larry', 'curly'] %}
  {{ usr }}:
    user.present
{% endfor %}
```

This templated sls file once generated will look like this:

```yaml
moe:
  user.present
larry:
  user.present
curly:
  user.present
```

Here's a more complex example:

```python
{% for usr in 'moe','larry','curly' %}
  {% for group in 'present' %}
    group:
    - present
  {%- endfor %}
  user:
    - present
    - gid_from_name: True
    - require:
      - group: {{ usr }}
  {%- endfor %}
```

### 5.4.2 Using Grains in SLS modules

Often times a state will need to behave differently on different systems. Salt grains objects are made available in the template context. The `grains` can be used from within sls modules:
```
apache:
  pkg.installed:
    {% if grains['os'] == 'RedHat' %}
      - name: httpd
    {% elif grains['os'] == 'Ubuntu' %}
      - name: apache2
    {% endif %}
```

### 5.4.3 Using Environment Variables in SLS modules

You can use `salt['environ.get']('VARNAME')` to use an environment variable in a Salt state.

```
MYENVVAR="world" salt-call state.template test.sls
```

Create a file with contents from an environment variable:

```
file.managed:
  - name: /tmp/hello
  - contents: {{ salt['environ.get']('MYENVVAR') }}
```

Error checking:

```
{% set myenvvar = salt['environ.get']('MYENVVAR') %}
{% if myenvvar %}
file.managed:
  - name: /tmp/hello
  - contents: {{ salt['environ.get']('MYENVVAR') }}
{% else %}
Fail - no environment passed in:
  test.fail_without_changes
{% endif %}
```

### 5.4.4 Calling Salt modules from templates

All of the Salt modules loaded by the minion are available within the templating system. This allows data to be gathered in real time on the target system. It also allows for shell commands to be run easily from within the sls modules.

The Salt module functions are also made available in the template context as `salt`:

The following example illustrates calling the `group_to_gid` function in the `file` execution module with a single positional argument called `some_group_that_exists`.

```
moe:
  user.present:
    - gid: {{ salt['file.group_to_gid']('some_group_that_exists') }}
```

One way to think about this might be that the `gid` key is being assigned a value equivalent to the following python pseudo-code:
```python
import salt.modules.file
file.group_to_gid('some_group_that_exists')
```

Note that for the above example to work, `some_group_that_exists` must exist before the state file is processed by the templating engine.

Below is an example that uses the `network.hw_addr` function to retrieve the MAC address for eth0:

```python
salt['network.hw_addr']('eth0')
```

To examine the possible arguments to each execution module function, one can examine the module reference documentation `/ref/modules/all`:

### 5.4.5 Advanced SLS module syntax

Lastly, we will cover some incredibly useful techniques for more complex State trees.

**Include declaration**

A previous example showed how to spread a Salt tree across several files. Similarly, `Requisites and Other Global State Arguments` span multiple files by using an `Include declaration`. For example:

```python
python/python-libs.sls:

python-dateutil:
  pkg.installed

python/django.sls:

include:
  - python.python-libs

django:
  pkg.installed:
    - require:
      - pkg: python-dateutil
```

**Extend declaration**

You can modify previous declarations by using an `Extend declaration`. For example the following modifies the Apache tree to also restart Apache when the vhosts file is changed:

```python
apache/apache.sls:

apache:
  pkg.installed

apache/mywebsite.sls:

include:
  - apache.apache

extend:
  apache:
    service:
```

---

5.4. States tutorial, part 3 - Templating, Includes, Extends 387
Using extend with require or watch

The `extend` statement works differently for `require` or `watch`. It appends to, rather than replacing the requisite component.

### Name declaration

You can override the *ID declaration* by using a *Name declaration*. For example, the previous example is a bit more maintainable if rewritten as follows:

```
apache/mywebsite.sls:

include:
    - apache.apache

extend:
    apache:
        service:
            running
            watch:
                file: mywebsite

mywebsite:
    file.managed:
        name: /etc/httpd/extra/httpd-vhosts.conf
        source: salt://apache/httpd-vhosts.conf
```

### Names declaration

Even more powerful is using a *Names declaration* to override the *ID declaration* for multiple states at once. This often can remove the need for looping in a template. For example, the first example in this tutorial can be rewritten without the loop:

```
stooges:
    user.present:
        - names:
            - moe
            - larry
            - curly
```

### 5.4.6 Next steps

In *part 4* we will discuss how to use Salt’s `file_roots` to set up a workflow in which states can be "promoted" from dev, to QA, to production.
5.5 States tutorial, part 4

Note: This tutorial builds on topics covered in part 1, part 2, and part 3. It is recommended that you begin there.

This part of the tutorial will show how to use salt's file_roots to set up a workflow in which states can be `promoted` from dev, to QA, to production.

5.5.1 Salt fileserver path inheritance

Salt's fileserver allows for more than one root directory per environment, like in the below example, which uses both a local directory and a secondary location shared to the salt master via NFS:

```
# In the master config file (/etc/salt/master)
file_roots:
    base:
        - /srv/salt
        - /mnt/salt-nfs/base
```

Salt's fileserver collapses the list of root directories into a single virtual environment containing all files from each root. If the same file exists at the same relative path in more than one root, then the top-most match `wins`. For example, if `/srv/salt/foo.txt` and `/mnt/salt-nfs/base/foo.txt` both exist, then `salt://foo.txt` will point to `/srv/salt/foo.txt`.

Note: When using multiple fileserver backends, the order in which they are listed in the fileserver_backend parameter also matters. If both roots and git backends contain a file with the same relative path, and roots appears before git in the fileserver_backend list, then the file in roots will `win`, and the file in gitfs will be ignored.

A more thorough explanation of how Salt's modular fileserver works can be found here. We recommend reading this.

5.5.2 Environment configuration

Configure a multiple-environment setup like so:

```
file_roots:
    base:
        - /srv/salt/prod
    qa:
        - /srv/salt/qa
        - /srv/salt/prod
    dev:
        - /srv/salt/dev
        - /srv/salt/qa
        - /srv/salt/prod
```

Given the path inheritance described above, files within `/srv/salt/prod` would be available in all environments. Files within `/srv/salt/qa` would be available in both qa, and dev. Finally, the files within `/srv/salt/dev` would only be available within the dev environment.
Based on the order in which the roots are defined, new files/states can be placed within \texttt{/srv/salt/dev}, and pushed out to the dev hosts for testing.

Those files/states can then be moved to the same relative path within \texttt{/srv/salt/qa}, and they are now available only in the dev and qa environments, allowing them to be pushed to QA hosts and tested.

Finally, if moved to the same relative path within \texttt{/srv/salt/prod}, the files are now available in all three environments.

### 5.5.3 Requesting files from specific fileserver environments

See \textit{here} for documentation on how to request files from specific environments.

### 5.5.4 Practical Example

As an example, consider a simple website, installed to \texttt{/var/www/foobarcom}. Below is a top.sls that can be used to deploy the website:

\texttt{/srv/salt/prod/top.sls:}

```plaintext
base:
  'web*prod*':
    - webserver.foobarcom
qa:
  'web*qa*':
    - webserver.foobarcom
dev:
  'web*dev*':
    - webserver.foobarcom
```

Using pillar, roles can be assigned to the hosts:

\texttt{/srv/pillar/top.sls:}

```plaintext
base:
  'web*prod*':
    - webserver.prod
  'web*qa*':
    - webserver.qa
  'web*dev*':
    - webserver.dev
```

\texttt{/srv/pillar/webserver/prod.sls:}

```plaintext
webserver_role: prod
```

\texttt{/srv/pillar/webserver/qa.sls:}

```plaintext
webserver_role: qa
```

\texttt{/srv/pillar/webserver/dev.sls:}

```plaintext
webserver_role: dev
```

And finally, the SLS to deploy the website:

\texttt{/srv/salt/prod/webserver/foobarcom.sls:}
Given the above SLS, the source for the website should initially be placed in /srv/salt/dev/webserver/src/foobarcom.

First, let's deploy to dev. Given the configuration in the top file, this can be done using `state.apply`:

```
salt --pillar 'webserver_role:dev' state.apply
```

However, in the event that it is not desirable to apply all states configured in the top file (which could be likely in more complex setups), it is possible to apply just the states for the foobarcom website, by invoking `state.apply` with the desired SLS target as an argument:

```
salt --pillar 'webserver_role:dev' state.apply webserver.foobarcom
```

Once the site has been tested in dev, then the files can be moved from /srv/salt/dev/webserver/src/foobarcom to /srv/salt/qa/webserver/src/foobarcom, and deployed using the following:

```
salt --pillar 'webserver_role:qa' state.apply webserver.foobarcom
```

Finally, once the site has been tested in qa, then the files can be moved from /srv/salt/qa/webserver/src/foobarcom to /srv/salt/prod/webserver/src/foobarcom, and deployed using the following:

```
salt --pillar 'webserver_role:prod' state.apply webserver.foobarcom
```

Thanks to Salt's fileserver inheritance, even though the files have been moved to within /srv/salt/prod, they are still available from the same `salt://` URI in both the qa and dev environments.

### 5.5.5 Continue Learning

The best way to continue learning about Salt States is to read through the reference documentation and to look through examples of existing state trees. Many pre-configured state trees can be found on GitHub in the saltstack-formulas collection of repositories.

If you have any questions, suggestions, or just want to chat with other people who are using Salt, we have a very active community and we'd love to hear from you.

In addition, by continuing to the Orchestrate Runner docs, you can learn about the powerful orchestration of which Salt is capable.

### 5.6 State System Reference

Salt offers an interface to manage the configuration or ```state``` of the Salt minions. This interface is a fully capable mechanism used to enforce the state of systems from a central manager.
5.6.1 Mod Aggregate State Runtime Modifications

New in version 2014.7.0.

The mod_aggregate system was added in the 2014.7.0 release of Salt and allows for runtime modification of the executing state data. Simply put, it allows for the data used by Salt’s state system to be changed on the fly at runtime, kind of like a configuration management JIT compiler or a runtime import system. All in all, it makes Salt much more dynamic.

How it Works

The best example is the pkg state. One of the major requests in Salt has long been adding the ability to install all packages defined at the same time. The mod_aggregate system makes this a reality. While executing Salt’s state system, when a pkg state is reached the mod_aggregate function in the state module is called. For pkg this function scans all of the other states that are slated to run, and picks up the references to name and pkgs, then adds them to pkgs in the first state. The result is a single call to yum, apt-get, pacman, etc as part of the first package install.

How to Use it

Note: Since this option changes the basic behavior of the state runtime, after it is enabled states should be executed using test=True to ensure that the desired behavior is preserved.

In config files

The first way to enable aggregation is with a configuration option in either the master or minion configuration files. Salt will invoke mod_aggregate the first time it encounters a state module that has aggregate support.

If this option is set in the master config it will apply to all state runs on all minions, if set in the minion config it will only apply to said minion.

Enable for all states:

```
state_aggregate: True
```

Enable for only specific state modules:

```
state_aggregate:
  - pkg
```

In states

The second way to enable aggregation is with the state-level aggregate keyword. In this configuration, Salt will invoke the mod_aggregate function the first time it encounters this keyword. Any additional occurrences of the keyword will be ignored as the aggregation has already taken place.

The following example will trigger mod_aggregate when the lamp_stack state is processed resulting in a single call to the underlying package manager.
Adding mod_aggregate to a State Module

Adding a mod_aggregate routine to an existing state module only requires adding an additional function to the state module called mod_aggregate.

The mod_aggregate function just needs to accept three parameters and return the low data to use. Since mod_aggregate is working on the state runtime level it does need to manipulate low data.

The three parameters are low, chunks, and running. The low option is the low data for the state execution which is about to be called. The chunks is the list of all of the low data dictionaries which are being executed by the runtime and the running dictionary is the return data from all of the state executions which have already be executed.

This example, simplified from the pkg state, shows how to create mod_aggregate functions:

```python
def mod_aggregate(low, chunks, running):
    '''
The mod_aggregate function which looks up all packages in the available
low chunks and merges them into a single pkgs ref in the present low data
'''
    pkgs = []
    # What functions should we aggregate?
    agg_enabled = [
        'installed',
        'latest',
        'removed',
        'purged',
    ]
    # The `low` data is just a dict with the state, function (fun) and
    # arguments passed in from the sls
    if low.get('fun') not in agg_enabled:
        return low
    # Now look into what other things are set to execute
    for chunk in chunks:
        if chunk.get('state') == 'pkg':
            if '__agg__' in chunk:
                continue
            # Check for the same function
            if chunk.get('fun') != low.get('fun'):
                continue
        # Pull out the pkg names!
```
if 'pkgs' in chunk:
    pkgs.extend(chunk['pkgs'])
    chunk['__agg__'] = True
elif 'name' in chunk:
    pkgs.append(chunk['name'])
    chunk['__agg__'] = True
if pkgs:
    if 'pkgs' in low:
        low['pkgs'].extend(pkgs)
    else:
        low['pkgs'] = pkgs
        # The low has been modified and needs to be returned to the state
        # runtime for execution
        return low

5.6.2 Altering States

Note: This documentation has been moved here.

5.6.3 File State Backups

In 0.10.2 a new feature was added for backing up files that are replaced by the file.managed and file.recurse states. The new feature is called the backup mode. Setting the backup mode is easy, but it can be set in a number of places. The backup_mode can be set in the minion config file:

```
backup_mode: minion
```

Or it can be set for each file:

```
/etc/ssh/sshd_config:
file.managed:
    - source: salt://ssh/sshd_config
    - backup: minion
```

Backed-up Files

The files will be saved in the minion cachedir under the directory named file_backup. The files will be in the location relative to where they were under the root filesystem and be appended with a timestamp. This should make them easy to browse.

Interacting with Backups

Starting with version 0.17.0, it will be possible to list, restore, and delete previously-created backups.

Listing

The backups for a given file can be listed using `file.list_backups`: 
# salt foo.bar.com file.list_backups /tmp/foo.txt
foo.bar.com:
    0:  
        Backup Time:  Sat Jul 27 2013 17:48:41.738027
        Size:         13
    1:  
        Backup Time:  Sat Jul 27 2013 17:48:28.369804
        Size:         35

Restoring

Restoring is easy using `file.restore_backup`, just pass the path and the numeric id found with `file.list_backups`:

```
# salt foo.bar.com file.restore_backup /tmp/foo.txt 1
foo.bar.com:
    0:  
        comment: Successfully restored /var/cache/salt/minion/file_backup/tmp/foo.txt_Sat_Jul_27_17:48:28_369804_2013 to /tmp/foo.txt
        result: True
```

The existing file will be backed up, just in case, as can be seen if `file.list_backups` is run again:

```
# salt foo.bar.com file.list_backups /tmp/foo.txt
foo.bar.com:
    0:  
        Backup Time:  Sat Jul 27 2013 18:00:19.822550
        Location:     /var/cache/salt/minion/file_backup/tmp/foo.txt_Sat_Jul_27_18:00:19_822550_2013
        Size:         53
    1:  
        Backup Time:  Sat Jul 27 2013 17:48:41.738027
```
Note: Since no state is being run, restoring a file will not trigger any watches for the file. So, if you are restoring a config file for a service, it will likely still be necessary to run a `service.restart`.

Deleting

Deleting backups can be done using `file.delete_backup`:

```bash
# salt foo.bar.com file.delete_backup /tmp/foo.txt

foo.bar.com:
----------
    comment:
    result:
    True
```

5.6.4 Understanding State Compiler Ordering

Note: This tutorial is an intermediate level tutorial. Some basic understanding of the state system and writing Salt Formulas is assumed.

Salt's state system is built to deliver all of the power of configuration management systems without sacrificing simplicity. This tutorial is made to help users understand in detail just how the order is defined for state executions in Salt.

This tutorial is written to represent the behavior of Salt as of version 0.17.0.

Compiler Basics

To understand ordering in depth some very basic knowledge about the state compiler is very helpful. No need to worry though, this is very high level!

High Data and Low Data

When defining Salt Formulas in YAML the data that is being represented is referred to by the compiler as High Data. When the data is initially loaded into the compiler it is a single large python dictionary, this dictionary can be viewed
This ``High Data'' structure is then compiled down to ``Low Data''. The Low Data is what is matched up to create individual executions in Salt’s configuration management system. The low data is an ordered list of single state calls to execute. Once the low data is compiled the evaluation order can be seen.

The low data can be viewed by running:

```
salt 'x' state.show_lowstate
```

Note: The state execution module contains MANY functions for evaluating the state system and is well worth a read! These routines can be very useful when debugging states or to help deepen one’s understanding of Salt’s state system.

As an example, a state written thusly:

```
apache:
    pkg.installed:
        - name: httpd
    service.running:
        - name: httpd
        - watch:
            - file: apache_conf
            - pkg: apache

apache_conf:
    file.managed:
        - name: /etc/httpd/conf.d/httpd.conf
        - source: salt://apache/httpd.conf
```

Will have High Data which looks like this represented in json:

```
{
    "apache": {
        "pkg": [
            {
                "name": "httpd"
            },
            "installed",
            {
                "order": 10000
            }
        ],
        "service": [
            {
                "name": "httpd"
            },
            {
                "watch": [
                    {
                        "file": "apache_conf"
                    },
                    {
                        "pkg": "apache"
                    }
                ]
            }
```

```
The subsequent Low Data will look like this:

```json
[

{

    "name": "httpd",
    "state": "pkg",
    "__id__": "apache",
    "fun": "installed",
    "__env__": "base",
    "__sls__": "blah",
    "__env__": "base",
    "order": 10000,

},

{

    "name": "httpd",
    "watch": [

        {
            "file": "apache_conf"
        },

        {
            "pkg": "apache"
        }

    ],
    "state": "service",
    "__id__": "apache",
    "fun": "running",
    "__env__": "base",
    "__sls__": "blah",
    "__env__": "base",
    "order": 10001,

}]
```
This tutorial discusses the Low Data evaluation and the state runtime.

### Ordering Layers

Salt defines 2 order interfaces which are evaluated in the state runtime and defines these orders in a number of passes.

#### Definition Order

**Note:** The Definition Order system can be disabled by turning the option `state_auto_order` to `False` in the master configuration file.

The top level of ordering is the **Definition Order**. The **Definition Order** is the order in which states are defined in salt formulas. This is very straightforward on basic states which do not contain `include` statements or a `top` file, as the states are just ordered from the top of the file, but the include system starts to bring in some simple rules for how the **Definition Order** is defined.

Looking back at the ```Low Data``` and ```High Data``` shown above, the order key has been transparently added to the data to enable the **Definition Order**.

#### The Include Statement

Basically, if there is an include statement in a formula, then the formulas which are included will be run BEFORE the contents of the formula which is including them. Also, the include statement is a list, so they will be loaded in the order in which they are included.

In the following case:

```plaintext
foo.sls

include:
  - bar
  - baz

bar.sls

include:
  - quo

baz.sls
```
include:
  - qux

In the above case if `state.apply foo` were called then the formulas will be loaded in the following order:

1. quo
2. bar
3. qux
4. baz
5. foo

**The order Flag**

The *Definition Order* happens transparently in the background, but the ordering can be explicitly overridden using the `order` flag in states:

```
apache:
  pkg.installed:
    - name: httpd
    - order: 1
```

This order flag will over ride the definition order, this makes it very simple to create states that are always executed first, last or in specific stages, a great example is defining a number of package repositories that need to be set up before anything else, or final checks that need to be run at the end of a state run by using `order: last` or `order: -1`.

When the order flag is explicitly set the *Definition Order* system will omit setting an order for that state and directly use the order flag defined.

**Lexicographical Fall-back**

Salt states were written to ALWAYS execute in the same order. Before the introduction of *Definition Order* in version 0.17.0 everything was ordered lexicographically according to the name of the state, then function then id.

This is the way Salt has always ensured that states always run in the same order regardless of where they are deployed, the addition of the *Definition Order* method mealy makes this finite ordering easier to follow.

The lexicographical ordering is still applied but it only has any effect when two order statements collide. This means that if multiple states are assigned the same order number that they will fall back to lexicographical ordering to ensure that every execution still happens in a finite order.

**Note:** If running with `state_auto_order: False` the `order` key is not set automatically, since the lexicographical order can be derived from other keys.

**Requisite Ordering**

Salt states are fully declarative, in that they are written to declare the state in which a system should be. This means that components can require that other components have been set up successfully. Unlike the other ordering systems, the *Requisite* system in Salt is evaluated at runtime.
The requisite system is also built to ensure that the ordering of execution never changes, but is always the same for a given set of states. This is accomplished by using a runtime that processes states in a completely predictable order instead of using an event loop based system like other declarative configuration management systems.

**Runtime Requisite Evaluation**

The requisite system is evaluated as the components are found, and the requisites are always evaluated in the same order. This explanation will be followed by an example, as the raw explanation may be a little dizzying at first as it creates a linear dependency evaluation sequence.

The ``Low Data`` is an ordered list or dictionaries, the state runtime evaluates each dictionary in the order in which they are arranged in the list. When evaluating a single dictionary it is checked for requisites, requisites are evaluated in order, require then watch then prereq.

**Note:** If using requisite in statements like require_in and watch_in these will be compiled down to require and watch statements before runtime evaluation.

Each requisite contains an ordered list of requisites, these requisites are looked up in the list of dictionaries and then executed. Once all requisites have been evaluated and executed then the requiring state can safely be run (or not run if requisites have not been met).

This means that the requisites are always evaluated in the same order, again ensuring one of the core design principals of Salt's State system to ensure that execution is always finite is intact.

**Simple Runtime Evaluation Example**

Given the above `Low Data` the states will be evaluated in the following order:

1. The pkg.installed is executed ensuring that the apache package is installed, it contains no requisites and is therefore the first defined state to execute.
2. The service.running state is evaluated but NOT executed, a watch requisite is found, therefore they are read in order, the runtime first checks for the file, sees that it has not been executed and calls for the file state to be evaluated.
3. The file state is evaluated AND executed, since it, like the pkg state does not contain any requisites.
4. The evaluation of the service state continues, it next checks the pkg requisite and sees that it is met, with all requisites met the service state is now executed.

**Best Practice**

The best practice in Salt is to choose a method and stick with it, official states are written using requisites for all associations since requisites create clean, traceable dependency trails and make for the most portable formulas. To accomplish something similar to how classical imperative systems function all requisites can be omitted and the failhard option then set to True in the master configuration, this will stop all state runs at the first instance of a failure.

In the end, using requisites creates very tight and fine grained states, not using requisites makes full sequence runs and while slightly easier to write, and gives much less control over the executions.
5.6.5 Extending External SLS Data

Sometimes a state defined in one SLS file will need to be modified from a separate SLS file. A good example of this is when an argument needs to be overwritten or when a service needs to watch an additional state.

The Extend Declaration

The standard way to extend is via the extend declaration. The extend declaration is a top level declaration like `include` and encapsulates ID declaration data included from other SLS files. A standard extend looks like this:

```yaml
include:
  - http
  - ssh
extend:
  apache:
    file:
      - name: /etc/httpd/conf/httpd.conf
      - source: salt://http/httpd2.conf
  ssh-server:
    service:
      - watch:
        - file: /etc/ssh/banner

/etc/ssh/banner:
  file.managed:
    - source: salt://ssh/banner
```

A few critical things happened here, first off the SLS files that are going to be extended are included, then the extend dec is defined. Under the extend dec 2 IDs are extended, the apache ID's file state is overwritten with a new name and source. Than the ssh server is extended to watch the banner file in addition to anything it is already watching.

Extend is a Top Level Declaration

This means that `extend` can only be called once in an sls, if if is used twice then only one of the extend blocks will be read. So this is WRONG:

```yaml
include:
  - http
  - ssh
extend:
  apache:
    file:
      - name: /etc/httpd/conf/httpd.conf
      - source: salt://http/httpd2.conf
  ssh-server:
    service:
      - watch:
        - file: /etc/ssh/banner

/etc/ssh/banner:
  file.managed:
    - source: salt://ssh/banner
```

# Second extend will overwrite the first!! Only make one
extend:
  ssh-server:
    service:
      - watch:
        - file: /etc/ssh/banner
The Requisite ``in'' Statement

Since one of the most common things to do when extending another SLS is to add states for a service to watch, or anything for a watcher to watch, the requisite in statement was added to 0.9.8 to make extending the watch and require lists easier. The ssh-server extend statement above could be more cleanly defined like so:

```
include:
  - ssh

/etc/ssh/banner:
  file.managed:
    - source: salt://ssh/banner
    - watch_in:
      - service: ssh-server
```

Rules to Extend By

There are a few rules to remember when extending states:

1. Always include the SLS being extended with an include declaration
2. Requisites (watch and require) are appended to, everything else is overwritten
3. extend is a top level declaration, like an ID declaration, cannot be declared twice in a single SLS
4. Many IDs can be extended under the extend declaration

5.6.6 Failhard Global Option

Normally, when a state fails Salt continues to execute the remainder of the defined states and will only refuse to execute states that require the failed state.

But the situation may exist, where you would want all state execution to stop if a single state execution fails. The capability to do this is called failing hard.

State Level Failhard

A single state can have a failhard set, this means that if this individual state fails that all state execution will immediately stop. This is a great thing to do if there is a state that sets up a critical config file and setting a require for each state that reads the config would be cumbersome. A good example of this would be setting up a package manager early on:

```
/etc/yum.repos.d/company.repo:
  file.managed:
    - source: salt://company/yumrepo.conf
    - user: root
    - group: root
    - mode: 644
    - order: 1
    - failhard: True
```

In this situation, the yum repo is going to be configured before other states, and if it fails to lay down the config file, than no other states will be executed.
Global Failhard

It may be desired to have failhard be applied to every state that is executed, if this is the case, then failhard can be set in the master configuration file. Setting failhard in the master configuration file will result in failing hard when any minion gathering states from the master have a state fail.

This is NOT the default behavior, normally Salt will only fail states that require a failed state.

Using the global failhard is generally not recommended, since it can result in states not being executed or even checked. It can also be confusing to see states failhard if an admin is not actively aware that the failhard has been set.

To use the global failhard set failhard: True in the master configuration file.

5.6.7 Global State Arguments

Note: This documentation has been moved here.

5.6.8 Highstate data structure definitions

The Salt State Tree

A state tree is a collection of SLS files and directories that live under the directory specified in file_roots.

Note: Directory names or filenames in the state tree cannot contain a period, with the exception of the period in the .sls file suffix.

Top file

The main state file that instructs minions what environment and modules to use during state execution.

Configurable via state_top.

See also:
A detailed description of the top file

Include declaration

Defines a list of Module reference strings to include in this SLS.

Occurs only in the top level of the SLS data structure.

Example:

```bash
include:
    - edit.vim
    - http.server
```
Module reference

The name of a SLS module defined by a separate SLS file and residing on the Salt Master. A module named `edit.vim` is a reference to the SLS file `salt://edit/vim.sls`.

ID declaration

Defines an individual highstate component. Always references a value of a dictionary containing keys referencing State declaration and Requisite declaration. Can be overridden by a Name declaration or a Names declaration. Occurs on the top level or under the Extend declaration. Must be unique across entire state tree. If the same ID declaration is used twice, only the first one matched will be used. All subsequent ID declarations with the same name will be ignored.

Note: Naming gotchas

In Salt versions earlier than 0.9.7, ID declarations containing dots would result in unpredictable output.

Extend declaration

Extends a Name declaration from an included SLS module. The keys of the extend declaration always refer to an existing ID declaration which have been defined in included SLS modules. Occurs only in the top level and defines a dictionary. States cannot be extended more than once in a single state run. Extend declarations are useful for adding-to or overriding parts of a State declaration that is defined in another SLS file. In the following contrived example, the shown `mywebsite.sls` file is include-ing and extend-ing the `apache.sls` module in order to add a watch declaration that will restart Apache whenever the Apache configuration file, `mywebsite` changes.

```plaintext
include:
  - apache

extend:
  apache:
    service:
      - watch:
        - file: mywebsite

mywebsite:
  file.managed:
    - name: /var/www/mysite
```

See also:

watch_in and require_in

Sometimes it is more convenient to use the `watch_in` or `require_in` syntax instead of extending another SLS file.

State Requisites
State declaration

A list which contains one string defining the Function declaration and any number of Function arg declaration dictionaries.

Can, optionally, contain a number of additional components like the name override components — name and names. Can also contain requisite declarations.

Occurs under an ID declaration.

Requisite declaration

A list containing requisite references.

Used to build the action dependency tree. While Salt states are made to execute in a deterministic order, this order is managed by requiring and watching other Salt states.

Occurs as a list component under a State declaration or as a key under an ID declaration.

Requisite reference

A single key dictionary. The key is the name of the referenced State declaration and the value is the ID of the referenced ID declaration.

Occurs as a single index in a Requisite declaration list.

Function declaration

The name of the function to call within the state. A state declaration can contain only a single function declaration.

For example, the following state declaration calls the installed function in the pkg state module:

```
httpd:
  pkg.installed: []
```

The function can be declared inline with the state as a shortcut. The actual data structure is compiled to this form:

```
httpd:
  pkg:
    - installed
```

Where the function is a string in the body of the state declaration. Technically when the function is declared in dot notation the compiler converts it to be a string in the state declaration list. Note that the use of the first example more than once in an ID declaration is invalid yaml.

INVALID:

```
httpd:
  pkg.installed
  service.running
```

When passing a function without arguments and another state declaration within a single ID declaration, then the long or "standard" format needs to be used since otherwise it does not represent a valid data structure.

VALID:
httpd:
  pkg.installed: []
  service.running: []

Occurs as the only index in the State declaration list.

**Function arg declaration**

A single key dictionary referencing a Python type which is to be passed to the named Function declaration as a parameter. The type must be the data type expected by the function.

Occurs under a Function declaration.

For example in the following state declaration user, group, and mode are passed as arguments to the `managed` function in the file state module:

```
/etc/http/conf/http.conf:
  file.managed:
    - user: root
    - group: root
    - mode: 644
```

**Name declaration**

Overrides the name argument of a State declaration. If name is not specified the ID declaration satisfies the name argument.

The name is always a single key dictionary referencing a string.

Overriding name is useful for a variety of scenarios.

For example, avoiding clashing ID declarations. The following two state declarations cannot both have `/etc/motd` as the ID declaration:

```
motd_perms:
  file.managed:
    - name: /etc/motd
    - mode: 644

motd_quote:
  file.append:
    - name: /etc/motd
    - text: "Of all smells, bread; of all tastes, salt."
```

Another common reason to override name is if the ID declaration is long and needs to be referenced in multiple places. In the example below it is much easier to specify `mywebsite` than to specify `/etc/apache2/sites-available/mywebsite.com` multiple times:

```
mywebsite:
  file.managed:
    - name: /etc/apache2/sites-available/mywebsite.com
    - source: salt://mywebsite.com

a2ensite mywebsite.com:
  cmd.wait:
    - unless: test -L /etc/apache2/sites-enabled/mywebsite.com
```
Names declaration

Expands the contents of the containing State declaration into multiple state declarations, each with its own name.

For example, given the following state declaration:

```yaml
python-pkgs:
  pkg.installed:
    - names:
      - python-django
      - python-crypto
      - python-yaml
```

Once converted into the low state data structure the above state declaration will be expanded into the following three state declarations:

```yaml
python-django:
  pkg.installed

python-crypto:
  pkg.installed

python-yaml:
  pkg.installed
```

Other values can be overridden during the expansion by providing an additional dictionary level.

New in version 2014.7.0.

```yaml
ius:
  pkgrepo.managed:
    - humanname: IUS Community Packages for Enterprise Linux 6 - $basearch
    - gpgcheck: 1
    - gpgkey: http://dl.iuscommunity.org/pub/ius/IUS-COMMUNITY-GPG-KEY
    - names:
      - ius
      - ius-devel:
        - baseurl: http://mirror.rackspace.com/ius/development/CentOS/6/$basearch
```

Large example

Here is the layout in yaml using the names of the high data structure components.

```yaml
<Include Declaration>:
  - <Module Reference>
  - <Module Reference>
```
<Extend Declaration>:
  <ID Declaration>:
    [<overrides>]

# standard declaration

<ID Declaration>:
  <State Module>:
    - <Function>
    - <Function Arg>
    - <Function Arg>
    - <Function Arg>
    - <Name>: <name>
    - <Requisite Declaration>:
      - <Requisite Reference>
      - <Requisite Reference>

# inline function and names

<ID Declaration>:
  <State Module>.<Function>:
    - <Function Arg>
    - <Function Arg>
    - <Function Arg>
    - <Names>:
      - <name>
      - <name>
      - <name>
      - <Requisite Declaration>:
        - <Requisite Reference>
        - <Requisite Reference>

# multiple states for single id

<ID Declaration>:
  <State Module>:
    - <Function>
    - <Function Arg>
    - <Name>: <name>
    - <Requisite Declaration>:
      - <Requisite Reference>
  <State Module>:
    - <Function>
    - <Function Arg>
    - <Names>:
      - <name>
      - <name>
      - <name>
    - <Requisite Declaration>:
      - <Requisite Reference>
5.6.9 Include and Exclude

Salt SLS files can include other SLS files and exclude SLS files that have been otherwise included. This allows for an SLS file to easily extend or manipulate other SLS files.

Include

When other SLS files are included, everything defined in the included SLS file will be added to the state run. When including define a list of SLS formulas to include:

```yaml
include:
    - http
    - libvirt
```

The include statement will include SLS formulas from the same environment that the including SLS formula is in. But the environment can be explicitly defined in the configuration to override the running environment, therefore if an SLS formula needs to be included from an external environment named `dev` the following syntax is used:

```yaml
include:
    - dev: http
```

**NOTE:** `include` does not simply inject the states where you place it in the SLS file. If you need to guarantee order of execution, consider using requisites.

Do not use dots in SLS file names or their directories

The initial implementation of `top.sls` and `Include declaration` followed the python import model where a slash is represented as a period. This means that a SLS file with a period in the name (besides the suffix period) cannot be referenced. For example, `webserver_1.0.sls` is not referenceable because `webserver_1.0` would refer to the directory/file `webserver_1/0.sls`.

The same applies for any subdirectories, this is especially `tricky` when git repos are created. Another command that typically can't render it's output is `state.show_sls` of a file in a path that contains a dot.

Relative Include

In Salt 0.16.0, the capability to include SLS formulas which are relative to the running SLS formula was added. Simply precede the formula name with a .:

```yaml
include:
    - .virt
    - .virt.hyper
```

In Salt 2015.8, the ability to include SLS formulas which are relative to the parents of the running SLS formula was added. In order to achieve this, precede the formula name with more than one . (dot). Much like Python's relative import abilities, two or more leading dots represent a relative include of the parent or parents of the current package, with each . representing one level after the first.

The following SLS configuration, if placed within `example.dev.virtual`, would result in `example.http` and `base` being included respectively:

```yaml
include:
    - ..http
    - ...base
```
Exclude

The exclude statement, added in Salt 0.10.3, allows an SLS to hard exclude another SLS file or a specific id. The component is excluded after the high data has been compiled, so nothing should be able to override an exclude.

Since the exclude can remove an id or an sls the type of component to exclude needs to be defined. An exclude statement that verifies that the running highstate does not contain the http sls and the /etc/vimrc id would look like this:

```yaml
exclude:
  - sls: http
  - id: /etc/vimrc
```

Note: The current state processing flow checks for duplicate IDs before processing excludes. An error occurs if duplicate IDs are present even if one of the IDs is targeted by an exclude.

5.6.10 State System Layers

The Salt state system is comprised of multiple layers. While using Salt does not require an understanding of the state layers, a deeper understanding of how Salt compiles and manages states can be very beneficial.

Function Call

The lowest layer of functionality in the state system is the direct state function call. State executions are executions of single state functions at the core. These individual functions are defined in state modules and can be called directly via the `state.single` command.

```shell
salt '*' state.single pkg.installed name='vim'
```

Low Chunk

The low chunk is the bottom of the Salt state compiler. This is a data representation of a single function call. The low chunk is sent to the state caller and used to execute a single state function.

A single low chunk can be executed manually via the `state.low` command.

```shell
salt '*' state.low '{name: vim, state: pkg, fun: installed}'
```

The passed data reflects what the state execution system gets after compiling the data down from sls formulas.

Low State

The Low State layer is the list of low chunks `"evaluated" in order. To see what the low state looks like for a highstate, run:

```shell
salt '*' state.show_lowstate
```

This will display the raw lowstate in the order which each low chunk will be evaluated. The order of evaluation is not necessarily the order of execution, since requisites are evaluated at runtime. Requisite execution and evaluation is finite; this means that the order of execution can be ascertained with 100% certainty based on the order of the low state.
High Data

High data is the data structure represented in YAML via SLS files. The High data structure is created by merging the data components rendered inside sls files (or other render systems). The High data can be easily viewed by executing the `state.show_highstate` or `state.show_sls` functions. Since this data is a somewhat complex data structure, it may be easier to read using the json, yaml, or pprint outputs:

```
salt '*' state.show_highstate --out yaml
salt '*' state.show_sls edit.vim --out pprint
```

SLS

Above "High Data", the logical layers are no longer technically required to be executed, or to be executed in a hierarchy. This means that how the High data is generated is optional and very flexible. The SLS layer allows for many mechanisms to be used to render sls data from files or to use the fileserver backend to generate sls and file data from external systems.

The SLS layer can be called directly to execute individual sls formulas.

---

Note: SLS Formulas have historically been called "SLS files". This is because a single SLS was only constituted in a single file. Now the term "SLS Formula" better expresses how a compartmentalized SLS can be expressed in a much more dynamic way by combining pillar and other sources, and the SLS can be dynamically generated.

To call a single SLS formula named `edit.vim`, execute `state.apply` and pass `edit.vim` as an argument:

```
salt '*' state.apply edit.vim
```

---

HighState

Calling SLS directly logically assigns what states should be executed from the context of the calling minion. The Highstate layer is used to allow for full contextual assignment of what is executed where to be tied to groups of, or individual, minions entirely from the master. This means that the environment of a minion, and all associated execution data pertinent to said minion, can be assigned from the master without needing to execute or configure anything on the target minion. This also means that the minion can independently retrieve information about its complete configuration from the master.

To execute the `highstate` use `state.apply`:

```
salt '*' state.apply
```

---

Orchestrate

The orchestrate layer expresses the highest functional layer of Salt's automated logic systems. The Overstate allows for stateful and functional orchestration of routines from the master. The orchestrate defines in data execution stages which minions should execute states, or functions, and in what order using requisite logic.

5.6.11 The Orchestrate Runner

---

Note: This documentation has been moved [here](#).
5.6.12 Ordering States

The way in which configuration management systems are executed is a hotly debated topic in the configuration management world. Two major philosophies exist on the subject, to either execute in an imperative fashion where things are executed in the order in which they are defined, or in a declarative fashion where dependencies need to be mapped between objects.

Imperative ordering is finite and generally considered easier to write, but declarative ordering is much more powerful and flexible but generally considered more difficult to create.

Salt has been created to get the best of both worlds. States are evaluated in a finite order, which guarantees that states are always executed in the same order, and the states runtime is declarative, making Salt fully aware of dependencies via the requisite system.

State Auto Ordering

Salt always executes states in a finite manner, meaning that they will always execute in the same order regardless of the system that is executing them. But in Salt 0.17.0, the state_auto_order option was added. This option makes states get evaluated in the order in which they are defined in sls files, including the top.sls file.

The evaluation order makes it easy to know what order the states will be executed in, but it is important to note that the requisite system will override the ordering defined in the files, and the order option described below will also override the order in which states are defined in sls files.

If the classic ordering is preferred (lexicographic), then set state_auto_order to False in the master configuration file. Otherwise, state_auto_order defaults to True.

Requisite Statements

Note: The behavior of requisites changed in version 0.9.7 of Salt. This documentation applies to requisites in version 0.9.7 and later.

Often when setting up states any single action will require or depend on another action. Salt allows for the building of relationships between states with requisite statements. A requisite statement ensures that the named state is evaluated before the state requiring it. There are three types of requisite statements in Salt, require, watch, and prereq.

These requisite statements are applied to a specific state declaration:

```
httpd:
  pkg.installed: []
  file.managed:
    - name: /etc/httpd/conf/httpd.conf
    - source: salt://httpd/httpd.conf
    - require:
      - pkg: httpd
```

In this example, the require requisite is used to declare that the file /etc/httpd/conf/httpd.conf should only be set up if the pkg state executes successfully.

The requisite system works by finding the states that are required and executing them before the state that requires them. Then the required states can be evaluated to see if they have executed correctly.

Require statements can refer to any state defined in Salt. The basic examples are pkg, service, and file, but any used state can be referenced.
In addition to state declarations such as pkg, file, etc., sls type requisites are also recognized, and essentially allow `chaining` of states. This provides a mechanism to ensure the proper sequence for complex state formulas, especially when the discrete states are split or groups into separate sls files:

```yaml
include:
  - network

httpd:
  pkg.installed: []
  service.running:
    - require:
      - pkg: httpd
      - sls: network
```

In this example, the httpd service running state will not be applied (i.e., the httpd service will not be started) unless both the httpd package is installed AND the network state is satisfied.

**Note:** Requisite matching

Requisites match on both the ID Declaration and the name parameter. Therefore, if using the pkgs or sources argument to install a list of packages in a pkg state, it's important to note that it is impossible to match an individual package in the list, since all packages are installed as a single state.

**Multiple Requisites**

The requisite statement is passed as a list, allowing for the easy addition of more requisites. Both requisite types can also be separately declared:

```yaml
httpd:
  pkg.installed: []
  service.running:
    - enable: True
    - watch:
      - file: /etc/httpd/conf/httpd.conf
    - require:
      - pkg: httpd
      - user: httpd
      - group: httpd
  file.managed:
    - name: /etc/httpd/conf/httpd.conf
    - source: salt://httpd/httpd.conf
    - require:
      - pkg: httpd
  user.present: []
  group.present: []
```

In this example, the httpd service is only going to be started if the package, user, group, and file are executed successfully.

**Requisite Documentation**

For detailed information on each of the individual requisites, please look here.
## The Order Option

Before using the `order` option, remember that the majority of state ordering should be done with a *Requisite declaration*, and that a requisite declaration will override an `order` option, so a state with order option should not require or required by other states.

The order option is used by adding an order number to a state declaration with the option `order`:

```yaml
vim:
  pkg.installed:
    - order: 1
```

By adding the order option to `1` this ensures that the vim package will be installed in tandem with any other state declaration set to the order `1`.

Any state declared without an order option will be executed after all states with order options are executed.

But this construct can only handle ordering states from the beginning. Certain circumstances will present a situation where it is desirable to send a state to the end of the line. To do this, set the order to `last`:

```yaml
vim:
  pkg.installed:
    - order: last
```

### 5.6.13 State Providers

New in version 0.9.8.

Salt predetermines what modules should be mapped to what uses based on the properties of a system. These determinations are generally made for modules that provide things like package and service management.

Sometimes in states, it may be necessary to use an alternative module to provide the needed functionality. For instance, an very old Arch Linux system may not be running systemd, so instead of using the systemd service module, you can revert to the default service module:

```yaml
httpd:
  service.running:
    - enable: True
    - provider: service
```

In this instance, the basic `service` module (which manages `sysvinit`-based services) will replace the `systemd` module which is used by default on Arch Linux.

This change only affects this one state though. If it is necessary to make this override for most or every service, it is better to just override the provider in the minion config file, as described here.

Also, keep in mind that this only works for states with an identically-named virtual module (`pkg`, `service`, etc.).

### Arbitrary Module Redirects

The provider statement can also be used for more powerful means, instead of overwriting or extending the module used for the named service an arbitrary module can be used to provide certain functionality.

```yaml
emacs:
  pkg.installed:
    - provider:
      - cmd: customcmd
```
In this example, the state is being instructed to use a custom module to invoke commands. Arbitrary module redirects can be used to dramatically change the behavior of a given state.

### 5.6.14 Requisites and Other Global State Arguments

#### Requisites

The Salt requisite system is used to create relationships between states. The core idea being that, when one state is dependent somehow on another, that inter-dependency can be easily defined. These dependencies are expressed by declaring the relationships using state names and ID’s or names. The generalized form of a requisite target is `<state name> : <ID or name>`. The specific form is defined as a Requisite Reference.

Requisites come in two types: Direct requisites (such as `require`), and requisite_ins (such as `require_in`). The relationships are directional: a direct requisite requires something from another state. However, a requisite_in inserts a requisite into the targeted state pointing to the targeting state. The following example demonstrates a direct requisite:

```sh
vim:
  pkg.installed: []

/etc/vimrc:
  file.managed:
    - source: salt://edit/vimrc
    - require:
      - pkg: vim
```

In the example above, the file `/etc/vimrc` depends on the vim package.

Requisite_in statements are the opposite. Instead of saying `I depend on something`, requisite_ins say `Someone depends on me`:

```sh
vim:
  pkg.installed:
    - require_in:
      - file: /etc/vimrc

/etc/vimrc:
  file.managed:
    - source: salt://edit/vimrc
```

So here, with a requisite_in, the same thing is accomplished as in the first example, but the other way around. The vim package is saying `/etc/vimrc depends on me`. This will result in a `require` being inserted into the `/etc/vimrc` state which targets the `vim` state.

In the end, a single dependency map is created and everything is executed in a finite and predictable order.

#### Requisite matching

Requisites need two pieces of information for matching: The state module name – e.g. `pkg` –, and the identifier – e.g. `vim` –, which can be either the ID (the first line in the stanza) or the `-name` parameter.

```sh
- require:
  - pkg: vim
```
Omitting state module in requisites

New in version 2016.3.0.

In version 2016.3.0, the state module name was made optional. If the state module is omitted, all states matching the ID will be required, regardless of which module they are using.

- require:
  - vim

State target matching

In order to understand how state targets are matched, it is helpful to know how the state compiler is working. Consider the following example:

Deploy server package:
  file.managed:
    - name: /usr/local/share/myapp.tar.xz
    - source: salt://myapp.tar.xz

Extract server package:
  archive.extracted:
    - name: /usr/local/share/myapp
    - source: /usr/local/share/myapp.tar.xz
    - archive_format: tar
    - onchanges:
      - file: Deploy server package

The first formula is converted to a dictionary which looks as follows (represented as YAML, some properties omitted for simplicity) as High Data:

Deploy server package:
  file:
    - managed
    - name: /usr/local/share/myapp.tar.xz
    - source: salt://myapp.tar.xz

The file.managed format used in the formula is essentially syntactic sugar: at the end, the target is file, which is used in the Extract server package state above.

Identifier matching

Requisites match on both the ID Declaration and the name parameter. This means that, in the "Deploy server package" example above, a require requisite would match with with Deploy server package or /usr/local/share/myapp.tar.xz, so either of the following versions for "Extract server package" works:

# (Archive arguments omitted for simplicity)
#
# Match by ID declaration
Extract server package:
  archive.extracted:
    - onchanges:
      - file: Deploy server package
# Match by name parameter
Direct Requisite and Requisite_in types

There are several direct requisite statements that can be used in Salt:

- require
- watch
- prereq
- use
- onchanges
- onfail

Each direct requisite also has a corresponding requisite_in:

- require_in
- watch_in
- prereq_in
- use_in
- onchanges_in
- onfail_in

All of the requisites define specific relationships and always work with the dependency logic defined above.

**require**

The use of `require` demands that the dependent state executes before the depending state. The state containing the `require` requisite is defined as the depending state. The state specified in the `require` statement is defined as the dependent state. If the dependent state's execution succeeds, the depending state will then execute. If the dependent state's execution fails, the depending state will not execute. In the first example above, the file `/etc/vimrc` will only execute after the vim package is installed successfully.

**Require an Entire SLS File**

As of Salt 0.16.0, it is possible to require an entire sls file. Do this first by including the sls file and then setting a state to `require` the included sls file:

```
include:
  - foo

bar:
  pkg.installed:
    - require:
      - sls: foo
```
This will add all of the state declarations found in the given sls file. This means that every state in sls foo will be required. This makes it very easy to batch large groups of states easily in any requisite statement.

```
watch
```

Watch statements are used to add additional behavior when there are changes in other states.

**Note:** If a state should only execute when another state has changes, and otherwise do nothing, the new on-changes requisite should be used instead of watch. Watch is designed to add additional behavior when there are changes, but otherwise the state executes normally.

The state containing the watch requisite is defined as the watching state. The state specified in the watch statement is defined as the watched state. When the watched state executes, it will return a dictionary containing a key named `changes`. Here are two examples of state return dictionaries, shown in json for clarity:

```
{
    "local": {
        "file_|-/tmp/foo_|-/tmp/foo_|-directory": {
            "comment": "Directory /tmp/foo updated",
            "__run_num__": 0,
            "changes": {
                "user": "bar",
            },
            "name": "/tmp/foo",
            "result": true
        }
    }
}
```

```
{
    "local": {
        "pkgrepo_|-salt-minion_|-salt-minion_|-managed": {
            "comment": "Package repo 'salt-minion' already configured",
            "__run_num__": 0,
            "changes": {},
            "name": "salt-minion",
            "result": true
        }
    }
}
```

If the `result` of the watched state is True, the watching state will execute normally, and if it is False, the watching state will never run. This part of watch mirrors the functionality of the require requisite.

If the `result` of the watched state is True and the `changes` key contains a populated dictionary (changes occurred in the watched state), then the watch requisite can add additional behavior. This additional behavior is defined by the mod_watch function within the watching state module. If the mod_watch function exists in the watching state module, it will be called in addition to the normal watching state. The return data from the mod_watch function is what will be returned to the master in this case; the return data from the main watching function is discarded.

If the `changes` key contains an empty dictionary, the watch requisite acts exactly like the require requisite (the watching state will execute if `result` is True, and fail if `result` is False in the watched state).

**Note:** Not all state modules contain mod_watch. If mod_watch is absent from the watching state module, the
watch requisite behaves exactly like a require requisite.

A good example of using watch is with a service.running state. When a service watches a state, then the service is reloaded/restarted when the watched state changes, in addition to Salt ensuring that the service is running.

```yaml
ntpd:
  service.running:
    - watch:
      - file: /etc/ntp.conf
  file.managed:
    - name: /etc/ntp.conf
    - source: salt://ntp/files/ntp.conf
```

prereq

New in version 0.16.0.

prereq allows for actions to be taken based on the expected results of a state that has not yet been executed. The state containing the prereq requisite is defined as the pre-requiring state. The state specified in the prereq statement is defined as the pre-required state.

When a prereq requisite is evaluated, the pre-required state reports if it expects to have any changes. It does this by running the pre-required single state as a test-run by enabling test=True. This test-run will return a dictionary containing a key named "changes". (See the watch section above for examples of "changes" dictionaries.)

If the "changes" key contains a populated dictionary, it means that the pre-required state expects changes to occur when the state is actually executed, as opposed to the test-run. The pre-requiring state will now actually run. If the pre-requiring state executes successfully, the pre-required state will then execute. If the pre-requiring state fails, the pre-required state will not execute.

If the "changes" key contains an empty dictionary, this means that changes are not expected by the pre-required state. Neither the pre-required state nor the pre-requiring state will run.

The best way to define how prereq operates is displayed in the following practical example: When a service should be shut down because underlying code is going to change, the service should be off-line while the update occurs. In this example, graceful-down is the pre-requiring state and site-code is the pre-required state.

```yaml
graceful-down:
  cmd.run:
    - name: service apache graceful
    - prereq:
      - file: site-code

site-code:
  file.recurse:
    - name: /opt/site_code
    - source: salt://site/code
```

In this case the apache server will only be shutdown if the site-code state expects to deploy fresh code via the file.recurse call. The site-code deployment will only be executed if the graceful-down run completes successfully.

onfail

New in version 2014.7.0.
The `onfail` requisite allows for reactions to happen strictly as a response to the failure of another state. This can be used in a number of ways, such as executing a second attempt to set up a service or begin to execute a separate thread of states because of a failure.

The `onfail` requisite is applied in the same way as `require` as `watch`:

```yaml
primary_mount:
  mount.mounted:
    - name: /mnt/share
    - device: 10.0.0.45:/share
    - fstype: nfs

backup_mount:
  mount.mounted:
    - name: /mnt/share
    - device: 192.168.40.34:/share
    - fstype: nfs
    - onfail:
      - mount: primary_mount
```

### onchanges

New in version 2014.7.0.

The `onchanges` requisite makes a state only apply if the required states generate changes, and if the watched state's 'result' is `True`. This can be a useful way to execute a post hook after changing aspects of a system.

If a state has multiple `onchanges` requisites then the state will trigger if any of the watched states changes.

**Note:** One easy-to-make mistake is to use `onchanges_in` when `onchanges` is supposed to be used. For example, the below configuration is not correct:

```yaml
myservice:
  pkg.installed:
    - name: myservice
  file.managed:
    - name: /etc/myservice/myservice.conf
    - source: salt://myservice/files/myservice.conf
    - mode: 600
  cmd.run:
    - name: /usr/libexec/myservice/post-changes-hook.sh
    - onchanges_in:
      - file: /etc/myservice/myservice.conf
```

This will set up a requisite relationship in which the `cmd.run` state always executes, and the `file.managed` state only executes if the `cmd.run` state has changes (which it always will, since the `cmd.run` state includes the command results as changes).

It may semantically seem like the the `cmd.run` state should only run when there are changes in the file state, but remember that requisite relationships involve one state watching another state, and a `requisite_in` does the opposite: it forces the specified state to watch the state with the `requisite_in`.

The correct usage would be:

```yaml
myservice:
  pkg.installed:
    - name: myservice
```
file.managed:
- name: /etc/myservice/myservice.conf
- source: salt://myservice/files/myservice.conf
- mode: 600

cmd.run:
- name: /usr/libexec/myservice/post-changes-hook.sh
  onchanges:
    - file: /etc/myservice/myservice.conf

use

The `use` requisite is used to inherit the arguments passed in another id declaration. This is useful when many files need to have the same defaults.

/etc/foo.conf:
  file.managed:
    - source: salt://foo.conf
    - template: jinja
    - mkdirs: True
    - user: apache
    - group: apache
    - mode: 755

/etc/bar.conf
  file.managed:
    - source: salt://bar.conf
    - use:
      - file: /etc/foo.conf

The `use` statement was developed primarily for the networking states but can be used on any states in Salt. This makes sense for the networking state because it can define a long list of options that need to be applied to multiple network interfaces.

The `use` statement does not inherit the requisites arguments of the targeted state. This means also a chain of `use` requisites would not inherit inherited options.

The _in versions of requisites

All of the requisites also have corresponding requisite_in versions, which do the reverse of their normal counterparts. The examples below all use require_in as the example, but note that all of the _in requisites work the same way: They result in a normal requisite in the targeted state, which targets the state which has defines the requisite_in. Thus, a require_in causes the target state to require the targeting state. Similarly, a watch_in causes the target state to watch the targeting state. This pattern continues for the rest of the requisites.

If a state declaration needs to be required by another state declaration then require_in can accommodate it. Therefore, these two sls files would be the same in the end:

Using require

httpd:
  pkg.installed: []
  service.running:
    - require:
      - pkg: httpd
Using `require_in`

```
httpd:
  pkg.installed:
    - require_in:
      - service: httpd
  service.running: []
```

The `require_in` statement is particularly useful when assigning a require in a separate sls file. For instance it may be common for httpd to require components used to set up PHP or mod_python, but the HTTP state does not need to be aware of the additional components that require it when it is set up:

```
httpd:
  pkg.installed: []
  service.running:
    - require:
      - pkg: httpd

php.sls
```

```
include:
  - http

php:
  pkg.installed:
    - require_in:
      - service: httpd

mod_python.sls
```

```
include:
  - http

mod_python:
  pkg.installed:
    - require_in:
      - service: httpd
```

Now the httpd server will only start if php or mod_python are first verified to be installed. Thus allowing for a requisite to be defined \``after the fact\''.

**Fire Event Notifications**

New in version 2015.8.0.

The `fire_event` option in a state will cause the minion to send an event to the Salt Master upon completion of that individual state.

The following example will cause the minion to send an event to the Salt Master with a tag of `salt/state_result/20150505121517726431/dasalt/nano` and the result of the state will be the data field of the event. Notice that the `name` of the state gets added to the tag.

```
nano_stuff:
  pkg.installed:
    - name: nano
    - fire_event: True
```
In the following example instead of setting `fire_event` to `True`, `fire_event` is set to an arbitrary string, which will cause the event to be sent with this tag: `salt/state_result/20150505121725642845/dasalt/custom/tag/nano/finished`

```
nano_stuff:
  pkg.installed:
    - name: nano
    - fire_event: custom/tag/nano/finished
```

### Altering States

The state altering system is used to make sure that states are evaluated exactly as the user expects. It can be used to double check that a state performed exactly how it was expected to, or to make 100% sure that a state only runs under certain conditions. The use of `unless` or `onlyif` options help make states even more stateful. The `check_cmd` option helps ensure that the result of a state is evaluated correctly.

### Reload

`reload_modules` is a boolean option that forces Salt to reload its modules after a state finishes. `reload_pillar` and `reload_grains` can also be set. See [Reloading Modules](#).

### Unless

New in version 2014.7.0.

The `unless` requisite specifies that a state should only run when any of the specified commands return `False`. The `unless` requisite operates as NAND and is useful in giving more granular control over when a state should execute.

**NOTE:** Under the hood `unless` calls `cmd.retcode` with `python_shell=True`. This means the commands referenced by `unless` will be parsed by a shell, so beware of side-effects as this shell will be run with the same privileges as the salt-minion. Also be aware that the boolean value is determined by the shell’s concept of `True` and `False`, rather than Python’s concept of `True` and `False`.

```
vim:
  pkg.installed:
    unless:
      - rpm -q vim-enhanced
      - ls /usr/bin/vim
```

In the example above, the state will only run if either the vim-enhanced package is not installed (returns `False`) or if `/usr/bin/vim` does not exist (returns `False`). The state will run if both commands return `False`.

However, the state will not run if both commands return `True`.

Unless checks are resolved for each name to which they are associated.

For example:

```
deploy_app:
  cmd.run:
    - names:
      - first_deploy_cmd
      - second_deploy_cmd
    - unless: ls /usr/bin/vim
```

In the above case, `some_check` will be run prior to each name -- once for `first_deploy_cmd` and a second time for `second_deploy_cmd`.

**Onlyif**

New in version 2014.7.0.

The `onlyif` requisite specifies that if each command listed in `onlyif` returns `True`, then the state is run. If any of the specified commands return `False`, the state will not run.

**NOTE:** Under the hood `onlyif` calls `cmd.retcode` with `python_shell=True`. This means the commands referenced by `onlyif` will be parsed by a shell, so beware of side-effects as this shell will be run with the same privileges as the salt-minion. Also be aware that the boolean value is determined by the shell’s concept of `True` and `False`, rather than Python’s concept of `True` and `False`.

```yaml
stop-volume:
  module.run:
    - name: glusterfs.stop_volume
    - m_name: work
    - onlyif:
      - gluster volume status work
    - order: 1

remove-volume:
  module.run:
    - name: glusterfs.delete
    - m_name: work
    - onlyif:
      - gluster volume info work
    - watch:
      - cmd: stop-volume
```

The above example ensures that the `stop_volume` and `delete` modules only run if the gluster commands return a `0` ret value.

**Listen/Listen_in**

New in version 2014.7.0.

`listen` and its counterpart `listen_in` trigger `mod_wait` functions for states, when those states succeed and result in changes, similar to how `watch` its counterpart `watch_in`. Unlike `watch` and `watch_in`, `listen` and `listen_in` will not modify the order of states and can be used to ensure your states are executed in the order they are defined. All `listen/listen_in` actions will occur at the end of a state run, after all states have completed.

```yaml
restart-apache2:
  service.running:
    - name: apache2
    - listen:
      - file: /etc/apache2/apache2.conf

configure-apache2:
  file.managed:
    - name: /etc/apache2/apache2.conf
    - source: salt://apache2/apache2.conf
```
This example will cause apache2 to be restarted when the apache2.conf file is changed, but the apache2 restart will happen at the end of the state run.

```yaml
class 'restart-apache2':
  service.running:
    - name: apache2

class 'configure-apache2':
  file.managed:
    - name: /etc/apache2/apache2.conf
    - source: salt://apache2/apache2.conf
    - listen_in:
      - service: apache2
```

This example does the same as the above example, but puts the state argument on the file resource, rather than the service resource.

**check_cmd**

New in version 2014.7.0.

Check Command is used for determining that a state did or did not run as expected.

**NOTE:** Under the hood check_cmd calls cmd.retcode with python_shell=True. This means the commands referenced by unless will be parsed by a shell, so beware of side-effects as this shell will be run with the same privileges as the salt-minion.

```bash
class 'comment-repo':
  file.replace:
    - name: /etc/yum.repos.d/fedora.repo
    - pattern: ^enabled=0
    - repl: enabled=1
    - check_cmd:
      - ! grep 'enabled=0' /etc/yum.repos.d/fedora.repo
```

This will attempt to do a replace on all enabled=0 in the .repo file, and replace them with enabled=1. The check_cmd is just a bash command. It will do a grep for enabled=0 in the file, and if it finds any, it will return a 0, which will be inverted by the leading !, causing check_cmd to set the state as failed. If it returns a 1, meaning it didn't find any enabled=0, it will be inverted by the leading !, returning a 0, and declaring the function succeeded.

**NOTE:** This requisite check_cmd functions differently than the check_cmd of the file.managed state.

**Overriding Checks**

There are two commands used for the above checks.

- `mod_run_check` is used to check for `onlyif` and `unless`. If the goal is to override the global check for these to variables, include a mod_run_check in the salt/states/ file.

- `mod_run_check_cmd` is used to check for the check_cmd options. To override this one, include a mod_run_check_cmd in the states file for the state.

**5.6.15 Startup States**

Sometimes it may be desired that the salt minion execute a state run when it is started. This alleviates the need for the master to initiate a state run on a new minion and can make provisioning much easier.
As of Salt 0.10.3 the minion config reads options that allow for states to be executed at startup. The options are `startup_states`, `sls_list`, and `top_file`.

The `startup_states` option can be passed one of a number of arguments to define how to execute states. The available options are:

- **highstate**: Execute `state.apply`
- **sls**: Read in the `sls_list` option and execute the named sls files
- **top**: Read in the `top_file` option and execute states based on that top file on the Salt Master

**Examples:**

Execute `state.apply` to run the `highstate` when starting the minion:

```
startup_states: highstate
```

Execute the sls files `edit.vim` and `hyper`:

```
startup_states: sls

sls_list:
  - edit.vim
  - hyper
```

## 5.6.16 State Testing

Executing a Salt state run can potentially change many aspects of a system and it may be desirable to first see what a state run is going to change before applying the run.

Salt has a test interface to report on exactly what will be changed, this interface can be invoked on any of the major state run functions:

```
salt '*' state.apply test=True
salt '*' state.apply mysls test=True
salt '*' state.single test=True
```

The test run is mandated by adding the `test=True` option to the states. The return information will show states that will be applied in yellow and the result is reported as `None`.

**Default Test**

If the value `test` is set to `True` in the minion configuration file then states will default to being executed in test mode. If this value is set then states can still be run by calling `test=False`:

```
salt '*' state.apply test=False
salt '*' state.apply mysls test=False
salt '*' state.single test=False
```
5.6.17 The Top File

Introduction

Most infrastructures are made up of groups of machines, each machine in the group performing a role similar to others. Those groups of machines work in concert with each other to create an application stack.

To effectively manage those groups of machines, an administrator needs to be able to create roles for those groups. For example, a group of machines that serve front-end web traffic might have roles which indicate that those machines should all have the Apache webserver package installed and that the Apache service should always be running.

In Salt, the file which contains a mapping between groups of machines on a network and the configuration roles that should be applied to them is called a top file.

Top files are named top.sls by default and they are so-named because they always exist in the ‘top’ of a directory hierarchy that contains state files. That directory hierarchy is called a state tree.

A Basic Example

Top files have three components:

- Environment: A state tree directory containing a set of state files to configure systems.
- Target: A grouping of machines which will have a set of states applied to them.
- State files: A list of state files to apply to a target. Each state file describes one or more states to be configured and enforced on the targeted machines.

The relationship between these three components is nested as follows:

- Environments contain targets
- Targets contain states

Putting these concepts together, we can describe a scenario in which all minions with an ID that begins with web have an apache state applied to them:

<table>
<thead>
<tr>
<th>Environment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base:</td>
<td># Apply SLS files from the directory root for the 'base' environment</td>
</tr>
<tr>
<td>'web*':</td>
<td># All minions with a minion_id that begins with 'web'</td>
</tr>
<tr>
<td>- apache</td>
<td># Apply the state file named 'apache.sls'</td>
</tr>
</tbody>
</table>

Environments

Environments are directory hierarchies which contain a top files and a set of state files.

Environments can be used in many ways, however there is no requirement that they be used at all. In fact, the most common way to deploy Salt is with a single environment, called base. It is recommended that users only create multiple environments if they have a use case which specifically calls for multiple versions of state trees.

Getting Started with Top Files

Each environment is defined inside a salt master configuration variable called, file_roots.

In the most common single-environment setup, only the base environment is defined in file_roots along with only one directory path for the state tree.
file_roots:
  base:
    - /srv/salt

In the above example, the top file will only have a single environment to pull from.

Next is a simple single-environment top file placed in /srv/salt/top.sls, illustrating that for the environment called `base`, all minions will have the state files named `core.sls` and `edit.sls` applied to them.

```
base:
  '*':
    - core
    - edit
```

Assuming the `file_roots` configuration from above, Salt will look in the /srv/salt directory for `core.sls` and `edit.sls`.

**Multiple Environments**

In some cases, teams may wish to create versioned state trees which can be used to test Salt configurations in isolated sets of systems such as a staging environment before deploying states into production.

For this case, multiple environments can be used to accomplish this task.

To create multiple environments, the `file_roots` option can be expanded:

```
file_roots:
  dev:
    - /srv/salt/dev
  qa:
    - /srv/salt/qa
  prod:
    - /srv/salt/prod
```

In the above, we declare three environments: `dev`, `qa` and `prod`. Each environment has a single directory assigned to it.

Our top file references the environments:

```
dev:
  'webserver*':
    - webserver
  'db*':
    - db
qa:
  'webserver*':
    - webserver
  'db*':
    - db
prod:
  'webserver*':
    - webserver
  'db*':
    - db
```

As seen above, the top file now declares the three environments and for each, target expressions are defined to map minions to state files. For example, all minions which have an ID beginning with the string `webserver` will have the `webserver` state from the requested environment assigned to it.
In this manner, a proposed change to a state could first be made in a state file in /srv/salt/dev and then be applied to development webservers before moving the state into QA by copying the state file into /srv/salt/qa.

Choosing an Environment to Target

The top file is used to assign a minion to an environment unless overridden using the methods described below. The environment in the top file must match valid fileserver environment (a.k.a. saltenv) in order for any states to be applied to that minion. When using the default fileserver backend, environments are defined in file_roots.

The states that will be applied to a minion in a given environment can be viewed using the state.show_top function.

Minions may be pinned to a particular environment by setting the environment value in the minion configuration file. In doing so, a minion will only request files from the environment to which it is assigned.

The environment may also be dynamically selected at runtime by passing it to the salt, salt-call or salt-ssh command. This is most commonly done with functions in the state module by using the saltenv argument. For example, to run a highstate on all minions, using only the top file and SLS files in the prod environment, run: salt '*' state.highstate saltenv=prod.

Note: Not all functions accept saltenv as an argument, see the documentation for an individual function documentation to verify.

Shorthand

If you assign only one SLS to a system, as in this example, a shorthand is also available:

```
base:
  '*': global
dev:
  'webserver*': webserver
  'db*': db
qa:
  'webserver*': webserver
  'db*': db
prod:
  'webserver*': webserver
  'db*': db
```

Advanced Minion Targeting

In the examples above, notice that all of the target expressions are globs. The default match type in top files (since version 2014.7.0) is actually the compound matcher, not the glob matcher as in the CLI.

A single glob, when passed through the compound matcher, acts the same way as matching by glob, so in most cases the two are indistinguishable. However, there is an edge case in which a minion ID contains whitespace. While it is not recommended to include spaces in a minion ID, Salt will not stop you from doing so. However, since compound expressions are parsed word-by-word, if a minion ID contains spaces it will fail to match. In this edge case, it will be necessary to explicitly use the glob matcher:

```
base:
  'minion 1':
```
The available match types which can be set for a target expression in the top file are:

<table>
<thead>
<tr>
<th>Match Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glob</td>
<td>Full minion ID or glob expression to match multiple minions (e.g. minion123 or minion*)</td>
</tr>
<tr>
<td>pcre</td>
<td>Perl-compatible regular expression (PCRE) matching a minion ID (e.g. web[0-3].domain.com)</td>
</tr>
<tr>
<td>grain</td>
<td>Match a grain, optionally using globbing (e.g. kernel:Linux or kernel:*BSD)</td>
</tr>
<tr>
<td>grain_pcre</td>
<td>Match a grain using PCRE (e.g. kernel:(Free</td>
</tr>
<tr>
<td>list</td>
<td>Comma-separated list of minions (e.g. minion1,minion2,minion3)</td>
</tr>
<tr>
<td>pillar</td>
<td>Pillar match, optionally using globbing (e.g. role:webserver or role:web*)</td>
</tr>
<tr>
<td>pillar_pcre</td>
<td>Pillar match using PCRE (e.g. role:web(server</td>
</tr>
<tr>
<td>pillar_exact</td>
<td>Pillar match with no globbing or PCRE (e.g. role:webserver)</td>
</tr>
<tr>
<td>ipcidr</td>
<td>Subnet or IP address (e.g. 172.17.0.0/16 or 10.2.9.80)</td>
</tr>
<tr>
<td>data</td>
<td>Match values kept in the minion’s datastore (created using the data execution module)</td>
</tr>
<tr>
<td>range</td>
<td>Range cluster</td>
</tr>
<tr>
<td>compound</td>
<td>Complex expression combining multiple match types (see here)</td>
</tr>
<tr>
<td>nodegroup</td>
<td>Pre-defined compound expressions in the master config file (see here)</td>
</tr>
</tbody>
</table>

Below is a slightly more complex top file example, showing some of the above match types:

```yaml
# All files will be taken from the file path specified in the base environment in the `file_roots` configuration value.

base:
  # All minions which begin with the strings 'nag1' or any minion with a grain set called 'role' with the value of 'monitoring' will have the 'server.sls' state file applied from the 'nagios/' directory.
  'nag1* or G@role:monitoring':
    - nagios.server

  # All minions get the following three state files applied
  '*':
    - ldap-client
    - networking
    - salt.minion

  # All minions which have an ID that begins with the phrase 'salt-master' will have an SLS file applied that is named 'master.sls' and is in the 'salt' directory, underneath the root specified in the `base` environment in the configuration value for `file_roots`.
  'salt-master*':
    - salt.master

  # Minions that have an ID matching the following regular expression will have the state file called 'web.sls' in the nagios/mon directory applied. Additionally, minions matching the regular expression will also have the 'server.sls' file in the apache/ directory applied.
```

5.6. State System Reference 431
# NOTE!
#
# Take note of the 'match' directive here, which tells Salt
# to treat the target string as a regex to be matched!

`\^(memcache|web).(qa|prod).loc$`:
- match: pcre
  - nagios.mon.web
  - apache.server

# Minions that have a grain set indicating that they are running
# the Ubuntu operating system will have the state file called
# 'ubuntu.sls' in the 'repos' directory applied.
#
# Again take note of the 'match' directive here which tells
# Salt to match against a grain instead of a minion ID.

`os:Ubuntu`:
- match: grain
  - repos.ubuntu

# Minions that are either RedHat or CentOS should have the 'epel.sls'
# state applied, from the 'repos/' directory.

`os:(RedHat|CentOS)`:
- match: grain_pcre
  - repos.epel

# The three minions with the IDs of 'foo', 'bar' and 'baz' should
# have 'database.sls' applied.

`foo,bar,baz`:
- match: list
  - database

# Any minion for which the pillar key 'somekey' is set and has a value
# of that key matching 'abc' will have the 'xyz.sls' state applied.

`somekey:abc`:
- match: pillar
  - xyz

---

**How Top Files Are Compiled**

When a highstate is executed and an environment is specified (either using the environment config option or by passing the saltignore when executing the highstate), then that environment’s top file is the only top file used to assign states to minions, and only states from the specified environment will be run.

The remainder of this section applies to cases in which a highstate is executed without an environment specified.

With no environment specified, the minion will look for a top file in each environment, and each top file will be processed to determine the SLS files to run on the minions. By default, the top files from each environment will be merged together. In configurations with many environments, such as with GitFS where each branch and tag is treated as a distinct environment, this may cause unexpected results as SLS files from older tags cause defunct SLS files to be included in the highstate. In cases like this, it can be helpful to set top_file_merging_strategy to same to force each environment to use its own top file.
Another option would be to set `state_top_saltenv` to a specific environment, to ensure that any top files in other environments are disregarded:

```
state_top_saltenv: base
```

With GitFS, it can also be helpful to simply manage each environment's top file separately, and/or manually specify the environment when executing the highstate to avoid any complicated merging scenarios. `gitfs_env_whitelist` and `gitfs_env_blacklist` can also be used to hide unneeded branches and tags from GitFS to reduce the number of top files in play.

When using multiple environments, it is not necessary to create a top file for each environment. The easiest-to-maintain approach is to use a single top file placed in the `base` environment. This is often infeasible with GitFS though, since branching/tagging can easily result in extra top files. However, when only the default (`roots`) file-server backend is used, a single top file in the `base` environment is the most common way of configuring a highstate.

The following minion configuration options affect how top files are compiled when no environment is specified:

- `state_top_saltenv`
- `top_file_merging_strategy`
- `env_order`
- `default_top`

### Top File Compilation Examples

For the scenarios below, assume the following configuration:

```
/etc/salt/master:
```

```
file_roots:
    base: /srv/salt/base
    dev: /srv/salt/dev
    qa: /srv/salt/qa
```

```
/srv/salt/base/top.sls:
```

```
base: 'x':
    - base1
dev: 'x':
    - dev1
qa: 'x':
    - qa1
```

```
/srv/salt/dev/top.sls:
```

```
base: 'minion1':
    - base2
dev:
```

5.6. State System Reference
Scenario 1 - dev Environment Specified

In this scenario, the highstate was either invoked with saltenv=dev or the minion has environment: dev set in the minion config file. The result will be that only the dev2 SLS from the dev environment will be part of the highstate, and it will be applied to minion2, while minion1 will have no states applied to it.

If the base environment were specified, the result would be that only the base1 SLS from the base environment would be part of the highstate, and it would be applied to all minions.

If the qa environment were specified, the highstate would exit with an error.

Scenario 2 - No Environment Specified, top_file_merging_strategy is `merge`

In this scenario, assuming that the base environment's top file was evaluated first, the base1, dev1, and qa1 states would be applied to all minions. If, for instance, the qa environment is not defined in /srv/salt/base/top.sls, then because there is no top file for the qa environment, no states from the qa environment would be applied.

Scenario 3 - No Environment Specified, top_file_merging_strategy is `same`

Changed in version 2016.11.0: In prior versions, ``same`` did not quite work as described below (see here). This has now been corrected. It was decided that changing something like top file handling in a point release had the potential to unexpectedly impact users' top files too much, and it would be better to make this correction in a feature release.

In this scenario, base1 from the base environment is applied to all minions. Additionally, dev2 from the dev environment is applied to minion2.

If default_top is unset (or set to base, which happens to be the default), then qa1 from the qa environment will be applied to all minions. If default_top were set to dev, then qa2 from the qa environment would be applied to all minions.

5.6.18 SLS Template Variable Reference

The template engines available to sls files and file templates come loaded with a number of context variables. These variables contain information and functions to assist in the generation of templates. See each variable below for its availability -- not all variables are available in all templating contexts.

Salt

The salt variable is available to abstract the salt library functions. This variable is a python dictionary containing all of the functions available to the running salt minion. It is available in all salt templates.
{% for file in salt['cmd.run']('ls -1 /opt/to_remove').splitlines() %}
/opt/to_remove/{{ file }}: file.absent
{% endfor %}

Opts

The `opts` variable abstracts the contents of the minion's configuration file directly to the template. The `opts` variable is a dictionary. It is available in all templates.

```python
{{ opts['cachedir'] }}
```

The `config.get` function also searches for values in the `opts` dictionary.

Pillar

The `pillar` dictionary can be referenced directly, and is available in all templates:

```python
{{ pillar['key'] }}
```

Using the `pillar.get` function via the `salt` variable is generally recommended since a default can be safely set in the event that the value is not available in pillar and dictionaries can be traversed directly:

```python
{{ salt['pillar.get']('key', 'failover_value') }}
{{ salt['pillar.get']('stuff:more:deeper') }}
```

Grains

The `grains` dictionary makes the minion's grains directly available, and is available in all templates:

```python
{{ grains['os'] }}
```

The `grains.get` function can be used to traverse deeper grains and set defaults:

```python
{{ salt['grains.get']('os') }}
```

saltenv

The `saltenv` variable is available in only in sls files when gathering the sls from an environment.

```python
{{ saltenv }}
```

sls

The `sls` variable contains the sls reference value, and is only available in the actual SLS file (not in any files referenced in that SLS). The sls reference value is the value used to include the sls in top files or via the include option.

```python
{{ sls }}
```
slspath

The slspath variable contains the path to the current sls file. The value of slspath in files referenced in the current sls depends on the reference method. For jinja includes slspath is the path to the current file. For salt includes slspath is the path to the included file.

```python
{{ slspath }}
```

## 5.6.19 State Modules

State Modules are the components that map to actual enforcement and management of Salt states.

### States are Easy to Write!

State Modules should be easy to write and straightforward. The information passed to the SLS data structures will map directly to the states modules.

Mapping the information from the SLS data is simple, this example should illustrate:

```
/etc/salt/master: # maps to "name"
file.managed: # maps to <filename>.<function> - e.g. "managed" in https://github.com/saltstack/salt/tree/develop/salt/states/file.py
    - user: root # one of many options passed to the manage function
    - group: root
    - mode: 644
    - source: salt://salt/master
```

Therefore this SLS data can be directly linked to a module, function, and arguments passed to that function.

This does issue the burden, that function names, state names and function arguments should be very human readable inside state modules, since they directly define the user interface.

### Keyword Arguments

Salt passes a number of keyword arguments to states when rendering them, including the environment, a unique identifier for the state, and more. Additionally, keep in mind that the requisites for a state are part of the keyword arguments. Therefore, if you need to iterate through the keyword arguments in a state, these must be considered and handled appropriately. One such example is in the pkgrepo.managed state, which needs to be able to handle arbitrary keyword arguments and pass them to module execution functions. An example of how these keyword arguments can be handled can be found [here](#).

### Using Custom State Modules

Place your custom state modules inside a _states directory within the file_roots specified by the master config file. These custom state modules can then be distributed in a number of ways. Custom state modules are distributed when state.apply is run, or by executing the saltutil.sync_states or saltutil.sync_all functions.

Any custom states which have been synced to a minion, that are named the same as one of Salt's default set of states, will take the place of the default state with the same name. Note that a state's default name is its filename (i.e. foo.py becomes state foo), but that its name can be overridden by using a __virtual__ function.
Cross Calling Execution Modules from States

As with Execution Modules, State Modules can also make use of the `__salt__` and `__grains__` data. See *cross calling execution modules*. It is important to note that the real work of state management should not be done in the state module unless it is needed. A good example is the pkg state module. This module does not do any package management work, it just calls the pkg execution module. This makes the pkg state module completely generic, which is why there is only one pkg state module and many backend pkg execution modules.

On the other hand some modules will require that the logic be placed in the state module, a good example of this is the file module. But in the vast majority of cases this is not the best approach, and writing specific execution modules to do the backend work will be the optimal solution.

Cross Calling State Modules

All of the Salt state modules are available to each other and state modules can call functions available in other state modules.

The variable `__states__` is packed into the modules after they are loaded into the Salt minion.

The `__states__` variable is a Python dictionary containing all of the state modules. Dictionary keys are strings representing the names of the modules and the values are the functions themselves.

Salt state modules can be cross-called by accessing the value in the `__states__` dict:

```python
ret = __states__['file.managed'](name='/tmp/myfile', source='salt://myfile')
```

This code will call the `managed` function in the `file` state module and pass the arguments `name` and `source` to it.

Return Data

A State Module must return a dict containing the following keys/values:

- **name**: The same value passed to the state as `name`.
- **changes**: A dict describing the changes made. Each thing changed should be a key, with its value being another dict with keys called `old` and `new` containing the old/new values. For example, the pkg state's changes dict has one key for each package changed, with the `old` and `new` keys in its sub-dict containing the old and new versions of the package. For example, the final changes dictionary for this scenario would look something like this:

  ```python
  ret['changes'].update({'my_pkg_name': {'old': '',
                                       'new': 'my_pkg_name-1.0'}})
  ```

- **result**: A tristate value. `True` if the action was successful, `False` if it was not, or `None` if the state was run in test mode, `test=True`, and changes would have been made if the state was not run in test mode.

<table>
<thead>
<tr>
<th></th>
<th>live mode</th>
<th>test mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>no changes</td>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>successful changes</td>
<td>True</td>
<td>None</td>
</tr>
<tr>
<td>failed changes</td>
<td>False</td>
<td>None</td>
</tr>
</tbody>
</table>

  *Note*: Test mode does not predict if the changes will be successful or not.

- **comment**: A string containing a summary of the result.
The return data can also, include the `pchanges` key, this stands for *predictive changes*. The `pchanges` key informs the State system what changes are predicted to occur.

**Note:** States should not return data which cannot be serialized such as frozensets.

### Test State

All states should check for and support `test` being passed in the options. This will return data about what changes would occur if the state were actually run. An example of such a check could look like this:

```python
# Return comment of changes if test.
if __opts__['test']:
    ret['result'] = None
    ret['comment'] = 'State Foo will execute with param {0}'.format(bar)
return ret
```

Make sure to test and return before performing any real actions on the minion.

**Note:** Be sure to refer to the result table listed above and displaying any possible changes when writing support for `test`. Looking for changes in a state is essential to `test=True` functionality. If a state is predicted to have no changes when `test=True` (or `test: true` in a config file) is used, then the result of the final state **should not** be `None`.

### Watcher Function

If the state being written should support the watch requisite then a watcher function needs to be declared. The watcher function is called whenever the watch requisite is invoked and should be generic to the behavior of the state itself.

The watcher function should accept all of the options that the normal state functions accept (as they will be passed into the watcher function).

A watcher function typically is used to execute state specific reactive behavior, for instance, the watcher for the service module restarts the named service and makes it useful for the watcher to make the service react to changes in the environment.

The watcher function also needs to return the same data that a normal state function returns.

### Mod_init Interface

Some states need to execute something only once to ensure that an environment has been set up, or certain conditions global to the state behavior can be predefined. This is the realm of the mod_init interface.

A state module can have a function called `mod_init` which executes when the first state of this type is called. This interface was created primarily to improve the pkg state. When packages are installed the package metadata needs to be refreshed, but refreshing the package metadata every time a package is installed is wasteful. The `mod_init` function for the pkg state sets a flag down so that the first, and only the first, package installation attempt will refresh the package database (the package database can of course be manually called to refresh via the `refresh` option in the pkg state).

The `mod_init` function must accept the Low State Data for the given executing state as an argument. The low state data is a dict and can be seen by executing the state.show_lowstate function. Then the `mod_init` function must return
a bool. If the return value is True, then the mod_init function will not be executed again, meaning that the needed behavior has been set up. Otherwise, if the mod_init function returns False, then the function will be called the next time.

A good example of the mod_init function is found in the pkg state module:

```python
def mod_init(low):
    '''
    Refresh the package database here so that it only needs to happen once
    '''
    if low['fun'] == 'installed' or low['fun'] == 'latest':
        rtag = __gen_rtag()
        if not os.path.exists(rtag):
            open(rtag, 'w+').write('')
        return True
    else:
        return False
```

The mod_init function in the pkg state accepts the low state data as `low` and then checks to see if the function being called is going to install packages, if the function is not going to install packages then there is no need to refresh the package database. Therefore if the package database is prepared to refresh, then return True and the mod_init will not be called the next time a pkg state is evaluated, otherwise return False and the mod_init will be called next time a pkg state is evaluated.

**Log Output**

You can call the logger from custom modules to write messages to the minion logs. The following code snippet demonstrates writing log messages:

```python
import logging

log = logging.getLogger(__name__)

log.info('Here is Some Information')
log.warning('You Should Not Do That')
log.error('It Is Busted')
```

**Full State Module Example**

The following is a simplistic example of a full state module and function. Remember to call out to execution modules to perform all the real work. The state module should only perform `before` and `after` checks.

1. Make a custom state module by putting the code into a file at the following path: `/srv/salt/_states/my_custom_state.py`.
2. Distribute the custom state module to the minions:
   ```
salt '*' saltutil.sync_states
   ```
3. Write a new state to use the custom state by making a new state file, for instance `/srv/salt/my_custom_state.sls`.
4. Add the following SLS configuration to the file created in Step 3:
   ```
   human_friendly_state_id: # An arbitrary state ID declaration.
   my_custom_state: # The custom state module name.
   ```
Example state module

```python
import salt.exceptions

def enforce_custom_thing(name, foo, bar=True):
    '''
    Enforce the state of a custom thing

    This state module does a custom thing. It calls out to the execution module `my_custom_module` in order to check the current system and perform any needed changes.

    name
        The thing to do something to
    foo
        A required argument
    bar : True
        An argument with a default value
    '''
    ret = {
        'name': name,
        'changes': {},
        'result': False,
        'comment': '',
        'pchanges': {},
    }

    # Start with basic error-checking. Do all the passed parameters make sense
    # and agree with each-other?
    if bar == True and foo.startswith('Foo'):
        raise salt.exceptions.SaltInvocationError(
            'Argument "foo" cannot start with "Foo" if argument "bar" is True.')

    # Check the current state of the system. Does anything need to change?
    current_state = __salt__['my_custom_module.current_state'](name)

    if current_state == foo:
        ret['result'] = True
        ret['comment'] = 'System already in the correct state'
        return ret

    # The state of the system does need to be changed. Check if we're running
    # in "test=true" mode.
    if __opts__['test'] == True:
        ret['comment'] = 'The state of "{0}" will be changed.'.format(name)
        ret['pchanges'] = {
            'old': current_state,
            'new': 'Description, diff, whatever of the new state',
        }
```

```
- enforce_custom_thing  # The function in the custom state module.
- name: a_value        # Maps to the `name` parameter in the custom function.
- foo: Foo             # Specify the required `foo` parameter.
- bar: False           # Override the default value for the `bar`
```
# Return `None` when running with `test=true`.
ret['result'] = None

return ret

# Finally, make the actual change and return the result.
new_state = __salt__['my_custom_module.change_state'](name, foo)
ret['comment'] = 'The state of "{}" was changed!'.format(name)
ret['changes'] = {'old': current_state, 'new': new_state}
ret['result'] = True

return ret

5.6.20 State Management

State management, also frequently called Software Configuration Management (SCM), is a program that puts and keeps a system into a predetermined state. It installs software packages, starts or restarts services or puts configuration files in place and watches them for changes.

Having a state management system in place allows one to easily and reliably configure and manage a few servers or a few thousand servers. It allows configurations to be kept under version control.

Salt States is an extension of the Salt Modules that we discussed in the previous remote execution tutorial. Instead of calling one-off executions the state of a system can be easily defined and then enforced.

5.6.21 Understanding the Salt State System Components

The Salt state system is comprised of a number of components. As a user, an understanding of the SLS and renderer systems are needed. But as a developer, an understanding of Salt states and how to write the states is needed as well.

Note: States are compiled and executed only on minions that have been targeted. To execute functions directly on masters, see runners.

Salt SLS System

The primary system used by the Salt state system is the SLS system. SLS stands for SaLt State.

The Salt States are files which contain the information about how to configure Salt minions. The states are laid out in a directory tree and can be written in many different formats.

The contents of the files and the way they are laid out is intended to be as simple as possible while allowing for maximum flexibility. The files are laid out in states and contains information about how the minion needs to be configured.
SLS File Layout

SLS files are laid out in the Salt file server.

A simple layout can look like this:

```
top.sls
ssh.sls
sshd_config
users/init.sls
users/admin.sls
salt/master.sls
web/init.sls
```

The `top.sls` file is a key component. The `top.sls` files is used to determine which SLS files should be applied to which minions.

The rest of the files with the `.sls` extension in the above example are state files.

Files without a `.sls` extensions are seen by the Salt master as files that can be downloaded to a Salt minion.

States are translated into dot notation. For example, the `ssh.sls` file is seen as the `ssh` state and the `users/admin.sls` file is seen as the `users.admin` state.

Files named `init.sls` are translated to be the state name of the parent directory, so the `web/init.sls` file translates to the `web` state.

In Salt, everything is a file; there is no "magic translation" of files and file types. This means that a state file can be distributed to minions just like a plain text or binary file.

SLS Files

The Salt state files are simple sets of data. Since SLS files are just data they can be represented in a number of different ways.

The default format is YAML generated from a Jinja template. This allows for the states files to have all the language constructs of Python and the simplicity of YAML.

State files can then be complicated Jinja templates that translate down to YAML, or just plain and simple YAML files.

The State files are simply common data structures such as dictionaries and lists, constructed using a templating language such as YAML.

Here is an example of a Salt State:

```
vim:
  pkg.installed: []
salt:
  pkg.latest:
    - name: salt
  service.running:
    - names:
      - salt-master
      - salt-minion
    - require:
      - pkg: salt
    - watch:
      - file: /etc/salt/minion
```
This short stanza will ensure that vim is installed, Salt is installed and up to date, the salt-master and salt-minion daemons are running and the Salt minion configuration file is in place. It will also ensure everything is deployed in the right order and that the Salt services are restarted when the watched file updated.

The Top File

The top file controls the mapping between minions and the states which should be applied to them.

The top file specifies which minions should have which SLS files applied and which environments they should draw those SLS files from.

The top file works by specifying environments on the top-level.

Each environment contains target expressions to match minions. Finally, each target expression contains a list of Salt states to apply to matching minions:

This above example uses the base environment which is built into the default Salt setup.

The base environment has target expressions. The first one matches all minions, and the SLS files below it apply to all minions.

The second expression is a regular expression that will match all minions with an ID matching saltmaster.* and specifies that for those minions, the salt.master state should be applied. To

**Important:** Since version 2014.7.0, the default matcher (when one is not explicitly defined as in the second expression in the above example) is the compound matcher. Since this matcher parses individual words in the expression, minion IDs containing spaces will not match properly using this matcher. Therefore, if your target expression is designed to match a minion ID containing spaces, it will be necessary to specify a different match type (such as glob). For example:

A full table of match types available in the top file can be found [here](#).
Reloading Modules

Some Salt states require that specific packages be installed in order for the module to load. As an example the `pip` state module requires the `pip` package for proper name and version parsing.

In most of the common cases, Salt is clever enough to transparently reload the modules. For example, if you install a package, Salt reloads modules because some other module or state might require just that package which was installed.

On some edge-cases salt might need to be told to reload the modules. Consider the following state file which we'll call `pep8.sls`:

```python
python-pip:
    cmd.run:
        - name: |
          easy_install --script-dir=/usr/bin -U pip
        - cwd: /

pep8:
    pip.installed:
        - require:
        - cmd: python-pip
```

The above example installs `pip` using `easy_install` from `setuptools` and installs `pep8` using `pip`, which, as told earlier, requires `pip` to be installed system-wide. Let's execute this state:

```
salt-call state.apply pep8
```

The execution output would be something like:

```
---
State: - pip
Name: pep8
Function: installed
Result: False
Comment: State pip.installed found in sls pep8 is unavailable

Changes:

Summary
---
Succeeded: 1
Failed: 1
Total: 2
```

If we executed the state again the output would be:

```
---
State: - pip
Name: pep8
Function: installed
Result: True
Comment: Package was successfully installed
Changes: pep8==1.4.6: Installed

Summary
---
Succeeded: 2
```
Since we installed `pip` using `cmd`, Salt has no way to know that a system-wide package was installed.

On the second execution, since the required `pip` package was installed, the state executed correctly.

**Note:** Salt does not reload modules on every state run because doing so would greatly slow down state execution.

So how do we solve this *edge-case*? `reload_modules`!

`reload_modules` is a boolean option recognized by salt on all available states which forces salt to reload its modules once a given state finishes.

The modified state file would now be:

```python
python-pip:
  cmd.run:
    - name: |
        easy_install --script-dir=/usr/bin -U pip
    - cwd: /
    - reload_modules: true

pep8:
  pip.installed:
    - require:
      - cmd: python-pip
```

Let's run it, once:

```
salt-call state.apply pep8
```

The output is:

```
----------
State: - pip
Name: pep8
Function: installed
 Result: True
Comment: Package was successfully installed
Changes: pep8==1.4.6: Installed
----------
Succeeded: 2
Failed: 0
----------
Total: 2
```
6.1 Event System

The Salt Event System is used to fire off events enabling third party applications or external processes to react to behavior within Salt.

The event system is comprised of two primary components:

- The event sockets which publish events.
- The event library which can listen to events and send events into the salt system.

6.1.1 Event types

Salt Master Events

These events are fired on the Salt Master event bus. This list is not comprehensive.

Authentication events

**salt/auth**

Fired when a minion performs an authentication check with the master.

**Variables**

- **id** -- The minion ID.
- **act** -- The current status of the minion key: accept, pend, reject.
- **pub** -- The minion public key.

---

**Note:** Minions fire auth events on fairly regular basis for a number of reasons. Writing reactors to respond to events through the auth cycle can lead to infinite reactor event loops (minion tries to auth, reactor responds by doing something that generates another auth event, minion sends auth event, etc.). Consider reacting to salt/key or salt/minion/<MID>/start or firing a custom event tag instead.
Start events

salt/minion/<MID>/start
Fired every time a minion connects to the Salt master.

Variables  id -- The minion ID.

Key events

salt/key
Fired when accepting and rejecting minions keys on the Salt master. These happen as a result of actions undertaken by the salt-key command.

Variables
- id -- The minion ID.
- act -- The new status of the minion key: accept, delete,

Warning: If a master is in auto_accept mode, salt/key events will not be fired when the keys are accepted. In addition, pre-seeding keys (like happens through Salt-Cloud) will not cause firing of these events.

Job events

salt/job/<JID>/new
Fired as a new job is sent out to minions.

Variables
- jid -- The job ID.
- tgt -- The target of the job: *, a minion ID, G@os_family:RedHat, etc.
- tgt_type -- The type of targeting used: glob, grain, compound, etc.
- fun -- The function to run on minions: test.ping, network.interfaces, etc.
- arg -- A list of arguments to pass to the function that will be called.
- minions -- A list of minion IDs that Salt expects will return data for this job.
- user -- The name of the user that ran the command as defined in Salt's Publisher ACL or external auth.

salt/job/<JID>/ret/<MID>
Fired each time a minion returns data for a job.

Variables
- id -- The minion ID.
- jid -- The job ID.
- retcode -- The return code for the job.
- fun -- The function the minion ran. E.g., test.ping.
- return -- The data returned from the execution module.
**salt/job/**<JID>/prog/<MID>/RUN NUM**
Fired each time a each function in a state run completes execution. Must be enabled using the `state_events` option.

Variables
- `data` -- The data returned from the state module function.
- `id` -- The minion ID.
- `jid` -- The job ID.

**Presence events**

**salt/presence/present**
Events fired on a regular interval about currently connected, newly connected, or recently disconnected minions. Requires the `presence_events` setting to be enabled.

Variables
- `present` -- A list of minions that are currently connected to the Salt master.

**salt/presence/change**
Fired when the Presence system detects new minions connect or disconnect.

Variables
- `new` -- A list of minions that have connected since the last presence event.
- `lost` -- A list of minions that have disconnected since the last presence event.

**Cloud Events**

Unlike other Master events, `salt-cloud` events are not fired on behalf of a Salt Minion. Instead, `salt-cloud` events are fired on behalf of a VM. This is because the minion-to-be may not yet exist to fire events to or also may have been destroyed.

This behavior is reflected by the `name` variable in the event data for `salt-cloud` events as compared to the `id` variable for Salt Minion-triggered events.

**salt/cloud/**<VM NAME>/creating**
Fired when salt-cloud starts the VM creation process.

Variables
- `name` -- the name of the VM being created.
- `event` -- description of the event.
- `provider` -- the cloud provider of the VM being created.
- `profile` -- the cloud profile for the VM being created.

**salt/cloud/**<VM NAME>/deploying**
Fired when the VM is available and salt-cloud begins deploying Salt to the new VM.

Variables
- `name` -- the name of the VM being created.
- `event` -- description of the event.
- `kwargs` -- options available as the deploy script is invoked: `conf_file`, `deploy_command`, `display_ssh_output`, `host`, `keep_tmp`, `key_filename`, `make_minion`, `minion_conf`, `name`, `parallel`, `preseed_minion_keys`, `script`, `script_args`, `script_env`, `sock_dir`, `start_action`, `sudo`, `tmp_dir`, `tty`, `username`

**salt/cloud/<VM NAME>/requesting**
Fired when salt-cloud sends the request to create a new VM.

Variables

- `event` -- description of the event.
- `location` -- the location of the VM being requested.
- `kwargs` -- options available as the VM is being requested: `Action`, `ImageId`, `InstanceType`, `KeyName`, `MaxCount`, `MinCount`, `SecurityGroup`

**salt/cloud/<VM NAME>/querying**
Fired when salt-cloud queries data for a new instance.

Variables

- `event` -- description of the event.
- `instance_id` -- the ID of the new VM.

**salt/cloud/<VM NAME>/tagging**
Fired when salt-cloud tags a new instance.

Variables

- `event` -- description of the event.
- `tags` -- tags being set on the new instance.

**salt/cloud/<VM NAME>/waiting_for_ssh**
Fired while the salt-cloud deploy process is waiting for ssh to become available on the new instance.

Variables

- `event` -- description of the event.
- `ip_address` -- IP address of the new instance.

**salt/cloud/<VM NAME>/deploy_script**
Fired once the deploy script is finished.

Variables

- `event` -- description of the event.

**salt/cloud/<VM NAME>/created**
Fired once the new instance has been fully created.

Variables

- `name` -- the name of the VM being created.
- `event` -- description of the event.
- `instance_id` -- the ID of the new instance.
- `provider` -- the cloud provider of the VM being created.
- `profile` -- the cloud profile for the VM being created.

**salt/cloud/<VM NAME>/destroying**
Fired when salt-cloud requests the destruction of an instance.
Variables

- **name** -- the name of the VM being created.
- **event** -- description of the event.
- **instance_id** -- the ID of the new instance.

salt/cloud/<VM NAME>/destroyed

Fired when an instance has been destroyed.

Variables

- **name** -- the name of the VM being created.
- **event** -- description of the event.
- **instance_id** -- the ID of the new instance.

### 6.1.2 Listening for Events

Salt’s Event Bus is used heavily within Salt and it is also written to integrate heavily with existing tooling and scripts. There is a variety of ways to consume it.

**From the CLI**

The quickest way to watch the event bus is by calling the `state.event` runner:

```
salt-run state.event pretty=True
```

That runner is designed to interact with the event bus from external tools and shell scripts. See the documentation for more examples.

**Remotely via the REST API**

Salt’s event bus can be consumed `salt.netapi.rest_cherrypy.app.Events` as an HTTP stream from external tools or services.

```
curl -SsNk https://salt-api.example.com:8000/events?token=05A3
```

**From Python**

Python scripts can access the event bus only as the same system user that Salt is running as.

The event system is accessed via the event library and can only be accessed by the same system user that Salt is running as. To listen to events a SaltEvent object needs to be created and then the get_event function needs to be run. The SaltEvent object needs to know the location that the Salt Unix sockets are kept. In the configuration this is the `sock_dir` option. The `sock_dir` option defaults to ``/var/run/salt/master`` on most systems.

The following code will check for a single event:

```python
import salt.config
import salt.utils.event

opts = salt.config.client_config('/etc/salt/master')
```
```python
import fnmatch

import salt.config
import salt.utils.event

opts = salt.config.client_config('/etc/salt/master')

sevent = salt.utils.event.get_event(
    'master',
    sock_dir=opts['sock_dir'],
    transport=opts['transport'],
    opts=opts)

while True:
    ret = sevent.get_event(full=True)
    if ret is None:
        continue
    if fnmatch.fnmatch(ret['tag'], 'salt/job/*/ret/*'):
        do_something_with_job_return(ret['data'])
```

### 6.1.3 Firing Events

It is possible to fire events on either the minion's local bus or to fire events intended for the master.
To fire a local event from the minion on the command line call the `event.fire` execution function:
```
salt-call event.fire '{"data": "message to be sent in the event"}' 'tag'
```

To fire an event to be sent up to the master from the minion call the `event.send` execution function. Remember YAML can be used at the CLI in function arguments:
```
salt-call event.send 'myco/mytag/success' '{success: True, message: "It works!"}'
```

If a process is listening on the minion, it may be useful for a user on the master to fire an event to it:
```
# Job on minion
import salt.utils.event
event = salt.utils.event.MinionEvent(**__opts__)
for evdata in event.iter_events(tag='customtag/ '):
    return evdata  # do your processing here...
```
```
salt minionname event.fire '{"data": "message for the minion"}' 'customtag/african/ unladen'
```

6.1.4 Firing Events from Python

From Salt execution modules

Events can be very useful when writing execution modules, in order to inform various processes on the master when a certain task has taken place. This is easily done using the normal cross-calling syntax:
```
# /srv/salt/_modules/my_custom_module.py
def do_something():
    '''
    Do something and fire an event to the master when finished
    
    CLI Example::
    ,
   , salt '*' my_custom_module:do_something
    ''',
    # do something!
    __salt__['event.send']('myco/my_custom_module/finished', { 
        'finished': True,
        'message': "The something is finished!",
    })
```

From Custom Python Scripts

Firing events from custom Python code is quite simple and mirrors how it is done at the CLI:
```
import salt.client
caller = salt.client.Caller()
caller.sminion.functions['event.send'](
```
6.2 Beacons

Beacons let you use the Salt event system to monitor non-Salt processes. The beacon system allows the minion to hook into a variety of system processes and continually monitor these processes. When monitored activity occurs in a system process, an event is sent on the Salt event bus that can be used to trigger a reactor.

Salt beacons can currently monitor and send Salt events for many system activities, including:

- file system changes
- system load
- service status
- shell activity, such as user login
- network and disk usage

See beacon modules for a current list.

Note: Salt beacons are an event generation mechanism. Beacons leverage the Salt reactor system to make changes when beacon events occur.

6.2.1 Configuring Beacons

Salt beacons do not require any changes to the system components that are being monitored, everything is configured using Salt.

Beacons are typically enabled by placing a beacons: top level block in /etc/salt/minion or any file in /etc/salt/minion.d/ such as /etc/salt/minion.d/beacons.conf:

```
beacons:
  inotify:
    /etc/important_file: {}
    /opt: {}
```

The beacon system, like many others in Salt, can also be configured via the minion pillar, grains, or local config file.

Note: The inotify beacon only works on OSes that have inotify kernel support. Currently this excludes FreeBSD, Mac OS X, and Windows.

Beacon Monitoring Interval

Beacons monitor on a 1-second interval by default. To set a different interval, provide an interval argument to a beacon. The following beacons run on 5- and 10-second intervals:
Avoiding Event Loops

It is important to carefully consider the possibility of creating a loop between a reactor and a beacon. For example, one might set up a beacon which monitors whether a file is read which in turn fires a reactor to run a state which in turn reads the file and re-fires the beacon.

To avoid these types of scenarios, the disable_during_state_run argument may be set. If a state run is in progress, the beacon will not be run on its regular interval until the minion detects that the state run has completed, at which point the normal beacon interval will resume.

Note: For beacon writers: If you need extra stuff to happen, like closing file handles for the disable_during_state_run to actually work, you can add a close() function to the beacon to run those extra things. See the inotify beacon.

6.2.2 Beacon Example

This example demonstrates configuring the inotify beacon to monitor a file for changes, and then restores the file to its original contents if a change was made.

Create Watched File

Create the file named /etc/important_file and add some simple content:
Add Beacon Configs to Minion

On the Salt minion, add the following configuration to `/etc/salt/minion.d/beacons.conf`:

```yaml
beacons:
  inotify:
    /etc/important_file:
      mask: "modify"
      disable_during_state_run: True
```

Save the configuration file and restart the minion service. The beacon is now set up to notify Salt upon modifications made to the file.

**Note:** The `disable_during_state_run: True` parameter prevents the inotify beacon from generating reactor events due to Salt itself modifying the file.

View Events on the Master

On your Salt master, start the event runner using the following command:

```
salt-run state.event pretty=true
```

This runner displays events as they are received by the master on the Salt event bus. To test the beacon you set up in the previous section, make and save a modification to `/etc/important_file`. You'll see an event similar to the following on the event bus:

```
salt/beacon/larry/inotify//etc/important_file {
  "_stamp": "2015-09-09T15:59:37.972753",
  "data": {
    "change": "IN_IGNORED",
    "id": "larry",
    "path": "/etc/important_file"
  },
  "tag": "salt/beacon/larry/inotify//etc/important_file"
}
```

This indicates that the event is being captured and sent correctly. Now you can create a reactor to take action when this event occurs.

Create a Reactor

This reactor reverts the file named `/etc/important_file` to the contents provided by Salt each time it is modified.

Reactor SLS

On your Salt master, create a file named `/srv/reactor/revert.sls`.
Note: If the /srv/reactor directory doesn’t exist, create it.

```bash
mkdir -p /srv/reactor
```

Add the following to /srv/reactor/revert.sls:

```yaml
revert-file:
  local.state.apply:
    - tgt: {{ data['data']['id'] }}
    - mods: maintain_important_file
```

Note: In addition to setting disable_during_state_run: True for an inotify beacon whose reaction is to modify the watched file, it is important to ensure the state applied is also idempotent.

Note: The expression `{{ data['data']['id'] }}` is correct as it matches the event structure shown above.

**State SLS**

Create the state sls file referenced by the reactor sls file. This state file will be located at /srv/salt/maintain_important_file.sls.

```yaml
important_file:
  file.managed:
    - name: /etc/important_file
    - contents: |
      important_config: True
```

**Master Config**

Configure the master to map the inotify beacon event to the revert reaction in /etc/salt/master.d/reactor.conf:

```yaml
reactor:
  - salt/beacon/*/inotify//etc/important_file:
    - /srv/reactor/revert.sls
```

Note: You can have only one top level reactor section, so if one already exists, add this code to the existing section. See Understanding the Structure of Reactor Formulas to learn more about reactor SLS syntax.

**Start the Salt Master in Debug Mode**

To help with troubleshooting, start the Salt master in debug mode:

```bash
service salt-master stop
salt-master -l debug
```
When debug logging is enabled, event and reactor data are displayed so you can discover syntax and other issues.

**Trigger the Reactor**

On your minion, make and save another change to `/etc/important_file`. On the Salt master, you’ll see debug messages that indicate the event was received and the `state.apply` job was sent. When you inspect the file on the minion, you’ll see that the file contents have been restored to `important_config: True`.

All beacons are configured using a similar process of enabling the beacon, writing a reactor SLS (and state SLS if needed), and mapping a beacon event to the reactor SLS.

### 6.2.3 Writing Beacon Plugins

Beacon plugins use the standard Salt loader system, meaning that many of the constructs from other plugin systems holds true, such as the `__virtual__` function.

The important function in the Beacon Plugin is the `beacon` function. When the beacon is configured to run, this function will be executed repeatedly by the minion. The `beacon` function therefore cannot block and should be as lightweight as possible. The `beacon` also must return a list of dicts, each dict in the list will be translated into an event on the master.

Please see the `inotify` beacon as an example.

**The beacon Function**

The beacons system will look for a function named `beacon` in the module. If this function is not present then the beacon will not be fired. This function is called on a regular basis and defaults to being called on every iteration of the minion, which can be tens to hundreds of times a second. This means that the `beacon` function cannot block and should not be CPU or IO intensive.

The beacon function will be passed in the configuration for the executed beacon. This makes it easy to establish a flexible configuration for each called beacon. This is also the preferred way to ingest the beacon's configuration as it allows for the configuration to be dynamically updated while the minion is running by configuring the beacon in the minion's pillar.

**The Beacon Return**

The information returned from the beacon is expected to follow a predefined structure. The returned value needs to be a list of dictionaries (standard python dictionaries are preferred, no ordered dicts are needed).

The dictionaries represent individual events to be fired on the minion and master event buses. Each dict is a single event. The dict can contain any arbitrary keys but the `tag` key will be extracted and added to the tag of the fired event.

The return data structure would look something like this:

```json
[{
  'changes': ['/foo/bar'],
  'tag': 'foo'
},
{
  'changes': ['/foo/baz'],
  'tag': 'bar'
}]
```

**Calling Execution Modules**

Execution modules are still the preferred location for all work and system interaction to happen in Salt. For this reason the `__salt__` variable is available inside the beacon.
Please be careful when calling functions in \_salt\_, while this is the preferred means of executing complicated routines in Salt not all of the execution modules have been written with beacons in mind. Watch out for execution modules that may be CPU intense or IO bound. Please feel free to add new execution modules and functions to back specific beacons.

**Distributing Custom Beacons**

Custom beacons can be distributed to minions using `saltutil`, see `Dynamic Module Distribution`.

### 6.3 Reactor System

Salt's Reactor system gives Salt the ability to trigger actions in response to an event. It is a simple interface to watching Salt's event bus for event tags that match a given pattern and then running one or more commands in response.

This system binds sls files to event tags on the master. These sls files then define reactions. This means that the reactor system has two parts. First, the reactor option needs to be set in the master configuration file. The reactor option allows for event tags to be associated with sls reaction files. Second, these reaction files use highdata (like the state system) to define reactions to be executed.

#### 6.3.1 Event System

A basic understanding of the event system is required to understand reactors. The event system is a local ZeroMQ PUB interface which fires salt events. This event bus is an open system used for sending information notifying Salt and other systems about operations.

The event system fires events with a very specific criteria. Every event has a tag. Event tags allow for fast top level filtering of events. In addition to the tag, each event has a data structure. This data structure is a dict, which contains information about the event.

#### 6.3.2 Mapping Events to Reactor SLS Files

Reactor SLS files and event tags are associated in the master config file. By default this is /etc/salt/master, or /etc/salt/master.d/reactor.conf.

New in version 2014.7.0: Added Reactor support for `salt://` file paths.

In the master config section `reactor:` is a list of event tags to be matched and each event tag has a list of reactor SLS files to be run.

```
reactor: # Master config section "reactor"

- 'salt/minion/*/start': # Match tag "salt/minion/*/start"
  - /srv/reactor/start.sls # Things to do when a minion starts
  - /srv/reactor/monitor.sls # Other things to do

- 'salt/cloud/*/destroyed': # Glob can be used to match tags
  - /srv/reactor/destroy/*.*.sls # Glob can be used to match file names

- 'myco/custom/event/tag': # React to custom event tags
  - salt://reactor/mycustom.sls # Reactor files can come from the salt fileserver
```
Reactors sls files are similar to state and pillar sls files. They are by default yaml + Jinja templates and are passed familiar context variables.

They differ because of the addition of the `tag` and `data` variables.

- The `tag` variable is just the tag in the fired event.
- The `data` variable is the event's data dict.

Here is a simple reactor sls:

```jinja
{% if data['id'] == 'mysql1' %}
highstate_run:
  local.state.apply:
    - tgt: mysql1
{% endif %}
```

This simple reactor sls uses Jinja to further refine the reaction to be made. If the `id` in the event data is `mysql1` (in other words, if the name of the minion is `mysql1`) then the following reaction is defined. The same data structure and compiler used for the state system is used for the reactor system. The only difference is that the data is matched up to the salt command API and the runner system. In this example, a command is published to the `mysql1` minion with a function of `state.apply`. Similarly, a runner can be called:

```jinja
{% if data['data']['orchestrate'] == 'refresh' %}
orchestrate_run:
  runner.state.orchestrate
{% endif %}
```

This example will execute the state.orchestrate runner and initiate an orchestrate execution.

### 6.3.3 The Goal of Writing Reactor SLS Files

Reactor SLS files share the familiar syntax from Salt States but there are important differences. The goal of a Reactor file is to process a Salt event as quickly as possible and then to optionally start a new process in response.

1. The Salt Reactor watches Salt’s event bus for new events.
2. The event tag is matched against the list of event tags under the `reactor` section in the Salt Master config.
3. The SLS files for any matches are Rendered into a data structure that represents one or more function calls.
4. That data structure is given to a pool of worker threads for execution.

Matching and rendering Reactor SLS files is done sequentially in a single process. Complex Jinja that calls out to slow Execution or Runner modules slows down the rendering and causes other reactions to pile up behind the current one. The worker pool is designed to handle complex and long-running processes such as Salt Orchestrate.

**tl;dr:** Rendering Reactor SLS files MUST be simple and quick. The new process started by the worker threads can be long-running.
Jinja Context

Reactor files only have access to a minimal Jinja context. grains and pillar are not available. The salt object is available for calling Runner and Execution modules but it should be used sparingly and only for quick tasks for the reasons mentioned above.

Advanced State System Capabilities

Reactor SLS files, by design, do not support Requisites, ordering, onlyif/unless conditionals and most other powerful constructs from Salt's State system.

Complex Master-side operations are best performed by Salt's Orchestrate system so using the Reactor to kick off an Orchestrate run is a very common pairing.

For example:

```bash
# /etc/salt/master.d/reactor.conf
# A custom event containing: {"foo": "Foo!", "bar": "bar*", "baz": "Baz!"}
reactor:
  - myco/custom/event:
    - /srv/reactor/some_event.sls

# /srv/reactor/some_event.sls
invoke_orchestrate_file:
  runner.state.orchestrate:
    - mods: orch.do_complex_thing
    - pillar:
      event_tag: {{ tag }}
      event_data: {{ data | json() }}

# /srv/salt/orch/do_complex_thing.sls
{% set tag = salt.pillar.get('event_tag') %}
{% set data = salt.pillar.get('event_data') %}

# Pass data from the event to a custom runner function.
# The function expects a 'foo' argument.
do_first_thing:
  salt.runner:
    - name: custom_runner.custom_function
      foo: {{ data.foo }}

# Wait for the runner to finish then send an execution to minions.
# Forward some data from the event down to the minion's state run.
do_second_thing:
  salt.state:
    - tgt: {{ data.bar }}
    - sls:
      - do_thing_on_minion
      - pillar:
        baz: {{ data.baz }}
      - require:
        - salt: do_first_thing
```
Beacons and Reactors

An event initiated by a beacon, when it arrives at the master will be wrapped inside a second event, such that the data object containing the beacon information will be `data['data']`, rather than `data`.

For example, to access the `id` field of the beacon event in a reactor file, you will need to reference `{ { data['data'][id] } }` rather than `{ { data['id'] } }` as for events initiated directly on the event bus.

See the [beacon documentation](#) for examples.

### 6.3.4 Fire an event

To fire an event from a minion call `event.send`

```
salt-call event.send 'foo' '{orchestrate: refresh}'
```

After this is called, any reactor sls files matching event tag `foo` will execute with `{ { data['data'][orchestrate] } }` equal to `refresh`.

See [salt.modules.event](#) for more information.

### 6.3.5 Knowing what event is being fired

The best way to see exactly what events are fired and what data is available in each event is to use the `state.event runner`.

See also:

* [Common Salt Events](#)

Example usage:

```
salt-run state.event pretty=True
```

Example output:

```
salt/job/2015021301905721678/new {  
    "_stamp": "2015-02-13T00:19:05.724583",  
    "arg": [],  
    "fun": "test.ping",  
    "jid": "20150213001905721678",  
    "minions": [  
        "jerry"  
    ],  
    "tgt": ",",  
    "tgt_type": "glob",  
    "user": "root"
}
salt/job/2015021301910749506/ret/jerry {
    "_stamp": "2015-02-13T00:19:11.136730",  
    "cmd": "_return",  
    "fun": "saltutil.find_job",  
    "fun_args": [  
        "20150213001905721678"
    ],  
    "id": "jerry",
```
6.3.6 Debugging the Reactor

The best window into the Reactor is to run the master in the foreground with debug logging enabled. The output will include when the master sees the event, what the master does in response to that event, and it will also include the rendered SLS file (or any errors generated while rendering the SLS file).

1. Stop the master.
2. Start the master manually:

   ```
   salt-master -l debug
   ```

3. Look for log entries in the form:

   ```
   [DEBUG ] Gathering reactors for tag foo/bar
   [DEBUG ] Compiling reactions for tag foo/bar
   [DEBUG ] Rendered data from file: /path/to/the/reactor_file.sls:
   <... Rendered output appears here. ...>
   ```

   The rendered output is the result of the Jinja parsing and is a good way to view the result of referencing Jinja variables. If the result is empty then Jinja produced an empty result and the Reactor will ignore it.

6.3.7 Understanding the Structure of Reactor Formulas

I.e., when to use `arg` and `kward` and when to specify the function arguments directly.

While the reactor system uses the same basic data structure as the state system, the functions that will be called using that data structure are different functions than are called via Salt's state system. The Reactor can call Runner modules using the `runner` prefix, Wheel modules using the `wheel` prefix, and can also cause minions to run Execution modules using the `local` prefix.

Changed in version 2014.7.0: The `cmd` prefix was renamed to `local` for consistency with other parts of Salt. A backward-compatible alias was added for `cmd`.

The Reactor runs on the master and calls functions that exist on the master. In the case of Runner and Wheel functions the Reactor can just call those functions directly since they exist on the master and are run on the master.

In the case of functions that exist on minions and are run on minions, the Reactor still needs to call a function on the master in order to send the necessary data to the minion so the minion can execute that function.

The Reactor calls functions exposed in Salt's Python API documentation, and thus the structure of Reactor files very transparently reflects the function signatures of those functions.

Calling Execution modules on Minions

The Reactor sends commands down to minions in the exact same way Salt's CLI interface does. It calls a function locally on the master that sends the name of the function as well as a list of any arguments and a dictionary of any keyword arguments that the minion should use to execute that function.
Specifically, the Reactor calls the async version of this function. You can see that function has `arg` and `kwarg` parameters which are both values that are sent down to the minion.

Executing remote commands maps to the LocalClient interface which is used by the salt command. This interface more specifically maps to the cmd_async method inside of the LocalClient class. This means that the arguments passed are being passed to the cmd_async method, not the remote method. A field starts with local to use the LocalClient subsystem. The result is, to execute a remote command, a reactor formula would look like this:

```python
clean_tmp:
    local.cmd.run:
    - tgt: '*'
    - arg:
        - rm -rf /tmp/*
```

The arg option takes a list of arguments as they would be presented on the command line, so the above declaration is the same as running this salt command:

```
salt '*' cmd.run 'rm -rf /tmp/*'
```

Use the expr_form argument to specify a matcher:

```python
clean_tmp:
    local.cmd.run:
    - tgt: 'os:Ubuntu'
    - expr_form: grain
    - arg:
        - rm -rf /tmp/*

clean_tmp:
    local.cmd.run:
    - tgt: 'G@roles:hbase_master'
    - expr_form: compound
    - arg:
        - rm -rf /tmp/*
```

**Note:** An easy mistake to make here is to use tgt_type instead of expr_form, since the job cache and events all refer to the targeting method as tgt_type. As of the Nitrogen release of Salt, expr_form will be deprecated in favor of using tgt_type, to help with this confusion.

Any other parameters in the `LocalClient().cmd()` method can be specified as well.

**Calling Runner modules and Wheel modules**

Calling Runner modules and Wheel modules from the Reactor uses a more direct syntax since the function is being executed locally instead of sending a command to a remote system to be executed there. There are no `arg` or `kwarg` parameters (unless the Runner function or Wheel function accepts a parameter with either of those names.)

For example:

```python
clear_the_grains_cache_for_all_minions:
    runner.cache.clear_grains
```

If the **the runner takes arguments** then they must be specified as keyword arguments.
spin_up_more_web_machines:
    runner.cloud.profile:
        - prof: centos_6
        - instances:
            - web11  # These VM names would be generated via Jinja in a
            - web12  # real-world example.

To determine the proper names for the arguments, check the documentation or source code for the runner function you wish to call.

### Passing event data to Minions or Orchestrate as Pillar

An interesting trick to pass data from the Reactor script to `state.apply` is to pass it as inline Pillar data since both functions take a keyword argument named `pillar`.

The following example uses Salt's Reactor to listen for the event that is fired when the key for a new minion is accepted on the master using `salt-key`.

`/etc/salt/master.d/reactor.conf`:

```
reactor:
    - 'salt/key':
      - /srv/salt/haproxy/react_new_minion.sls
```

The Reactor then fires a :state:`apply` command targeted to the HAProxy servers and passes the ID of the new minion from the event to the state file via inline Pillar.

`/srv/salt/haproxy/react_new_minion.sls`:

```yaml
{% if data['act'] == 'accept' and data['id'].startswith('web') %}
add_new_minion_to_pool:
    local.state.apply:
        - tgt: 'haproxy*'
        - arg:
            - haproxy.refresh_pool
        - kwarg:
            pillar:
                new_minion: {{ data['id'] }}
{% endif %}
```

The above command is equivalent to the following command at the CLI:

```
salt 'haproxy*' state.apply haproxy.refresh_pool 'pillar={new_minion: minionid}'
```

This works with Orchestrate files as well:

```
call_some_orchestrate_file:
    runner.state.orchestrate:
        - mods: some_orchestrate_file
        - pillar:
            stuff: things
```

Which is equivalent to the following command at the CLI:

```
salt-run state.orchestrate some_orchestrate_file pillar='(stuff: things)'
```
Finally, that data is available in the state file using the normal Pillar lookup syntax. The following example is grabbing web server names and IP addresses from Salt Mine. If this state is invoked from the Reactor then the custom Pillar value from above will be available and the new minion will be added to the pool but with the disabled flag so that HAProxy won't yet direct traffic to it.

```
/srv/salt/haproxy/refresh_pool.sls:

{% set new_minion = salt['pillar.get']('new_minion') %}
listen web *:80
    balance source
    {% for server,ip in salt['mine.get']('web*', 'network.interfaces', ['eth0']).items() %}
        {% if server == new_minion %}
            server {{ server }} {{ ip }}:80 disabled
        {% else %}
            server {{ server }} {{ ip }}:80 check
        {% endif %}
    {% endfor %}
```

### 6.3.8 A Complete Example

In this example, we're going to assume that we have a group of servers that will come online at random and need to have keys automatically accepted. We'll also add that we don't want all servers being automatically accepted. For this example, we'll assume that all hosts that have an id that starts with `ink` will be automatically accepted and have state.apply executed. On top of this, we're going to add that a host coming up that was replaced (meaning a new key) will also be accepted.

Our master configuration will be rather simple. All minions that attempt to authenticate will match the tag of salt/auth. When it comes to the minion key being accepted, we get a more refined tag that includes the minion id, which we can use for matching.

```
/etc/salt/master.d/reactor.conf:

reactor:
    - 'salt/auth':
      - /srv/reactor/auth-pending.sls
    - 'salt/minion/ink*/start':
      - /srv/reactor/auth-complete.sls
```

In this sls file, we say that if the key was rejected we will delete the key on the master and then also tell the master to ssh in to the minion and tell it to restart the minion, since a minion process will die if the key is rejected.

We also say that if the key is pending and the id starts with ink we will accept the key. A minion that is waiting on a pending key will retry authentication every ten seconds by default.

```
/srv/reactor/auth-pending.sls:

{% if not data['result'] and data['id'].startswith('ink') %}
minion_remove:
    wheel.key.delete:
        - match: {{ data['id'] }}
minion_rejoin:
    local.cmd.run:
        - tgt: salt-master.domain.tld
        - arg:
            - ssh -o UserKnownHostsFile=/dev/null -o StrictHostKeyChecking=no "{{ data['id'][0:8] }}" 'sleep 10 && /etc/init.d/salt-minion restart'
```
No if statements are needed here because we already limited this action to just Ink servers in the master configuration.

/srv/reactor/auth-complete.sls:

```yaml
{% if 'act' in data and data['act'] == 'pend' and data['id'].startswith('ink') %}
minion_add:
  wheel.key.accept:
    - match: {{ data['id'] }}
{% endif %}
```

The above will also return the highstate result data using the smtp_return returner (use virtualname like when using from the command line with --return). The returner needs to be configured on the minion for this to work. See salt.returners.smtp_return documentation for that.

### 6.3.9 Syncing Custom Types on Minion Start

Salt will sync all custom types (by running a `saltutil.sync_all`) on every highstate. However, there is a chicken-and-egg issue where, on the initial highstate, a minion will not yet have these custom types synced when the top file is first compiled. This can be worked around with a simple reactor which watches for minion_start events, which each minion fires when it first starts up and connects to the master.

On the master, create `/srv/reactor/sync_grains.sls` with the following contents:

```yaml
sync_grains:
  local.saltutil.sync_grains:
    - tgt: {{ data['id'] }}
```

And in the master config file, add the following reactor configuration:

```yaml
reactor:
  - 'salt/minion/*/start':
    - /srv/reactor/sync_grains.sls
```

This will cause the master to instruct each minion to sync its custom grains when it starts, making these grains available when the initial highstate is executed.

Other types can be synced by replacing `local.saltutil.sync_grains` with `local.saltutil.sync_modules`, `local.saltutil.sync_all`, or whatever else suits the intended use case.

Also, if it is not desirable that every minion syncs on startup, the * can be replaced with a different glob to narrow down the set of minions which will match that reactor (e.g. salt/minion/appsrv*/start, which would only match minion IDs beginning with appsrv).
Orchestration

7.1 Orchestrate Runner

Orchestration is accomplished in salt primarily through the Orchestrate Runner. Added in version 0.17.0, this Salt Runner can use the full suite of Requisites and Other Global State Arguments available in states, and can also execute states/functions using salt-ssh.

7.1.1 The Orchestrate Runner

New in version 0.17.0.

Note: Orchestrate Deprecates OverState

The Orchestrate Runner (originally called the state.sls runner) offers all the functionality of the OverState, but with some advantages:

- All Requisites and Other Global State Arguments available in states can be used.
- The states/functions will also work on salt-ssh minions.

The Orchestrate Runner was added with the intent to eventually deprecate the OverState system, however the OverState will still be maintained until Salt 2015.8.0.

The orchestrate runner generalizes the Salt state system to a Salt master context. Whereas the state.sls, state.highstate, et al functions are concurrently and independently executed on each Salt minion, the state.orchestrate runner is executed on the master, giving it a master-level view and control over requisites, such as state ordering and conditionals. This allows for inter minion requisites, like ordering the application of states on different minions that must not happen simultaneously, or for halting the state run on all minions if a minion fails one of its states.

If you want to setup a load balancer in front of a cluster of web servers, for example, you can ensure the load balancer is setup before the web servers or stop the state run altogether if one of the minions does not set up correctly.

The state.sls, state.highstate, et al functions allow you to statefully manage each minion and the state.orchestrate runner allows you to statefully manage your entire infrastructure.

Executing the Orchestrate Runner

The Orchestrate Runner command format is the same as for the state.sls function, except that since it is a runner, it is executed with salt-run rather than salt. Assuming you have a state.sls file called
The following command run on the master will apply the states defined in that file.

```
salt-run state.orchestrate orch.webserver
```

**Note:** `state.orch` is a synonym for `state.orchestrate`

Changed in version 2014.1.1: The runner function was renamed to `state.orchestrate` to avoid confusion with the `state.sls` execution function. In versions 0.17.0 through 2014.1.0, `state.sls` must be used.

### Examples

#### Function

To execute a function, use `salt.function`:

```python
# /srv/salt/orch/cleanfoo.sls
cmd.run:
    salt.function:
    - tgt: '*'
    - arg:
        - rm -rf /tmp/foo
```

```
salt-run state.orchestrate orch.cleanfoo
```

If you omit the ``name`` argument, the ID of the state will be the default name, or in the case of `salt.function`, the execution module function to run. You can specify the ``name`` argument to avoid conflicting IDs:

```python
copy_some_file:
    salt.function:
        - name: file.copy
        - tgt: '*'
        - arg:
            - rm -rf /tmp/copy_of_file
            - /path/to/file
        - kwarg:
            remove_existing: true
```

#### State

To execute a state, use `salt.state`.

```python
# /srv/salt/orch/webserver.sls
install_nginx:
    salt.state:
    - tgt: 'web*'
    - sls:
        nginx
```

```
salt-run state.orchestrate orch.webserver
```
Highstate

To run a highstate, set `highstate: True` in your state config:

```bash
# /srv/salt/orch/web_setup.sls
webserver_setup:
  salt.state:
  - tgt: 'web*
  - highstate: True

salt-run state.orchestrate orch.web_setup
```

More Complex Orchestration

Many states/functions can be configured in a single file, which when combined with the full suite of `Requisites and Other Global State Arguments`, can be used to easily configure complex orchestration tasks. Additionally, the states/functions will be executed in the order in which they are defined, unless prevented from doing so by any `Requisites and Other Global State Arguments`, as is the default in SLS files since 0.17.0.

```bash
bootstrap_servers:
  salt.function:
  - name: cmd.run
  - tgt: 10.0.0.0/24
  - tgt_type: ipcidr
  - arg:
    - bootstrap

storage_setup:
  salt.state:
  - tgt: 'role:storage'
  - tgt_type: grain
  - sls: ceph
  - require:
    - salt: webserver_setup

webserver_setup:
  salt.state:
  - tgt: 'web*
  - highstate: True
```

Given the above setup, the orchestration will be carried out as follows:

1. The shell command `bootstrap` will be executed on all minions in the 10.0.0.0/24 subnet.
2. A Highstate will be run on all minions whose ID starts with `web`, since the `storage_setup` state requires it.
3. Finally, the `ceph` SLS target will be executed on all minions which have a grain called `role` with a value of `storage`.

**Note:** Remember, `salt-run` is always executed on the master.
8.1 Getting Started

Salt SSH is very easy to use, simply set up a basic roster file of the systems to connect to and run salt-ssh commands in a similar way as standard salt commands.

- Salt ssh is considered production ready in version 2014.7.0
- Python is required on the remote system (unless using the -r option to send raw ssh commands)
- On many systems, the salt-ssh executable will be in its own package, usually named salt-ssh
- The Salt SSH system does not supersede the standard Salt communication systems, it simply offers an SSH-based alternative that does not require ZeroMQ and a remote agent. Be aware that since all communication with Salt SSH is executed via SSH it is substantially slower than standard Salt with ZeroMQ.
- At the moment fileserver operations must be wrapped to ensure that the relevant files are delivered with the salt-ssh commands. The state module is an exception, which compiles the state run on the master, and in the process finds all the references to salt:// paths and copies those files down in the same tarball as the state run. However, needed fileserver wrappers are still under development.

8.2 Salt SSH Roster

The roster system in Salt allows for remote minions to be easily defined.

Note: See the SSH roster docs for more details.

Simply create the roster file, the default location is /etc/salt/roster:

<table>
<thead>
<tr>
<th>host</th>
<th>IP address</th>
<th>user</th>
<th>username</th>
<th>passwd</th>
<th>sudo</th>
</tr>
</thead>
<tbody>
<tr>
<td>web1</td>
<td>192.168.42.1</td>
<td>fred</td>
<td>foobarbaz</td>
<td>foobarbaz</td>
<td>True</td>
</tr>
</tbody>
</table>

This is a very basic roster file where a Salt ID is being assigned to an IP address. A more elaborate roster can be created:
web2:
  host: 192.168.42.2

Note: sudo works only if NOPASSWD is set for user in /etc/sudoers: fred ALL=(ALL) NOPASSWD: ALL

8.3 Deploy ssh key for salt-ssh

By default, salt-ssh will generate key pairs for ssh, the default path will be /etc/salt/pki/master/ssh/salt-ssh.rsa
You can use ssh-copy-id, (the OpenSSH key deployment tool) to deploy keys to your servers.

```
ssh-copy-id -i /etc/salt/pki/master/ssh/salt-ssh.rsa.pub user@server.demo.com
```

One could also create a simple shell script, named salt-ssh-copy-id.sh as follows:

```
#!/bin/bash
if [ -z $1 ]; then
  echo $0 user@host.com
  exit 0
fi
ssh-copy-id -i /etc/salt/pki/master/ssh/salt-ssh.rsa.pub $1
```

Note: Be certain to chmod +x salt-ssh-copy-id.sh.

```
./salt-ssh-copy-id.sh user@server1.host.com
./salt-ssh-copy-id.sh user@server2.host.com
```

Once keys are successfully deployed, salt-ssh can be used to control them.

8.4 Calling Salt SSH

Note: salt-ssh on RHEL/CentOS 5
The salt-ssh command requires at least python 2.6, which is not installed by default on RHEL/CentOS 5. An easy workaround in this situation is to use the -r option to run a raw shell command that installs python26:

```
salt-ssh centos-5-minion -r 'yum -y install epel-release ; yum -y install python26'
```

The salt-ssh command can be easily executed in the same way as a salt command:

```
salt-ssh '*' test.ping
```

Commands with salt-ssh follow the same syntax as the salt command.

The standard salt functions are available! The output is the same as salt and many of the same flags are available. Please see http://docs.saltstack.com/ref/cli/salt-ssh.html for all of the available options.
8.4.1 Raw Shell Calls

By default salt-ssh runs Salt execution modules on the remote system, but salt-ssh can also execute raw shell commands:

```
salt-ssh '*' -r 'ifconfig'
```

8.5 States Via Salt SSH

The Salt State system can also be used with salt-ssh. The state system abstracts the same interface to the user in salt-ssh as it does when using standard salt. The intent is that Salt Formulas defined for standard salt will work seamlessly with salt-ssh and vice-versa.

The standard Salt States walkthroughs function by simply replacing salt commands with salt-ssh.

8.6 Targeting with Salt SSH

Due to the fact that the targeting approach differs in salt-ssh, only glob and regex targets are supported as of this writing, the remaining target systems still need to be implemented.

**Note:** By default, Grains are settable through salt-ssh. By default, these grains will *not* be persisted across reboots.

See the ``thin_dir`` setting in *Roster documentation* for more details.

8.7 Configuring Salt SSH

Salt SSH takes its configuration from a master configuration file. Normally, this file is in `/etc/salt/master`. If one wishes to use a customized configuration file, the `-c` option to Salt SSH facilitates passing in a directory to look inside for a configuration file named `master`.

8.7.1 Minion Config

New in version 2015.5.1.

Minion config options can be defined globally using the master configuration option `ssh_minion_opts`. It can also be defined on a per-minion basis with the `minion_opts` entry in the roster.

8.8 Running Salt SSH as non-root user

By default, Salt read all the configuration from `/etc/salt/`. If you are running Salt SSH with a regular user you have to modify some paths or you will get "Permission denied" messages. You have to modify two parameters: `pki_dir` and `cachedir`. Those should point to a full path writable for the user.

It's recommended not to modify `/etc/salt` for this purpose. Create a private copy of `/etc/salt` for the user and run the command with `-c /new/config/path`. 
8.9 Define CLI Options with Saltfile

If you are commonly passing in CLI options to `salt-ssh`, you can create a Saltfile to automatically use these options. This is common if you're managing several different salt projects on the same server.

So you can `cd` into a directory that has a Saltfile with the following YAML contents:

```yaml
salt-ssh:
  config_dir: path/to/config/dir
  ssh_max_procs: 30
  ssh_wipe: True
```

Instead of having to call `salt-ssh --config-dir=path/to/config/dir --max-procs=30 --wipe \\ test.ping` you can call `salt-ssh * test.ping`.

Boolean-style options should be specified in their YAML representation.

**Note:** The option keys specified must match the destination attributes for the options specified in the parser `salt.utils.parsers.SaltSSHOptionParser`. For example, in the case of the `--wipe` command line option, its `dest` is configured to be `ssh_wipe` and thus this is what should be configured in the Saltfile. Using the names of flags for this option, being `wipe: True` or `w: True`, will not work.

8.10 Debugging salt-ssh

One common approach for debugging `salt-ssh` is to simply use the tarball that salt ships to the remote machine and call `salt-call` directly.

To determine the location of `salt-call`, simply run `salt-ssh` with the `-ltrace` flag and look for a line containing the string, `SALT_ARGV`. This contains the `salt-call` command that `salt-ssh` attempted to execute.

It is recommended that one modify this command a bit by removing the `-l quiet,--metadata` and `--output json` to get a better idea of what's going on on the target system.

8.10.1 Salt Rosters

Salt rosters are pluggable systems added in Salt 0.17.0 to facilitate the `salt-ssh` system. The roster system was created because `salt-ssh` needs a means to identify which systems need to be targeted for execution.

See also:

`roster modules`

**Note:** The Roster System is not needed or used in standard Salt because the master does not need to be initially aware of target systems, since the Salt Minion checks itself into the master.

Since the roster system is pluggable, it can be easily augmented to attach to any existing systems to gather information about what servers are presently available and should be attached to by `salt-ssh`. By default the roster file is located at `/etc/salt/roster`.

476 Chapter 8. Salt SSH
How Rosters Work

The roster system compiles a data structure internally referred to as targets. The targets is a list of target systems and attributes about how to connect to said systems. The only requirement for a roster module in Salt is to return the targets data structure.

Targets Data

The information which can be stored in a roster target is the following:

\[
\begin{array}{ll}
\text{<Salt ID>:} & \text{# The id to reference the target system with} \\
\text{host:} & \text{# The IP address or DNS name of the remote host} \\
\text{user:} & \text{# The user to log in as} \\
\text{passwd:} & \text{# The password to log in with} \\
\text{port:} & \text{# The target system's ssh port number} \\
\text{sudo:} & \text{# Boolean to run command via sudo} \\
\text{sudo_user:} & \text{# Str: Set this to execute Salt as a sudo user other than root.} \\
\text{# This user must be in the same system group as the remote user} \\
\text{# that is used to login and is specified above. Alternatively,} \\
\text{# the user must be a super-user.} \\
\text{tty:} & \text{# Boolean: Set this option to True if sudo is also set to} \\
\text{# True and requiretty is also set on the target system} \\
\text{priv:} & \text{# File path to ssh private key, defaults to salt-ssh.rsa} \\
\text{timeout:} & \text{# Number of seconds to wait for response when establishing} \\
\text{# an SSH connection} \\
\text{minion_opts:} & \text{# Dictionary of minion opts} \\
\text{thin_dir:} & \text{# The target system's storage directory for Salt} \\
\text{# components. Defaults to /tmp/salt-<hash>.} \\
\text{cmd_umask:} & \text{# umask to enforce for the salt-call command. Should be in} \\
\text{# octal (so for 0077 in YAML you would do 0077, or 63)}
\end{array}
\]

**thin_dir**

Salt needs to upload a standalone environment to the target system, and this defaults to /tmp/salt-<hash>). This directory will be cleaned up per normal systems operation.

If you need a persistent Salt environment, for instance to set persistent grains, this value will need to be changed.
9.1 Configuration

Salt Cloud provides a powerful interface to interact with cloud hosts. This interface is tightly integrated with Salt, and new virtual machines are automatically connected to your Salt master after creation.

Since Salt Cloud is designed to be an automated system, most configuration is done using the following YAML configuration files:

- `/etc/salt/cloud`: The main configuration file, contains global settings that apply to all cloud hosts. See Salt Cloud Configuration.

- `/etc/salt/cloud.providers.d/*.conf`: Contains settings that configure a specific cloud host, such as credentials, region settings, and so on. Since configuration varies significantly between each cloud host, a separate file should be created for each cloud host. In Salt Cloud, a provider is synonymous with a cloud host (Amazon EC2, Google Compute Engine, Rackspace, and so on). See Provider Specifics.

- `/etc/salt/cloud.profiles.d/*.conf`: Contains settings that define a specific VM type. A profile defines the systems specs and image, and any other settings that are specific to this VM type. Each specific VM type is called a profile, and multiple profiles can be defined in a profile file. Each profile references a parent provider that defines the cloud host in which the VM is created (the provider settings are in the provider configuration explained above). Based on your needs, you might define different profiles for web servers, database servers, and so on. See VM Profiles.

9.2 Configuration Inheritance

Configuration settings are inherited in order from the cloud config => providers => profile.

For example, if you wanted to use the same image for all virtual machines for a specific provider, the image name could be placed in the provider file. This value is inherited by all profiles that use that provider, but is overridden if a image name is defined in the profile.
Most configuration settings can be defined in any file, the main difference being how that setting is inherited.

### 9.3 QuickStart

The Salt Cloud *Quickstart* walks you through defining a provider, a VM profile, and shows you how to create virtual machines using Salt Cloud.

Note that if you installed Salt via Salt Bootstrap, it may not have automatically installed salt-cloud for you. Use your distribution's package manager to install the `salt-cloud` package from the same repo that you used to install Salt. These repos will automatically be setup by Salt Bootstrap.

If there is no `salt-cloud` package, install with `pip install salt-cloud`.

### 9.4 Using Salt Cloud

#### 9.4.1 salt-cloud

Provision virtual machines in the cloud with Salt

**Synopsis**

```
salt-cloud -m /etc/salt/cloud.map
salt-cloud -m /etc/salt/cloud.map NAME
salt-cloud -m /etc/salt/cloud.map NAME1 NAME2
salt-cloud -p PROFILE NAME
salt-cloud -p PROFILE NAME1 NAME2 NAME3 NAME4 NAME5 NAME6
```

**Description**

Salt Cloud is the system used to provision virtual machines on various public clouds via a cleanly controlled profile and mapping system.

**Options**

```
--version
   Print the version of Salt that is running.
--versions-report
   Show program's dependencies and version number, and then exit
-h, --help
   Show the help message and exit
-c CONFIG_DIR, --config-dir=CONFIG_dir
   The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.
```
Execution Options

-L LOCATION, --location=LOCATION
Specify which region to connect to.

-a ACTION, --action=ACTION
Perform an action that may be specific to this cloud provider. This argument requires one or more instance names to be specified.

-f <FUNC-NAME> <PROVIDER>, --function=<FUNC-NAME> <PROVIDER>
Perform an function that may be specific to this cloud provider, that does not apply to an instance. This argument requires a provider to be specified (i.e.: nova).

-p PROFILE, --profile=PROFILE
Select a single profile to build the named cloud VMs from. The profile must be defined in the specified profiles file.

-m MAP, --map=MAP
Specify a map file to use. If used without any other options, this option will ensure that all of the mapped VMs are created. If the named VM already exists then it will be skipped.

-H, --hard
When specifying a map file, the default behavior is to ensure that all of the VMs specified in the map file are created. If the --hard option is set, then any VMs that exist on configured cloud providers that are not specified in the map file will be destroyed. Be advised that this can be a destructive operation and should be used with care.

-d, --destroy
Pass in the name(s) of VMs to destroy, salt-cloud will search the configured cloud providers for the specified names and destroy the VMs. Be advised that this is a destructive operation and should be used with care. Can be used in conjunction with the -m option to specify a map of VMs to be deleted.

-P, --parallel
Normally when building many cloud VMs they are executed serially. The -P option will run each cloud vm build in a separate process allowing for large groups of VMs to be build at once.

Be advised that some cloud provider’s systems don’t seem to be well suited for this influx of vm creation. When creating large groups of VMs watch the cloud provider carefully.

-u, --update-bootstrap
Update salt-bootstrap to the latest stable bootstrap release.

-y, --assume-yes
Default yes in answer to all confirmation questions.

-k, --keep-tmp
Do not remove files from /tmp/ after deploy.sh finishes.

--show-deploy-args
Include the options used to deploy the minion in the data returned.

--script-args=SCRIPT_ARGS
Script arguments to be fed to the bootstrap script when deploying the VM.

Query Options

-Q, --query
Execute a query and return some information about the nodes running on configured cloud providers.
-F, --full-query
Execute a query and print out all available information about all cloud VMs. Can be used in conjunction with -m to display only information about the specified map.

-S, --select-query
Execute a query and print out selected information about all cloud VMs. Can be used in conjunction with -m to display only information about the specified map.

--list-providers
Display a list of configured providers.

--list-profiles
New in version 2014.7.0.
Display a list of configured profiles. Pass in a cloud provider to view the provider’s associated profiles, such as digital_ocean, or pass in all to list all the configured profiles.

Cloud Providers Listings

--list-locations
Display a list of locations available in configured cloud providers. Pass the cloud provider that available locations are desired on, aka `linode`, or pass `all` to list locations for all configured cloud providers.

--list-images
Display a list of images available in configured cloud providers. Pass the cloud provider that available images are desired on, aka `linode`, or pass `all` to list images for all configured cloud providers.

--list-sizes
Display a list of sizes available in configured cloud providers. Pass the cloud provider that available sizes are desired on, aka `AWS`, or pass `all` to list sizes for all configured cloud providers.

Cloud Credentials

--set-password
Configure password for a cloud provider and save it to the keyring. PROVIDER can be specified with or without a driver, for example: `--set-password bob rackspace` or more specific `--set-password bob rackspace:openstack` DEPRECATED!

Output Options

--out
Pass in an alternative outputer to display the return of data. This outputer can be any of the available outputters:

    grains, highstate, json, key, overstatestage, pprint, raw, txt, yaml

Some outputters are formatted only for data returned from specific functions; for instance, the grains outputter will not work for non-grains data.

If an outputer is used that does not support the data passed into it, then Salt will fall back on the pprint outputer and display the return data using the Python pprint standard library module.

Note: If using --out=json, you will probably want --static as well. Without the static option, you will get a separate JSON string per minion which makes JSON output invalid as a whole. This is due to using an
iterative outputer. So if you want to feed it to a JSON parser, use \texttt{--static} as well.

\begin{verbatim}
\texttt{--out-indent} OUTPUT_INDENT, \texttt{--output-indent} OUTPUT_INDENT
\end{verbatim}
Print the output indented by the provided value in spaces. Negative values disable indentation. Only applicable in outputers that support indentation.

\begin{verbatim}
\texttt{--out-file}=OUTPUT_FILE, \texttt{--output-file}=OUTPUT_FILE
\end{verbatim}
Write the output to the specified file.

\texttt{--no-color}
Disable all colored output

\texttt{--force-color}
Force colored output

\texttt{\textbf{Note:} When using colored output the color codes are as follows:}
green denotes success, red denotes failure, blue denotes changes and success and yellow denotes an expected future change in configuration.

\section*{Examples}
To create 4 VMs named web1, web2, db1, and db2 from specified profiles:

\begin{verbatim}
salt-cloud -p fedora_rackspace web1 web2 db1 db2
\end{verbatim}

To read in a map file and create all VMs specified therein:

\begin{verbatim}
salt-cloud -m /path/to/cloud.map
\end{verbatim}

To read in a map file and create all VMs specified therein in parallel:

\begin{verbatim}
salt-cloud -m /path/to/cloud.map -P
\end{verbatim}

To delete any VMs specified in the map file:

\begin{verbatim}
salt-cloud -m /path/to/cloud.map -d
\end{verbatim}

To delete any VMs NOT specified in the map file:

\begin{verbatim}
salt-cloud -m /path/to/cloud.map -H
\end{verbatim}

To display the status of all VMs specified in the map file:

\begin{verbatim}
salt-cloud -m /path/to/cloud.map -Q
\end{verbatim}

\texttt{\textbf{See also}}

\texttt{salt-cloud(7) salt(7) salt-master(1) salt-minion(1)}

\subsection*{9.4.2 Salt Cloud basic usage}
Salt Cloud needs, at least, one configured Provider and Profile to be functional.
Creating a VM

To create a VM with salt cloud, use command:

```
salt-cloud -p <profile> name_of_vm
```

Assuming there is a profile configured as following:

```
fedora_rackspace:
  provider: my-rackspace-config
  image: Fedora 17
  size: 256 server
  script: bootstrap-salt
```

Then, the command to create new VM named `fedora_http_01` is:

```
salt-cloud -p fedora_rackspace fedora_http_01
```

Destroying a VM

To destroy a created-by-salt-cloud VM, use command:

```
salt-cloud -d name_of_vm
```

For example, to delete the VM created on above example, use:

```
salt-cloud -d fedora_http_01
```

9.4.3 VM Profiles

Salt cloud designates virtual machines inside the profile configuration file. The profile configuration file defaults to `/etc/salt/cloud.profiles` and is a yaml configuration. The syntax for declaring profiles is simple:

```
fedora_rackspace:
  provider: my-rackspace-config
  image: Fedora 17
  size: 256 server
  script: bootstrap-salt
```

It should be noted that the `script` option defaults to `bootstrap-salt`, and does not normally need to be specified. Further examples in this document will not show the `script` option.

A few key pieces of information need to be declared and can change based on the cloud provider. A number of additional parameters can also be inserted:

```
centos_rackspace:
  provider: my-rackspace-config
  image: CentOS 6.2
  size: 1024 server
  minion:
    master: salt.example.com
    append_domain: webs.example.com
  grains:
    role: webserver
```

The image must be selected from available images. Similarly, sizes must be selected from the list of sizes. To get a list of available images and sizes use the following command:

```
salt-cloud --list-images openstack
salt-cloud --list-sizes openstack
```

Some parameters can be specified in the main Salt cloud configuration file and then are applied to all cloud profiles. For instance if only a single cloud provider is being used then the provider option can be declared in the Salt cloud configuration file.

### Multiple Configuration Files

In addition to `/etc/salt/cloud.profiles`, profiles can also be specified in any file matching `cloud.profiles.d/*conf` which is a sub-directory relative to the profiles configuration file(with the above configuration file as an example, `/etc/salt/cloud.profiles.d/*.conf`). This allows for more extensible configuration, and plays nicely with various configuration management tools as well as version control systems.

### Larger Example

```yaml
rhel_ec2:
    provider: my-ec2-config
    image: ami-e565ba8c
    size: t1.micro
    minion:
        cheese: edam

ubuntu_ec2:
    provider: my-ec2-config
    image: ami-7e2da54e
    size: t1.micro
    minion:
        cheese: edam

ubuntu_rackspace:
    provider: my-rackspace-config
    image: Ubuntu 12.04 LTS
    size: 256 server
    minion:
        cheese: edam

fedora_rackspace:
    provider: my-rackspace-config
    image: Fedora 17
    size: 256 server
    minion:
        cheese: edam

cent_linode:
    provider: my-linode-config
    image: CentOS 6.2 64bit
    size: Linode 512

cent_gogrid:
    provider: my-gogrid-config
    image: 12834
```
9.4.4 Cloud Map File

A number of options exist when creating virtual machines. They can be managed directly from profiles and the command line execution, or a more complex map file can be created. The map file allows for a number of virtual machines to be created and associated with specific profiles. The map file is designed to be run once to create these more complex scenarios using salt-cloud.

Map files have a simple format, specify a profile and then a list of virtual machines to make from said profile:

```
fedora_small:
  - web1
  - web2
  - web3
fedora_high:
  - redis1
  - redis2
  - redis3
cent_high:
  - riak1
  - riak2
  - riak3
```

This map file can then be called to roll out all of these virtual machines. Map files are called from the salt-cloud command with the `-m` option:

```
$ salt-cloud -m /path/to/mapfile
```

Remember, that as with direct profile provisioning the `-P` option can be passed to create the virtual machines in parallel:

```
$ salt-cloud -m /path/to/mapfile -P
```

Note: Due to limitations in the GoGrid API, instances cannot be provisioned in parallel with the GoGrid driver. Map files will work with GoGrid, but the `-P` argument should not be used on maps referencing GoGrid instances.

A map file can also be enforced to represent the total state of a cloud deployment by using the `--hard` option. When using the hard option any vms that exist but are not specified in the map file will be destroyed:

```
$ salt-cloud -m /path/to/mapfile -P -H
```

Be careful with this argument, it is very dangerous! In fact, it is so dangerous that in order to use it, you must explicitly enable it in the main configuration file.

```
enable_hard_maps: True
```

A map file can include grains and minion configuration options:
fedora_small:
- web1:
  minion:
    log_level: debug
  grains:
    cheese: tasty
    omelet: du fromage
- web2:
  minion:
    log_level: warn
  grains:
    cheese: more tasty
    omelet: with peppers

A map file may also be used with the various query options:

```
$ salt-cloud -m /path/to/mapfile -Q
{'ec2': {'web1': {'id': 'i-e6aqfegb', 'image': None, 'private_ips': [], 'public_ips': [], 'size': None, 'state': 0}, 'web2': {'Absent'}}
```

...or with the delete option:

```
$ salt-cloud -m /path/to/mapfile -d
The following virtual machines are set to be destroyed:
  web1
  web2

Proceed? [N/y]
```

**Warning:** Specifying Nodes with Maps on the Command Line Specifying the name of a node or nodes with the maps options on the command line is not supported. This is especially important to remember when using `--destroy` with maps; `salt-cloud` will ignore any arguments passed in which are not directly relevant to the map file. **When using `--destroy` with a map, every node in the map file will be deleted!** Maps don’t provide any useful information for destroying individual nodes, and should not be used to destroy a subset of a map.

**Setting up New Salt Masters**

Bootstrapping a new master in the map is as simple as:

```
fedora_small:
  - web1:
    make_master: True
  - web2
  - web3
```

Notice that ALL bootstrapped minions from the map will answer to the newly created salt-master.

To make any of the bootstrapped minions answer to the bootstrapping salt-master as opposed to the newly created salt-master, as an example:
The above says the minion running on the newly created salt-master responds to the local master, ie, the master used to bootstrap these VMs.

Another example:

```
fedora_small:
  - web1:
    make_master: True
    minion:
      master: <the local master ip address>
      local_master: True
  - web2
  - web3
```

The above example makes the `web3` minion answer to the local master, not the newly created master.

### 9.4.5 Cloud Actions

Once a VM has been created, there are a number of actions that can be performed on it. The `reboot` action can be used across all providers, but all other actions are specific to the cloud provider. In order to perform an action, you may specify it from the command line, including the name(s) of the VM to perform the action on:

```
$ salt-cloud -a reboot vm_name
$ salt-cloud -a reboot vm1 vm2 vm2
```

Or you may specify a map which includes all VMs to perform the action on:

```
$ salt-cloud -a reboot -m /path/to/mapfile
```

The following is a list of actions currently supported by salt-cloud:

```
all providers:
  - reboot
ec2:
  - start
  - stop
joyent:
  - stop
linode:
  - start
  - stop
```

Another useful reference for viewing more salt-cloud actions is the :ref:`Salt Cloud Feature Matrix <salt-cloud-feature-matrix>`
9.4.6 Cloud Functions

Cloud functions work much the same way as cloud actions, except that they don't perform an operation on a specific instance, and so do not need a machine name to be specified. However, since they perform an operation on a specific cloud provider, that provider must be specified.

```
$ salt-cloud -f show_image ec2 image=ami-fd20ad94
```

There are three universal salt-cloud functions that are extremely useful for gathering information about instances on a provider basis:

- **list_nodes**: Returns some general information about the instances for the given provider.
- **list_nodes_full**: Returns all information about the instances for the given provider.
- **list_nodes_select**: Returns select information about the instances for the given provider.

```
$ salt-cloud -f list_nodes linode
$ salt-cloud -f list_nodes_full linode
$ salt-cloud -f list_nodes_select linode
```

Another useful reference for viewing salt-cloud functions is the [Salt Cloud Feature Matrix](#).

9.5 Core Configuration

9.5.1 Install Salt Cloud

Salt Cloud is now part of Salt proper. It was merged in as of Salt version 2014.1.0.

On Ubuntu, install Salt Cloud by using following command:

```
sudo add-apt-repository ppa:saltstack/salt
sudo apt-get update
sudo apt-get install salt-cloud
```

If using Salt Cloud on OS X, `curl-ca-bundle` must be installed. Presently, this package is not available via `brew`, but it is available using MacPorts:

```
sudo port install curl-ca-bundle
```

Salt Cloud depends on `apache-libcloud`. Libcloud can be installed via `pip` with `pip install apache-libcloud`.

**Installing Salt Cloud for development**

Installing Salt for development enables Salt Cloud development as well, just make sure `apache-libcloud` is installed as per above paragraph.

See these instructions: [Installing Salt for development](#).

9.5.2 Core Configuration

A number of core configuration options and some options that are global to the VM profiles can be set in the cloud configuration file. By default this file is located at `/etc/salt/cloud`.
Thread Pool Size

When salt cloud is operating in parallel mode via the -P argument, you can control the thread pool size by specifying the `pool_size` parameter with a positive integer value.

By default, the thread pool size will be set to the number of VMs that salt cloud is operating on.

```
pool_size: 10
```

Minion Configuration

The default minion configuration is set up in this file. Minions created by salt-cloud derive their configuration from this file. Almost all parameters found in *Configuring the Salt Minion* can be used here.

```
minion:
  master: saltmaster.example.com
```

In particular, this is the location to specify the location of the salt master and its listening port, if the port is not set to the default.

Similar to most other settings, Minion configuration settings are inherited across configuration files. For example, the master setting might be contained in the main *cloud* configuration file as demonstrated above, but additional settings can be placed in the provider or profile:

```
ec2-web:
  size: t1.micro
  minion:
    environment: test
    startup_states: sls
    sls_list:
      - web
```

Cloud Configuration Syntax

The data specific to interacting with public clouds is set up here.

Cloud provider configuration settings can live in several places. The first is in /etc/salt/cloud:

```
# /etc/salt/cloud
providers:
  my-aws-migrated-config:
    id: HJGRYCILJLKJYG
    key: 'kdjgfgsm;woormg/aserigjksjdhasdfgn'
    keyname: test
    securitygroup: quick-start
    private_key: /root/test.pem
    driver: ec2
```

Cloud provider configuration data can also be housed in /etc/salt/cloud.providers or any file matching /etc/salt/cloud.providers.d/*.conf. All files in any of these locations will be parsed for cloud provider data.

Using the example configuration above:
# /etc/salt/cloud.providers
# or could be /etc/salt/cloud.providers.d/*.conf
my-aws-config:
  id: HJGRYCILJLKJYG
  key: 'kdjgfsqm;woormgl/aserigjksjdasdfgn'
  keyname: test
  securitygroup: quick-start
  private_key: /root/test.pem
  driver: ec2

Note: Salt Cloud provider configurations within /etc/cloud.provider.d/ should not specify the `providers` starting key.

It is also possible to have multiple cloud configuration blocks within the same alias block. For example:

```
production-config:
  - id: HJGRYCILJLKJYG
    key: 'kdjgfsqm;woormgl/aserigjksjdasdfgn'
    keyname: test
    securitygroup: quick-start
    private_key: /root/test.pem
    driver: ec2

    - user: example_user
      apikey: 123984bjjas87034
      driver: rackspace
```

However, using this configuration method requires a change with profile configuration blocks. The provider alias needs to have the provider key value appended as in the following example:

```
rhel_aws_dev:
  provider: production-config:ec2
  image: ami-e565ba8c
  size: t1.micro

rhel_aws_prod:
  provider: production-config:ec2
  image: ami-e565ba8c
  size: High-CPU Extra Large Instance

database_prod:
  provider: production-config:rackspace
  image: Ubuntu 12.04 LTS
  size: 256 server
```

Notice that because of the multiple entries, one has to be explicit about the provider alias and name, from the above example, `production-config: ec2`.

This data interactions with the salt-cloud binary regarding its `--list-location`, `--list-images`, and `--list-sizes` which needs a cloud provider as an argument. The argument used should be the configured cloud provider alias. If the provider alias has multiple entries, `<provider-alias>: <provider-name>` should be used.

To allow for a more extensible configuration, `--providers-config`, which defaults to `/etc/salt/cloud.providers`, was added to the cli parser. It allows for the providers' configuration to be added on a per-file basis.

9.5. Core Configuration
Pillar Configuration

It is possible to configure cloud providers using pillars. This is only used when inside the cloud module. You can setup a variable called `cloud` that contains your profile and provider to pass that information to the cloud servers instead of having to copy the full configuration to every minion. In your pillar file, you would use something like this:

```yaml
cloud:
  ssh_key_name: saltstack
  ssh_key_file: /root/.ssh/id_rsa
  update_cachedir: True
  diff_cache_events: True
  change_password: True

providers:
  my-nova:
    identity_url: https://identity.api.rackspacecloud.com/v2.0/
    compute_region: IAD
    user: myuser
    api_key: apikey
    tenant: 123456
    driver: nova

  my-openstack:
    identity_url: https://identity.api.rackspacecloud.com/v2.0/tokens
    user: user2
    apikey: apikey2
    tenant: 654321
    compute_region: DFW
    driver: openstack
    compute_name: cloudServersOpenStack

profiles:
  ubuntu-nova:
    provider: my-nova
    size: performance1-8
    image: bb02b1a3-bc77-4d17-ab5b-421d89850fca
    script_args: git develop

  ubuntu-openstack:
    provider: my-openstack
    size: performance1-8
    image: bb02b1a3-bc77-4d17-ab5b-421d89850fca
    script_args: git develop
```

Cloud Configurations

Scaleway

To use Salt Cloud with Scaleway, you need to get an access key and an API token. API tokens are unique identifiers associated with your Scaleway account. To retrieve your access key and API token, log-in to the Scaleway control panel, open the pull-down menu on your account name and click on “My Credentials” link.

If you do not have API token you can create one by clicking the “Create New Token” button on the right corner.
Salt Documentation, Release 2016.3.6

my-scaleway-config:
   access_key: 15cf404d-4560-41b1-9a0c-21c3d5c4ff1f
   token: a7347ec8-5de1-4024-a5e3-24b77d1ba91d
   driver: scaleway

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be provider: my-scaleway-config.

Rackspace

Rackspace cloud requires two configuration options; a user and an apikey:

my-rackspace-config:
   user: example_user
   apikey: 123984bjjas87034
   driver: rackspace

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be provider: my-rackspace-config.

Amazon AWS

A number of configuration options are required for Amazon AWS including id, key, keyname, securitygroup, and private_key:

my-aws-quick-start:
   id: HJGRYCILJLKJYG
   key: 'kdjgfsmg;woormgl/aserigjksjdhasdfgn'
   keyname: test
   securitygroup: quick-start
   private_key: /root/test.pem
   driver: ec2

my-aws-default:
   id: HJGRYCILJLKJYG
   key: 'kdjgfsmg;woormgl/aserigjksjdhasdfgn'
   keyname: test
   securitygroup: default
   private_key: /root/test.pem
   driver: ec2

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be either provider: my-aws-quick-start or provider: my-aws-default.

Linode

Linode requires a single API key, but the default root password also needs to be set:
The password needs to be 8 characters and contain lowercase, uppercase, and numbers.

**Note:** In the cloud profile that uses this provider configuration, the syntax for the **provider** required field would be **provider: my-linode-config**

### Joyent Cloud

The Joyent cloud requires three configuration parameters: The username and password that are used to log into the Joyent system, as well as the location of the private SSH key associated with the Joyent account. The SSH key is needed to send the provisioning commands up to the freshly created virtual machine.

**my-joyent-config:**
- **user:** fred
- **password:** saltybacon
- **private_key:** /root/joyent.pem
- **driver:** joyent

**Note:** In the cloud profile that uses this provider configuration, the syntax for the **provider** required field would be **provider: my-joyent-config**

### GoGrid

To use Salt Cloud with GoGrid, log into the GoGrid web interface and create an API key. Do this by clicking on "My Account" and then going to the API Keys tab.

The **apikey** and the **sharedsecret** configuration parameters need to be set in the configuration file to enable interfacing with GoGrid:

**my-gogrid-config:**
- **apikey:** asdff7896asdh789
- **sharedsecret:** saltybacon
- **driver:** gogrid

**Note:** In the cloud profile that uses this provider configuration, the syntax for the **provider** required field would be **provider: my-gogrid-config.**
OpenStack

OpenStack configuration differs between providers, and at the moment several options need to be specified. This module has been officially tested against the HP and the Rackspace implementations, and some examples are provided for both.

# For HP

```yaml
my-openstack-hp-config:
  compute_name: Compute
  compute_region: 'az-1.region-a.geo-1'
  tenant: myuser-tenant1
  user: myuser
  ssh_key_name: mykey
  ssh_key_file: '/etc/salt/hpcloud/mykey.pem'
  password: mypass
  driver: openstack
```

# For Rackspace

```yaml
my-openstack-rackspace-config:
  identity_url: 'https://identity.api.rackspacecloud.com/v2.0/tokens'
  compute_name: cloudServersOpenStack
  protocol: ipv4
  compute_region: DFW
  protocol: ipv4
  user: myuser
  tenant: 5555555
  password: mypass
  driver: openstack
```

If you have an API key for your provider, it may be specified instead of a password:

```yaml
my-openstack-hp-config:
  apikey: 901d3f579h23c8v73q9

my-openstack-rackspace-config:
  apikey: 901d3f579h23c8v73q9
```

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be either provider: my-openstack-hp-config or provider: my-openstack-rackspace-config.

You will certainly need to configure the user, tenant, and either password or apikey.

If your OpenStack instances only have private IP addresses and a CIDR range of private addresses are not reachable from the salt-master, you may set your preference to have Salt ignore it:

```yaml
my-openstack-config:
  ignore_cidr: 192.168.0.0/16
```

For in-house OpenStack Essex installation, libcloud needs the service_type:

```yaml
my-openstack-config:
  identity_url: 'http://control.openstack.example.org:5000/v2.0/
  compute_name : Compute Service
  service_type : compute
```

9.5. Core Configuration
DigitalOcean

Using Salt for DigitalOcean requires a client_key and an api_key. These can be found in the DigitalOcean web interface, in the `"My Settings"` section, under the API Access tab.

```
my-digitalocean-config:
  driver: digital_ocean
  personal_access_token: xxx
  location: New York 1
```

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be `provider: my-digital-ocean-config`.

Parallels

Using Salt with Parallels requires a user, password and URL. These can be obtained from your cloud provider.

```
my-parallels-config:
  user: myuser
  password: xyzzy
  url: https://api.cloud.xmission.com:4465/paci/v1.0/
  driver: parallels
```

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be `provider: my-parallels-config`.

Proxmox

Using Salt with Proxmox requires a user, password, and URL. These can be obtained from your cloud host. Both PAM and PVE users can be used.

```
my-proxmox-config:
  driver: proxmox
  user: saltcloud@pve
  password: xyzzy
  url: your.proxmox.host
```

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be `provider: my-proxmox-config`.

LXC

The lxc driver uses saltify to install salt and attach the lxc container as a new lxc minion. As soon as we can, we manage baremetal operation over SSH. You can also destroy those containers via this driver.
devhost10-lxc:
    target: devhost10
    driver: lxc

And in the map file:

devhost10-lxc:
    provider: devhost10-lxc
    from_container: ubuntu
    backing: lvm
    sudo: True
    size: 3g
    ip: 10.0.3.9
    minion:
        master: 10.5.0.1
        master_port: 4506
    lxc_conf:
        - lxc.utsname: superlxc

**Note:** In the cloud profile that uses this provider configuration, the syntax for the `provider` required field would be `provider: devhost10-lxc`.

---

**Saltify**

The Saltify driver is a new, experimental driver designed to install Salt on a remote machine, virtual or bare metal, using SSH. This driver is useful for provisioning machines which are already installed, but not Salted. For more information about using this driver and for configuration examples, please see the [Getting Started with Saltify documentation](#).

---

**Extending Profiles and Cloud Providers Configuration**

As of 0.8.7, the option to extend both the profiles and cloud providers configuration and avoid duplication was added. The extends feature works on the current profiles configuration, but, regarding the cloud providers configuration, only works in the new syntax and respective configuration files, i.e. `/etc/salt/salt/cloud.providers` or `/etc/salt/cloud.providers.d/*.conf`.

**Note:** Extending cloud profiles and providers is not recursive. For example, a profile that is extended by a second profile is possible, but the second profile cannot be extended by a third profile.

Also, if a profile (or provider) is extending another profile and each contains a list of values, the lists from the extending profile will override the list from the original profile. The lists are not merged together.

---

**Extending Profiles**

Some example usage on how to use `extends` with profiles. Consider `/etc/salt/salt/cloud.profiles` containing:

```
development-instances:
    provider: my-ec2-config
```
size: t1.micro
ssh_username: ec2_user
securitygroup:  
  - default
deploy: False

Amazon-Linux-AMI-2012.09-64bit:
  image: ami-54cf5c3d
  extends: development-instances

Fedora-17:
  image: ami-08d97e61
  extends: development-instances

CentOS-5:
  provider: my-aws-config
  image: ami-09b61d60
  extends: development-instances

The above configuration, once parsed would generate the following profiles data:

```
[{
  'deploy': False,
  'image': 'ami-08d97e61',
  'profile': 'Fedora-17',
  'provider': 'my-ec2-config',
  'securitygroup': ['default'],
  'size': 't1.micro',
  'ssh_username': 'ec2_user'},
{
  'deploy': False,
  'image': 'ami-09b61d60',
  'profile': 'CentOS-5',
  'provider': 'my-aws-config',
  'securitygroup': ['default'],
  'size': 't1.micro',
  'ssh_username': 'ec2_user'},
{
  'deploy': False,
  'image': 'ami-54cf5c3d',
  'profile': 'Amazon-Linux-AMI-2012.09-64bit',
  'provider': 'my-ec2-config',
  'securitygroup': ['default'],
  'size': 't1.micro',
  'ssh_username': 'ec2_user'},
{
  'deploy': False,
  'profile': 'development-instances',
  'provider': 'my-ec2-config',
  'securitygroup': ['default'],
  'size': 't1.micro',
  'ssh_username': 'ec2_user'}]
```

Pretty cool right?

**Extending Providers**

Some example usage on how to use `extends` within the cloud providers configuration. Consider `/etc/salt/salt/cloud.providers` containing:
my-develop-envs:
- id: HJGRYCIILJKJYG
  key: 'kdjgfsmg;woormgl/aserigksjdhasdfgn'
  keyname: test
  securitygroup: quick-start
  private_key: /root/test.pem
  location: ap-southeast-1
  availability_zone: ap-southeast-1b
  driver: ec2
- user: myuser@mycorp.com
  password: mypass
  ssh_key_name: mykey
  ssh_key_file: '/etc/salt/ibm/mykey.pem'
  location: Raleigh
  driver: ibmsce

my-productions-envs:
- extends: my-develop-envs:ibmsce
  user: my-production-user@mycorp.com
  location: us-east-1
  availability_zone: us-east-1

The above configuration, once parsed would generate the following providers data:

```json
'my-develop-envs': [
  {
    'availability_zone': 'ap-southeast-1b',
    'id': 'HJGRYCIILJKJYG',
    'key': 'kdjgfsmg;woormgl/aserigksjdhasdfgn',
    'keyname': 'test',
    'location': 'ap-southeast-1',
    'private_key': '/root/test.pem',
    'driver': 'aws',
    'securitygroup': 'quick-start'
  },
  {
    'location': 'Raleigh',
    'password': 'mypass',
    'driver': 'ibmsce',
    'ssh_key_file': '/etc/salt/ibm/mykey.pem',
    'ssh_key_name': 'mykey',
    'user': 'myuser@mycorp.com'
  }
],
'my-productions-envs': [
  {
    'availability_zone': 'us-east-1',

```
9.6 Windows Configuration

9.6.1 Spinning up Windows Minions

It is possible to use Salt Cloud to spin up Windows instances, and then install Salt on them. This functionality is available on all cloud providers that are supported by Salt Cloud. However, it may not necessarily be available on all Windows images.

Requirements

Salt Cloud makes use of `impacket` and `winexe` to set up the Windows Salt Minion installer.

`impacket` is usually available as either the `impacket` or the `python-impacket` package, depending on the distribution. More information on `impacket` can be found at the project home:

- impacket project home

`winexe` is less commonly available in distribution-specific repositories. However, it is currently being built for various distributions in 3rd party channels:

- RPMs at phone.net
- OpenSuse Build Service

 Optionally WinRM can be used instead of `winexe` if the python module `pywinrm` is available and WinRM is supported on the target Windows version. Information on `pywinrm` can be found at the project home:

- pywinrm project home

Additionally, a copy of the Salt Minion Windows installer must be present on the system on which Salt Cloud is running. This installer may be downloaded from saltstack.com:

- SaltStack Download Area

Firewall Settings

Because Salt Cloud makes use of `smbclient` and `winexe`, port 445 must be open on the target image. This port is not generally open by default on a standard Windows distribution, and care must be taken to use an image in which this port is open, or the Windows firewall is disabled.

If supported by the cloud provider, a PowerShell script may be used to open up this port automatically, using the cloud provider’s `userdata`. The following script would open up port 445, and apply the changes:

```powershell
New-NetFirewallRule -Name "SMB445" -DisplayName "SMB445" -Protocol TCP -LocalPort 445
Set-Item (dir wsman:\localhost\Listener\*\Port -Recurse).pspath 445 -Force
Restart-Service winrm
</powershell>
```

For EC2, this script may be saved as a file, and specified in the provider or profile configuration as `userdata_file`. For instance:

```
userdata_file: /etc/salt/windows-firewall.ps1
```

If you are using WinRM on EC2 the HTTPS port for the WinRM service must also be enabled in your userdata. By default EC2 Windows images only have insecure HTTP enabled. To enable HTTPS and basic authentication required by `pywinrm` consider the following userdata example:
<powershell>
New-NetFirewallRule -Name "SMB445" -DisplayName "SMB445" -Protocol TCP -LocalPort 445
New-NetFirewallRule -Name "WINRM5986" -DisplayName "WINRM5986" -Protocol TCP -LocalPort 5986

winrm quickconfig -q
winrm set winrm/config/winrs '/*@{MaxMemoryPerShellMB="300"}')
winrm set winrm/config '@{MaxTimeoutms="1800000"}')

$SourceStoreScope = 'LocalMachine'
$SourceStorename = 'Remote Desktop'

$cert = $SourceStore.Certificates | Where-Object -FilterScript {$_ .subject -like '*'}

$DestStoreScope = 'LocalMachine'
$DestStoreName = 'My'

$DestStore = New-Object -TypeName System.Security.Cryptography.X509Certificates.X509Store -ArgumentList $DestStoreName, $DestStoreScope
$DestStore.Add($cert)

$SourceStore.Close()
$DestStore.Close()

winrm create winrm/config/listener?Address=*+Transport=HTTPS `@{Hostname="($certId)";CertificateThumbprint="($cert.Thumbprint)"}'}

Restart-Service winrm
</powershell>

No certificate store is available by default on EC2 images and creating one does not seem possible without an MMC (cannot be automated). To use the default EC2 Windows images the above copies the RDP store.

Configuration

Configuration is set as usual, with some extra configuration settings. The location of the Windows installer on the machine that Salt Cloud is running on must be specified. This may be done in any of the regular configuration files (main, providers, profiles, maps). For example:

Setting the installer in /etc/salt/cloud.providers:

```yaml
my-softlayer:
  driver: softlayer
  user: MYUSER1138
  apikey: 'e3b68aa711e6deadc62d5b76355674beef7cc3116062dadbcafe5f7e465bfdc9'
  minion:
    master: saltmaster.example.com
  win_installer: /root/Salt-Minion-2014.7.0-AMD64-Setup.exe
  win_username: Administrator
```

9.6. Windows Configuration
The default Windows user is *Administrator*, and the default Windows password is blank.

If WinRM is to be used, `use_winrm` needs to be set to `True`. `winrm_port` can be used to specify a custom port (must be HTTPS listener).

### Auto-Generated Passwords on EC2

On EC2, when the `win_password` is set to `auto`, Salt Cloud will query EC2 for an auto-generated password. This password is expected to take at least 4 minutes to generate, adding additional time to the deploy process.

When the EC2 API is queried for the auto-generated password, it will be returned in a message encrypted with the specified `keyname`. This requires that the appropriate `private_key` file is also specified. Such a profile configuration might look like:

```
windows-server-2012:
    provider: my-ec2-config
    image: ami-c49c8dac
    size: m1.small
    securitygroup: windows
    keyname: mykey
    private_key: /root/mykey.pem
    userdata_file: /etc/salt/windows-firewall.ps1
    win_installer: /root/Salt-Minion-2014.7.0-AMD64-Setup.exe
    win_username: Administrator
    win_password: auto
```

## 9.7 Cloud Provider Specifics

### 9.7.1 Getting Started With Aliyun ECS

The Aliyun ECS (Elastic Computer Service) is one of the most popular public cloud hosts in China. This cloud host can be used to manage aliyun instance using salt-cloud.

http://www.aliyun.com/

### Dependencies

This driver requires the Python `requests` library to be installed.

### Configuration

Using Salt for Aliyun ECS requires aliyun access key id and key secret. These can be found in the aliyun web interface, in the "User Center" section, under "My Service" tab.

```
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.

my-aliyun-config:
    # aliyun Access Key ID
```

```
```
id: wDEwGrgedg3435gDgxd
# aliyun Access Key Secret
driver: aliyun
key: GDd45t43RDBTrkkkg43934t34qT43t4dgegerGEGg
location: cn-qingdao

Note: Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

Profiles

Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles` or in the `/etc/salt/cloud.profiles.d/` directory:

```
aliyun_centos:
    provider: my-aliyun-config
    size: ecs.t1.small
    location: cn-qingdao
    securitygroup: G19890096784427999
    image: centos6u3_64_20G_aliaegis_20130816.vhd
```

Sizes can be obtained using the `--list-sizes` option for the `salt-cloud` command:

```
# salt-cloud --list-sizes my-aliyun-config
my-aliyun-config:
    ---------
    aliyun:
        ---------
        ecs.c1.large:
            ---------
            CpuCoreCount: 8
            InstanceTypeId: ecs.c1.large
            MemorySize: 16.0

...SNIP...
```

Images can be obtained using the `--list-images` option for the `salt-cloud` command:

```
# salt-cloud --list-images my-aliyun-config
my-aliyun-config:
    ---------
    aliyun:
        ---------
        centos5u8_64_20G_aliaegis_20131231.vhd:
```

9.7. Cloud Provider Specifics
Locations can be obtained using the `--list-locations` option for the `salt-cloud` command:

```
my-aliyun-config:
  ----------
aliyun:
  ----------
  cn-beijing:
  ----------
    LocalName: 
    RegionId: cn-beijing
  cn-hangzhou:
  ----------
    LocalName: 
    RegionId: cn-hangzhou
  cn-hongkong:
  ----------
    LocalName: 
    RegionId: cn-hongkong
  cn-qingdao:
  ----------
    LocalName: 
    RegionId: cn-qingdao
```

Security Group can be obtained using the `-f list_securitygroup` option for the `salt-cloud` command:

```
# salt-cloud --location=cn-qingdao -f list_securitygroup my-aliyun-config
my-aliyun-config:
  ----------
```
9.7.2 Getting Started With Azure

New in version 2014.1.0.

Azure is a cloud service by Microsoft providing virtual machines, SQL services, media services, and more. This document describes how to use Salt Cloud to create a virtual machine on Azure, with Salt installed.

Dependencies

- Microsoft Azure SDK for Python >= 1.0.2
- The python-requests library, for Python < 2.7.9.
- A Microsoft Azure account
- OpenSSL (to generate the certificates)
- Salt

Note: The Azure driver is currently being updated to work with the new version of the Python Azure SDK, 1.0.0. However until that process is complete, this driver will not work with Azure 1.0.0. Please be sure you’re running on a minimum version of 0.10.2 and less than version 1.0.0.

See Issue #27980 for more information.

Configuration

Set up the provider config at /etc/salt/cloud.providers.d/azure.conf:

```yaml
# Note: This example is for /etc/salt/cloud.providers.d/azure.conf

my-azure-config:
  driver: azure
  subscription_id: 3287abc8-f98a-c678-3bde-326766fd3617
  certificate_path: /etc/salt/azure.pem

# Set up the location of the salt master
#
minion:
  master: saltmaster.example.com
```

Note: Aliyun ECS REST API documentation is available from Aliyun ECS API.
# Optional

management_host: management.core.windows.net

The certificate used must be generated by the user. OpenSSL can be used to create the management certificates. Two certificates are needed: a .cer file, which is uploaded to Azure, and a .pem file, which is stored locally.

To create the .pem file, execute the following command:

```
openssl req -x509 -nodes -days 365 -newkey rsa:1024 -keyout /etc/salt/azure.pem -out /etc/salt/azure.pem
```

To create the .cer file, execute the following command:

```
openssl x509 -inform pem -in /etc/salt/azure.pem -outform der -out /etc/salt/azure.cer
```

After creating these files, the .cer file will need to be uploaded to Azure via the "Upload a Management Certificate" action of the "Management Certificates" tab within the "Settings" section of the management portal.

Optionally, a `management_host` may be configured, if necessary for the region.

---

**Note:** Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

---

**Cloud Profiles**

Set up an initial profile at `/etc/salt/cloud.profiles`:

```
azure-ubuntu:
  provider: my-azure-config
  image: 'b39f27a88b8c64d52b05eac6a62ebad85__Ubuntu-12_04_3-LTS-amd64-server-20131003-en-us-30GB'
  size: Small
  location: 'East US'
  ssh_username: azureuser
  ssh_password: verybadpass
  slot: production
  media_link: 'http://portalvhdabcdefghijklmn.blob.core.windows.net/vhds'
  virtual_network_name: azure-virtual-network
  subnet_name: azure-subnet
```

These options are described in more detail below. Once configured, the profile can be realized with a salt command:

```
salt-cloud -p azure-ubuntu newinstance
```

This will create an salt minion instance named `newinstance` in Azure. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```
salt newinstance test.ping
```
Profile Options

The following options are currently available for Azure.

**provider**

The name of the provider as configured in `/etc/salt/cloud.providers.d/azure.conf`.

**image**

The name of the image to use to create a VM. Available images can be viewed using the following command:

```
salt-cloud --list-images my-azure-config
```

**size**

The name of the size to use to create a VM. Available sizes can be viewed using the following command:

```
salt-cloud --list-sizes my-azure-config
```

**location**

The name of the location to create a VM in. Available locations can be viewed using the following command:

```
salt-cloud --list-locations my-azure-config
```

**affinity_group**

The name of the affinity group to create a VM in. Either a location or an affinity_group may be specified, but not both. See Affinity Groups below.

**ssh_username**

The user to use to log into the newly-created VM to install Salt.

**ssh_password**

The password to use to log into the newly-created VM to install Salt.

**slot**

The environment to which the hosted service is deployed. Valid values are staging or production. When set to production, the resulting URL of the new VM will be `<vm_name>.cloudapp.net`. When set to staging, the resulting URL will contain a generated hash instead.
media_link

This is the URL of the container that will store the disk that this VM uses. Currently, this container must already exist. If a VM has previously been created in the associated account, a container should already exist. In the web interface, go into the Storage area and click one of the available storage selections. Click the Containers link, and then copy the URL from the container that will be used. It generally looks like:

```
http://portalvhdaabcdefghijklmn.blob.core.windows.net/vhds
```

service_name

The name of the service in which to create the VM. If this is not specified, then a service will be created with the same name as the VM.

virtual_network_name

Optional. The name of the virtual network for the VM to join. If this is not specified, then no virtual network will be joined.

subnet_name

Optional. The name of the subnet in the virtual network for the VM to join. Requires that a virtual_network_name is specified.

Show Instance

This action is a thin wrapper around --full-query, which displays details on a single instance only. In an environment with several machines, this will save a user from having to sort through all instance data, just to examine a single instance.

```
salt-cloud -a show_instance myinstance
```

Destroying VMs

There are certain options which can be specified in the global cloud configuration file (usually /etc/salt/cloud) which affect Salt Cloud's behavior when a VM is destroyed.

cleanup_disks

New in version 2015.8.0.

Default is False. When set to True, Salt Cloud will wait for the VM to be destroyed, then attempt to destroy the main disk that is associated with the VM.
cleanup_vhds

New in version 2015.8.0.
Default is False. Requires cleanup_disks to be set to True. When also set to True, Salt Cloud will ask Azure to delete the VHD associated with the disk that is also destroyed.

cleanup_services

New in version 2015.8.0.
Default is False. Requires cleanup_disks to be set to True. When also set to True, Salt Cloud will wait for the disk to be destroyed, then attempt to remove the service that is associated with the VM. Because the disk belongs to the service, the disk must be destroyed before the service can be.

Managing Hosted Services

New in version 2015.8.0.
An account can have one or more hosted services. A hosted service is required in order to create a VM. However, as mentioned above, if a hosted service is not specified when a VM is created, then one will automatically be created with the name of the name. The following functions are also available.

create_service

Create a hosted service. The following options are available.

name

Required. The name of the hosted service to create.

label

Required. A label to apply to the hosted service.

description

Optional. A longer description of the hosted service.

location

Required, if affinity_group is not set. The location in which to create the hosted service. Either the location or the affinity_group must be set, but not both.

affinity_group

Required, if location is not set. The affinity group in which to create the hosted service. Either the location or the affinity_group must be set, but not both.
extended_properties

Optional. Dictionary containing name/value pairs of hosted service properties. You can have a maximum of 50 extended property name/value pairs. The maximum length of the Name element is 64 characters, only alphanumeric characters and underscores are valid in the Name, and the name must start with a letter. The value has a maximum length of 255 characters.

CLI Example

The following example illustrates creating a hosted service.

```
salt-cloud -f create_service my-azure name=my-service label=my-service location='WestUS'
```

show_service

Return details about a specific hosted service. Can also be called with `get_service`.

```
salt-cloud -f show_storage my-azure name=my-service
```

list_services

List all hosted services associates with the subscription.

```
salt-cloud -f list_services my-azure-config
```

delete_service

Delete a specific hosted service.

```
salt-cloud -f delete_service my-azure name=my-service
```

Managing Storage Accounts

New in version 2015.8.0.

Salt Cloud can manage storage accounts associated with the account. The following functions are available. Deprecated marked as deprecated are marked as such as per the SDK documentation, but are still included for completeness with the SDK.

create_storage

Create a storage account. The following options are supported.

name

Required. The name of the storage account to create.
label

Required. A label to apply to the storage account.

description

Optional. A longer description of the storage account.

location

Required, if affinity_group is not set. The location in which to create the storage account. Either the location or the affinity_group must be set, but not both.

affinity_group

Required, if location is not set. The affinity group in which to create the storage account. Either the location or the affinity_group must be set, but not both.

extended_properties

Optional. Dictionary containing name/value pairs of storage account properties. You can have a maximum of 50 extended property name/value pairs. The maximum length of the Name element is 64 characters, only alphanumeric characters and underscores are valid in the Name, and the name must start with a letter. The value has a maximum length of 255 characters.

geo_replication_enabled

Deprecated. Replaced by the account_type parameter.

account_type

Specifies whether the account supports locally-redundant storage, geo-redundant storage, zone-redundant storage, or read access geo-redundant storage. Possible values are:

- Standard_LRS
- Standard_ZRS
- Standard_GRS
- Standard_RAGRS

CLI Example

The following example illustrates creating a storage account.

```bash
salt-cloud -f create_storage my-azure name=my-storage label=my-storage location='West US'
```
list_storage

List all storage accounts associates with the subscription.

```
salt-cloud -f list_storage my-azure-config
```

show_storage

Return details about a specific storage account. Can also be called with get_storage.

```
salt-cloud -f show_storage my-azure name=my-storage
```

update_storage

Update details concerning a storage account. Any of the options available in create_storage can be used, but the name cannot be changed.

```
salt-cloud -f update_storage my-azure name=my-storage label=my-storage
```

delete_storage

Delete a specific storage account.

```
salt-cloud -f delete_storage my-azure name=my-storage
```

show_storage_keys

Returns the primary and secondary access keys for the specified storage account.

```
salt-cloud -f show_storage_keys my-azure name=my-storage
```

regenerate_storage_keys

Regenerate storage account keys. Requires a key_type (``primary'' or ``secondary'') to be specified.

```
salt-cloud -f regenerate_storage_keys my-azure name=my-storage key_type=primary
```

Managing Disks

New in version 2015.8.0.

When a VM is created, a disk will also be created for it. The following functions are available for managing disks. Deprecated marked as deprecated are marked as such as per the SDK documentation, but are still included for completeness with the SDK.
show_disk

Return details about a specific disk. Can also be called with get_disk.

```
salt-cloud -f show_disk my-azure name=my-disk
```

list_disks

List all disks associated with the account.

```
salt-cloud -f list_disks my-azure
```

update_disk

Update details for a disk. The following options are available.

**name**

Required. The name of the disk to update.

**has_operating_system**

Deprecated.

**label**

Required. The label for the disk.

**media_link**

Deprecated. The location of the disk in the account, including the storage container that it is in. This should not need to be changed.

**new_name**

Deprecated. If renaming the disk, the new name.

**os**

Deprecated.
CLI Example

The following example illustrates updating a disk.

```shell
salt-cloud -f update_disk my-azure name=my-disk label=my-disk
```

delete_disk

Delete a specific disk.

```shell
salt-cloud -f delete_disk my-azure name=my-disk
```

Managing Service Certificates

New in version 2015.8.0.

Stored at the cloud service level, these certificates are used by your deployed services. For more information on service certificates, see the following link:

- Manage Certificates

The following functions are available.

list_service_certificates

List service certificates associated with the account.

```shell
salt-cloud -f list_service_certificates my-azure
```

show_service_certificate

Show the data for a specific service certificate associated with the account. The name, thumbprint, and thumbalgorithm can be obtained from list_service_certificates. Can also be called with get_service_certificate.

```shell
salt-cloud -f show_service_certificate my-azure name=my_service_certificate \
    thumbalgorithm=sha1 thumbprint=0123456789ABCDEF
```

add_service_certificate

Add a service certificate to the account. This requires that a certificate already exists, which is then added to the account. For more information on creating the certificate itself, see:

- Create a Service Certificate for Azure

The following options are available.

name

Required. The name of the hosted service that the certificate will belong to.
data

Required. The base-64 encoded form of the pfx file.

certificate_format

Required. The service certificate format. The only supported value is pfx.

password

The certificate password.

```
salt-cloud -f add_service_certificate my-azure name=my-cert \   data='...CERT_DATA...' certificate_format=pfx password=verybadpass
```

delete_service_certificate

Delete a service certificate from the account. The name, thumbprint, and thumbalgorithm can be obtained from list_service_certificates.

```
salt-cloud -f delete_service_certificate my-azure \   name=my_service_certificate \   thumbalgorithm=sha1 thumbprint=0123456789ABCDEF
```

Managing Management Certificates

New in version 2015.8.0.

A Azure management certificate is an X.509 v3 certificate used to authenticate an agent, such as Visual Studio Tools for Windows Azure or a client application that uses the Service Management API, acting on behalf of the subscription owner to manage subscription resources. Azure management certificates are uploaded to Azure and stored at the subscription level. The management certificate store can hold up to 100 certificates per subscription. These certificates are used to authenticate your Windows Azure deployment.

For more information on management certificates, see the following link.

- Manage Certificates

The following functions are available.

list_management_certificates

List management certificates associated with the account.

```
salt-cloud -f list_management_certificates my-azure
```
show_management_certificate

Show the data for a specific management certificate associated with the account. The name, thumbprint, and thumbalgorithm can be obtained from list_management_certificates. Can also be called with get_management_certificate.

```bash
salt-cloud -f show_management_certificate my-azure name=my_management_certificate \  thumbalgorithm=sha1 thumbprint=0123456789ABCDEF
```

add_management_certificate

Management certificates must have a key length of at least 2048 bits and should reside in the Personal certificate store. When the certificate is installed on the client, it should contain the private key of the certificate. To upload to the certificate to the Microsoft Azure Management Portal, you must export it as a .cer format file that does not contain the private key. For more information on creating management certificates, see the following link:

- Create and Upload a Management Certificate for Azure

The following options are available.

public_key

A base64 representation of the management certificate public key.

thumbprint

The thumbprint that uniquely identifies the management certificate.

data

The certificate's raw data in base-64 encoded .cer format.

```bash
salt-cloud -f add_management_certificate my-azure public_key='...PUBKEY...' \  thumbprint=0123456789ABCDEF data='...CERT_DATA...'
```

delete_management_certificate

Delete a management certificate from the account. The thumbprint can be obtained from list_management_certificates.

```bash
salt-cloud -f delete_management_certificate my-azure thumbprint=0123456789ABCDEF
```

Virtual Network Management

New in version 2015.8.0.

The following are functions for managing virtual networks.
list_virtual_networks

List input endpoints associated with the deployment.

```bash
call-cloud -f list_virtual_networks my-azure service=myservice deployment=mydeployment
```

**Managing Input Endpoints**

New in version 2015.8.0.

Input endpoints are used to manage port access for roles. Because endpoints cannot be managed by the Azure Python SDK, Salt Cloud uses the API directly. With versions of Python before 2.7.9, the `requests-python` package needs to be installed in order for this to work. Additionally, the following needs to be set in the master's configuration file:

```python
requests_lib: True
```

The following functions are available.

**list_input_endpoints**

List input endpoints associated with the deployment.

```bash
call-cloud -f list_input_endpoints my-azure service=myservice deployment=mydeployment
```

**show_input_endpoint**

Show an input endpoint associated with the deployment.

```bash
call-cloud -f show_input_endpoint my-azure service=myservice deployment=mydeployment name=SSH
```

**add_input_endpoint**

Add an input endpoint to the deployment. Please note that there may be a delay before the changes show up. The following options are available.

**service**

Required. The name of the hosted service which the VM belongs to.

**deployment**

Required. The name of the deployment that the VM belongs to. If the VM was created with Salt Cloud, the deployment name probably matches the VM name.
role

Required. The name of the role that the VM belongs to. If the VM was created with Salt Cloud, the role name probably matches the VM name.

name

Required. The name of the input endpoint. This typically matches the port that the endpoint is set to. For instance, port 22 would be called SSH.

port

Required. The public (Internet-facing) port that is used for the endpoint.

local_port

Optional. The private port on the VM itself that will be matched with the port. This is typically the same as the port. If this value is not specified, it will be copied from port.

protocol

Required. Either tcp or udp.

enable_direct_server_return

Optional. If an internal load balancer exists in the account, it can be used with a direct server return. The default value is False. Please see the following article for an explanation of this option.

- Load Balancing for Azure Infrastructure Services

timeout_for_tcp_idle_connection

Optional. The default value is 4. Please see the following article for an explanation of this option.

- Configurable Idle Timeout for Azure Load Balancer

CLI Example

The following example illustrates adding an input endpoint.

```
salt-cloud -f add_input_endpoint my-azure service=myservice deployment=mydeployment role=myrole name=HTTP local_port=80 port=80 protocol=tcp enable_direct_server_return=False timeout_for_tcp_idle_connection=4
```
update_input_endpoint

Updates the details for a specific input endpoint. All options from `add_input_endpoint` are supported.

```
salt-cloud -f update_input_endpoint my-azure service=myservice \
    deployment=mydeployment role=myrole name=HTTP local_port=80 \
    port=80 protocol=tcp enable_direct_server_return=False \
    timeout_for_tcp_idle_connection=4
```

delete_input_endpoint

Delete an input endpoint from the deployment. Please note that there may be a delay before the changes show up. The following items are required.

**CLI Example**

The following example illustrates deleting an input endpoint.

```
salt-cloud -f delete_input_endpoint my-azure service=myservice \
    deployment=mydeployment role=myrole name=HTTP
```

Managing Affinity Groups

New in version 2015.8.0.

Affinity groups allow you to group your Azure services to optimize performance. All services and VMs within an affinity group will be located in the same region. For more information on Affinity groups, see the following link:

- Create an Affinity Group in the Management Portal
The following functions are available.

**list_affinity_groups**

List input endpoints associated with the account

```
salt-cloud -f list_affinity_groups my-azure
```

**show_affinity_group**

Show an affinity group associated with the account

```
salt-cloud -f show_affinity_group my-azure service=myservice \ deployment=mydeployment name=SSH
```

**create_affinity_group**

Create a new affinity group. The following options are supported.

- **name**

  Required. The name of the new affinity group.

- **location**

  Required. The region in which the affinity group lives.

- **label**

  Required. A label describing the new affinity group.

- **description**

  Optional. A longer description of the affinity group.

```
salt-cloud -f create_affinity_group my-azure name=my_affinity_group \ label=my-affinity-group location='West US'
```

**update_affinity_group**

Update an affinity group's properties

```
salt-cloud -f update_affinity_group my-azure name=my_group label=my_group
```

520 Chapter 9. Salt Cloud
delete_affinity_group

Delete a specific affinity group associated with the account

```bash
salt-cloud -f delete_affinity_group my-azure name=my_affinity_group
```

Managing Blob Storage

New in version 2015.8.0.

Azure storage containers and their contents can be managed with Salt Cloud. This is not as elegant as using one of the other available clients in Windows, but it benefits Linux and Unix users, as there are fewer options available on those platforms.

Blob Storage Configuration

Blob storage must be configured differently than the standard Azure configuration. Both a `storage_account` and a `storage_key` must be specified either through the Azure provider configuration (in addition to the other Azure configuration) or via the command line.

```bash
storage_account: mystorage
storage_key: ffhj334fDSGFEGDFGFDewr34fwfsFSDFwe==
```

`storage_account`

This is one of the storage accounts that is available via the `list_storage` function.

`storage_key`

Both a primary and a secondary `storage_key` can be obtained by running the `show_storage_keys` function. Either key may be used.

Blob Functions

The following functions are made available through Salt Cloud for managing blob storage.

`make_blob_url`

Creates the URL to access a blob

```bash
salt-cloud -f make_blob_url my-azure container=mycontainer blob=myblob
```

`container`

Name of the container.
blob

Name of the blob.

account

Name of the storage account. If not specified, derives the host base from the provider configuration.

protocol

Protocol to use: `http' or `https'. If not specified, derives the host base from the provider configuration.

host_base

Live host base URL. If not specified, derives the host base from the provider configuration.

list_storage_containers

List containers associated with the storage account

```
salt-cloud -f list_storage_containers my-azure
```

create_storage_container

Create a storage container

```
salt-cloud -f create_storage_container my-azure name=mycontainer
```

name

Name of container to create.

meta_name_values

Optional. A dict with name_value pairs to associate with the container as metadata. Example:{`Category':test'}

blob_public_access

Optional. Possible values include: container, blob

fail_on_exist

Specify whether to throw an exception when the container exists.
show_storage_container

Show a container associated with the storage account

```
salt-cloud -f show_storage_container my-azure name=myservice
```

name

Name of container to show.

show_storage_container_metadata

Show a storage container's metadata

```
salt-cloud -f show_storage_container_metadata my-azure name=myservice
```

name

Name of container to show.

lease_id

If specified, show_storage_container_metadata only succeeds if the container's lease is active and matches this ID.

set_storage_container_metadata

Set a storage container's metadata

```
salt-cloud -f set_storage_container my-azure name=mycontainer \          x_ms_meta_name_values='"my_name": "my_value"'
```

name

Name of existing container. meta_name_values \```````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````````
name

Name of existing container.

lease_id

If specified, `show_storage_container_acls` only succeeds if the container's lease is active and matches this ID.

`set_storage_container_acls`

Set a storage container's acl

```
salt-cloud -f set_storage_container my-azure name=mycontainer
```

name

Name of existing container.

signed_identifiers

SignedIdentifiers instance

blob_public_access

Optional. Possible values include: container, blob

lease_id

If specified, `set_storage_container_acls` only succeeds if the container's lease is active and matches this ID.

delete_storage_container

Delete a container associated with the storage account

```
salt-cloud -f delete_storage_container my-azure name=mycontainer
```

name

Name of container to create.

fail_not_exist

Specify whether to throw an exception when the container exists.
lease_id

If specified, delete_storage_container only succeeds if the container's lease is active and matches this ID.

lease_storage_container

Lease a container associated with the storage account

```
salt-cloud -f lease_storage_container my-azure name=mycontainer
```

name

Name of container to create.

lease_action

Required. Possible values: acquire|renew|release|break|change

lease_id

Required if the container has an active lease.

lease_duration

Specifies the duration of the lease, in seconds, or negative one (-1) for a lease that never expires. A non-infinite lease can be between 15 and 60 seconds. A lease duration cannot be changed using renew or change. For backwards compatibility, the default is 60, and the value is only used on an acquire operation.

lease_break_period

Optional. For a break operation, this is the proposed duration of seconds that the lease should continue before it is broken, between 0 and 60 seconds. This break period is only used if it is shorter than the time remaining on the lease. If longer, the time remaining on the lease is used. A new lease will not be available before the break period has expired, but the lease may be held for longer than the break period. If this header does not appear with a break operation, a fixed-duration lease breaks after the remaining lease period elapses, and an infinite lease breaks immediately.

proposed_lease_id

Optional for acquire, required for change. Proposed lease ID, in a GUID string format.
list_blobs

List blobs associated with the container

```
salt-cloud -f list_blobs my-azure container=mycontainer
```

container

The name of the storage container

prefix

Optional. Filters the results to return only blobs whose names begin with the specified prefix.

marker

Optional. A string value that identifies the portion of the list to be returned with the next list operation. The operation returns a marker value within the response body if the list returned was not complete. The marker value may then be used in a subsequent call to request the next set of list items. The marker value is opaque to the client.

maxresults

Optional. Specifies the maximum number of blobs to return, including all BlobPrefix elements. If the request does not specify maxresults or specifies a value greater than 5,000, the server will return up to 5,000 items. Setting maxresults to a value less than or equal to zero results in error response code 400 (Bad Request).

include

Optional. Specifies one or more datasets to include in the response. To specify more than one of these options on the URI, you must separate each option with a comma. Valid values are:

<table>
<thead>
<tr>
<th>snapshots:</th>
<th>Specifies that snapshots should be included in the enumeration. Snapshots are listed from oldest to newest in the response.</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata:</td>
<td>Specifies that blob metadata be returned in the response.</td>
</tr>
<tr>
<td>uncommittedblobs:</td>
<td>Specifies that blobs for which blocks have been uploaded, but which have not been committed using Put Block List (REST API), be included in the response.</td>
</tr>
<tr>
<td>copy:</td>
<td>Version 2012-02-12 and newer. Specifies that metadata related to any current or previous Copy Blob operation should be included in the response.</td>
</tr>
</tbody>
</table>
delimiter

Optional. When the request includes this parameter, the operation returns a BlobPrefix element in the response body that acts as a placeholder for all blobs whose names begin with the same substring up to the appearance of the delimiter character. The delimiter may be a single character or a string.

show_blob_service_properties

Show a blob's service properties

```
salt-cloud -f show_blob_service_properties my-azure
```

set_blob_service_properties

Sets the properties of a storage account's Blob service, including Windows Azure Storage Analytics. You can also use this operation to set the default request version for all incoming requests that do not have a version specified.

```
salt-cloud -f set_blob_service_properties my-azure
```

properties

a StorageServiceProperties object.

timeout

Optional. The timeout parameter is expressed in seconds.

show_blob_properties

Returns all user-defined metadata, standard HTTP properties, and system properties for the blob.

```
salt-cloud -f show_blob_properties my-azure container=mycontainer blob=myblob
```

container

Name of existing container.

blob

Name of existing blob.

lease_id

Required if the blob has an active lease.
**set_blob_properties**

Set a blob's properties

```
salt-cloud -f set_blob_properties my-azure
```

**container**

Name of existing container.

**blob**

Name of existing blob.

**blob_cache_control**

Optional. Modifies the cache control string for the blob.

**blob_content_type**

Optional. Sets the blob's content type.

**blob_content_md5**

Optional. Sets the blob's MD5 hash.

**blob_content_encoding**

Optional. Sets the blob's content encoding.

**blob_content_language**

Optional. Sets the blob's content language.

**lease_id**

Required if the blob has an active lease.

**blob_content_disposition**

Optional. Sets the blob's Content-Disposition header. The Content-Disposition response header field conveys additional information about how to process the response payload, and also can be used to attach additional metadata. For example, if set to attachment, it indicates that the user-agent should not display the response, but instead show a Save As dialog with a filename other than the blob name specified.
put_blob

Upload a blob

```
salt-cloud -f put_blob my-azure container=base name=top.sls blob_path=/srv/salt/top.sls
salt-cloud -f put_blob my-azure container=base name=content.txt blob_content='Some
!
content'
```

container

Name of existing container.

name

Name of existing blob.

blob_path

The path on the local machine of the file to upload as a blob. Either this or blob_content must be specified.

blob_content

The actual content to be uploaded as a blob. Either this or blob_path must be specified.

cache_control

Optional. The Blob service stores this value but does not use or modify it.

content_language

Optional. Specifies the natural languages used by this resource.

content_md5

Optional. An MD5 hash of the blob content. This hash is used to verify the integrity of the blob during transport. When this header is specified, the storage service checks the hash that has arrived with the one that was sent. If the two hashes do not match, the operation will fail with error code 400 (Bad Request).

blob_content_type

Optional. Set the blob's content type.

blob_content_encoding

Optional. Set the blob's content encoding.
blob_content_language
Optional. Set the blob's content language.

blob_content_md5
Optional. Set the blob's MD5 hash.

blob_cache_control
Optional. Sets the blob's cache control.

meta_name_values
A dict containing name, value for metadata.

lease_id
Required if the blob has an active lease.

get_blob
Download a blob

```
salt-cloud -f get_blob my-azure
    container=base name=top.sls
    local_path=/srv/salt/top.
    ..sls
```

```
salt-cloud -f get_blob my-azure
    container=base name=content.txt
    return_content=True
```

container
Name of existing container.

name
Name of existing blob.

local_path
The path on the local machine to download the blob to. Either this or return_content must be specified.

return_content
Whether or not to return the content directly from the blob. If specified, must be True or False. Either this or the local_path must be specified.
Optional. The snapshot parameter is an opaque DateTime value that, when present, specifies the blob snapshot to retrieve.

lease_id

Required if the blob has an active lease.

progress_callback

callback for progress with signature function(current, total) where current is the number of bytes transferred so far, and total is the size of the blob.

max_connections

Maximum number of parallel connections to use when the blob size exceeds 64MB. Set to 1 to download the blob chunks sequentially. Set to 2 or more to download the blob chunks in parallel. This uses more system resources but will download faster.

max_retries

Number of times to retry download of blob chunk if an error occurs.

retry_wait

Sleep time in secs between retries.

9.7.3 Getting Started With DigitalOcean

DigitalOcean is a public cloud host that specializes in Linux instances.

Configuration

Using Salt for DigitalOcean requires a personal_access_token, an ssh_key_file, and at least one SSH key name in ssh_key_names. More ssh_key_names can be added by separating each key with a comma. The personal_access_token can be found in the DigitalOcean web interface in the "Apps & API" section. The SSH key name can be found under the "SSH Keys" section.

```
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.

my-digitalocean-config:
  driver: digital_ocean
  personal_access_token: xxx
  ssh_key_file: /path/to/ssh/key/file
  ssh_key_names: my-key-name,my-key-name-2
  location: New York 1
```
Note: Changed in version 2015.8.0.

The \texttt{provider} parameter in cloud provider definitions was renamed to \texttt{driver}. This change was made to avoid confusion with the \texttt{provider} parameter that is used in cloud profile definitions. Cloud provider definitions now use \texttt{driver} to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use \texttt{provider} to refer to provider configurations that you define.

Profiles

Cloud Profiles

Set up an initial profile at \texttt{/etc/salt/cloud.profiles} or in the \texttt{/etc/salt/cloud.profiles.d/} directory:

```plaintext
digitalocean-ubuntu:
  provider: my-digitalocean-config
  image: 14.04 x64
  size: 512MB
  location: New York 1
  private_networking: True
  backups_enabled: True
  ipv6: True
  create_dns_record: True
```

Locations can be obtained using the \texttt{--list-locations} option for the \texttt{salt-cloud} command:

```bash
# salt-cloud --list-locations my-digitalocean-config
my-digitalocean-config:
  digital_ocean:
    Amsterdam 1:
      available: False
      features: [u'backups']
      name: Amsterdam 1
      sizes: []
      slug: ams1

...SNIP...
```

Sizes can be obtained using the \texttt{--list-sizes} option for the \texttt{salt-cloud} command:

```bash
# salt-cloud --list-sizes my-digitalocean-config
my-digitalocean-config:
  digital_ocean:
    512MB:
      cost_per_hour:
```

532 Chapter 9. Salt Cloud
Images can be obtained using the `--list-images` option for the `salt-cloud` command:

```
# salt-cloud --list-images my-digitalocean-config
my-digitalocean-config:
    digital_ocean:
        10.1:
            created_at: 2015-01-20T20:04:34Z
            distribution: FreeBSD
            id: 10144573
            min_disk_size: 20
            name: 10.1
            public: True
...SNIP...
```

### Profile Specifics:

**ssh_username**

If using a FreeBSD image from Digital Ocean, you'll need to set the `ssh_username` setting to `freebsd` in your profile configuration.

```
digitalocean-freebsd:
    provider: my-digitalocean-config
    image: 10.2
    size: 512MB
    ssh_username: freebsd
```

### Miscellaneous Information
Note: DigitalOcean's concept of Applications is nothing more than a pre-configured instance (same as a normal Droplet). You will find examples such as Docker 0.7 Ubuntu 13.04 x64 and Wordpress on Ubuntu 12.10 when using the --list-images option. These names can be used just like the rest of the standard instances when specifying an image in the cloud profile configuration.

Note: If your domain’s DNS is managed with DigitalOcean, and your minion name matches your DigitalOcean managed DNS domain, you can automatically create A and AAA records for newly created droplets. Use create_dns_record: True in your config to enable this. Adding delete_dns_record: True to also delete records when a droplet is destroyed is optional. Due to limitations in salt-cloud design, the destroy code does not have access to the VM config data. WHETHER YOU ADD create_dns_record: True OR NOT, salt-cloud WILL attempt to delete your DNS records if the minion name matches. This will prevent advertising any recycled IP addresses for destroyed minions.

Note: Additional documentation is available from DigitalOcean.

9.7.4 Getting Started With AWS EC2

Amazon EC2 is a very widely used public cloud platform and one of the core platforms Salt Cloud has been built to support.

Previously, the suggested driver for AWS EC2 was the aws driver. This has been deprecated in favor of the ec2 driver. Configuration using the old aws driver will still function, but that driver is no longer in active development.

Dependencies

This driver requires the Python requests library to be installed.

Configuration

The following example illustrates some of the options that can be set. These parameters are discussed in more detail below.

```
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.

my-ec2-southeast-public-ips:
  # Set up the location of the salt master
  #
  minion:
    master: saltmaster.example.com

  # Set up grains information, which will be common for all nodes
  # using this provider
  grains:
    node_type: broker
    release: 1.0.1

  # Specify whether to use public or private IP for deploy script.

```
# Valid options are:
# private_ips - The salt-cloud command is run inside the EC2
# public_ips - The salt-cloud command is run outside of EC2
#
ssh_interface: public_ips

# Optionally configure the Windows credential validation number of
# retries and delay between retries. This defaults to 10 retries
# with a one second delay between retries
win_deploy_auth_retries: 10
win_deploy_auth_retry_delay: 1

# Set the EC2 access credentials (see below)
#
id: 'use-instance-role-credentials'
key: 'use-instance-role-credentials'

# Make sure this key is owned by root with permissions 0400.
#
private_key: /etc/salt/my_test_key.pem
keyname: my_test_key
securitygroup: default

# Optionally configure default region
# Use salt-cloud --list-locations <provider> to obtain valid regions
#
location: ap-southeast-1
availability_zone: ap-southeast-1b

# Configure which user to use to run the deploy script. This setting is
# dependent upon the AMI that is used to deploy. It is usually safer to
# configure this individually in a profile, than globally. Typical users
# are:
#
# Amazon Linux -> ec2-user
# RHEL -> ec2-user
# CentOS -> ec2-user
# Ubuntu -> ubuntu
#
ssh_username: ec2-user

# Optionally add an IAM profile
iam_profile: 'arn:aws:iam::123456789012:instance-profile/ExampleInstanceProfile'

driver: ec2

my-ec2-southeast-private-ips:
# Set up the location of the salt master
#
minion:
  master: saltmaster.example.com

# Specify whether to use public or private IP for deploy script.
#
# Valid options are:
# private_ips - The salt-master is also hosted with EC2
# public_ips - The salt-master is hosted outside of EC2
# ssh_interface: private_ips

# Optionally configure the Windows credential validation number of
# retries and delay between retries. This defaults to 10 retries
# with a one second delay between retries
win_deploy_auth_retries: 10
win_deploy_auth_retry_delay: 1

# Set the EC2 access credentials (see below)
#
# id: 'use-instance-role-credentials'
# key: 'use-instance-role-credentials'

# Make sure this key is owned by root with permissions 0400.
#
# private_key: /etc/salt/my_test_key.pem
# keyname: my_test_key

# This one should NOT be specified if VPC was not configured in AWS to be
# the default. It might cause an error message which says that network
# interfaces and an instance-level security groups may not be specified
# on the same request.
#
# securitygroup: default

# Optionally configure default region
#
# location: ap-southeast-1
# availability_zone: ap-southeast-1b

# Configure which user to use to run the deploy script. This setting is
# dependent upon the AMI that is used to deploy. It is usually safer to
# configure this individually in a profile, than globally. Typical users
# are:
#
# Amazon Linux -> ec2-user
# RHEL -> ec2-user
# CentOS -> ec2-user
# Ubuntu -> ubuntu
#
# ssh_username: ec2-user

# Optionally add an IAM profile
iam_profile: 'my other profile name'

driver: ec2

---

**Note:** Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.
Access Credentials

The id and key settings may be found in the Security Credentials area of the AWS Account page:

https://portal.aws.amazon.com/gp/aws/securityCredentials

Both are located in the Access Credentials area of the page, under the Access Keys tab. The id setting is labeled Access Key ID, and the key setting is labeled Secret Access Key.

Note: if either id or key is set to `use-instance-role-credentials` it is assumed that Salt is running on an AWS instance, and the instance role credentials will be retrieved and used. Since both the id and key are required parameters for the AWS ec2 provider, it is recommended to set both to `use-instance-role-credentials` for this functionality.

A `static` and `permanent` Access Key ID and Secret Key can be specified, but this is not recommended. Instance role keys are rotated on a regular basis, and are the recommended method of specifying AWS credentials.

Windows Deploy Timeouts

For Windows instances, it may take longer than normal for the instance to be ready. In these circumstances, the provider configuration can be configured with a win_deploy_auth_retries and/or a win_deploy_auth_retry_delay setting, which default to 10 retries and a one second delay between retries. These retries and timeouts relate to validating the Administrator password once AWS provides the credentials via the AWS API.

Key Pairs

In order to create an instance with Salt installed and configured, a key pair will need to be created. This can be done in the EC2 Management Console, in the Key Pairs area. These key pairs are unique to a specific region. Keys in the us-east-1 region can be configured at:

https://console.aws.amazon.com/ec2/home?region=us-east-1#s=KeyPairs

Keys in the us-west-1 region can be configured at

https://console.aws.amazon.com/ec2/home?region=us-west-1#s=KeyPairs

...and so on. When creating a key pair, the browser will prompt to download a pem file. This file must be placed in a directory accessible by Salt Cloud, with permissions set to either 0400 or 0600.

Security Groups

An instance on EC2 needs to belong to a security group. Like key pairs, these are unique to a specific region. These are also configured in the EC2 Management Console. Security groups for the us-east-1 region can be configured at:

https://console.aws.amazon.com/ec2/home?region=us-east-1#s=SecurityGroups

...and so on.

A security group defines firewall rules which an instance will adhere to. If the salt-master is configured outside of EC2, the security group must open the SSH port (usually port 22) in order for Salt Cloud to install Salt.

IAM Profile

Amazon EC2 instances support the concept of an instance profile, which is a logical container for the IAM role. At the time that you launch an EC2 instance, you can associate the instance with an instance profile, which in turn
corresponds to the IAM role. Any software that runs on the EC2 instance is able to access AWS using the permissions associated with the IAM role.

Scaffolding the profile is a 2-step configuration process:

1. Configure an IAM Role from the IAM Management Console.
2. Attach this role to a new profile. It can be done with the AWS CLI:

```
> aws iam create-instance-profile --instance-profile-name PROFILE_NAME
> aws iam add-role-to-instance-profile --instance-profile-name PROFILE_NAME --role-name ROLE_NAME
```

Once the profile is created, you can use the PROFILE_NAME to configure your cloud profiles.

### Cloud Profiles

Set up an initial profile at /etc/salt/cloud.profiles:

```yaml
base_ec2_private:
  provider: my-ec2-southeast-private-ips
  image: ami-e565ba8c
  size: t2.micro
  ssh_username: ec2-user

base_ec2_public:
  provider: my-ec2-southeast-public-ips
  image: ami-e565ba8c
  size: t2.micro
  ssh_username: ec2-user

base_ec2_db:
  provider: my-ec2-southeast-public-ips
  image: ami-e565ba8c
  size: m1.xlarge
  ssh_username: ec2-user
  volumes:
  - { size: 10, device: /dev/sdf }
  - { size: 10, device: /dev/sdg, type: io1, iops: 1000 }
  - { size: 10, device: /dev/sdh, type: io1, iops: 1000 }
  - { size: 10, device: /dev/sdi, tags: {"Environment": "production"} }
  # optionally add tags to profile:
  tag: {"Environment": 'production', 'Role': 'database'}
  # force grains to sync after install
  sync_after_install: grains

base_ec2_vpc:
  provider: my-ec2-southeast-public-ips
  image: ami-a73264ce
  size: m1.xlarge
  ssh_username: ec2-user
  script: /etc/salt/cloud.deploy.d/user_data.sh
  network_interfaces:
  - DeviceIndex: 0
    PrivateIpAddresses:
      - Primary: True
  #auto assign public ip (not EIP)
  AssociatePublicIpAddress: True
```
The profile can now be realized with a salt command:

```bash
# salt-cloud -p base_ec2 ami.example.com
# salt-cloud -p base_ec2_public ami.example.com
# salt-cloud -p base_ec2_private ami.example.com
```

This will create an instance named `ami.example.com` in EC2. The minion that is installed on this instance will have an id of `ami.example.com`. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```bash
# salt 'ami.example.com' test.ping
```

**Required Settings**

The following settings are always required for EC2:

```bash
# Set the EC2 login data
my-ec2-config:
  id: HJGRYCILJKJYG
  key: 'kdjgfsjmg;woormgl/aserigjksjdasdfgn'
  keyname: test
  securitygroup: quick-start
  private_key: /root/test.pem
  driver: ec2
```

**Optional Settings**

EC2 allows a userdata file to be passed to the instance to be created. This functionality was added to Salt in the 2015.5.0 release.

```bash
my-ec2-config:
  # Pass userdata to the instance to be created
  userdata_file: /etc/salt/my-userdata-file
```

EC2 allows a location to be set for servers to be deployed in. Availability zones exist inside regions, and may be added to increase specificity.

```bash
my-ec2-config:
  # Optionally configure default region
  location: ap-southeast-1
  availability_zone: ap-southeast-1b
```
EC2 instances can have a public or private IP, or both. When an instance is deployed, Salt Cloud needs to log into it via SSH to run the deploy script. By default, the public IP will be used for this. If the salt-cloud command is run from another EC2 instance, the private IP should be used.

```
my-ec2-config:
    # Specify whether to use public or private IP for deploy script
    # private_ips or public_ips
    ssh_interface: public_ips
```

Many EC2 instances do not allow remote access to the root user by default. Instead, another user must be used to run the deploy script using sudo. Some common usernames include ec2-user (for Amazon Linux), ubuntu (for Ubuntu instances), admin (official Debian) and bitnami (for images provided by Bitnami).

```
my-ec2-config:
    # Configure which user to use to run the deploy script
    ssh_username: ec2-user
```

Multiple usernames can be provided, in which case Salt Cloud will attempt to guess the correct username. This is mostly useful in the main configuration file:

```
my-ec2-config:
    ssh_username:
        - ec2-user
        - ubuntu
        - admin
        - bitnami
```

Multiple security groups can also be specified in the same fashion:

```
my-ec2-config:
    securitygroup:
        - default
        - extra
```

EC2 instances can be added to an AWS Placement Group by specifying the placementgroup option:

```
my-ec2-config:
    placementgroup: my-aws-placement-group
```

Your instances may optionally make use of EC2 Spot Instances. The following example will request that spot instances be used and your maximum bid will be $0.10. Keep in mind that different spot prices may be needed based on the current value of the various EC2 instance sizes. You can check current and past spot instance pricing via the EC2 API or AWS Console.

```
my-ec2-config:
    spot_config:
        spot_price: 0.10
```

By default, the spot instance type is set to 'one-time', meaning it will be launched and, if it's ever terminated for whatever reason, it will not be recreated. If you would like your spot instances to be relaunched after a termination (by your or AWS), set the type to 'persistent'.

NOTE: Spot instances are a great way to save a bit of money, but you do run the risk of losing your spot instances if the current price for the instance size goes above your maximum bid.

The following parameters may be set in the cloud configuration file to control various aspects of the spot instance launching:

- `wait_for_spot_timeout`: seconds to wait before giving up on spot instance launch (default=600)
• **wait_for_spot_interval**: seconds to wait in between polling requests to determine if a spot instance is available (default=30)

• **wait_for_spot_interval_multiplier**: a multiplier to add to the interval in between requests, which is useful if AWS is throttling your requests (default=1)

• **wait_for_spot_max_failures**: maximum number of failures before giving up on launching your spot instance (default=10)

If you find that you’re being throttled by AWS while polling for spot instances, you can set the following in your core cloud configuration file that will double the polling interval after each request to AWS.

```yaml
wait_for_spot_interval: 1
wait_for_spot_interval_multiplier: 2
```

See the [AWS Spot Instances](https://aws.amazon.com/documentation/ec2/spot-instance/) documentation for more information.

Block device mappings enable you to specify additional EBS volumes or instance store volumes when the instance is launched. This setting is also available on each cloud profile. Note that the number of instance stores varies by instance type. If more mappings are provided than are supported by the instance type, mappings will be created in the order provided and additional mappings will be ignored. Consult the [AWS documentation](https://aws.amazon.com/documentation/ec2/instance-store/) for a listing of the available instance stores, and device names.

```yaml
my-ec2-config:
  block_device_mappings:
    - DeviceName: /dev/sdb
      VirtualName: ephemeral0
    - DeviceName: /dev/sdc
      VirtualName: ephemeral1
```

You can also use block device mappings to change the size of the root device at the provisioning time. For example, assuming the root device is `/dev/sda`, you can set its size to 100G by using the following configuration.

```yaml
my-ec2-config:
  block_device_mappings:
    - DeviceName: /dev/sda
      Ebs.VolumeSize: 100
      Ebs.VolumeType: gp2
      Ebs.SnapshotId: dummy0
    - DeviceName: /dev/sdb
      # required for devices > 2TB
      Ebs.VolumeType: gp2
      Ebs.VolumeSize: 3001
```

Existing EBS volumes may also be attached (not created) to your instances or you can create new EBS volumes based on EBS snapshots. To simply attach an existing volume use the `volume_id` parameter.

```yaml
device: /dev/xvdj
volume_id: vol-12345abcd
```

Or, to create a volume from an EBS snapshot, use the `snapshot` parameter.

```yaml
device: /dev/xvdj
snapshot: snap-abcd12345
```

Note that `volume_id` will take precedence over the `snapshot` parameter.

Tags can be set once an instance has been launched.
Setting up a Master inside EC2

Salt Cloud can configure Salt Masters as well as Minions. Use the `make_master` setting to use this functionality.

```yaml
my-ec2-config:
  tag:
    tag0: value
    tag1: value
```

When creating a Salt Master inside EC2 with `make_master: True`, or when the Salt Master is already located and configured inside EC2, by default, minions connect to the master’s public IP address during Salt Cloud’s provisioning process. Depending on how your security groups are defined, the minions may or may not be able to communicate with the master. In order to use the master’s private IP in EC2 instead of the public IP, set the `salt_interface` to `private_ips`.

```yaml
my-ec2-config:
  # Optionally set the IP configuration to private_ips
  salt_interface: private_ips
```

Modify EC2 Tags

One of the features of EC2 is the ability to tag resources. In fact, under the hood, the names given to EC2 instances by salt-cloud are actually just stored as a tag called Name. Salt Cloud has the ability to manage these tags:

```bash
salt-cloud -a get_tags mymachine
salt-cloud -a set_tags mymachine tag1=somestuff tag2='Other stuff'
salt-cloud -a del_tags mymachine tag1,tag2,tag3
```

It is possible to manage tags on any resource in EC2 with a Resource ID, not just instances:

```bash
salt-cloud -f get_tags my_ec2 resource_id=af5467ba
salt-cloud -f set_tags my_ec2 resource_id=af5467ba tag1=somestuff
tsalt-cloud -f del_tags my_ec2 resource_id=af5467ba tag1,tag2,tag3
```

Rename EC2 Instances

As mentioned above, EC2 instances are named via a tag. However, renaming an instance by renaming its tag will cause the salt keys to mismatch. A rename function exists which renames both the instance, and the salt keys.

```bash
salt-cloud -a rename mymachine newname=yourmachine
```

Rename on Destroy

When instances on EC2 are destroyed, there will be a lag between the time that the action is sent, and the time that Amazon cleans up the instance. During this time, the instance still retails a Name tag, which will cause a collision if the creation of an instance with the same name is attempted before the cleanup occurs. In order to avoid such
collisions, Salt Cloud can be configured to rename instances when they are destroyed. The new name will look something like:

```
myinstance-DEL20f5b8ad4eb64ed88f2c428df80a1a0c
```

In order to enable this, add `rename_on_destroy` line to the main configuration file:

```
my-ec2-config:
  rename_on_destroy: True
```

### Listing Images

Normally, images can be queried on a cloud provider by passing the `--list-images` argument to Salt Cloud. This still holds true for EC2:

```
salt-cloud --list-images my-ec2-config
```

However, the full list of images on EC2 is extremely large, and querying all of the available images may cause Salt Cloud to behave as if frozen. Therefore, the default behavior of this option may be modified, by adding an `owner` argument to the provider configuration:

```
owner: aws-marketplace
```

The possible values for this setting are `amazon`, `aws-marketplace`, `self`, `<AWS account ID>` or `all`. The default setting is `amazon`. Take note that `all` and `aws-marketplace` may cause Salt Cloud to appear as if it is freezing, as it tries to handle the large amount of data.

It is also possible to perform this query using different settings without modifying the configuration files. To do this, call the `avail_images` function directly:

```
salt-cloud -f avail_images my-ec2-config owner=aws-marketplace
```

### EC2 Images

The following are lists of available AMI images, generally sorted by OS. These lists are on 3rd-party websites, are not managed by Salt Stack in any way. They are provided here as a reference for those who are interested, and contain no warranty (express or implied) from anyone affiliated with Salt Stack. Most of them have never been used, much less tested, by the Salt Stack team.

- Arch Linux
- FreeBSD
- Fedora
- CentOS
- Ubuntu
- Debian
- OmniOS
- All Images on Amazon
show_image

This is a function that describes an AMI on EC2. This will give insight as to the defaults that will be applied to an instance using a particular AMI.

```bash
$ salt-cloud -f show_image ec2 image=ami-fd20ad94
```

show_instance

This action is a thin wrapper around --full-query, which displays details on a single instance only. In an environment with several machines, this will save a user from having to sort through all instance data, just to examine a single instance.

```bash
$ salt-cloud -a show_instance myinstance
```

ebs_optimized

This argument enables switching of the EbsOptimized setting which default to `false'. Indicates whether the instance is optimized for EBS I/O. This optimization provides dedicated throughput to Amazon EBS and an optimized configuration stack to provide optimal Amazon EBS I/O performance. This optimization isn’t available with all instance types. Additional usage charges apply when using an EBS-optimized instance.

This setting can be added to the profile or map file for an instance.

If set to True, this setting will enable an instance to be EbsOptimized

```yaml
ebs_optimized: True
```

This can also be set as a cloud provider setting in the EC2 cloud configuration:

```yaml
my-ec2-config:
  ebs_optimized: True
```

del_root_vol_on_destroy

This argument overrides the default DeleteOnTermination setting in the AMI for the EBS root volumes for an instance. Many AMIs contain `false' as a default, resulting in orphaned volumes in the EC2 account, which may unknowingly be charged to the account. This setting can be added to the profile or map file for an instance.

If set, this setting will apply to the root EBS volume

```yaml
del_root_vol_on_destroy: True
```

This can also be set as a cloud provider setting in the EC2 cloud configuration:

```yaml
my-ec2-config:
  del_root_vol_on_destroy: True
```

del_all_vols_on_destroy

This argument overrides the default DeleteOnTermination setting in the AMI for the not-root EBS volumes for an instance. Many AMIs contain `false' as a default, resulting in orphaned volumes in the EC2 account, which may unknowingly be charged to the account. This setting can be added to the profile or map file for an instance.
If set, this setting will apply to any (non-root) volumes that were created by salt-cloud using the `volumes` setting.

The volumes will not be deleted under the following conditions:
* If a volume is detached before terminating the instance
* If a volume is created without this setting and attached to the instance

```
del_all_vols_on_destroy: True
```

This can also be set as a cloud provider setting in the EC2 cloud configuration:

```
my-ec2-config:
  del_all_vols_on_destroy: True
```

The setting for this may be changed on all volumes of an existing instance using one of the following commands:

```
salt-cloud -a delvol_on_destroy myinstance
salt-cloud -a keepvol_on_destroy myinstance
salt-cloud -a show_delvol_on_destroy myinstance
```

The setting for this may be changed on a volume on an existing instance using one of the following commands:

```
salt-cloud -a delvol_on_destroy myinstance device=/dev/sda1
salt-cloud -a delvol_on_destroy myinstance volume_id=vol-1a2b3c4d
salt-cloud -a keepvol_on_destroy myinstance device=/dev/sda1
salt-cloud -a keepvol_on_destroy myinstance volume_id=vol-1a2b3c4d
salt-cloud -a show_delvol_on_destroy myinstance device=/dev/sda1
salt-cloud -a show_delvol_on_destroy myinstance volume_id=vol-1a2b3c4d
```

### EC2 Termination Protection

EC2 allows the user to enable and disable termination protection on a specific instance. An instance with this protection enabled cannot be destroyed. The EC2 driver adds a `show_term_protect` action to the regular EC2 functionality.

```
salt-cloud -a show_term_protect mymachine
salt-cloud -a enable_term_protect mymachine
salt-cloud -a disable_term_protect mymachine
```

### Alternate Endpoint

Normally, EC2 endpoints are build using the region and the service_url. The resulting endpoint would follow this pattern:

```
ec2.<region>.<service_url>
```

This results in an endpoint that looks like:

```
ec2.us-east-1.amazonaws.com
```

There are other projects that support an EC2 compatibility layer, which this scheme does not account for. This can be overridden by specifying the endpoint directly in the main cloud configuration file:

```
my-ec2-config:
  endpoint: myendpoint.example.com:1138/services/Cloud
```
Volume Management

The EC2 driver has several functions and actions for management of EBS volumes.

Creating Volumes

A volume may be created, independent of an instance. A zone must be specified. A size or a snapshot may be specified (in GiB). If neither is given, a default size of 10 GiB will be used. If a snapshot is given, the size of the snapshot will be used.

The following parameters may also be set (when providing a snapshot OR size):

- **type**: choose between standard (magnetic disk), gp2 (SSD), or io1 (provisioned IOPS). (default=standard)
- **iops**: the number of IOPS (only applicable to io1 volumes) (default varies on volume size)
- **encrypted**: enable encryption on the volume (default=false)

```
salt-cloud -f create_volume ec2 zone=us-east-1b
salt-cloud -f create_volume ec2 zone=us-east-1b size=10
salt-cloud -f create_volume ec2 zone=us-east-1b snapshot=snap12345678
salt-cloud -f create_volume ec2 size=10 type=standard
salt-cloud -f create_volume ec2 size=10 type=gp2
salt-cloud -f create_volume ec2 size=10 type=io1 iops=1000
```

Attaching Volumes

Unattached volumes may be attached to an instance. The following values are required; name or instance_id, volume_id, and device.

```
salt-cloud -a attach_volume myinstance volume_id=vol-12345 device=/dev/sdb1
```

Show a Volume

The details about an existing volume may be retrieved.

```
salt-cloud -a show_volume myinstance volume_id=vol-12345
salt-cloud -f show_volume ec2 volume_id=vol-12345
```

Detaching Volumes

An existing volume may be detached from an instance.

```
salt-cloud -a detach_volume myinstance volume_id=vol-12345
```

Deleting Volumes

A volume that is not attached to an instance may be deleted.

```
salt-cloud -f delete_volume ec2 volume_id=vol-12345
```
Managing Key Pairs

The EC2 driver has the ability to manage key pairs.

Creating a Key Pair

A key pair is required in order to create an instance. When creating a key pair with this function, the return data will contain a copy of the private key. This private key is not stored by Amazon, will not be obtainable past this point, and should be stored immediately.

```
salt-cloud -f create_keypair ec2 keyname=mykeypair
```

Importing a Key Pair

```
salt-cloud -f import_keypair ec2 keyname=mykeypair file=/path/to/id_rsa.pub
```

Show a Key Pair

This function will show the details related to a key pair, not including the private key itself (which is not stored by Amazon).

```
salt-cloud -f show_keypair ec2 keyname=mykeypair
```

Delete a Key Pair

This function removes the key pair from Amazon.

```
salt-cloud -f delete_keypair ec2 keyname=mykeypair
```

Launching instances into a VPC

Simple launching into a VPC

In the amazon web interface, identify the id of the subnet into which your image should be created. Then, edit your cloud.profiles file like so:-

```
profile-id:
  provider: provider-name
  subnetid: subnet-XXXXXXXX
  image: ami-XXXXXXXX
  size: m1.medium
  ssh_username: ubuntu
  securitygroupid:
    - sg-XXXXXXXX
```
Specifying interface properties

New in version 2014.7.0.

Launching into a VPC allows you to specify more complex configurations for the network interfaces of your virtual machines, for example:-

```yaml
profile-id:
  provider: provider-name
  image: ami-XXXXXXXX
  size: m1.medium
  ssh_username: ubuntu

# Do not include either 'subnetid' or 'securitygroupid' here if you are
# going to manually specify interface configuration
#
network_interfaces:
  - DeviceIndex: 0
    SubnetId: subnet-XXXXXXXX
    SecurityGroupId:
      - sg-XXXXXXXX

    # Uncomment this line if you would like to set an explicit private
    # IP address for the ec2 instance
    #
    # PrivateIpAddress: 192.168.1.66

    # Uncomment this to associate an existing Elastic IP Address with
    # this network interface:
    #
    # associate_eip: eipalloc-XXXXXXXX

    # You can allocate more than one IP address to an interface. Use the
    # 'ip addr list' command to see them.
    #
    # SecondaryPrivateIpAddressCount: 2

    # Uncomment this to allocate a new Elastic IP Address to this
    # interface (will be associated with the primary private ip address
    # of the interface
    #
    # allocate_new_eip: True

    # Uncomment this instead to allocate a new Elastic IP Address to
    # both the primary private ip address and each of the secondary ones
    #
    allocate_new_eips: True

    # Uncomment this if you're creating NAT instances. Allows an instance
    # to accept IP packets with destinations other than itself.
    # SourceDestCheck: False
```

Note that it is an error to assign a `subnetid` or `securitygroupid` to a profile where the interfaces are manually configured like this. These are both really properties of each network interface, not of the machine itself.
9.7.5 Getting Started With GoGrid

GoGrid is a public cloud host that supports Linux and Windows.

Configuration

To use Salt Cloud with GoGrid log into the GoGrid web interface and create an API key. Do this by clicking on "My Account" and then going to the API Keys tab.

The apikey and the sharedsecret configuration parameters need to be set in the configuration file to enable interfacing with GoGrid:

```yaml
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.
my-gogrid-config:
  driver: gogrid
  apikey: asdff7896asdh789
  sharedsecret: saltybacon
```

Note: A Note about using Map files with GoGrid:

Due to limitations in the GoGrid API, instances cannot be provisioned in parallel with the GoGrid driver. Map files will work with GoGrid, but the -P argument should not be used on maps referencing GoGrid instances.

Note: Changed in version 2015.8.0.

The provider parameter in cloud provider definitions was renamed to driver. This change was made to avoid confusion with the provider parameter that is used in cloud profile definitions. Cloud provider definitions now use driver to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use provider to refer to provider configurations that you define.

Profiles

Cloud Profiles

Set up an initial profile at /etc/salt/cloud.profiles or in the /etc/salt/cloud.profiles.d/ directory:

```yaml
# gogrid_512:
  provider: my-gogrid-config
  size: 512MB
  image: CentOS 6.2 (64-bit) w/ None
```

Sizes can be obtained using the --list-sizes option for the salt-cloud command:

```bash
salt-cloud --list-sizes my-gogrid-config
```

```bash
my-gogrid-config:------------
gogrid:------------
512MB:
```
---

bandwidth:
  None
disk:
  30
driver:
get_uuid:
  id:
    512MB
name:
  512MB
price:
  0.095
ram:
  512
uuid:
  bde1e4d7c3a643536e42a35142c7caac34b060e9

---

Images can be obtained using the `--list-images` option for the `salt-cloud` command:

```shell
# salt-cloud --list-images my-gogrid-config
my-gogrid-config:
  --
  gogrid:
    --
    CentOS 6.4 (64-bit) w/ None:
      --
      driver:
      extra:
        --
        get_uuid:
          id:
            18094
          name:
            CentOS 6.4 (64-bit) w/ None
          uuid:
            bfd405389919e061aa6261828a96cf54c8d6c25c
      ...
```

Assigning IPs

New in version 2015.8.0.

The GoGrid API allows IP addresses to be manually assigned. Salt Cloud supports this functionality by allowing an IP address to be specified using the `assign_public_ip` argument. This likely makes the most sense inside a map file, but it may also be used inside a profile.

```yaml
gogrid_512:
  provider: my-gogrid-config
  size: 512MB
  image: CentOS 6.2 (64-bit) w/ None
  assign_public_ip: 11.38.257.42
```
9.7.6 Getting Started With Google Compute Engine

Google Compute Engine (GCE) is Google-infrastructure as a service that lets you run your large-scale computing workloads on virtual machines. This document covers how to use Salt Cloud to provision and manage your virtual machines hosted within Google's infrastructure.

You can find out more about GCE and other Google Cloud Platform services at https://cloud.google.com.

Dependencies

- LibCloud >= 0.14.1
- A Google Cloud Platform account with Compute Engine enabled
- A registered Service Account for authorization
- Oh, and obviously you’ll need salt

Google Compute Engine Setup

1. Sign up for Google Cloud Platform
   
   Go to https://cloud.google.com and use your Google account to sign up for Google Cloud Platform and complete the guided instructions.

2. Create a Project
   
   Next, go to the console at https://cloud.google.com/console and create a new Project. Make sure to select your new Project if you are not automatically directed to the Project.

   Projects are a way of grouping together related users, services, and billing. You may opt to create multiple Projects and the remaining instructions will need to be completed for each Project if you wish to use GCE and Salt Cloud to manage your virtual machines.

3. Enable the Google Compute Engine service
   
   In your Project, either just click Compute Engine to the left, or go to the APIs & auth section and APIs link and enable the Google Compute Engine service.

4. Create a Service Account
   
   To set up authorization, navigate to APIs & auth section and then the Credentials link and click the CREATE NEW CLIENT ID button. Select Service Account and click the Create Client ID button. This will automatically download a .json file, which may or may not be used in later steps, depending on your version of libcloud.

   Look for a new Service Account section in the page and record the generated email address for the matching key/fingerprint. The email address will be used in the service_account_email_address of the /etc/salt/cloud.providers or the /etc/salt/cloud.providers.d/*.conf file.

5. Key Format
   
   Note: If you are using libcloud >= 0.17.0 it is recommended that you use the JSON format file you downloaded above and skip to the Provider Configuration section below, using the JSON file in place of `NEW.pem' in the documentation.

   If you are using an older version of libcloud or are unsure of the version you have, please follow the instructions below to generate and format a new P12 key.
In the new Service Account section, click Generate new P12 key, which will automatically download a .p12 private key file. The .p12 private key needs to be converted to a format compatible with libcloud. This new Google-generated private key was encrypted using notasecret as a passphrase. Use the following command and record the location of the converted private key and record the location for use in the service_account_private_key of the /etc/salt/cloud file:

```
oppenssl pkcs12 -in ORIG.p12\npassin pass:notasecret -nodes -nocerts | openssl rsa -out NEW.pem
```

**Provider Configuration**

Set up the provider cloud config at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/*.conf:

```
gce-config:
# Set up the Project name and Service Account authorization
project: "your-project-id"
service_account_email_address: "123-a5gt@developer.gserviceaccount.com"
service_account_private_key: "/path/to/your/NEW.pem"

# Set up the location of the salt master
minion:
    master: saltmaster.example.com

# Set up grains information, which will be common for all nodes
# using this provider
grains:
    node_type: broker
    release: 1.0.1

driver: gce
```

**Note:** The value provided for project must not contain underscores or spaces and is labeled as `"Project ID"` on the Google Developers Console.

**Note:** Changed in version 2015.8.0.

The provider parameter in cloud provider definitions was renamed to driver. This change was made to avoid confusion with the provider parameter that is used in cloud profile definitions. Cloud provider definitions now use driver to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use provider to refer to provider configurations that you define.

**Profile Configuration**

Set up an initial profile at /etc/salt/cloud.profiles or /etc/salt/cloud.profiles.d/*.conf:

```
my-gce-profile:
    image: centos-6
    size: n1-standard-1
    location: europe-west1-b
    network: default
```
The profile can be realized now with a salt command:

```
salt-cloud -p my-gce-profile gce-instance
```

This will create an salt minion instance named `gce-instance` in GCE. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once the instance has been created with a salt-minion installed, connectivity to it can be verified with Salt:

```
salt gce-instance test.ping
```

### GCE Specific Settings

Consult the sample profile below for more information about GCE specific settings. Some of them are mandatory and are properly labeled below but typically also include a hard-coded default.

#### Initial Profile

Set up an initial profile at `/etc/salt/cloud.profiles` or `/etc/salt/cloud.profiles.d/gce.conf`:

```yaml
my-gce-profile:
  image: centos-6
  size: n1-standard-1
  location: europe-west1-b
  network: default
  tags: ['one', 'two', 'three']
  metadata: {'one': '1', 'two': 'two'}
  use_persistent_disk: True
  delete_boot_pd: False
  make_master: False
  provider: gce-config
  ssh_interface: public_ips
  external_ip: "ephemeral"
```

#### image

Image is used to define what Operating System image should be used to for the instance. Examples are Debian 7 (wheezy) and CentOS 6. Required.

#### size

A `size`, in GCE terms, refers to the instance’s `machine type`. See the on-line documentation for a complete list of GCE machine types. Required.
location

A `location`, in GCE terms, refers to the instance's `zone`. GCE has the notion of both Regions (e.g. us-central1, europe-west1, etc) and Zones (e.g. us-central1-a, us-central1-b, etc). Required.

network

Use this setting to define the network resource for the instance. All GCE projects contain a network named `default` but it's possible to use this setting to create instances belonging to a different network resource.

tags

GCE supports instance/network tags and this setting allows you to set custom tags. It should be a list of strings and must be parse-able by the python ast.literal_eval() function to convert it to a python list.

metadata

GCE supports instance metadata and this setting allows you to set custom metadata. It should be a hash of key/value strings and parse-able by the python ast.literal_eval() function to convert it to a python dictionary.

use_persistent_disk

Use this setting to ensure that when new instances are created, they will use a persistent disk to preserve data between instance terminations and re-creations.

delete_boot_pd

In the event that you wish the boot persistent disk to be permanently deleted when you destroy an instance, set delete_boot_pd to True.

ssh_interface

New in version 2015.5.0.
Specify whether to use public or private IP for deploy script.
Valid options are:
  - private_ips: The salt-master is also hosted with GCE
  - public_ips: The salt-master is hosted outside of GCE

external_ip

Per instance setting: Used a named fixed IP address to this host.
Valid options are:
  - ephemeral: The host will use a GCE ephemeral IP
• None: No external IP will be configured on this host.

Optionally, pass the name of a GCE address to use a fixed IP address. If the address does not already exist, it will be created.

**ex_disk_type**

GCE supports two different disk types, `pd-standard` and `pd-ssd`. The default disk type setting is `pd-standard`. To specify using an SSD disk, set `pd-ssd` as the value.

New in version 2014.7.0.

**ip_forwarding**

GCE instances can be enabled to use IP Forwarding. When set to `True`, this option allows the instance to send/receive non-matching src/dst packets. Default is `False`.

**Profile with scopes**

Scopes can be specified by setting the optional `ex_service_accounts` key in your cloud profile. The following example enables the bigquery scope.

```yaml
my-gce-profile:
  image: centos-6
  ssh_username: salt
  size: f1-micro
  location: us-central1-a
  network: default
  tags: ['"one", "two", "three"]
  metadata: {'"one": "1", "2": "two",
              "sshKeys": ""
             }
  use_persistent_disk: True
  delete_boot_pd: False
  deploy: False
  make_master: False
  provider: gce-config
  ex_service_accounts:
    - scopes:
      - bigquery
```

Email can also be specified as an (optional) parameter.

```yaml
my-gce-profile:
  ...snip
  ex_service_accounts:
    - scopes:
      - bigquery
    email: default
```

There can be multiple entries for scopes since `ex-service_accounts` accepts a list of dictionaries. For more information refer to the libcloud documentation on specifying service account scopes.
SSH Remote Access

GCE instances do not allow remote access to the root user by default. Instead, another user must be used to run the deploy script using sudo. Append something like this to `/etc/salt/cloud.profiles` or `/etc/salt/cloud.profiles.d/*.conf`:

```yaml
my-gce-profile:
  ...
  # SSH to GCE instances as gceuser
  ssh_username: gceuser
  # Use the local private SSH key file located here
  ssh_keyfile: /etc/cloud/google_compute_engine
```

If you have not already used this SSH key to login to instances in this GCE project you will also need to add the public key to your projects metadata at [https://cloud.google.com/console](https://cloud.google.com/console). You could also add it via the metadata setting too:

```yaml
my-gce-profile:
  ...
  metadata: '{"one": "1", "2": "two",
    "sshKeys": "gceuser:ssh-rsa <Your SSH Public Key> gceuser@host"}'
```

Single instance details

This action is a thin wrapper around `--full-query`, which displays details on a single instance only. In an environment with several machines, this will save a user from having to sort through all instance data, just to examine a single instance.

```
salt-cloud -a show_instance myinstance
```

Destroy, persistent disks, and metadata

As noted in the provider configuration, it’s possible to force the boot persistent disk to be deleted when you destroy the instance. The way that this has been implemented is to use the instance metadata to record the cloud profile used when creating the instance. When `destroy` is called, if the instance contains a `salt-cloud-profile` key, its value is used to reference the matching profile to determine if `delete_boot_pd` is set to `True`.

Be aware that any GCE instances created with salt cloud will contain this custom `salt-cloud-profile` metadata entry.

List various resources

It’s also possible to list several GCE resources similar to what can be done with other providers. The following commands can be used to list GCE zones (locations), machine types (sizes), and images.

```
salt-cloud --list-locations gce
salt-cloud --list-sizes gce
salt-cloud --list-images gce
```
Persistent Disk

The Compute Engine provider provides functions via salt-cloud to manage your Persistent Disks. You can create and destroy disks as well as attach and detach them from running instances.

Create

When creating a disk, you can create an empty disk and specify its size (in GB), or specify either an `image' or `snapshot'.

```
salt-cloud -f create_disk gce disk_name=pd location=us-central1-b size=200
```

Delete

Deleting a disk only requires the name of the disk to delete

```
salt-cloud -f delete_disk gce disk_name=old-backup
```

Attach

Attaching a disk to an existing instance is really an `action' and requires both an instance name and disk name. It's possible to use this action to create bootable persistent disks if necessary. Compute Engine also supports attaching a persistent disk in READONLY mode to multiple instances at the same time (but then cannot be attached in READ_WRITE to any instance).

```
salt-cloud -a attach_disk myinstance disk_name=pd mode=READ_WRITE boot=yes
```

Detach

Detaching a disk is also an action against an instance and only requires the name of the disk. Note that this does not safely sync and unmount the disk from the instance. To ensure no data loss, you must first make sure the disk is unmounted from the instance.

```
salt-cloud -a detach_disk myinstance disk_name=pd
```

Show disk

It's also possible to look up the details for an existing disk with either a function or an action.

```
salt-cloud -a show_disk myinstance disk_name=pd
salt-cloud -f show_disk gce disk_name=pd
```

Create snapshot

You can take a snapshot of an existing disk's content. The snapshot can then in turn be used to create other persistent disks. Note that to prevent data corruption, it is strongly suggested that you unmount the disk prior to taking a snapshot. You must name the snapshot and provide the name of the disk.
Delete snapshot

You can delete a snapshot when it's no longer needed by specifying the name of the snapshot.

```
salt-cloud -f delete_snapshot gce name=backup-20140226
```

Show snapshot

Use this function to look up information about the snapshot.

```
salt-cloud -f show_snapshot gce name=backup-20140226
```

Networking

Compute Engine supports multiple private networks per project. Instances within a private network can easily communicate with each other by an internal DNS service that resolves instance names. Instances within a private network can also communicate with either directly without needing special routing or firewall rules even if they span different regions/zones.

Networks also support custom firewall rules. By default, traffic between instances on the same private network is open to all ports and protocols. Inbound SSH traffic (port 22) is also allowed but all other inbound traffic is blocked.

Create network

New networks require a name and CIDR range. New instances can be created and added to this network by setting the network name during create. It is not possible to add/remove existing instances to a network.

```
salt-cloud -f create_network gce name=mynet cidr=10.10.10.0/24
```

Destroy network

Destroy a network by specifying the name. Make sure that there are no instances associated with the network prior to deleting it or you'll have a bad day.

```
salt-cloud -f delete_network gce name=mynet
```

Show network

Specify the network name to view information about the network.

```
salt-cloud -f show_network gce name=mynet
```
Create address

Create a new named static IP address in a region.

```
salt-cloud -f create_address gce name=my-fixed-ip region=us-central1
```

Delete address

Delete an existing named fixed IP address.

```
salt-cloud -f delete_address gce name=my-fixed-ip region=us-central1
```

Show address

View details on a named address.

```
salt-cloud -f show_address gce name=my-fixed-ip region=us-central1
```

Create firewall

You’ll need to create custom firewall rules if you want to allow other traffic than what is described above. For instance, if you run a web service on your instances, you'll need to explicitly allow HTTP and/or SSL traffic. The firewall rule must have a name and it will use the 'default' network unless otherwise specified with a 'network' attribute. Firewalls also support instance tags for source/destination.

```
salt-cloud -f create_fwrule gce name=web allow=tcp:80,tcp:443,icmp
```

Delete firewall

Deleting a firewall rule will prevent any previously allowed traffic for the named firewall rule.

```
salt-cloud -f delete_fwrule gce name=web
```

Show firewall

Use this function to review an existing firewall rule’s information.

```
salt-cloud -f show_fwrule gce name=web
```

Load Balancer

Compute Engine possess a load-balancer feature for splitting traffic across multiple instances. Please reference the documentation for a more complete description.

The load-balancer functionality is slightly different than that described in Google’s documentation. The concept of TargetPool and ForwardingRule are consolidated in salt-cloud/libcloud. HTTP Health Checks are optional.
HTTP Health Check

HTTP Health Checks can be used as a means to toggle load-balancing across instance members, or to detect if an HTTP site is functioning. A common use-case is to set up a health check URL and if you want to toggle traffic on/off to an instance, you can temporarily have it return a non-200 response. A non-200 response to the load-balancer’s health check will keep the LB from sending any new traffic to the “down” instance. Once the instance’s health check URL beings returning 200-responses, the LB will again start to send traffic to it. Review Compute Engine’s documentation for allowable parameters. You can use the following salt-cloud functions to manage your HTTP health checks.

```
salt-cloud -f create_hc gce name=myhc path=/ port=80
salt-cloud -f delete_hc gce name=myhc
salt-cloud -f show_hc gce name=myhc
```

Load-balancer

When creating a new load-balancer, it requires a name, region, port range, and list of members. There are other optional parameters for protocol, and list of health checks. Deleting or showing details about the LB only requires the name.

```
salt-cloud -f create_lb gce name=lb region=... ports=80 members=w1,w2,w3
salt-cloud -f delete_lb gce name=lb
salt-cloud -f show_lb gce name=lb
```

You can also create a load balancer using a named fixed IP address by specifying the name of the address. If the address does not exist yet it will be created.

```
salt-cloud -f create_lb gce name=my-lb region=us-central1 ports=234 members=s1,s2,s3 address=my-lb-ip
```

Attach and Detach LB

It is possible to attach or detach an instance from an existing load-balancer. Both the instance and load-balancer must exist before using these functions.

```
salt-cloud -f attach_lb gce name=lb member=w4
salt-cloud -f detach_lb gce name=lb member=oops
```

9.7.7 Getting Started With HP Cloud

HP Cloud is a major public cloud platform and uses the libcloud openstack driver. The current version of OpenStack that HP Cloud uses is Havana. When an instance is booted, it must have a floating IP added to it in order to connect to it and further below you will see an example that adds context to this statement.

Set up a cloud provider configuration file

To use the openstack driver for HP Cloud, set up the cloud provider configuration file as in the example shown below:

/etc/salt/cloud.providers.d/hpcloud.conf:
hpcloud-config:
  # Set the location of the salt-master
  #
  minion:
    master: saltmaster.example.com

  # Configure HP Cloud using the OpenStack plugin
  #
  identity_url: https://region-b.geo-1.identity.hpcloudsvc.com:35357/v2.0/tokens
  compute_name: Compute
  protocol: ipv4

  # Set the compute region:
  #
  compute_region: region-b.geo-1

  # Configure HP Cloud authentication credentials
  #
  user: myname
  tenant: myname-project1
  password: xxxxxxxxxx

  # keys to allow connection to the instance launched
  #
  ssh_key_name: yourkey
  ssh_key_file: /path/to/key/yourkey.priv

  driver: openstack

The subsequent example that follows is using the openstack driver.

Note: Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

Compute Region

Originally, HP Cloud, in its OpenStack Essex version (1.0), had 3 availability zones in one region, US West (region-a.geo-1), which each behaved each as a region.

This has since changed, and the current OpenStack Havana version of HP Cloud (1.1) now has simplified this and now has two regions to choose from:

<table>
<thead>
<tr>
<th>Region</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>region-a.geo-1</td>
<td>US West</td>
</tr>
<tr>
<td>region-b.geo-1</td>
<td>US East</td>
</tr>
</tbody>
</table>

Authentication

The `user` is the same user as is used to log into the HP Cloud management UI. The `tenant` can be found in the upper left under `"Project/Region/Scope"`. It is often named the same as `user` albeit with a `-project1` appended.
The **password** is of course what you created your account with. The management UI also has other information such as being able to select US East or US West.

### Set up a cloud profile config file

The profile shown below is a know working profile for an Ubuntu instance. The profile configuration file is stored in the following location:

```
/etc/salt/cloud.profiles.d/hp_ae1_ubuntu.conf
```

```
hp_ae1_ubuntu:
  provider: hp_ae1
  image: 9302692b-b787-4b52-a3a6-daebb79cb498
  ignore_cidr: 10.0.0.1/24
  networks:
    - floating: Ext-Net
  size: standard.small
  ssh_key_file: /root/keys/test.key
  ssh_key_name: test
  ssh_username: ubuntu
```

Some important things about the example above:

- The **image** parameter can use either the image name or image ID which you can obtain by running in the example below (this case US East):

```
# salt-cloud --list-images hp_ae1
```

- The parameter **ignore_cidr** specifies a range of addresses to ignore when trying to connect to the instance. In this case, it’s the range of IP addresses used for an private IP of the instance.

- The parameter **networks** is very important to include. In previous versions of Salt Cloud, this is what made it possible for salt-cloud to be able to attach a floating IP to the instance in order to connect to the instance and set up the minion. The current version of salt-cloud doesn’t require it, though having it is of no harm either. Newer versions of salt-cloud will use this, and without it, will attempt to find a list of floating IP addresses to use regardless.

- The **ssh_key_file** and **ssh_key_name** are the keys that will make it possible to connect to the instance to set up the minion

- The **ssh_username** parameter, in this case, being that the image used will be ubuntu, will make it possible to not only log in but install the minion

### Launch an instance

To instantiate a machine based on this profile (example):

```
# salt-cloud -p hp_ae1_ubuntu ubuntu_instance_1
```

After several minutes, this will create an instance named `ubuntu_instance_1` running in HP Cloud in the US East region and will set up the minion and then return information about the instance once completed.

### Manage the instance

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:
Salt Documentation, Release 2016.3.6

# salt ubuntu_instance_1 ping

**SSH to the instance**

Additionally, the instance can be accessed via SSH using the floating IP assigned to it

```shell
# ssh ubuntu@<floating_ip>
```

**Using a private IP**

Alternatively, in the cloud profile, using the private IP to log into the instance to set up the minion is another option, particularly if salt-cloud is running within the cloud on an instance that is on the same network with all the other instances (minions).

The example below is a modified version of the previous example. Note the use of `ssh_interface`:

```yaml
hp_ae1_ubuntu:
  provider: hp_ae1
  image: 9302692b-b787-4b52-a3a6-daebb79cb498
  size: standard.small
  ssh_key_file: /root/keys/test.key
  ssh_key_name: test
  ssh_username: ubuntu
  ssh_interface: private_ips
```

With this setup, salt-cloud will use the private IP address to ssh into the instance and set up the salt-minion

### 9.7.8 Getting Started With Joyent

Joyent is a public cloud host that supports SmartOS, Linux, FreeBSD, and Windows.

**Dependencies**

This driver requires the Python `requests` library to be installed.

**Configuration**

The Joyent cloud requires three configuration parameters. The user name and password that are used to log into the Joyent system, and the location of the private ssh key associated with the Joyent account. The ssh key is needed to send the provisioning commands up to the freshly created virtual machine.

```yaml
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.

my-joyent-config:
  driver: joyent
  user: fred
  password: saltybacon
  private_key: /root/mykey.pem
  keyname: mykey
```

9.7. Cloud Provider Specifics

563
Note: Changed in version 2015.8.0.

The provider parameter in cloud provider definitions was renamed to driver. This change was made to avoid confusion with the provider parameter that is used in cloud profile definitions. Cloud provider definitions now use driver to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use provider to refer to provider configurations that you define.

Profiles

Cloud Profiles

Set up an initial profile at /etc/salt/cloud.profiles or in the /etc/salt/cloud.profiles.d/ directory:

```
joyent_512
  provider: my-joyent-config
  size: g4-highcpu-512M
  image: ubuntu-16.04
```

Sizes can be obtained using the --list-sizes option for the salt-cloud command:

```
# salt-cloud --list-sizes my-joyent-config
my-joyent-config:
  -----------
    joyent:
      -----------
        g4-highcpu-512M:
          -----------
            default: False
description: Compute Optimized 512M RAM - 1 vCPU - 10 GB Disk
disk: 10240
group: Compute Optimized
id: 14aea8fc-0f8-11e5-bfe4-a7458d6c6c99
lwp: 4000
memory: 512
name: g4-highcpu-512M
swap: 2048
vcpus: 0
version: 1.0.3
...SNIP...
```

Images can be obtained using the --list-images option for the salt-cloud command:
```yaml
# salt-cloud --list-images my-joyent-config
my-joyent-config:
    joyent:
        base:
            description:
                A 32-bit SmartOS image with just essential packages installed. Ideal for users who are comfortable with setting up their own environment and tools.
            files:
                compression: gzip
                sha1: b00a77408ddd9aeac85085b68b1cd22a07353956
                size: 106918297
            homepage: http://wiki.joyent.com/jpc2/Base+Instance
            id: 00aec452-6e81-11e4-8474-ebfec9a1a911
            name: base
            os: smartos
            owner: 9dce1460-0e4c-4417-ab8b-25ca478c5a78
            public: True
            published_at: 2014-11-17T17:41:46Z
            requirements:
            state: active
            type: smartmachine
            version: 14.3.0
...SNIP...
```

**SmartDataCenter**

This driver can also be used with the Joyent SmartDataCenter project. More details can be found at:

Using SDC requires that an `api_host_suffix` is set. The default value for this is `.api.joyentcloud.com`. All characters, including the leading `.`, should be included:

```
api_host_suffix: .api.myhostname.com
```
Miscellaneous Configuration

The following configuration items can be set in either provider or profile configuration files.

use_ssl

When set to True (the default), attach https:// to any URL that does not already have http:// or https:// included at the beginning. The best practice is to leave the protocol out of the URL, and use this setting to manage it.

verify_ssl

When set to True (the default), the underlying web library will verify the SSL certificate. This should only be set to False for debugging.

9.7.9 Getting Started With LXC

The LXC module is designed to install Salt in an LXC container on a controlled and possibly remote minion. In other words, Salt will connect to a minion, then from that minion:

- Provision and configure a container for networking access
- Use those modules to deploy salt and re-attach to master.
  - lxc runner
  - lxc module
  - seed

Limitations

- You can only act on one minion and one provider at a time.
- Listing images must be targeted to a particular LXC provider (nothing will be outputted with all)

Operation

Salt’s LXC support does use lxc.init via the lxc.cloud_init_interface and seeds the minion via seed.mkconfig.

You can provide to those lxc VMs a profile and a network profile like if you were directly using the minion module. Order of operation:

- Create the LXC container on the desired minion (clone or template)
- Change LXC config options (if any need to be changed)
- Start container
- Change base passwords if any
- Change base DNS configuration if necessary
- Wait for LXC container to be up and ready for ssh
• Test SSH connection and bailout in error
• Upload deploy script and seeds, then re-attach the minion.

Provider configuration

Here is a simple provider configuration:

```
# Note: This example goes in /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.
devhost10-lxc:
  target: devhost10
  driver: lxc
```

Note: Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

Profile configuration

Please read tutorial-lxc before anything else. And specially tutorial-lxc-profiles.

Here are the options to configure your containers:

- `target` Host minion id to install the lxc Container into
- `lxc_profile` Name of the profile or inline options for the LXC vm creation/cloning, please see tutorial-lxc-profiles-container.
- `network_profile` Name of the profile or inline options for the LXC vm network settings, please see tutorial-lxc-profiles-network.
- `nic_opts` Totally optional. Per interface new-style configuration options mappings which will override any profile default option:

  ```
  eth0: {'mac': '00:16:3e:01:29:40',
         'gateway': None, (default)
         'link': 'br0', (default)
         'gateway': None, (default)
         'netmask': '', (default)
         'ip': '22.1.4.25'}
  ```

- `password` password for root and sysadmin users
- `dnsservers` List of DNS servers to use. This is optional.
- `minion` minion configuration (see Minion Configuration in Salt Cloud)
- `bootstrap_delay` specify the time to wait (in seconds) between container creation and salt bootstrap execution. It is useful to ensure that all essential services have started before the bootstrap script is executed. By default there's no wait time between container creation and bootstrap unless you are on systemd where we wait that the system is no more in starting state.
- `bootstrap_shell` shell for bootstraping script (default: /bin/sh)
script defaults to salt-bootstrap

script_args arguments which are given to the bootstrap script. the {0} placeholder will be replaced by the path which contains the minion config and key files, eg:

```
script_args="-c {0}"
```

Using profiles:

```
# Note: This example would go in /etc/salt/cloud.profiles or any file in the
# /etc/salt/cloud.profiles.d/ directory.
devhost10-lxc:
  provider: devhost10-lxc
  lxc_profile: foo
  network_profile: bar
  minion:
    master: 10.5.0.1
    master_port: 4506
```

Using inline profiles (eg to override the network bridge):

```
devhost11-lxc:
  provider: devhost10-lxc
  lxc_profile:
    clone_from: foo
  network_profile:
    eth0:
      link: lxcbr0
  minion:
    master: 10.5.0.1
    master_port: 4506
```

Using a lxc template instead of a clone:

```
devhost11-lxc:
  provider: devhost10-lxc
  lxc_profile:
    template: ubuntu
    # options:
    #  release: trusty
  network_profile:
    eth0:
      link: lxcbr0
  minion:
    master: 10.5.0.1
    master_port: 4506
```

Static ip:

```
# Note: This example would go in /etc/salt/cloud.profiles or any file in the
# /etc/salt/cloud.profiles.d/ directory.
devhost10-lxc:
  provider: devhost10-lxc
  nic_opts:
    eth0:
      ipv4: 10.0.3.9
  minion:
    master: 10.5.0.1
    master_port: 4506
```
DHCP:

```bash
# Note: This example would go in /etc/salt/cloud.profiles or any file in the
# /etc/salt/cloud.profiles.d/ directory.
devhost10-lxc:
  provider: devhost10-lxc
  minion:
    master: 10.5.0.1
    master_port: 4506
```

Driver Support

- Container creation
- Image listing (LXC templates)
- Running container information (IP addresses, etc.)

### 9.7.10 Getting Started With Linode

Linode is a public cloud host with a focus on Linux instances.

Starting with the 2015.8.0 release of Salt, the Linode driver uses Linode's native REST API. There are no external dependencies required to use the Linode driver, other than a Linode account.

Provider Configuration

Linode requires a single API key, but the default root password for new instances also needs to be set. The password needs to be eight characters and contain lowercase, uppercase, and numbers.

Set up the provider cloud configuration file at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/*.conf`.

```
my-linode-config:
  apikey: 'asldkgfakl; sdfjsjaslfjaklsdjf; askldjfaaklsjdfhasldsdadfgdhdfk'
  password: 'F00barbaz'
  driver: linode
```

Note: Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

Profile Configuration

Linode profiles require a `provider`, `size`, `image`, and `location`. Set up an initial profile at `/etc/salt/cloud.profiles` or in the `/etc/salt/cloud.profiles.d/` directory:
linode_1024:
  provider: my-linode-config
  size: Linode 2048
  image: CentOS 7
  location: London, England, UK

The profile can be realized now with a salt command:

```
salt-cloud -p linode_1024 linode-instance
```

This will create an salt minion instance named `linode-instance` in Linode. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once the instance has been created with a salt-minion installed, connectivity to it can be verified with Salt:

```
salt linode-instance test.ping
```

### Listing Sizes

Sizes can be obtained using the `--list-sizes` option for the `salt-cloud` command:

```
# salt-cloud --list-sizes my-linode-config
my-linode-config:
  ----------
  linode:
    ----------
    Linode 1024:
      ----------
      AVAIL:
        10:
          500
        2:
          500
        3:
          500
        4:
          500
        6:
          500
        7:
          500
        8:
          500
        9:
          500
      CORES:
        1
      DISK:
        24
      HOURLY:
        0.015
      LABEL:
        Linode 1024
...SNIP...
```
Listing Images

Images can be obtained using the --list-images option for the salt-cloud command:

```
# salt-cloud --list-images my-linode-config
my-linode-config:
  ----------
  linode:
  ----------
  Arch Linux 2015.02:
  ----------
  CREATE_DT:
  2015-02-20 14:17:16.0
  DISTRIBUTIONID:
  138
  IS64BIT:
  1
  LABEL:
  Arch Linux 2015.02
  MINIMAGESIZE:
  800
  REQUIRESPVOPSKERNEL:
  1
...
```

Listing Locations

Locations can be obtained using the --list-locations option for the salt-cloud command:

```
# salt-cloud --list-locations my-linode-config
my-linode-config:
  ----------
  linode:
  ----------
  Atlanta, GA, USA:
  ----------
  ABBR:
  atlanta
  DATACENTERID:
  4
  LOCATION:
  Atlanta, GA, USA
...
```

Linode Specific Settings

There are several options outlined below that can be added to either the Linode provider of profile configuration files. Some options are mandatory and are properly labeled below but typically also include a hard-coded default.

image

Image is used to define what Operating System image should be used for the instance. Examples are Ubuntu 14.04 LTS and CentOS 7. This option should be specified in the profile config. Required.
location

Location is used to define which Linode data center the instance will reside in. Required.

size

Size is used to define the instance’s `plan type` which includes memory, storage, and price. Required.

assign_private_ip

New in version 2016.3.0.
Assigns a private IP address to a Linode when set to True. Default is False.

private_ip

Deprecated in favor of assign_private_ip in Salt 2016.3.0.

ssh_interface

New in version 2016.3.0.
Specify whether to use a public or private IP for the deploy script. Valid options are:

- `public_ips`: The salt-master is hosted outside of Linode. Default.
- `private_ips`: The salt-master is also hosted within Linode.

If specifying `private_ips`, the Linodes must be hosted within the same data center and have the Network Helper enabled on your entire account. The instance that is running the Salt-Cloud provisioning command must also have a private IP assigned to it.

Newer accounts created on Linode have the Network Helper setting enabled by default, account-wide. Legacy accounts do not have this setting enabled by default. To enable the Network Helper on your Linode account, please see Linode's Network Helper documentation.

If you're running into problems, be sure to restart the instance that is running Salt Cloud after adding its own private IP address or enabling the Network Helper.

clonefrom

Setting the clonefrom option to a specified instance enables the new instance to be cloned from the named instance instead of being created from scratch. If using the clonefrom option, it is likely a good idea to also specify `script_args: -C` if a minion is already installed on the to-be-cloned instance. See the Cloning section below for more information.

Cloning

To clone a Linode, add a profile with a clonefrom key, and a script_args: `-C`. clonelfrom should be the name of the Linode that is the source for the clone. script_args: `-C` passes a `-C` to the salt-bootstrap script, which only configures the minion and doesn't try to install a new copy of salt-minion. This way the minion gets
new keys and the keys get pre-seeded on the master, and the /etc/salt/minion file has the right minion `id:' declaration.

Cloning requires a post 2015-02-01 salt-bootstrap.

It is safest to clone a stopped machine. To stop a machine run

```
salt-cloud -a stop machine_to_clone
```

To create a new machine based on another machine, add an entry to your linode cloud profile that looks like this:

```
li-clone:
  provider: my-linode-config
  clonefrom: machine_to_clone
  script_args: -C -F
```

Then run salt-cloud as normal, specifying `-p li-clone`. The profile name can be anything; It doesn't have to be `li-clone`.

`clonefrom:` is the name of an existing machine in Linode from which to clone. `script_args: -C -F` is necessary to avoid re-deploying Salt via salt-bootstrap. `-C` will just re-deploy keys so the new minion will not have a duplicate key or minion_id on the Master, and `-F` will force a rewrite of the Minion config file on the new Minion. If `-F` isn't provided, the new Minion will have the `machine_to_clone`'s Minion ID, instead of its own Minion ID, which can cause problems.

---

**Note:** Pull Request #733 to the salt-bootstrap repo makes the `-F` argument non-necessary. Once that change is released into a stable version of the Bootstrap Script, the `-C` argument will be sufficient for the `script_args` setting.

If the `machine_to_clone` does not have Salt installed on it, refrain from using the `script_args: -C -F` altogether, because the new machine will need to have Salt installed.

### 9.7.11 Getting Started with OpenNebula

OpenNebula is an open-source solution for the comprehensive management of virtualized data centers to enable the mixed use of private, public, and hybrid IaaS clouds.

**Dependencies**

The driver requires Python's `lxml` library to be installed. It also requires an OpenNebula installation running version 4.12.

**Configuration**

The following example illustrates some of the options that can be set. These parameters are discussed in more detail below.

```
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.

my-opennebula-provider:
  # Set up the location of the salt master
  
  minion:
```
Access Credentials

The Salt Cloud driver for OpenNebula was written using OpenNebula's native XML RPC API. Every interaction with OpenNebula's API requires a username and password to make the connection from the machine running Salt Cloud to API running on the OpenNebula instance. Based on the access credentials passed in, OpenNebula filters the commands that the user can perform or the information for which the user can query. For example, the images that a user can view with a `--list-images` command are the images that the connected user and the connected user's groups can access.

Key Pairs

Salt Cloud needs to be able to access a virtual machine in order to install the Salt Minion by using a public/private key pair. The virtual machine will need to be seeded with the public key, which is laid down by the OpenNebula template. Salt Cloud then uses the corresponding private key, provided by the `private_key` setting in the cloud provider file, to SSH into the new virtual machine.

To seed the virtual machine with the public key, the public key must be added to the OpenNebula template. If using the OpenNebula web interface, navigate to the template, then click Update. Click the Context tab. Under the Network & SSH section, click Add SSH Contextualization and paste the public key in the Public Key box. Don't forget to save your changes by clicking the green Update button.

Note: The key pair must not have a pass-phrase.

Cloud Profiles

Set up an initial profile at either `/etc/salt/cloud.profiles` or the `/etc/salt/cloud.profiles.d` directory.
The profile can now be realized with a salt command:

```
salt-cloud -p my-opennebula-profile my-new-vm
```

This will create a new instance named `my-new-vm` in OpenNebula. The minion that is installed on this instance will have a minion id of `my-new-vm`. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```
salt my-new-vm test.ping
```

OpenNebula uses an image --> template --> virtual machine paradigm where the template draws on the image, or disk, and virtual machines are created from templates. Because of this, there is no need to define a size in the cloud profile. The size of the virtual machine is defined in the template.

**Required Settings**

The following settings are always required for OpenNebula:

```
my-opennebula-config:
  xml_rpc: http://localhost:26633/RPC2
  user: oneadmin
  password: JHGhgsayu32jsa
  driver: opennebula
```

**Required Settings for VM Deployment**

The settings defined in the **Required Settings** section are required for all interactions with OpenNebula. However, when deploying a virtual machine via Salt Cloud, an additional setting, `private_key`, is also required:

```
my-opennebula-config:
  private_key: /path/to/private/key
```

**Listing Images**

Images can be queried on OpenNebula by passing the `--list-images` argument to Salt Cloud:

```
salt-cloud --list-images opennebula
```

**Listing Locations**

In OpenNebula, locations are defined as `hosts`. Locations, or `hosts`, can be queried on OpenNebula by passing the `--list-locations` argument to Salt Cloud:

```
salt-cloud --list-locations opennebula
```
Listing Sizes

Sizes are defined by templates in OpenNebula. As such, the `--list-sizes` call returns an empty dictionary since there are no sizes to return.

Additional OpenNebula API Functionality

The Salt Cloud driver for OpenNebula was written using OpenNebula's native XML RPC API. As such, many `--function` and `--action` calls were added to the OpenNebula driver to enhance support for an OpenNebula infrastructure with additional control from Salt Cloud. See the OpenNebula function definitions for more information.

9.7.12 Getting Started With OpenStack

OpenStack is one the most popular cloud projects. It's an open source project to build public and/or private clouds. You can use Salt Cloud to launch OpenStack instances.

Dependencies

- Libcloud >= 0.13.2

Configuration

- Using the new format, set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/openstack.conf`:

```yaml
my-openstack-config:
    # Set the location of the salt-master
    #
    minion:
        master: saltmaster.example.com

    # Configure the OpenStack driver
    #
    identity_url: http://identity.youopenstack.com/v2.0/tokens
    compute_name: nova
    protocol: ipv4

    compute_region: RegionOne

    # Configure Openstack authentication credentials
    #
    user: myname
    password: 123456
    tenant: myproject

    driver: openstack

    # skip SSL certificate validation (default false)
    insecure: false
```
Note: Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

Using nova client to get information from OpenStack

One of the best ways to get information about OpenStack is using the `novaclient` python package (available in pypi as python-novaclient). The client configuration is a set of environment variables that you can get from the Dashboard. Log in and then go to Project -> Access & security -> API Access and download the "OpenStack RC file". Then:

```bash
source /path/to/your/rcfile
nova credentials
nova endpoints
```

In the `nova endpoints` output you can see the information about `compute_region` and `compute_name`.

Compute Region

It depends on the OpenStack cluster that you are using. Please, have a look at the previous sections.

Authentication

The `user` and `password` is the same user as is used to log into the OpenStack Dashboard.

Profiles

Here is an example of a profile:

```yaml
openstack_512:
  provider: my-openstack-config
  size: m1.tiny
  image: cirros-0.3.1-x86_64-uec
  ssh_key_file: /tmp/test.pem
  ssh_key_name: test
  ssh_interface: private_ips
```

The following list explains some of the important properties.

- `size` can be one of the options listed in the output of `nova flavor-list`.
- `image` can be one of the options listed in the output of `nova image-list`.
- `ssh_key_file` The SSH private key that the salt-cloud uses to SSH into the VM after its first booted in order to execute a command or script. This private key's `public key` must be the openstack public key inserted into the `authorized_key`'s file of the VM's root user account.
- `ssh_key_name` The name of the openstack SSH public key that is inserted into the `authorized_keys` file of the VM's root user account. Prior to using this public key, you must use openstack commands or the horizon web UI to load that key into the tenant's account. Note that this openstack tenant must be the one you defined in the cloud provider.

9.7. Cloud Provider Specifics
ssh_interface  This option allows you to create a VM without a public IP. If this option is omitted and the VM does not have a public IP, then the salt-cloud waits for a certain period of time and then destroys the VM. With the nova drive, private cloud networks can be defined here.

For more information concerning cloud profiles, see here.

change_password

If no ssh_key_file is provided, and the server already exists, change_password will use the api to change the root password of the server so that it can be bootstrapped.

```yaml
change_password: True
```

userdata_file

Use userdata_file to specify the userdata file to upload for use with cloud-init if available.

```yaml
userdata_file: /etc/salt/cloud-init/packages.yml
```

### 9.7.13 Getting Started With Parallels

Parallels Cloud Server is a product by Parallels that delivers a cloud hosting solution. The PARALLELS module for Salt Cloud enables you to manage instances hosted using PCS. Further information can be found at:

http://www.parallels.com/products/pcs/

- Using the old format, set up the cloud configuration at /etc/salt/cloud:

```yaml
# Set up the location of the salt master
#
minion:
  master: saltmaster.example.com

# Set the PARALLELS access credentials (see below)
#
PARALLELS.user: myuser
PARALLELS.password: badpass

# Set the access URL for your PARALLELS host
#
PARALLELS.url: https://api.cloud.xmission.com:4465/paci/v1.0/
```

- Using the new format, set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/parallels.conf:

```yaml
my-parallels-config:
  # Set up the location of the salt master
  #
  minion:
    master: saltmaster.example.com

  # Set the PARALLELS access credentials (see below)
  #
  user: myuser
```
password: badpass

# Set the access URL for your PARALLELS provider
# url: https://api.cloud.xmission.com:4465/paci/v1.0/
driver: parallels

Note: Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

Access Credentials

The `user`, `password`, and `url` will be provided to you by your cloud host. These are all required in order for the PARALLELS driver to work.

Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles` or `/etc/salt/cloud.profiles.d/parallels.conf`:

```
parallels-ubuntu:
    provider: my-parallels-config
    image: ubuntu-12.04-x86_64
```

The profile can be realized now with a salt command:

```
# salt-cloud -p parallels-ubuntu myubuntu
```

This will create an instance named `myubuntu` on the cloud host. The minion that is installed on this instance will have an `id` of `myubuntu`. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```
# salt myubuntu test.ping
```

Required Settings

The following settings are always required for PARALLELS:

- Using the old cloud configuration format:

  ```
  PARALLELS.user: myuser
  PARALLELS.password: badpass
  PARALLELS.url: https://api.cloud.xmission.com:4465/paci/v1.0/
  ```

- Using the new cloud configuration format:
Optional Settings

Unlike other cloud providers in Salt Cloud, Parallels does not utilize a size setting. This is because Parallels allows the end-user to specify a more detailed configuration for their instances than is allowed by many other cloud hosts. The following options are available to be used in a profile, with their default settings listed.

```python
# Description of the instance. Defaults to the instance name.
desc: <instance_name>

# How many CPU cores, and how fast they are (in MHz)
cpu_number: 1
cpu_power: 1000

# How many megabytes of RAM
ram: 256

# Bandwidth available, in kbps
bandwidth: 100

# How many public IPs will be assigned to this instance
ip_num: 1

# Size of the instance disk (in GiB)
disk_size: 10

# Username and password
ssh_username: root
password: <value from PARALLELS.password>

# The name of the image, from `salt-cloud --list-images parallels`
image: ubuntu-12.04-x86_64
```

9.7.14 Getting Started With ProfitBricks

ProfitBricks provides an enterprise-grade Infrastructure as a Service (IaaS) solution that can be managed through a browser-based “Data Center Designer” (DCD) tool or via an easy to use API. A unique feature of the ProfitBricks platform is that it allows you to define your own settings for cores, memory, and disk size without being tied to a particular instance size.

Dependencies

- profitbricks >= 2.3.0
Configuration

- Using the new format, set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/profitbricks.conf`:

```bash
my-profitbricks-config:
  # Set the location of the salt-master
  #
  minion:
    master: saltmaster.example.com

  # Configure ProfitBricks authentication credentials
  #
  username: user@domain.com
  password: 123456
  datacenter: 9e6709a0-6bf9-4bd6-8692-60349c70ce0e
  # Connect to public LAN ID 1.
  public_lan: 1
  ssh_public_key: /path/to/id_rsa.pub
  ssh_private_key: /path/to/id_rsa

  driver: profitbricks
```

**Note:** Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

**Virtual Data Center**

ProfitBricks uses the concept of Virtual Data Centers. These are logically separated from one another and allow you to have a self-contained environment for all servers, volumes, networking, snapshots, and so forth.

A list of existing virtual data centers can be retrieved with the following command:

```
salt-cloud -f list_datacenters my-profitbricks-config
```

**Authentication**

The `username` and `password` are the same as those used to log into the ProfitBricks `''Data Center Designer``.

**Profiles**

Here is an example of a profile:

```bash
profitbricks_production:
  provider: my-profitbricks-config
  size: Micro Instance
  image: 2f98b678-6e7e-11e5-b680-52540066fee9
  disk_size: 10
```
### Properties

The following list explains some of the important properties.

- **size**: Can be one of the options listed in the output of the following command:
  ```
  salt-cloud --list-sizes my-profitbricks
  ```

- **image**: Can be one of the options listed in the output of the following command:
  ```
  salt-cloud --list-images my-profitbricks
  ```

- **disk_size**: This option allows you to override the size of the disk as defined by the size. The disk size is set in gigabytes (GB).

- **cores**: This option allows you to override the number of CPU cores as defined by the size.

- **ram**: This option allows you to override the amount of RAM defined by the size. The value must be a multiple of 256, e.g. 256, 512, 768, 1024, and so forth.

- **public_lan**: This option will connect the instance to the specified public LAN. If no LAN exists, then a new public LAN will be created. The value accepts a LAN ID (integer).

- **private_lan**: This option will connect the instance to the specified private LAN. If no LAN exists, then a new private LAN will be created. The value accepts a LAN ID (integer).

- **ssh_private_key**: Full path to the SSH private key file.

- **ssh_public_key**: Full path to the SSH public key file.

- **ssh_interface**: This option will use the private LAN IP for node connections (such as as bootstrapping the node) instead of the public LAN IP. The value accepts `private_lan`.

- **deploy**: Set to False if Salt should not be installed on the node.

For more information concerning cloud profiles, see [here](#).

### 9.7.15 Getting Started With Proxmox

Proxmox Virtual Environment is a complete server virtualization management solution, based on OpenVZ (in Proxmox up to 3.4)/LXC (from Proxmox 4.0 and up) and full virtualization with KVM. Further information can be found at:

http://www.proxmox.org/

#### Dependencies

- IPy >= 0.81
- requests >= 2.2.1

Please note: This module allows you to create OpenVZ/LXC containers and KVM VMs, but installing Salt on it will only be done on containers rather than a KVM virtual machine.
• Set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/proxmox.conf:

```yaml
my-proxmox-config:
  # Set up the location of the salt master
  #
  minion:
    master: saltmaster.example.com

  # Set the PROXMOX access credentials (see below)
  #
  user: myuser@pve
  password: badpass

  # Set the access URL for your PROXMOX host
  #
  url: your.proxmox.host
  driver: proxmox
```

**Note:** Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

### Access Credentials

The `user`, `password`, and `url` will be provided to you by your cloud host. These are all required in order for the PROXMOX driver to work.

### Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles` or `/etc/salt/cloud.profiles.d/proxmox.conf`:

• Configure a profile to be used:

```yaml
proxmox-ubuntu:
  provider: my-proxmox-config
  image: local:vztmpl/ubuntu-12.04-standard_12.04-1_amd64.tar.gz
  technology: lxc

  # host needs to be set to the configured name of the proxmox host
  # and not the ip address or FQDN of the server
  host: myvmhost
  ip_address: 192.168.100.155
  password: topsecret
```

The profile can be realized now with a salt command:

```
# salt-cloud -p proxmox-ubuntu myubuntu
```

This will create an instance named `myubuntu` on the cloud host. The minion that is installed on this instance will have a hostname of `myubuntu`. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.
Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```bash
# salt myubuntu test.ping
```

**Required Settings**

The following settings are always required for PROXMOX:

- Using the new cloud configuration format:

```yaml
my-proxmox-config:
  driver: proxmox
  user: saltcloud@pve
  password: xyzzy
  url: your.proxmox.host
```

**Optional Settings**

Unlike other cloud providers in Salt Cloud, Proxmox does not utilize a size setting. This is because Proxmox allows the end-user to specify a more detailed configuration for their instances, than is allowed by many other cloud providers. The following options are available to be used in a profile, with their default settings listed.

```yaml
# Description of the instance.
desc: <instance_name>

# How many CPU cores, and how fast they are (in MHz)
cpus: 1
cpuunits: 1000

# How many megabytes of RAM
memory: 256

# How much swap space in MB
swap: 256

# Whether to auto boot the vm after the host reboots
onboot: 1

# Size of the instance disk (in GiB)
disk: 10

# Host to create this vm on
host: myvmhost

# Nameservers. Defaults to host
nameserver: 8.8.8.8 8.8.4.4

# Username and password
ssh_username: root
password: <value from PROXMOX.password>

# The name of the image, from `salt-cloud --list-images proxmox`
image: local:vztmpl/ubuntu-12.04-standard_12.04-1_amd64.tar.gz

# Whether or not to verify the SSL cert on the Proxmox host
verify_ssl: False
QEMU

Some functionalities works differently if you use `qemu` as technology. In order to create a new VM with qemu, you need to specify some more information. You can also clone a qemu template which already is on your Proxmox server.

QEMU profile file (for a new VM):

```yaml
proxmox-win7:
  # Image of the new VM
  image: image.iso  # You can get all your available images using 'salt-cloud --list-images provider_name' (Ex: 'salt-cloud --list-images my-proxmox-config')

  # Technology used to create the VM ('qemu', 'openvz'(on Proxmox <4.x) or 'lxc'(on Proxmox 4.x+))
  technology: qemu

  # Proxmox node name
  host: node_name

  # Proxmox password
  password: your_password

  # Workaround https://github.com/saltstack/salt/issues/27821
  size: ''

  # RAM size (MB)
  memory: 2048

  # OS Type enum (other / wxp / w2k / w2k3 / w2k8 / wvista / win7 / win8 / l24 / l26 / solaris)
  ostype: win7

  # Hard disk location
  sata0: <location>:<size>, format=qcow2/vmdk/raw, size=<size>GB #Example: local:/dev/sda1,format=qcow2,size=120GB

  # CD/DVD Drive
  ide2: <content_location>,media=cdrom #Example: local:iso/name.iso,media=cdrom

  # Network Device
  net0:<model>,bridge=<bridge> #Example: e1000,bridge=vmbr0

  # Enable QEMU Guest Agent (0 / 1)
  agent: 1

  # VM name
  name: Test
```

More information about these parameters can be found on Proxmox API (http://pve.proxmox.com/pve2-api-doc/) under the `POST` method of nodes/{node}/qemu

QEMU profile file (for a clone):
proxmox-win7:
# Enable Clone
clone: 1

# New VM description
clone_description: 'description'

# New VM name
clone_name: 'name'

# New VM format (qcow2 / raw / vmdk)
clone_format: qcow2

# Full clone (1) or Link clone (0)
clone_full: 0

# VMID of Template to clone
clone_from: ID

# Technology used to create the VM ('qemu' or 'lxc')
technology: qemu

# Proxmox node name
host: node_name

# Proxmox password
password: your_password

# Workaround https://github.com/saltstack/salt/issues/27821
size: ''

More information can be found on Proxmox API under the `POST` method of `/nodes/{node}/qemu/{vmid}/clone`

**Note:** The Proxmox API offers a lot more options and parameters, which are not yet supported by this salt-cloud `overlay`. Feel free to add your contribution by forking the github repository and modifying the following file: `salt/salt/cloud/clouds/proxmox.py`. An easy way to support more parameters for VM creation would be to add the names of the optional parameters in the `create_nodes(vmin)` function, under the `qemu` technology. But it requires you to dig into the code ...

#### 9.7.16 Getting Started With Rackspace

Rackspace is a major public cloud platform which may be configured using either the `rackspace` or the `openstack` driver, depending on your needs.

Please note that the `rackspace` driver is intended only for 1st gen instances, aka, `''the old cloud''` at Rackspace. It is required for 1st gen instances, but will not work with OpenStack-based instances. Unless you explicitly have a reason to use it, it is highly recommended that you use the `openstack` driver instead.

**Dependencies**

- Libcloud >= 0.13.2
Configuration

To use the `openstack` driver (recommended), set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/rackspace.conf`:

```yaml
my-rackspace-config:
    # Set the location of the salt-master
    minion:
        master: saltmaster.example.com

    # Configure Rackspace using the OpenStack plugin
    identity_url: 'https://identity.api.rackspacecloud.com/v2.0/tokens'
    compute_name: cloudServersOpenStack
    protocol: ipv4

    # Set the compute region:
    compute_region: DFW

    # Configure Rackspace authentication credentials
    user: myname
    tenant: 123456
    apikey: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

    driver: openstack
```

To use the `rackspace` driver, set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/rackspace.conf`:

```yaml
my-rackspace-config:
    driver: rackspace
    # The Rackspace login user
    user: fred
    # The Rackspace user's apikey
    apikey: 901d3f579h23c8v73q9
```

The settings that follow are for using Rackspace with the `openstack` driver, and will not work with the `rackspace` driver.

---

**Note:** Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

---

**Compute Region**

Rackspace currently has six compute regions which may be used:

```
DFW -> Dallas/Forth Worth
ORD -> Chicago
```
Authentication

The user is the same user as is used to log into the Rackspace Control Panel. The tenant and apikey can be found in the API Keys area of the Control Panel. The apikey will be labeled as API Key (and may need to be generated), and tenant will be labeled as Cloud Account Number.

An initial profile can be configured in /etc/salt/cloud.profiles or /etc/salt/cloud.profiles.d/rackspace.conf:

```
openstack_512:
    provider: my-rackspace-config
    size: 512 MB Standard
    image: Ubuntu 12.04 LTS (Precise Pangolin)
```

To instantiate a machine based on this profile:

```
# salt-cloud -p openstack_512 myinstance
```

This will create a virtual machine at Rackspace with the name myinstance. This operation may take several minutes to complete, depending on the current load at the Rackspace data center.

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```
# salt myinstance test.ping
```

RackConnect Environments

Rackspace offers a hybrid hosting configuration option called RackConnect that allows you to use a physical firewall appliance with your cloud servers. When this service is in use the public_ip assigned by nova will be replaced by a NAT ip on the firewall. For salt-cloud to work properly it must use the newly assigned "access ip" instead of the Nova assigned public ip. You can enable that capability by adding this to your profiles:

```
openstack_512:
    provider: my-openstack-config
    size: 512 MB Standard
    image: Ubuntu 12.04 LTS (Precise Pangolin)
    rackconnect: True
```

Managed Cloud Environments

Rackspace offers a managed service level of hosting. As part of the managed service level you have the ability to choose from base of lamp installations on cloud server images. The post build process for both the base and the lamp installations used Chef to install things such as the cloud monitoring agent and the cloud backup agent. It also takes care of installing the lamp stack if selected. In order to prevent the post installation process from stomping over the bootstrapping you can add the below to your profiles.
openstack_512:
  provider: my-rackspace-config
  size: 512 MB Standard
  image: Ubuntu 12.04 LTS (Precise Pangolin)
  managedcloud: True

First and Next Generation Images

Rackspace provides two sets of virtual machine images, first, and next generation. As of 0.8.9 salt-cloud will default to using the next generation images. To force the use of first generation images, on the profile configuration please add:

FreeBSD-9.0-512:
  provider: my-rackspace-config
  size: 512 MB Standard
  image: FreeBSD 9.0
  force_first_gen: True

Private Subnets

By default salt-cloud will not add Rackspace private networks to new servers. To enable a private network to a server instantiated by salt cloud, add the following section to the provider file (typically /etc/salt/cloud.providers.d/rackspace.conf)

networks:
  - fixed:
      # This is the private network
      private-network-id
      # This is Rackspace's "PublicNet"
      - 00000000-0000-0000-0000-000000000000
      # This is Rackspace's "ServiceNet"
      - 11111111-1111-1111-1111-111111111111

To get the Rackspace private network ID, go to Networking, Networks and hover over the private network name.

The order of the networks in the above code block does not map to the order of the ethernet devices on newly created servers. Public IP will always be first (eth0) followed by servicenet (eth1) and then private networks.

Enabling the private network per above gives the option of using the private subnet for all master-minion communication, including the bootstrap install of salt-minion. To enable the minion to use the private subnet, update the master: line in the minion: section of the providers file. To configure the master to only listen on the private subnet IP, update the interface: line in the /etc/salt/master file to be the private subnet IP of the salt master.

9.7.17 Getting Started With Saltify

The Saltify driver is a new, experimental driver for installing Salt on existing machines (virtual or bare metal).

Dependencies

The Saltify driver has no external dependencies.
Configuration

Because the Saltify driver does not use an actual cloud provider host, it has a simple provider configuration. The only thing that is required to be set is the driver name, and any other potentially useful information, like the location of the salt-master:

```yaml
# Note: This example is for /etc/salt/cloud.providers file or any file in
# the /etc/salt/cloud.providers.d/ directory.
my-saltify-config:
  minion:
    master: 111.222.333.444
  provider: saltify
```

Profiles

Saltify requires a profile to be configured for each machine that needs Salt installed. The initial profile can be set up at `/etc/salt/cloud.profiles` or in the `/etc/salt/cloud.profiles.d/` directory. Each profile requires both an `ssh_host` and an `ssh_username` key parameter as well as either an `key_filename` or a `password`.

Profile configuration example:

```yaml
# /etc/salt/cloud.profiles.d/saltify.conf
salt-this-machine:
  ssh_host: 12.34.56.78
  ssh_username: root
  key_filename: '/etc/salt/mysshkey.pem'
  provider: my-saltify-config
```

The machine can now be ``Salted`` with the following command:

```
salt-cloud -p salt-this-machine my-machine
```

This will install salt on the machine specified by the cloud profile, `salt-this-machine`, and will give the machine the minion id of `my-machine`. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once a salt-minion has been successfully installed on the instance, connectivity to it can be verified with Salt:

```
salt my-machine test.ping
```

Using Map Files

The settings explained in the section above may also be set in a map file. An example of how to use the Saltify driver with a map file follows:

```yaml
# /etc/salt/saltify-map
make_salty:
  - my-instance-0:
    ssh_host: 12.34.56.78
    ssh_username: root
    password: very-bad-password
```
- my-instance-1:
  ssh_host: 44.33.22.11
  ssh_username: root
  password: another-bad-pass

Note: When using a cloud map with the Saltify driver, the name of the profile to use, in this case make_salty, must be defined in a profile config. For example:

```bash
# /etc/salt/cloud.profiles.d/saltify.conf
make_salty:
  provider: my-saltify-config
```

The machines listed in the map file can now be ``Salted'' by applying the following salt map command:

```bash
class-cloud -m /etc/salt/saltify-map
```

This command will install salt on the machines specified in the map and will give each machine their minion id of my-instance-0 and my-instance-1, respectively. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Connectivity to the new ``Salted'' instances can now be verified with Salt:

```bash
salt 'my-instance-*' test.ping
```

### 9.7.18 Getting Started With Scaleway

Scaleway is the first IaaS host worldwide to offer an ARM based cloud. It’s the ideal platform for horizontal scaling with BareMetal SSD servers. The solution provides on demand resources: it comes with on-demand SSD storage, movable IPs, images, security group and an Object Storage solution. [https://scaleway.com](https://scaleway.com)

#### Configuration

Using Salt for Scaleway, requires an access key and an API token. API tokens are unique identifiers associated with your Scaleway account. To retrieve your access key and API token, log-in to the Scaleway control panel, open the pull-down menu on your account name and click on ``My Credentials'' link.

If you do not have API token you can create one by clicking the ``Create New Token'' button on the right corner.

```bash
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.
my-scaleway-config:
  access_key: 15cf404d-4560-41b1-9a0c-21c3d5c4ff1f
  token: a7347ec8-5de1-4024-a5e3-24b77d1ba91d
  driver: scaleway
```

#### Note: Changed in version 2015.8.0.

The provider parameter in cloud provider definitions was renamed to driver. This change was made to avoid confusion with the provider parameter that is used in cloud profile definitions. Cloud provider definitions now use driver to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use provider to refer to provider configurations that you define.
Profiles

Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles` or in the `/etc/salt/cloud.profiles.d/` directory:

```yaml
scalewa-ubuntu:
  provider: my-scaleway-config
  image: Ubuntu Trusty (14.04 LTS)
```

Images can be obtained using the `--list-images` option for the `salt-cloud` command:

```
# salt-cloud --list-images my-scaleway-config
my-scaleway-config:
  ----------
  scaleway:
  ----------
  069fd876-eb04-44ab-a9cd-47e2fa3e5309:
    arch: arm
    creation_date: 2015-03-12T09:35:45.764477+00:00
    default_bootscript: 
      { 'kernel': 
        { 'dtb': '', 'title': 'Pimouss 3.2.34-30-std', 'id':  
          'cfda4308-cd6f-4e51-9744-905fc8da370f', 'path': 
          'kernel/pimouss-uImage-3.2.34-30-std'}, 
        'title': '3.2.34-std #30 (stable)', 'id': 'c5af0215-2516-4316-befc-
          5dalcfa609c', 'initrd': { 'path': 'initrd/c1-uInitrd', 'id': '1be14b1b-e24c-
          48e5-b0b6-7ba452e42b92', 'title': 'C1 initrd'}, 
        'bootcmdargs': { 'id': 'd22c4dde-e5a4-47ad-abb9-d3b54d542ff', 'value': 'ip=dhcp boot=local root=/dev/
          nbd0 USE_XNBD=1 nbd.max_parts=8'}, 
        'organization': '11111111-1111-4111-8111-
          111111111111', 'public': True}
      extra_volumes: 
        []
    id: 
      069fd876-eb04-44ab-a9cd-47e2fa3e5309
    modification_date: 2015-04-24T12:02:16.820256+00:00
    name: Ubuntu Vivid (15.04)
    organization: a283af0b-d13e-42e1-a43f-855ffbf281ab
    public: True
    root_volume:
      { 'name': 'distrib-ubuntu-vivid-2015-03-12_10:32-snapshot', 'id': 'a6d02e63-8dee-4bce-b627-b21730f35a05', 'volume_type': 'l_ssd', 'size': '51200000000L'}
...
```

Execute a query and return all information about the nodes running on configured cloud providers using the `-Q` option for the `salt-cloud` command:

```
# salt-cloud -F
[INFO ] salt-cloud starting
[INFO ] Starting new HTTPS connection (1): api.scaleway.com
my-scaleway-config:
  ----------
```

Chapter 9. Salt Cloud
scaleway:
    ----------
salt-manager:
    ----------
    creation_date:
        2015-06-03T08:17:38.818068+00:00
    hostname:
        salt-manager

Note: Additional documentation about Scaleway can be found at https://www.scaleway.com/docs.

9.7.19 Getting Started With SoftLayer

SoftLayer is a public cloud host, and baremetal hardware hosting service.

Dependencies

The SoftLayer driver for Salt Cloud requires the softlayer package, which is available at PyPI:

https://pypi.python.org/pypi/SoftLayer

This package can be installed using pip or easy_install:

# pip install softlayer
# easy_install softlayer

Configuration

Set up the cloud config at /etc/salt/cloud.providers:

# Note: These examples are for /etc/salt/cloud.providers

my-softlayer:
    # Set up the location of the salt master
    minion:
        master: saltmaster.example.com

    # Set the SoftLayer access credentials (see below)
    user: MYUSER1138
    apikey: 'e3b68aa711e6deadc62d5b76355674beef7cc3116062ddbacafe5f7e465bfdc9'
    driver: softlayer

my-softlayer-hw:
    # Set up the location of the salt master
    minion:
        master: saltmaster.example.com

    # Set the SoftLayer access credentials (see below)
    user: MYUSER1138
    apikey: 'e3b68aa711e6deadc62d5b76355674beef7cc3116062ddbacafe5f7e465bfdc9'
driver: softlayer_hw

Note: Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

Access Credentials

The `user` setting is the same user as is used to log into the SoftLayer Administration area. The `apikey` setting is found inside the Admin area after logging in:

- Hover over the `Account` menu item.
- Click the `Users` link.
- Find the API Key column and click View.

Profiles

Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles`:

```yaml
base_softlayer_ubuntu:
  provider: my-softlayer
  image: UBUNTU_LATEST
  cpu_number: 1
  ram: 1024
  disk_size: 100
  local_disk: True
  hourly_billing: True
  domain: example.com
  location: sjc01
  # Optional
  max_net_speed: 1000
  private_vlan: 396
  private_network: True
  private_ssh: True
  # May be used instead of image
  global_identifier: 320d8be5-46c0-dead-cafe-13e3c51
```

Most of the above items are required; optional items are specified below.

image

Images to build an instance can be found using the `--list-images` option:

```bash
# salt-cloud --list-images my-softlayer
```
The setting used will be labeled as `template`.

### cpu_number

This is the number of CPU cores that will be used for this instance. This number may be dependent upon the image that is used. For instance:

```yaml
Red Hat Enterprise Linux 6 - Minimal Install (64 bit) (1 - 4 Core):
    name: Red Hat Enterprise Linux 6 - Minimal Install (64 bit) (1 - 4 Core)
    template: REDHAT_6_64

Red Hat Enterprise Linux 6 - Minimal Install (64 bit) (5 - 100 Core):
    name: Red Hat Enterprise Linux 6 - Minimal Install (64 bit) (5 - 100 Core)
    template: REDHAT_6_64
```

Note that the template (meaning, the `image` option) for both of these is the same, but the names suggest how many CPU cores are supported.

### ram

This is the amount of memory, in megabytes, that will be allocated to this instance.

### disk_size

The amount of disk space that will be allocated to this image, in gigabytes.

```yaml
base_software_ubuntu:
    disk_size: 100
```

### Using Multiple Disks

SoftLayer allows up to 5 disks to be specified for a virtual machine upon creation. Multiple disks can be specified either as a list or a comma-delimited string. The first `disk_size` specified in the string or list will be the first disk size assigned to the VM.

List Example: `. code-block:: yaml`
```
    base_software_ubuntu: disk_size: [100, 20, 20]
```

String Example: `. code-block:: yaml`
```
    base_software_ubuntu: disk_size: '100, 20, 20'
```
**local_disk**

When true the disks for the computing instance will be provisioned on the host which it runs, otherwise SAN disks will be provisioned.

**hourly_billing**

When true the computing instance will be billed on hourly usage, otherwise it will be billed on a monthly basis.

**domain**

The domain name that will be used in the FQDN (Fully Qualified Domain Name) for this instance. The domain setting will be used in conjunction with the instance name to form the FQDN.

**use_fqdn**

If set to True, the Minion will be identified by the FQDN (Fully Qualified Domain Name) which is a result of combining the domain configuration value and the Minion name specified either via the CLI or a map file rather than only using the short host name, or Minion ID. Default is False.

New in version 2016.3.0.

For example, if the value of domain is *example.com* and a new VM was created via the CLI with `salt-cloud -p base_softlayer_ubuntu my-vm`, the resulting Minion ID would be `my-vm.example.com`.

**Note:** When enabling the *use_fqdn* setting, the Minion ID will be the FQDN and will interact with salt commands with the FQDN instead of the short hostname. However, due to the way the SoftLayer API is constructed, some Salt Cloud functions such as listing nodes or destroying VMs will only list the short hostname of the VM instead of the FQDN.

Example output displaying the SoftLayer hostname quirk mentioned in the note above (note the Minion ID is *my-vm.example.com*, but the VM to be destroyed is listed with its short hostname, *my-vm*):

```
# salt-key -L
Accepted Keys:
my-vm.example.com
Denied Keys:
Unaccepted Keys:
Rejected Keys:
#
# salt my-vm.example.com test.ping
my-vm.example.com:
  True
#
# salt-cloud -d my-vm.example.com
[INFO] salt-cloud starting
The following virtual machines are set to be destroyed:
  softlayer-config:
    softlayer:
```

Chapter 9. Salt Cloud
my-vm

Proceed? [N/y] y
... proceeding

[INFO] Destroying in non-parallel mode.

softlayer-config:
   ---------
   softlayer:
   ---------
   my-vm:
   True

location

Images to build an instance can be found using the --list-locations option:

```
# salt-cloud --list-location my-softlayer
```

max_net_speed

Specifies the connection speed for the instance's network components. This setting is optional. By default, this is set to 10.

post_uri

Specifies the uri location of the script to be downloaded and run after the instance is provisioned.

Example: .. code-block:: yaml

```
```

public_vlan

If it is necessary for an instance to be created within a specific frontend VLAN, the ID for that VLAN can be specified in either the provider or profile configuration.

This ID can be queried using the list_vlans function, as described below. This setting is optional.

private_vlan

If it is necessary for an instance to be created within a specific backend VLAN, the ID for that VLAN can be specified in either the provider or profile configuration.

This ID can be queried using the list_vlans function, as described below. This setting is optional.
private_network

If a server is to only be used internally, meaning it does not have a public VLAN associated with it, this value would be set to True. This setting is optional. The default is False.

private_ssh

Whether to run the deploy script on the server using the public IP address or the private IP address. If set to True, Salt Cloud will attempt to SSH into the new server using the private IP address. The default is False. This setting is optional.

global_identifier

When creating an instance using a custom template, this option is set to the corresponding value obtained using the list_custom_images function. This option will not be used if an image is set, and if an image is not set, it is required.

The profile can be realized now with a salt command:

```
# salt-cloud -p base_softlayerUbuntu myserver
```

Using the above configuration, this will create myserver.example.com.

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```
# salt 'myserver.example.com' test.ping
```

Cloud Profiles

Set up an initial profile at /etc/salt/cloud.profiles:

```

base_softlayer_hw_centos:
  provider: my-softlayer-hw
  # CentOS 6.0 - Minimal Install (64 bit)
  image: 13963
  # 2 x 2.0 GHz Core Bare Metal Instance - 2 GB Ram
  size: 1921
  # 500GB SATA II
  hdd: 1267
  # San Jose 01
  location: 168642
  domain: example.com
  # Optional
  vlan: 396
  port_speed: 273
  bandwidth: 248
```

Most of the above items are required; optional items are specified below.

image

Images to build an instance can be found using the --list-images option:
# salt-cloud --list-images my-softlayer-hw

A list of id’s and names will be provided. The `name will describe the operating system and architecture. The id will be the setting to be used in the profile.

**size**

Sizes to build an instance can be found using the `--list-sizes` option:

# salt-cloud --list-sizes my-softlayer-hw

A list of id’s and names will be provided. The `name will describe the speed and quantity of CPU cores, and the amount of memory that the hardware will contain. The id will be the setting to be used in the profile.

**hdd**

There is currently only one size of hard disk drive (HDD) that is available for hardware instances on SoftLayer:

| 1267: 500GB SATA II |

The hdd setting in the profile should be 1267. Other sizes may be added in the future.

**location**

Locations to build an instance can be found using the `--list-images` option:

# salt-cloud --list-locations my-softlayer-hw

A list of IDs and names will be provided. The location will describe the location in human terms. The id will be the setting to be used in the profile.

**domain**

The domain name that will be used in the FQDN (Fully Qualified Domain Name) for this instance. The domain setting will be used in conjunction with the instance name to form the FQDN.

**vlan**

If it is necessary for an instance to be created within a specific VLAN, the ID for that VLAN can be specified in either the provider or profile configuration.

This ID can be queried using the list_vlans function, as described below.

**port_speed**

Specifies the speed for the instance’s network port. This setting refers to an ID within the SoftLayer API, which sets the port speed. This setting is optional. The default is 273, or, 100 Mbps Public & Private Networks. The following settings are available:
• 273: 100 Mbps Public & Private Networks
• 274: 1 Gbps Public & Private Networks
• 21509: 10 Mbps Dual Public & Private Networks (up to 20 Mbps)
• 21513: 100 Mbps Dual Public & Private Networks (up to 200 Mbps)
• 2314: 1 Gbps Dual Public & Private Networks (up to 2 Gbps)
• 272: 10 Mbps Public & Private Networks

**bandwidth**

Specifies the network bandwidth available for the instance. This setting refers to an ID within the SoftLayer API, which sets the bandwidth. This setting is optional. The default is 248, or, 5000 GB Bandwidth. The following settings are available:

- 248: 5000 GB Bandwidth
- 129: 6000 GB Bandwidth
- 130: 8000 GB Bandwidth
- 131: 10000 GB Bandwidth
- 36: Unlimited Bandwidth (10 Mbps Uplink)
- 125: Unlimited Bandwidth (100 Mbps Uplink)

**Actions**

The following actions are currently supported by the SoftLayer Salt Cloud driver.

**show_instance**

This action is a thin wrapper around `--full-query`, which displays details on a single instance only. In an environment with several machines, this will save a user from having to sort through all instance data, just to examine a single instance.

```bash
$ salt-cloud -a show_instance myinstance
```

**Functions**

The following functions are currently supported by the SoftLayer Salt Cloud driver.

**list_vlans**

This function lists all VLANs associated with the account, and all known data from the SoftLayer API concerning those VLANs.

```bash
$ salt-cloud -f list_vlans my-softlayer
$ salt-cloud -f list_vlans my-softlayer-hw
```

The *id* returned in this list is necessary for the *vlan* option when creating an instance.
list_custom_images

This function lists any custom templates associated with the account, that can be used to create a new instance.

```
$ salt-cloud -f list_custom_images my-softlayer
```

The `globalIdentifier` returned in this list is necessary for the `global_identifier` option when creating an image using a custom template.

Optional Products for SoftLayer HW

The softlayer_hw driver supports the ability to add optional products, which are supported by SoftLayer's API. These products each have an ID associated with them, that can be passed into Salt Cloud with the `optional_products` option:

```
softlayer_hw_test:
    provider: my-softlayer-hw
    # CentOS 6.0 - Minimal Install (64 bit)
    image: 13963
    # 2 x 2.0 GHz Core Bare Metal Instance - 2 GB Ram
    size: 1921
    # 500GB SATA II
    hdd: 1267
    # San Jose 01
    location: 168642
    domain: example.com
    optional_products:
        # MySQL for Linux
        - id: 28
        # Business Continuance Insurance
        - id: 104
```

These values can be manually obtained by looking at the source of an order page on the SoftLayer web interface. For convenience, many of these values are listed here:

Public Secondary IP Addresses

- 22: 4 Public IP Addresses
- 23: 8 Public IP Addresses

Primary IPv6 Addresses

- 17129: 1 IPv6 Address

Public Static IPv6 Addresses

- 1481: /64 Block Static Public IPv6 Addresses

OS-Specific Addon

- 17139: XenServer Advanced for XenServer 6.x

9.7. Cloud Provider Specifics
• 17141: XenServer Enterprise for XenServer 6.x
• 2334: XenServer Advanced for XenServer 5.6
• 2335: XenServer Enterprise for XenServer 5.6
• 13915: Microsoft WebMatrix
• 21276: VMware vCenter 5.1 Standard

Control Panel Software

• 121: cPanel/WHM with Fantastico and RVskin
• 20778: Parallels Plesk Panel 11 (Linux) 100 Domain w/ Power Pack
• 20786: Parallels Plesk Panel 11 (Windows) 100 Domain w/ Power Pack
• 20787: Parallels Plesk Panel 11 (Linux) Unlimited Domain w/ Power Pack
• 20792: Parallels Plesk Panel 11 (Windows) Unlimited Domain w/ Power Pack
• 2340: Parallels Plesk Panel 10 (Linux) 100 Domain w/ Power Pack
• 2339: Parallels Plesk Panel 10 (Linux) Unlimited Domain w/ Power Pack
• 13704: Parallels Plesk Panel 10 (Windows) Unlimited Domain w/ Power Pack

Database Software

• 29: MySQL 5.0 for Windows
• 28: MySQL for Linux
• 21501: Riak 1.x
• 20893: MongoDB
• 30: Microsoft SQL Server 2005 Express
• 92: Microsoft SQL Server 2005 Workgroup
• 90: Microsoft SQL Server 2005 Standard
• 94: Microsoft SQL Server 2005 Enterprise
• 1330: Microsoft SQL Server 2008 Express
• 1340: Microsoft SQL Server 2008 Web
• 1337: Microsoft SQL Server 2008 Workgroup
• 1334: Microsoft SQL Server 2008 Standard
• 1331: Microsoft SQL Server 2008 Enterprise
• 2179: Microsoft SQL Server 2008 Express R2
• 2173: Microsoft SQL Server 2008 Web R2
• 2183: Microsoft SQL Server 2008 Workgroup R2
• 2180: Microsoft SQL Server 2008 Standard R2
• 2176: Microsoft SQL Server 2008 Enterprise R2
Anti-Virus & Spyware Protection

- 594: McAfee VirusScan Anti-Virus - Windows
- 414: McAfee Total Protection - Windows

Insurance

- 104: Business Continuance Insurance

Monitoring

- 55: Host Ping
- 56: Host Ping and TCP Service Monitoring

Notification

- 57: Email and Ticket

Advanced Monitoring

- 2302: Monitoring Package - Basic
- 2303: Monitoring Package - Advanced
- 2304: Monitoring Package - Premium Application

Response

- 58: Automated Notification
- 59: Automated Reboot from Monitoring
- 60: 24x7x365 NOC Monitoring, Notification, and Response

Intrusion Detection & Protection

- 413: McAfee Host Intrusion Protection w/Reporting

Hardware & Software Firewalls

- 411: APF Software Firewall for Linux
- 894: Microsoft Windows Firewall
- 410: 10Mbps Hardware Firewall
- 409: 100Mbps Hardware Firewall
- 408: 1000Mbps Hardware Firewall
9.7.20 Getting Started with VEXXHOST

VEXXHOST is a cloud computing host which provides Canadian cloud computing services which are based in Montreal and use the libcloud OpenStack driver. VEXXHOST currently runs the Havana release of OpenStack. When provisioning new instances, they automatically get a public IP and private IP address. Therefore, you do not need to assign a floating IP to access your instance after it’s booted.

Cloud Provider Configuration

To use the openstack driver for the VEXXHOST public cloud, you will need to set up the cloud provider configuration file as in the example below:

```
my-vexxhost-config:
    # Set the location of the salt-master
    #
    minion:
        master: saltmaster.example.com

    # Configure VEXXHOST using the OpenStack plugin
    #
    identity_url: http://auth.api.thenebulacloud.com:5000/v2.0/tokens
    compute_name: nova

    # Set the compute region:
    #
    compute_region: na-yul-nhs1

    # Configure VEXXHOST authentication credentials
    #
    user: your-tenant-id
    password: your-api-key
    tenant: your-tenant-name

    # keys to allow connection to the instance launched
    #
    ssh_key_name: yourkey
    ssh_key_file: /path/to/key/yourkey.priv

    driver: openstack
```

Note: Changed in version 2015.8.0.

The provider parameter in cloud provider definitions was renamed to driver. This change was made to avoid confusion with the provider parameter that is used in cloud profile definitions. Cloud provider definitions now use driver to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use provider to refer to provider configurations that you define.

Authentication

All of the authentication fields that you need can be found by logging into your VEXXHOST customer center. Once you’ve logged in, you will need to click on “CloudConsole” and then click on “API Credentials”.
Cloud Profile Configuration

In order to get the correct image UUID and the instance type to use in the cloud profile, you can run the following command respectively:

```
# salt-cloud --list-images=vexxhost-config
# salt-cloud --list-sizes=vexxhost-config
```

Once you have that, you can go ahead and create a new cloud profile. This profile will build an Ubuntu 12.04 LTS `nb.2G` instance.

`/etc/salt/cloud.profiles.d/vh_ubuntu1204_2G.conf`:

```
vh_ubuntu1204_2G:
    provider: my-vexxhost-config
    image: 4051139f-750d-4d72-8ef0-074f2ccc7e5a
    size: nb.2G
```

Provision an instance

To create an instance based on the sample profile that we created above, you can run the following `salt-cloud` command.

```
# salt-cloud -p vh_ubuntu1204_2G vh_instance1
```

Typically, instances are provisioned in under 30 seconds on the VEXXHOST public cloud. After the instance provisions, it will be set up a minion and then return all the instance information once it’s complete.

Once the instance has been setup, you can test connectivity to it by running the following command:

```
# salt vh_instance1 test.ping
```

You can now continue to provision new instances and they will all automatically be set up as minions of the master you’ve defined in the configuration file.

9.7.21 Getting Started With VMware

New in version 2015.5.4.

**Author**: Nitin Madhok <nmadhok@clemson.edu>

The VMware cloud module allows you to manage VMware ESX, ESXi, and vCenter.

Dependencies

The vmware module for Salt Cloud requires the `pyVmomi` package, which is available at PyPI:

https://pypi.python.org/pypi/pyvmomi

This package can be installed using `pip` or `easy_install`:

```
pip install pyvmomi
easy_install pyvmomi
```
Note: Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, the machine that you are running the proxy minion process from must have either Python 2.7.9 or newer. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python version 2.6 to 2.7.8. If the version of Python running the salt-cloud command is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 for more information.

Note: pyVmomi doesn’t expose the ability to specify the locale when connecting to VMware. This causes parsing issues when connecting to an instance of VMware running under a non-English locale. Until this feature is added upstream Issue #38402 contains a workaround.

Configuration

The VMware cloud module needs the vCenter or ESX/ESXi URL, username and password to be set up in the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/vmware.conf:

```
my-vmware-config:
    driver: vmware
    user: 'DOMAIN\user'
    password: 'verybadpass'
    url: '10.20.30.40'

vcenter01:
    driver: vmware
    user: 'DOMAIN\user'
    password: 'verybadpass'
    url: 'vcenter01.domain.com'
    protocol: 'https'
    port: 443

vcenter02:
    driver: vmware
    user: 'DOMAIN\user'
    password: 'verybadpass'
    url: 'vcenter02.domain.com'
    protocol: 'http'
    port: 80

esx01:
    driver: vmware
    user: 'admin'
    password: 'verybadpass'
    url: 'esx01.domain.com'
```

Note: Optionally, `protocol` and `port` can be specified if the vCenter server is not using the defaults. Default is `protocol: https` and `port: 443`.

Note: Changed in version 2015.8.0.

The `provider` parameter in cloud provider configuration was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile configuration. Cloud provider configuration
now uses **driver** to refer to the salt-cloud driver that provides the underlying functionality to connect to a cloud provider, while cloud profile configuration continues to use **provider** to refer to the cloud provider configuration that you define.

## Profiles

Set up an initial profile at `/etc/salt/cloud.profiles` or `/etc/salt/cloud.profiles.d/vmware.conf`:

```yaml
vmware-centos6.5:
  provider: vcenter01
  clonefrom: test-vm

  ## Optional arguments
  num_cpus: 4
  memory: 8GB
  devices:
    cd:
      CD/DVD drive 1:
        device_type: datastore_iso_file
        iso_path: "[nap004-1] vmimages/tools-isoimages/linux.iso"
      CD/DVD drive 2:
        device_type: client_device
        mode: atapi
        controller: IDE 2
      CD/DVD drive 3:
        device_type: client_device
        mode: passthrough
        controller: IDE 3
  disk:
    Hard disk 1:
      size: 30
    Hard disk 2:
      size: 20
      controller: SCSI controller 2
    Hard disk 3:
      size: 5
      controller: SCSI controller 3
  network:
    Network adapter 1:
      name: 10.20.30-400-Test
      switch_type: standard
      ip: 10.20.30.123
      gateway: [10.20.30.110]
      subnet_mask: 255.255.255.128
      domain: example.com
    Network adapter 2:
      name: 10.30.40-500-Dev-DHCP
      adapter_type: e1000
      switch_type: distributed
    Network adapter 3:
      name: 10.40.50-600-Prod
      adapter_type: vmxnet3
      switch_type: distributed
      ip: 10.40.50.123
      gateway: [10.40.50.110]
      subnet_mask: 255.255.255.128
```

### 9.7. Cloud Provider Specifics
domain: example.com

scsi:
  SCSI controller 1:
    type: lsilogic
  SCSI controller 2:
    type: lsilogic_sas
    bus_sharing: virtual
  SCSI controller 3:
    type: paravirtual
    bus_sharing: physical

ide:
  IDE 2
  IDE 3

domain: example.com
dns_servers:
  - 123.127.255.240
  - 123.127.255.241
  - 123.127.255.242

resourcepool: Resources
cluster: Prod
datastore: HUGE-DATASTORE-Cluster
datacenter: DC1
host: c4212n-002.domain.com
template: False
power_on: True
extra_config:
  mem.hotadd: 'yes'
  guestinfo.foo: bar
  guestinfo.domain: foobar.com
  guestinfo.customVariable: customValue

deploy: True
customization: True
private_key: /root/.ssh/mykey.pem
ssh_username: cloud-user
password: veryVeryBadPassword

minion:
  master: 123.127.193.105

file_map:
  /path/to/local/custom/script: /path/to/remote/script
  /path/to/local/file: /path/to/remote/file
  /srv/salt/yum/epel.repo: /etc/yum.repos.d/epel.repo

hardware_version: 10
image: centos64Guest

**provider** Enter the name that was specified when the cloud provider config was created.

**clonefrom** Enter the name of the VM/template to clone from. If not specified, the VM will be created without cloning.

**num_cpus** Enter the number of vCPUS that you want the VM/template to have. If not specified, the current VM/template's vCPU count is used.
memory Enter the memory size (in MB or GB) that you want the VM/template to have. If not specified, the current VM/template's memory size is used. Example memory: 8GB or memory: 8192MB.

devices Enter the device specifications here. Currently, the following devices can be created or reconfigured:

cd Enter the CD/DVD drive specification here. If the CD/DVD drive doesn't exist, it will be created with the specified configuration. If the CD/DVD drive already exists, it will be reconfigured with the specifications. The following options can be specified per CD/DVD drive:

device_type Specify how the CD/DVD drive should be used. Currently supported types are client_device and datastore_iso_file. Default is device_type: client_device

iso_path Enter the path to the iso file present on the datastore only if device_type: datastore_iso_file. The syntax to specify this is iso_path: "[datastoreName] vmimages/tools-isoimages/linux.iso". This field is ignored if device_type: client_device

mode Enter the mode of connection only if device_type: client_device. Currently supported modes are passthrough and atapi. This field is ignored if device_type: datastore_iso_file. Default is mode: passthrough

controller Specify the IDE controller label to which this drive should be attached. This should be specified only when creating both the specified IDE controller as well as the CD/DVD drive at the same time.

disk Enter the disk specification here. If the hard disk doesn't exist, it will be created with the provided size. If the hard disk already exists, it will be expanded if the provided size is greater than the current size of the disk.

size Enter the size of disk in GB

thin_provision Specifies whether the disk should be thin provisioned or not. Default is thin_provision: False. .. versionadded:: 2016.3.0

controller Specify the SCSI controller label to which this disk should be attached. This should be specified only when creating both the specified SCSI controller as well as the hard disk at the same time.

network Enter the network adapter specification here. If the network adapter doesn't exist, a new network adapter will be created with the specified network name, type and other configuration. If the network adapter already exists, it will be reconfigured with the specifications. The following additional options can be specified per network adapter (See example above):

name Enter the network name you want the network adapter to be mapped to.

adapter_type Enter the network adapter type you want to create. Currently supported types are vmxnet, vmxnet2, vmxnet3, e1000 and e1000e. If no type is specified, by default vmxnet3 will be used.

switch_type Enter the type of switch to use. This decides whether to use a standard switch network or a distributed virtual portgroup. Currently supported types are standard for standard portgroups and distributed for distributed virtual portgroups.

ip Enter the static IP you want the network adapter to be mapped to. If the network specified is DHCP enabled, you do not have to specify this.

gateway Enter the gateway for the network as a list. If the network specified is DHCP enabled, you do not have to specify this.

subnet_mask Enter the subnet mask for the network. If the network specified is DHCP enabled, you do not have to specify this.
domain Enter the domain to be used with the network adapter. If the network specified is DHCP enabled, you do not have to specify this.

scsi Enter the SCSI controller specification here. If the SCSI controller doesn't exist, a new SCSI controller will be created of the specified type. If the SCSI controller already exists, it will be reconfigured with the specifications. The following additional options can be specified per SCSI controller:

type Enter the SCSI controller type you want to create. Currently supported types are lsilogic, lsilogic_sas and paravirtual. Type must be specified when creating a new SCSI controller.

bus_sharing Specify this if sharing of virtual disks between virtual machines is desired. The following can be specified:

virtual Virtual disks can be shared between virtual machines on the same server.

physical Virtual disks can be shared between virtual machines on any server.

no Virtual disks cannot be shared between virtual machines.

ide Enter the IDE controller specification here. If the IDE controller doesn't exist, a new IDE controller will be created. If the IDE controller already exists, no further changes to it will be made.

domain Enter the global domain name to be used for DNS. If not specified and if the VM name is a FQDN, domain is set to the domain from the VM name. Default is local.

dns_servers Enter the list of DNS servers to use in order of priority.

resourcepool Enter the name of the resourcepool to which the new virtual machine should be attached. This determines what compute resources will be available to the clone.

---

**Note:**

- For a clone operation from a virtual machine, it will use the same resourcepool as the original virtual machine unless specified.

- For a clone operation from a template to a virtual machine, specifying either this or cluster is required. If both are specified, the resourcepool value will be used.

- For a clone operation to a template, this argument is ignored.

---

cluster Enter the name of the cluster whose resource pool the new virtual machine should be attached to.

---

**Note:**

- For a clone operation from a virtual machine, it will use the same cluster’s resourcepool as the original virtual machine unless specified.

- For a clone operation from a template to a virtual machine, specifying either this or resourcepool is required. If both are specified, the resourcepool value will be used.

- For a clone operation to a template, this argument is ignored.

---

datastore Enter the name of the datastore or the datastore cluster where the virtual machine should be located on physical storage. If not specified, the current datastore is used.

---

**Note:**

- If you specify a datastore cluster name, DRS Storage recommendation is automatically applied.

- If you specify a datastore name, DRS Storage recommendation is disabled.
**folder** Enter the name of the folder that will contain the new virtual machine.

---

**Note:**
- For a clone operation from a VM/template, the new VM/template will be added to the same folder that the original VM/template belongs to unless specified.
- If both folder and datacenter are specified, the folder value will be used.

**datacenter** Enter the name of the datacenter that will contain the new virtual machine.

---

**Note:**
- For a clone operation from a VM/template, the new VM/template will be added to the same folder that the original VM/template belongs to unless specified.
- If both folder and datacenter are specified, the folder value will be used.

**host** Enter the name of the target host where the virtual machine should be registered.

If not specified:

---

**Note:**
- If resource pool is not specified, current host is used.
- If resource pool is specified, and the target pool represents a stand-alone host, the host is used.
- If resource pool is specified, and the target pool represents a DRS-enabled cluster, a host selected by DRS is used.
- If resource pool is specified and the target pool represents a cluster without DRS enabled, an InvalidArgument exception be thrown.

**template** Specifies whether the new virtual machine should be marked as a template or not. Default is `template: False`.

**power_on** Specifies whether the new virtual machine should be powered on or not. If `template: True` is set, this field is ignored. Default is `power_on: True`.

**extra_config** Specifies the additional configuration information for the virtual machine. This describes a set of modifications to the additional options. If the key is already present, it will be reset with the new value provided. Otherwise, a new option is added. Keys with empty values will be removed.

**deploy** Specifies if salt should be installed on the newly created VM. Default is `True` so salt will be installed using the bootstrap script. If `template: True` or `power_on: False` is set, this field is ignored and salt will not be installed.

**customization** Specify whether the new virtual machine should be customized or not. If `customization: False` is set, the new virtual machine will not be customized. Default is `customization: True`.

**private_key** Specify the path to the private key to use to be able to ssh to the VM.

**ssh_username** Specify the username to use in order to ssh to the VM. Default is `root`.

**password** Specify a password to use in order to ssh to the VM. If `private_key` is specified, you do not need to specify this.
**minion** Specify custom minion configuration you want the salt minion to have. A good example would be to specify the `master` as the IP/DNS name of the master.

**file_map** Specify file/files you want to copy to the VM before the bootstrap script is run and salt is installed. A good example of using this would be if you need to put custom repo files on the server in case your server will be in a private network and cannot reach external networks.

**hardware_version** Specify the virtual hardware version for the vm/template that is supported by the host.

**image** Specify the guest id of the VM. For a full list of supported values see the VMware vSphere documentation:

```
```

**Note:** For a clone operation, this argument is ignored.

---

**Cloning a VM**

Cloning VMs/templates is the easiest and the preferred way to work with VMs using the VMware driver.

**Note:** Cloning operations are unsupported on standalone ESXi hosts, a vCenter server will be required.

Example of a minimal profile:

```
my-minimal-clone:
  provider: vcenter01
  clonefrom: 'test-vm'
```

When cloning a VM, all the profile configuration parameters are optional and the configuration gets inherited from the clone.

Example to add/resize a disk:

```
my-disk-example:
  provider: vcenter01
  clonefrom: 'test-vm'

  devices:
    disk:
      Hard disk 1:
        size: 30
```

Depending on the configuration of the VM that is getting cloned, the disk in the resulting clone will differ.

**Note:**

- If the VM has no disk named `Hard disk 1` an empty disk with the specified size will be added to the clone.
- If the VM has a disk named `Hard disk 1` and the size specified is larger than the original disk, an empty disk with the specified size will be added to the clone.
- If the VM has a disk named `Hard disk 1` and the size specified is smaller than the original disk, an empty disk with the original size will be added to the clone.

Example to reconfigure the memory and number of vCPUs:
Cloning a Template

Cloning a template works similar to cloning a VM except for the fact that a resource pool or cluster must be specified additionally in the profile.

Example of a minimal profile:

```yaml
my-template-clone:
  provider: vcenter01
  clonefrom: 'test-template'
  cluster: 'Prod'
```

Cloning from a Snapshot

New in version 2016.3.5.

Cloning from a snapshot requires that one of the supported options be set in the cloud profile.

Supported options are createNewChildDiskBacking, moveChildMostDiskBacking, moveAllDiskBackingsAndAllowSharing and moveAllDiskBackingsAndDisallowSharing.

Example of a minimal profile:

```yaml
my-template-clone:
  provider: vcenter01
  clonefrom: 'salt_vm'
  snapshot:
    disk_move_type: createNewChildDiskBacking
    # these types are also supported
    # disk_move_type: moveChildMostDiskBacking
    # disk_move_type: moveAllDiskBackingsAndAllowSharing
    # disk_move_type: moveAllDiskBackingsAndDisallowSharing
```

Creating a VM

New in version 2016.3.0.

Creating a VM from scratch means that more configuration has to be specified in the profile because there is no place to inherit configuration from.

**Note:** Unlike most cloud drivers that use prepared images, creating VMs using VMware cloud driver needs an installation method that requires no human interaction. For Example: preseeded ISO, kickstart URL or network PXE boot.

Example of a minimal profile:
my-minimal-profile:
  provider: esx01
  datastore: esx01-datastore
  resourcepool: Resources
  folder: vm

Note: The example above contains the minimum required configuration needed to create a VM from scratch. The resulting VM will only have 1 VCPU, 32MB of RAM and will not have any storage or networking.

Example of a complete profile:

my-complete-example:
  provider: esx01
  datastore: esx01-datastore
  resourcepool: Resources
  folder: vm
  num_cpus: 2
  memory: 8GB
  image: debian7_64Guest

  devices:
    scsi:
      SCSI controller 0:
        type: lsilogic_sas
    ide:
      IDE 0: {}
      IDE 1: {}
    disk:
      Hard disk 0:
        controller: 'SCSI controller 0'
        size: 20
        mode: 'independent_nonpersistent'
    cd:
      CD/DVD drive 0:
        controller: 'IDE 0'
        device_type: datastore_iso_file
        iso_path: '[esx01-datastore] debian-8-with-preseed.iso'
  network:
    Network adapter 0:
      name: 'VM Network'
      switch_type: standard

Note: Depending on VMware ESX/ESXi version, an exact match for image might not be available. In such cases, the closest match to another image should be used. In the example above, a Debian 8 VM is created using the image debian7_64Guest which is for a Debian 7 guest.

Specifying disk backing mode

New in version 2016.3.5.
Disk backing mode can now be specified when cloning a VM. This option can be set in the cloud profile as shown in example below:

```yaml
my-vm:
  provider: esx01
  datastore: esx01-datastore
  resourcepool: Resources
  folder: vm

  devices:
  - disk:
      Hard disk 1:
        mode: 'independent_nonpersistent'
        size: 42
      Hard disk 2:
        mode: 'independent_nonpersistent'
```

### 9.7.22 Getting Started With vSphere

**Note:** Deprecated since version 2016.11.0: The vsphere cloud driver has been deprecated in favor of the vmware cloud driver and will be removed in Salt 2016.11.0. Please refer to Getting started with VMware instead to get started with the configuration.

VMware vSphere is a management platform for virtual infrastructure and cloud computing.

**Dependencies**

The vsphere module for Salt Cloud requires the PySphere package, which is available at PyPI:

https://pypi.python.org/pypi/pysphere

This package can be installed using pip or easy_install:

```
# pip install pysphere
# easy_install pysphere
```

**Configuration**

Set up the cloud config at /etc/salt/cloud.providers or in the /etc/salt/cloud.providers.d/ directory:

```yaml
my-vsphere-config:
  driver: vsphere
  # Set the vSphere access credentials
  user: marco
  password: polo
  # Set the URL of your vSphere server
  url: 'vsphere.example.com'
```

**Note:** Changed in version 2015.8.0.
The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

Profiles

Cloud Profiles

vSphere uses a Managed Object Reference to identify objects located in vCenter. The MOR ID’s are used when configuring a vSphere cloud profile. Use the following reference when locating the MOR’s for the cloud profile.

http://kb.vmware.com/selfservice/microsites/search.do?cmd=displayKC&docType=kc&externalId=1017126&sliceId=1&docTypeID=DT_KB_1_1&dialogID=520386078&stateId=1%200%20520388386

Set up an initial profile at `/etc/salt/cloud.profiles` or in the `/etc/salt/cloud.profiles.d` directory:

```yaml
vsphere-centos:
    provider: my-vsphere-config
    image: centos
    # Optional
    datastore: datastore-15
    resourcepool: resgroup-8
    folder: salt-cloud
    host: host-9
    template: False
```

**provider**

Enter the name that was specified when the cloud provider profile was created.

**image**

Images available to build an instance can be found using the `--list-images` option:

```bash
# salt-cloud --list-images my-vsphere-config
```

**datastore**

The MOR of the datastore where the virtual machine should be located. If not specified, the current datastore is used.

**resourcepool**

The MOR of the resourcepool to be used for the new vm. If not set, it will use the same resourcepool as the original vm.
folder

Name of the folder that will contain the new VM. If not set, the VM will be added to the folder the original VM belongs to.

host

The MOR of the host where the vm should be registered.

If not specified:

- if resourcepool is not specified, the current host is used.
- if resourcepool is specified, and the target pool represents a stand-alone host, the host is used.
- if resourcepool is specified, and the target pool represents a DRS-enabled cluster, a host selected by DRS is used.
- if resourcepool is specified, and the target pool represents a cluster without DRS enabled, an InvalidArgument exception will be thrown.

template

Specifies whether or not the new virtual machine should be marked as a template. Default is False.

9.8 Miscellaneous Options

9.8.1 Miscellaneous Salt Cloud Options

This page describes various miscellaneous options available in Salt Cloud

Deploy Script Arguments

Custom deploy scripts are unlikely to need custom arguments to be passed to them, but salt-bootstrap has been extended quite a bit, and this may be necessary. script_args can be specified in either the profile or the map file, to pass arguments to the deploy script:

```python
ec2-amazon:
    provider: my-ec2-config
    image: ami-1624987f
    size: t1.micro
    ssh_username: ec2-user
    script: bootstrap-salt
    script_args: -c /tmp/
```

This has also been tested to work with pipes, if needed:

```python
script_args: | head
```
Selecting the File Transport

By default, Salt Cloud uses SFTP to transfer files to Linux hosts. However, if SFTP is not available, or specific SCP functionality is needed, Salt Cloud can be configured to use SCP instead.

```yaml
file_transport: sftp
file_transport: scp
```

Sync After Install

Salt allows users to create custom modules, grains, and states which can be synchronised to minions to extend Salt with further functionality.

This option will inform Salt Cloud to synchronise your custom modules, grains, states or all these to the minion just after it has been created. For this to happen, the following line needs to be added to the main cloud configuration file:

```yaml
sync_after_install: all
```

The available options for this setting are:

```yaml
modules
grains
states
all
```

Setting Up New Salt Masters

It has become increasingly common for users to set up multi-hierarchal infrastructures using Salt Cloud. This sometimes involves setting up an instance to be a master in addition to a minion. With that in mind, you can now lay down master configuration on a machine by specifying master options in the profile or map file.

```yaml
make_master: True
```

This will cause Salt Cloud to generate master keys for the instance, and tell salt-bootstrap to install the salt-master package, in addition to the salt-minion package.

The default master configuration is usually appropriate for most users, and will not be changed unless specific master configuration has been added to the profile or map:

```yaml
master:
  user: root
  interface: 0.0.0.0
```

Setting Up a Salt Syndic with Salt Cloud

In addition to setting up new Salt Masters, syndic’s can also be provisioned using Salt Cloud. In order to set up a Salt Syndic via Salt Cloud, a Salt Master needs to be installed on the new machine and a master configuration file needs to be set up using the `make_master` setting. This setting can be defined either in a profile config file or in a map file:

```yaml
make_master: True
```
To install the Salt Syndic, the only other specification that needs to be configured is the `syndic_master` key to specify the location of the master that the syndic will be reporting to. This modification needs to be placed in the `master` setting, which can be configured either in the profile, provider, or `/etc/salt/cloud` config file:

```yaml
master:
  syndic_master: 123.456.789  # may be either an IP address or a hostname
```

Many other Salt Syndic configuration settings and specifications can be passed through to the new syndic machine via the `master` configuration setting. See the Salt Syndic documentation for more information.

**SSH Port**

By default ssh port is set to port 22. If you want to use a custom port in provider, profile, or map blocks use `ssh_port` option.

New in version 2015.5.0.

```yaml
ssh_port: 2222
```

**Delete SSH Keys**

When Salt Cloud deploys an instance, the SSH pub key for the instance is added to the `known_hosts` file for the user that ran the salt-cloud command. When an instance is deployed, a cloud host generally recycles the IP address for the instance. When Salt Cloud attempts to deploy an instance using a recycled IP address that has previously been accessed from the same machine, the old key in the `known_hosts` file will cause a conflict.

In order to mitigate this issue, Salt Cloud can be configured to remove old keys from the `known_hosts` file when destroying the node. In order to do this, the following line needs to be added to the main cloud configuration file:

```yaml
delete_sshkeys: True
```

**Keeping /tmp/ Files**

When Salt Cloud deploys an instance, it uploads temporary files to `/tmp/` for salt-bootstrap to put in place. After the script has run, they are deleted. To keep these files around (mostly for debugging purposes), the `--keep-tmp` option can be added:

```
salt-cloud -p myprofile mymachine --keep-tmp
```

For those wondering why `/tmp/` was used instead of `/root/`, this had to be done for images which require the use of `sudo`, and therefore do not allow remote root logins, even for file transfers (which makes `/root/` unavailable).
Hide Output From Minion Install

By default Salt Cloud will stream the output from the minion deploy script directly to STDOUT. Although this can been very useful, in certain cases you may wish to switch this off. The following config option is there to enable or disable this output:

| display_ssh_output: False |

Connection Timeout

There are several stages when deploying Salt where Salt Cloud needs to wait for something to happen. The VM getting it's IP address, the VM's SSH port is available, etc.

If you find that the Salt Cloud defaults are not enough and your deployment fails because Salt Cloud did not wait log enough, there are some settings you can tweak.

---

**Note**

All settings should be provided in lowercase All values should be provided in seconds

You can tweak these settings globally, per cloud provider, or event per profile definition.

**wait_for_ip_timeout**

The amount of time Salt Cloud should wait for a VM to start and get an IP back from the cloud host. Default: varies by cloud provider (between 5 and 25 minutes)

**wait_for_ip_interval**

The amount of time Salt Cloud should sleep while querying for the VM's IP. Default: varies by cloud provider (between .5 and 10 seconds)

**ssh_connect_timeout**

The amount of time Salt Cloud should wait for a successful SSH connection to the VM. Default: varies by cloud provider (between 5 and 15 minutes)

**wait_for_passwd_timeout**

The amount of time until an ssh connection can be established via password or ssh key. Default: varies by cloud provider (mostly 15 seconds)

**wait_for_passwd_maxtries**

The number of attempts to connect to the VM until we abandon. Default: 15 attempts
wait_for_fun_timeout

Some cloud drivers check for an available IP or a successful SSH connection using a function, namely, SoftLayer, and SoftLayer-HW. So, the amount of time Salt Cloud should retry such functions before failing. Default: 15 minutes.

wait_for_spot_timeout

The amount of time Salt Cloud should wait before an EC2 Spot instance is available. This setting is only available for the EC2 cloud driver. Default: 10 minutes

Salt Cloud Cache

Salt Cloud can maintain a cache of node data, for supported providers. The following options manage this functionality.

update_cachedir

On supported cloud providers, whether or not to maintain a cache of nodes returned from a --full-query. The data will be stored in msgpack format under `<SALT_CACHEDIR>/cloud/active/<DRIVER>/<PROVIDER>/<NODE_NAME>.p`. This setting can be True or False.

diff_cache_events

When the cloud cachedir is being managed, if differences are encountered between the data that is returned live from the cloud host and the data in the cache, fire events which describe the changes. This setting can be True or False.

Some of these events will contain data which describe a node. Because some of the fields returned may contain sensitive data, the cache_event_strip_fields configuration option exists to strip those fields from the event return.

```yaml
cache_event_strip_fields:
  - password
  - priv_key
```

The following are events that can be fired based on this data.

salt/cloud/minionid/cache_node_new

A new node was found on the cloud host which was not listed in the cloud cachedir. A dict describing the new node will be contained in the event.

salt/cloud/minionid/cache_node_missing

A node that was previously listed in the cloud cachedir is no longer available on the cloud host.
salt/cloud/minionid/cache_node_diff

One or more pieces of data in the cloud cachedir has changed on the cloud host. A dict containing both the old and the new data will be contained in the event.

**SSH Known Hosts**

Normally when bootstrapping a VM, salt-cloud will ignore the SSH host key. This is because it does not know what the host key is before starting (because it doesn’t exist yet). If strict host key checking is turned on without the key in the `known_hosts` file, then the host will never be available, and cannot be bootstrapped.

If a provider is able to determine the host key before trying to bootstrap it, that provider’s driver can add it to the `known_hosts` file, and then turn on strict host key checking. This can be set up in the main cloud configuration file (normally `/etc/salt/cloud`) or in the provider-specific configuration file:

```
known_hosts_file: /path/to/.ssh/known_hosts
```

If this is not set, it will default to `/dev/null`, and strict host key checking will be turned off.

It is highly recommended that this option is *not* set, unless the user has verified that the provider supports this functionality, and that the image being used is capable of providing the necessary information. At this time, only the EC2 driver supports this functionality.

**SSH Agent**

New in version 2015.5.0.

If the ssh key is not stored on the server salt-cloud is being run on, set `ssh_agent`, and salt-cloud will use the forwarded ssh-agent to authenticate.

```
ssh_agent: True
```

**File Map Upload**

New in version 2014.7.0.

The `file_map` option allows an arbitrary group of files to be uploaded to the target system before running the deploy script. This functionality requires a provider uses salt.utils.cloud.bootstrap(), which is currently limited to the ec2, gce, openstack and nova drivers.

The `file_map` can be configured globally in `/etc/salt/cloud`, or in any cloud provider or profile file. For example, to upload an extra package or a custom deploy script, a cloud profile using `file_map` might look like:

```
ubuntu14:
    provider: ec2-config
    image: ami-98a1cf0
    size: t1.micro
    ssh_username: root
    securitygroup: default
    file_map:
        /local/path/to/custom/script: /remote/path/to/use/custom/script
        /local/path/to/package: /remote/path/to/store/package
```
9.9 Troubleshooting Steps

9.9.1 Troubleshooting Salt Cloud

This page describes various steps for troubleshooting problems that may arise while using Salt Cloud.

Virtual Machines Are Created, But Do Not Respond

Are TCP ports 4505 and 4506 open on the master? This is easy to overlook on new masters. Information on how to open firewall ports on various platforms can be found here.

Generic Troubleshooting Steps

This section describes a set of instructions that are useful to a large number of situations, and are likely to solve most issues that arise.

Version Compatibility

One of the most common issues that Salt Cloud users run into is import errors. These are often caused by version compatibility issues with Salt.

Salt 0.16.x works with Salt Cloud 0.8.9 or greater.
Salt 0.17.x requires Salt Cloud 0.8.11.
Releases after 0.17.x (0.18 or greater) should not encounter issues as Salt Cloud has been merged into Salt itself.

Debug Mode

Frequently, running Salt Cloud in debug mode will reveal information about a deployment which would otherwise not be obvious:

```
salt-cloud -p myprofile myinstance -l debug
```

Keep in mind that a number of messages will appear that look at first like errors, but are in fact intended to give developers factual information to assist in debugging. A number of messages that appear will be for cloud providers that you do not have configured; in these cases, the message usually is intended to confirm that they are not configured.

Salt Bootstrap

By default, Salt Cloud uses the Salt Bootstrap script to provision instances:

This script is packaged with Salt Cloud, but may be updated without updating the Salt package:

```
salt-cloud -u
```

The Bootstrap Log

If the default deploy script was used, there should be a file in the /tmp/ directory called bootstrap-salt.log. This file contains the full output from the deployment, including any errors that may have occurred.
Keeping Temp Files

Salt Cloud uploads minion-specific files to instances once they are available via SSH, and then executes a deploy script to put them into the correct place and install Salt. The `--keep-tmp` option will instruct Salt Cloud not to remove those files when finished with them, so that the user may inspect them for problems:

```
salt-cloud -p myprofile myinstance --keep-tmp
```

By default, Salt Cloud will create a directory on the target instance called `/tmp/.saltcloud/`. This directory should be owned by the user that is to execute the deploy script, and should have permissions of `0700`.

Most cloud hosts are configured to use `root` as the default initial user for deployment, and as such, this directory and all files in it should be owned by the `root` user.

The `/tmp/.saltcloud/` directory should the following files:

- A `deploy.sh` script. This script should have permissions of `0755`.
- A `.pem` and `.pub` key named after the minion. The `.pem` file should have permissions of `0600`. Ensure that the `.pem` and `.pub` files have been properly copied to the `/etc/salt/pki/minion/` directory.
- A file called `minion`. This file should have been copied to the `/etc/salt/` directory.
- Optionally, a file called `grains`. This file, if present, should have been copied to the `/etc/salt/` directory.

Unprivileged Primary Users

Some cloud hosts, most notably EC2, are configured with a different primary user. Some common examples are `ec2-user`, `ubuntu`, `fedora`, and `bitnami`. In these cases, the `/tmp/.saltcloud/` directory and all files in it should be owned by this user.

Some cloud hosts, such as EC2, are configured to not require these users to provide a password when using the `sudo` command. Because it is more secure to require `sudo` users to provide a password, other hosts are configured that way.

If this instance is required to provide a password, it needs to be configured in Salt Cloud. A password for `sudo` to use may be added to either the provider configuration or the profile configuration:

```
sudo_password: mypassword
```

/tmp/ is Mounted as noexec

It is more secure to mount the `/tmp/` directory with a `noexec` option. This is uncommon on most cloud hosts, but very common in private environments. To see if the `/tmp/` directory is mounted this way, run the following command:

```
mount | grep tmp
```

The if the output of this command includes a line that looks like this, then the `/tmp/` directory is mounted as `noexec`:

```
tmpfs on /tmp type tmpfs (rw,noexec)
```

If this is the case, then the `deploy_command` will need to be changed in order to run the deploy script through the `sh` command, rather than trying to execute it directly. This may be specified in either the provider or the profile config:
deploy_command: sh /tmp/.saltcloud/deploy.sh

Please note that by default, Salt Cloud will place its files in a directory called /tmp/.saltcloud/. This may be also be changed in the provider or profile configuration:

tmp_dir: /tmp/.saltcloud/

If this directory is changed, then the deploy_command need to be changed in order to reflect the tmp_dir configuration.

**Executing the Deploy Script Manually**

If all of the files needed for deployment were successfully uploaded to the correct locations, and contain the correct permissions and ownerships, the deploy script may be executed manually in order to check for other issues:

cd /tmp/.saltcloud/
./deploy.sh

**9.10 Extending Salt Cloud**

**9.10.1 Writing Cloud Driver Modules**

Salt Cloud runs on a module system similar to the main Salt project. The modules inside saltcloud exist in the salt/cloud/clouds directory of the salt source.

There are two basic types of cloud modules. If a cloud host is supported by libcloud, then using it is the fastest route to getting a module written. The Apache Libcloud project is located at:

http://libcloud.apache.org/

Not every cloud host is supported by libcloud. Additionally, not every feature in a supported cloud host is necessarily supported by libcloud. In either of these cases, a module can be created which does not rely on libcloud.

**All Driver Modules**

The following functions are required by all driver modules, whether or not they are based on libcloud.

**The __virtual__() Function**

This function determines whether or not to make this cloud module available upon execution. Most often, it uses get_configured_provider() to determine if the necessary configuration has been set up. It may also check for necessary imports, to decide whether to load the module. In most cases, it will return a True or False value. If the name of the driver used does not match the filename, then that name should be returned instead of True. An example of this may be seen in the Azure module:

https://github.com/saltstack/salt/tree/develop/salt/cloud/clouds/msazure.py
The get_configured_provider() Function

This function uses `config.is_provider_configured()` to determine whether all required information for this driver has been configured. The last value in the list of required settings should be followed by a comma.

Libcloud Based Modules

Writing a cloud module based on libcloud has two major advantages. First of all, much of the work has already been done by the libcloud project. Second, most of the functions necessary to Salt have already been added to the Salt Cloud project.

The create() Function

The most important function that does need to be manually written is the `create()` function. This is what is used to request a virtual machine to be created by the cloud host, wait for it to become available, and then (optionally) log in and install Salt on it.

A good example to follow for writing a cloud driver module based on libcloud is the module provided for Linode: https://github.com/saltstack/salt/tree/develop/salt/cloud/clouds/linode.py

The basic flow of a `create()` function is as follows:

- Send a request to the cloud host to create a virtual machine.
- Wait for the virtual machine to become available.
- Generate kwargs to be used to deploy Salt.
- Log into the virtual machine and deploy Salt.
- Return a data structure that describes the newly-created virtual machine.

At various points throughout this function, events may be fired on the Salt event bus. Four of these events, which are described below, are required. Other events may be added by the user, where appropriate.

When the `create()` function is called, it is passed a data structure called `vm_`. This dict contains a composite of information describing the virtual machine to be created. A dict called `__opts__` is also provided by Salt, which contains the options used to run Salt Cloud, as well as a set of configuration and environment variables.

The first thing the `create()` function must do is fire an event stating that it has started the create process. This event is tagged `salt/cloud/<vm name>/creating`. The payload contains the names of the VM, profile, and provider.

A set of kwargs is then usually created, to describe the parameters required by the cloud host to request the virtual machine.

An event is then fired to state that a virtual machine is about to be requested. It is tagged as `salt/cloud/<vm name>/requesting`. The payload contains most or all of the parameters that will be sent to the cloud host. Any private information (such as passwords) should not be sent in the event.

After a request is made, a set of deploy kwargs will be generated. These will be used to install Salt on the target machine. Windows options are supported at this point, and should be generated, even if the cloud host does not currently support Windows. This will save time in the future if the host does eventually decide to support Windows.

An event is then fired to state that the deploy process is about to begin. This event is tagged `salt/cloud/<vm name>/deploying`. The payload for the event will contain a set of deploy kwargs, useful for debugging purposes. Any private data, including passwords and keys (including public keys) should be stripped from the deploy kwargs before the event is fired.
If any Windows options have been passed in, the `salt.utils.cloud.deploy_windows()` function will be called. Otherwise, it will be assumed that the target is a Linux or Unix machine, and the `salt.utils.cloud.deploy_script()` will be called.

Both of these functions will wait for the target machine to become available, then the necessary port to log in, then a successful login that can be used to install Salt. Minion configuration and keys will then be uploaded to a temporary directory on the target by the appropriate function. On a Windows target, the Windows Minion Installer will be run in silent mode. On a Linux/Unix target, a deploy script (`bootstrap-salt.sh`, by default) will be run, which will auto-detect the operating system, and install Salt using its native package manager. These do not need to be handled by the developer in the cloud module.

The `salt.utils.cloud.validate_windows_cred()` function has been extended to take the number of retries and retry_delay parameters in case a specific cloud host has a delay between providing the Windows credentials and the credentials being available for use. In their `create()` function, or as a sub-function called during the creation process, developers should use the `win_deploy_auth_retries` and `win_deploy_auth_retry_delay` parameters from the provider configuration to allow the end-user the ability to customize the number of tries and delay between tries for their particular host.

After the appropriate deploy function completes, a final event is fired which describes the virtual machine that has just been created. This event is tagged `salt/cloud/<vm name>/created`. The payload contains the names of the VM, profile, and provider.

Finally, a dict (queried from the provider) which describes the new virtual machine is returned to the user. Because this data is not fired on the event bus it can, and should, return any passwords that were returned by the cloud host. In some cases (for example, Rackspace), this is the only time that the password can be queried by the user; post-creation queries may not contain password information (depending upon the host).

### The `libcloudfuncs` Functions

A number of other functions are required for all cloud hosts. However, with libcloud-based modules, these are all provided for free by the `libcloudfuncs` library. The following two lines set up the imports:

```python
from salt.cloud.libcloudfuncs import *  # pylint: disable=W0614,W0401
from salt.utils import namespaced_function
```

And then a series of declarations will make the necessary functions available within the cloud module.

```python
get_size = namespaced_function(get_size, globals())
ge_open = namespaced_function(get_open, globals())
avail_locations = namespaced_function(avail_locations, globals())
avail_images = namespaced_function(avail_images, globals())
avail_sizes = namespaced_function(avail_sizes, globals())
script = namespaced_function(script, globals())
destroy = namespaced_function(destroy, globals())
list_nodes = namespaced_function(list_nodes, globals())
list_nodes_full = namespaced_function(list_nodes_full, globals())
list_nodes_select = namespaced_function(list_nodes_select, globals())
show_instance = namespaced_function(show_instance, globals())
```

If necessary, these functions may be replaced by removing the appropriate declaration line, and then adding the function as normal.

These functions are required for all cloud modules, and are described in detail in the next section.
Non-Libcloud Based Modules

In some cases, using libcloud is not an option. This may be because libcloud has not yet included the necessary driver itself, or it may be that the driver that is included with libcloud does not contain all of the necessary features required by the developer. When this is the case, some or all of the functions in libcloudfuncs may be replaced. If they are all replaced, the libcloud imports should be absent from the Salt Cloud module.

A good example of a non-libcloud driver is the DigitalOcean driver:

https://github.com/saltstack/salt/tree/develop/salt/cloud/clouds/digital_ocean.py

The create() Function

The create() function must be created as described in the libcloud-based module documentation.

The get_size() Function

This function is only necessary for libcloud-based modules, and does not need to exist otherwise.

The get_image() Function

This function is only necessary for libcloud-based modules, and does not need to exist otherwise.

The avail_locations() Function

This function returns a list of locations available, if the cloud host uses multiple data centers. It is not necessary if the cloud host uses only one data center. It is normally called using the --list-locations option.

```
salt-cloud --list-locations my-cloud-provider
```

The avail_images() Function

This function returns a list of images available for this cloud provider. There are not currently any known cloud providers that do not provide this functionality, though they may refer to images by a different name (for example, `templates`). It is normally called using the --list-images option.

```
salt-cloud --list-images my-cloud-provider
```

The avail_sizes() Function

This function returns a list of sizes available for this cloud provider. Generally, this refers to a combination of RAM, CPU, and/or disk space. This functionality may not be present on some cloud providers. For example, the Parallels module breaks down RAM, CPU, and disk space into separate options, whereas in other providers, these options are baked into the image. It is normally called using the --list-sizes option.

```
salt-cloud --list-sizes my-cloud-provider
```
The `script()` Function

This function builds the deploy script to be used on the remote machine. It is likely to be moved into the `salt.utils.cloud` library in the near future, as it is very generic and can usually be copied wholesale from another module. An excellent example is in the Azure driver.

The `destroy()` Function

This function irreversibly destroys a virtual machine on the cloud provider. Before doing so, it should fire an event on the Salt event bus. The tag for this event is `salt/cloud/<vm name>/destroying`. Once the virtual machine has been destroyed, another event is fired. The tag for that event is `salt/cloud/<vm name>/destroyed`.

This function is normally called with the `-d` options:

```
   salt-cloud -d myinstance
```

The `list_nodes()` Function

This function returns a list of nodes available on this cloud provider, using the following fields:

- id (str)
- image (str)
- size (str)
- state (str)
- private_ips (list)
- public_ips (list)

No other fields should be returned in this function, and all of these fields should be returned, even if empty. The `private_ips` and `public_ips` fields should always be of a list type, even if empty, and the other fields should always be of a str type. This function is normally called with the `-Q` option:

```
   salt-cloud -Q
```

The `list_nodes_full()` Function

All information available about all nodes should be returned in this function. The fields in the `list_nodes()` function should also be returned, even if they would not normally be provided by the cloud provider. This is because some functions both within Salt and 3rd party will break if an expected field is not present. This function is normally called with the `-F` option:

```
   salt-cloud -F
```

The `list_nodes_select()` Function

This function returns only the fields specified in the `query.selection` option in `/etc/salt/cloud`. Because this function is so generic, all of the heavy lifting has been moved into the `salt.utils.cloud` library.

A function to call `list_nodes_select()` still needs to be present. In general, the following code can be used as-is:
def list_nodes_select(call=None):
    '''
    Return a list of the VMs that are on the provider, with select fields
    '''
    return salt.utils.cloud.list_nodes_select(
        list_nodes_full('function'), __opts__['query.selection'], call,
    )

However, depending on the cloud provider, additional variables may be required. For instance, some modules use a conn object, or may need to pass other options into list_nodes_full(). In this case, be sure to update the function appropriately:

def list_nodes_select(conn=None, call=None):
    '''
    Return a list of the VMs that are on the provider, with select fields
    '''
    if not conn:
        conn = get_conn()  # pylint: disable=E0602
    return salt.utils.cloud.list_nodes_select(
        list_nodes_full(conn, 'function'),
        __opts__['query.selection'],
        call,
    )

This function is normally called with the -S option:
salt-cloud -S

The show_instance() Function

This function is used to display all of the information about a single node that is available from the cloud provider. The simplest way to provide this is usually to call list_nodes_full(), and return just the data for the requested node. It is normally called as an action:
salt-cloud -a show_instance myinstance

Actions and Functions

Extra functionality may be added to a cloud provider in the form of an --action or a --function. Actions are performed against a cloud instance/virtual machine, and functions are performed against a cloud provider.

Actions

Actions are calls that are performed against a specific instance or virtual machine. The show_instance action should be available in all cloud modules. Actions are normally called with the -a option:
salt-cloud -a show_instance myinstance

Actions must accept a name as a first argument, may optionally support any number of kwargs as appropriate, and must accept an argument of call, with a default of None.
Before performing any other work, an action should normally verify that it has been called correctly. It may then perform the desired feature, and return useful information to the user. A basic action looks like:

```python
def show_instance(name, call=None):
    
    # Show the details from EC2 concerning an AMI
    
    if call != 'action':
        raise SaltCloudSystemExit(
            'The show_instance action must be called with -a or --action.'
        
    
    return _get_node(name)
```

Please note that generic kwargs, if used, are passed through to actions as `kwargs` and not `**kwargs`. An example of this is seen in the Functions section.

### Functions

Functions are called that are performed against a specific cloud provider. An optional function that is often useful is `show_image`, which describes an image in detail. Functions are normally called with the `-f` option:

```bash
call-cloud -f show_image my-cloud-provider image='Ubuntu 13.10 64-bit'
```

A function may accept any number of kwargs as appropriate, and must accept an argument of `call` with a default of `None`.

Before performing any other work, a function should normally verify that it has been called correctly. It may then perform the desired feature, and return useful information to the user. A basic function looks like:

```python
def show_image(kwargs, call=None):
    
    # Show the details from EC2 concerning an AMI
    
    if call != 'function':
        raise SaltCloudSystemExit(
            'The show_image action must be called with -f or --function.'
        
    
    params = {
        'ImageId.1': kwargs['image'],
        'Action': 'DescribeImages'
    
    result = query(params)
    log.info(result)
    
    return result
```

Take note that generic kwargs are passed through to functions as `kwargs` and not `**kwargs`.

### 9.10.2 Cloud deployment scripts

Salt Cloud works primarily by executing a script on the virtual machines as soon as they become available. The script that is executed is referenced in the cloud profile as the `script`. In older versions, this was the `os` argument. This was changed in 0.8.2.

A number of legacy scripts exist in the deploy directory in the salt-cloud source tree. The preferred method is currently to use the salt-bootstrap script. A stable version is included with each release tarball starting with 0.8.4. The most
updated version can be found at:

https://github.com/saltstack/salt-bootstrap

Note that, somewhat counter-intuitively, this script is referenced as bootstrap-salt in the configuration.

You can specify a deploy script in the cloud configuration file (/etc/salt/cloud by default):

```
script: bootstrap-salt
```

Or in a provider:

```
my-provider:
    # snip...
    script: bootstrap-salt
```

Or in a profile:

```
my-profile:
    provider: my-provider
    # snip...
    script: bootstrap-salt
```

If you do not specify a script argument in your cloud configuration file, provider configuration or profile configuration, the "bootstrap-salt" script will be used by default.

Other Generic Deploy Scripts

If you want to be assured of always using the latest Salt Bootstrap script, there are a few generic templates available in the deploy directory of your saltcloud source tree:

```
curl-bootstrap
curl-bootstrap-git
python-bootstrap
wget-bootstrap
wget-bootstrap-git
```

These are example scripts which were designed to be customized, adapted, and refit to meet your needs. One important use of them is to pass options to the salt-bootstrap script, such as updating to specific git tags.

Custom Deploy Scripts

If the Salt Bootstrap script does not meet your needs, you may write your own. The script should be written in shell and is a Jinja template. Deploy scripts need to execute a number of functions to do a complete salt setup. These functions include:

1. Install the salt minion. If this can be done via system packages this method is HIGHLY preferred.

2. Add the salt minion keys before the minion is started for the first time. The minion keys are available as strings that can be copied into place in the Jinja template under the dict named ``vm``.

3. Start the salt-minion daemon and enable it at startup time.

4. Set up the minion configuration file from the ``minion`` data available in the Jinja template.

A good, well commented example of this process is the Fedora deployment script:

https://github.com/saltstack/salt-cloud/blob/master/saltcloud/deploy/Fedora.sh
A number of legacy deploy scripts are included with the release tarball. None of them are as functional or complete as Salt Bootstrap, and are still included for academic purposes.

Custom deploy scripts are picked up from /etc/salt/cloud.deploy.d by default, but you can change the location of deploy scripts with the cloud configuration deploy_scripts_search_path. Additionally, if your deploy script has the extension .sh, you can leave out the extension in your configuration.

For example, if your custom deploy script is located in /etc/salt/cloud.deploy.d/my_deploy.sh, you could specify it in a cloud profile like this:

```
my-profile:
    provider: my-provider
    # snip...
    script: my_deploy
```

You're also free to use the full path to the script if you like. Using full paths, your script doesn't have to live inside /etc/salt/cloud.deploy.d or whatever you've configured with deploy_scripts_search_path.

### Post-Deploy Commands

Once a minion has been deployed, it has the option to run a salt command. Normally, this would be the state.apply, which would finish provisioning the VM. Another common option (for testing) is to use test.ping. This is configured in the main cloud config file:

```
start_action: state.apply
```

This is currently considered to be experimental functionality, and may not work well with all cloud hosts. If you experience problems with Salt Cloud hanging after Salt is deployed, consider using Startup States instead:

http://docs.saltstack.com/ref/states/startup.html

### Skipping the Deploy Script

For whatever reason, you may want to skip the deploy script altogether. This results in a VM being spun up much faster, with absolutely no configuration. This can be set from the command line:

```
salt-cloud --no-deploy -p micro_aws my_instance
```

Or it can be set from the main cloud config file:

```
deploy: False
```

Or it can be set from the provider's configuration:

```
RACKSPACE.user: example_user
RACKSPACE.apikey: 123984bjjas87034
RACKSPACE.deploy: False
```

Or even on the VM's profile settings:

```
ubuntu_aws:
    provider: my-ec2-config
    image: ami-7e2da54e
    size: t1.micro
    deploy: False
```
The default for deploy is True.
In the profile, you may also set the script option to None:

```
script: None
```

This is the slowest option, since it still uploads the None deploy script and executes it.

### Updating Salt Bootstrap

Salt Bootstrap can be updated automatically with `salt-cloud`:

```
salt-cloud -u
salt-cloud --update-bootstrap
```

Bear in mind that this updates to the latest stable version from:

To update Salt Bootstrap script to the develop version, run the following command on the Salt minion host with salt-cloud installed:

```
salt-call config.gather_bootstrap_script 'https://bootstrap.saltstack.com/develop/bootstrap-salt.sh'
```

Or just download the file manually:

```
curl -L 'https://bootstrap.saltstack.com/develop' > /etc/salt/cloud.deploy.d/bootstrap-
```

### Keeping /tmp/ Files

When Salt Cloud deploys an instance, it uploads temporary files to /tmp/ for salt-bootstrap to put in place. After the script has run, they are deleted. To keep these files around (mostly for debugging purposes), the --keep-tmp option can be added:

```
salt-cloud -p myprofile mymachine --keep-tmp
```

For those wondering why /tmp/ was used instead of /root/, this had to be done for images which require the use of sudo, and therefore do not allow remote root logins, even for file transfers (which makes /root/ unavailable).

### Deploy Script Arguments

Custom deploy scripts are unlikely to need custom arguments to be passed to them, but salt-bootstrap has been extended quite a bit, and this may be necessary. `script_args` can be specified in either the profile or the map file, to pass arguments to the deploy script:

```
aws-amazon:
    provider: my-ec2-config
    image: ami-1624987f
    size: t1.micro
    ssh_username: ec2-user
    script: bootstrap-salt
    script_args: -c /tmp/
```
This has also been tested to work with pipes, if needed:

```
script_args: | head
```

## 9.11 Using Salt Cloud from Salt

### 9.11.1 Using the Salt Modules for Cloud

In addition to the `salt-cloud` command, Salt Cloud can be called from Salt, in a variety of different ways. Most users will be interested in either the execution module or the state module, but it is also possible to call Salt Cloud as a runner.

Because the actual work will be performed on a remote minion, the normal Salt Cloud configuration must exist on any target minion that needs to execute a Salt Cloud command. Because Salt Cloud now supports breaking out configuration into individual files, the configuration is easily managed using Salt’s own `file.managed` state function. For example, the following directories allow this configuration to be managed easily:

```
/etc/salt/cloud.providers.d/
/etc/salt/cloud.profiles.d/
```

### Minion Keys

Keep in mind that when creating minions, Salt Cloud will create public and private minion keys, upload them to the minion, and place the public key on the machine that created the minion. It will not attempt to place any public minion keys on the master, unless the minion which was used to create the instance is also the Salt Master. This is because granting arbitrary minions access to modify keys on the master is a serious security risk, and must be avoided.

### Execution Module

The `cloud` module is available to use from the command line. At the moment, almost every standard Salt Cloud feature is available to use. The following commands are available:

**list_images**

This command is designed to show images that are available to be used to create an instance using Salt Cloud. In general they are used in the creation of profiles, but may also be used to create an instance directly (see below). Listing images requires a provider to be configured, and specified:

```
salt myminion cloud.list_images my-cloud-provider
```

**list_sizes**

This command is designed to show sizes that are available to be used to create an instance using Salt Cloud. In general they are used in the creation of profiles, but may also be used to create an instance directly (see below). This command is not available for all cloud providers; see the provider-specific documentation for details. Listing sizes requires a provider to be configured, and specified:
list_locations

This command is designed to show locations that are available to be used to create an instance using Salt Cloud. In general they are used in the creation of profiles, but may also be used to create an instance directly (see below). This command is not available for all cloud providers; see the provider-specific documentation for details. Listing locations requires a provider to be configured, and specified:

```
salt myminion cloud.list_locations my-cloud-provider
```

query

This command is used to query all configured cloud providers, and display all instances associated with those accounts. By default, it will run a standard query, returning the following fields:

- **id** The name or ID of the instance, as used by the cloud provider.
- **image** The disk image that was used to create this instance.
- **private_ips** Any public IP addresses currently assigned to this instance.
- **public_ips** Any private IP addresses currently assigned to this instance.
- **size** The size of the instance; can refer to RAM, CPU(s), disk space, etc., depending on the cloud provider.
- **state** The running state of the instance; for example, running, stopped, pending, etc. This state is dependent upon the provider.

This command may also be used to perform a full query or a select query, as described below. The following usages are available:

```
salt myminion cloud.query
salt myminion cloud.query list_nodes
salt myminion cloud.query list_nodes_full
```

full_query

This command behaves like the query command, but lists all information concerning each instance as provided by the cloud provider, in addition to the fields returned by the query command.

```
salt myminion cloud.full_query
```

select_query

This command behaves like the query command, but only returned select fields as defined in the `/etc/salt/cloud` configuration file. A sample configuration for this section of the file might look like:

```
query.selection:
  - id
  - key_name
```
This configuration would only return the `id` and `key_name` fields, for those cloud providers that support those two fields. This would be called using the following command:

```
salt myminion cloud.select_query
```

### profile

This command is used to create an instance using a profile that is configured on the target minion. Please note that the profile must be configured before this command can be used with it.

```
salt myminion cloud.profile ec2-centos64-x64 my-new-instance
```

Please note that the execution module does not run in parallel mode. Using multiple minions to create instances can effectively perform parallel instance creation.

### create

This command is similar to the `profile` command, in that it is used to create a new instance. However, it does not require a profile to be pre-configured. Instead, all of the options that are normally configured in a profile are passed directly to Salt Cloud to create the instance:

```
salt myminion cloud.create my-ec2-config my-new-instance
   image=ami-1624987f size='t1.micro' ssh_username=ec2-user
   securitygroup=default delvol_on_destroy=True
```

Please note that the execution module does not run in parallel mode. Using multiple minions to create instances can effectively perform parallel instance creation.

### destroy

This command is used to destroy an instance or instances. This command will search all configured providers and remove any instance(s) which matches the name(s) passed in here. The results of this command are non-reversible and should be used with caution.

```
salt myminion cloud.destroy myinstance
salt myminion cloud.destroy myinstance1,myinstance2
```

### action

This command implements both the `action` and the `function` commands used in the standard `salt-cloud` command. If one of the standard `action` commands is used, an instance name must be provided. If one of the standard `function` commands is used, a provider configuration must be named.

```
salt myminion cloud.action start instance=myinstance
salt myminion cloud.action show_image provider=my-ec2-config
   image=ami-1624987f
```

The actions available are largely dependent upon the module for the specific cloud provider. The following actions are available for all cloud providers:

- **list_nodes** This is a direct call to the `query` function as described above, but is only performed against a single cloud provider. A provider configuration must be included.
**list_nodes_select** This is a direct call to the `full_query` function as described above, but is only performed against a single cloud provider. A provider configuration must be included.

**list_nodes_select** This is a direct call to the `select_query` function as described above, but is only performed against a single cloud provider. A provider configuration must be included.

**show_instance** This is a thin wrapper around `list_nodes`, which returns the full information about a single instance. An instance name must be provided.

### State Module

A subset of the execution module is available through the `cloud` state module. Not all functions are currently included, because there is currently insufficient code for them to perform statefully. For example, a command to create an instance may be issued with a series of options, but those options cannot currently be statefully managed. Additional states to manage these options will be released at a later time.

**cloud.present**

This state will ensure that an instance is present inside a particular cloud provider. Any option that is normally specified in the `cloud.create` execution module and function may be declared here, but only the actual presence of the instance will be managed statefully.

```
my-instance-name:
  cloud.present:
    - provider: my-ec2-config
    - image: ami-1624987f
    - size: 't1.micro'
    - ssh_username: ec2-user
    - securitygroup: default
    - delvol_on_destroy: True
```

**cloud.profile**

This state will ensure that an instance is present inside a particular cloud provider. This function calls the `cloud.profile` execution module and function, but as with `cloud.present`, only the actual presence of the instance will be managed statefully.

```
my-instance-name:
  cloud.profile:
    - profile: ec2-centos64-x64
```

**cloud.absent**

This state will ensure that an instance (identified by name) does not exist in any of the cloud providers configured on the target minion. Please note that this state is *non-reversible* and may be considered especially destructive when issued as a cloud state.

```
my-instance-name:
  cloud.absent
```
Runner Module

The `cloud` runner module is executed on the master, and performs actions using the configuration and Salt modules on the master itself. This means that any public minion keys will also be properly accepted by the master.

Using the functions in the runner module is no different than using those in the execution module, outside of the behavior described in the above paragraph. The following functions are available inside the runner:

- `list_images`
- `list_sizes`
- `list_locations`
- `query`
- `full_query`
- `select_query`
- `profile`
- `destroy`
- `action`

Outside of the standard usage of `salt-run` itself, commands are executed as usual:

```
salt-run cloud.profile ec2-centos64-x86_64 my-instance-name
```

CloudClient

The execution, state, and runner modules ultimately all use the CloudClient library that ships with Salt. To use the CloudClient library locally (either on the master or a minion), create a client object and issue a command against it:

```
import salt.cloud
import pprint
client = salt.cloud.CloudClient('/etc/salt/cloud')
nodes = client.query()
pprint.pprint(nodes)
```

Reactor

Examples of using the reactor with Salt Cloud are available in the `ec2-autoscale-reactor` and `salt-cloud-reactor` formulas.

9.12 Feature Comparison

9.12.1 Feature Matrix

A number of features are available in most cloud hosts, but not all are available everywhere. This may be because the feature isn't supported by the cloud host itself, or it may only be that the feature has not yet been added to Salt Cloud. In a handful of cases, it is because the feature does not make sense for a particular cloud provider (Saltify, for instance).

This matrix shows which features are available in which cloud hosts, as far as Salt Cloud is concerned. This is not a comprehensive list of all features available in all cloud hosts, and should not be used to make business decisions.
concerning choosing a cloud host. In most cases, adding support for a feature to Salt Cloud requires only a little effort.

**Legacy Drivers**

Both AWS and Rackspace are listed as ``Legacy''. This is because those drivers have been replaced by other drivers, which are generally the preferred method for working with those hosts.

The EC2 driver should be used instead of the AWS driver, when possible. The OpenStack driver should be used instead of the Rackspace driver, unless the user is dealing with instances in ``the old cloud'' in Rackspace.

**Note for Developers**

When adding new features to a particular cloud host, please make sure to add the feature to this table. Additionally, if you notice a feature that is not properly listed here, pull requests to fix them is appreciated.

**Standard Features**

These are features that are available for almost every cloud host.

<table>

### Functions

These are features that are performed against a specific cloud provider, and require the name of the provider to be passed in. For example:

```bash
# salt-cloud -f list_images my_digitalocean
```

## 9.13 Tutorials

### 9.13.1 Salt Cloud Quickstart

Salt Cloud is built-in to Salt, and the easiest way to run Salt Cloud is directly from your Salt Master.

Note that if you installed Salt via Salt Bootstrap, it may not have automatically installed salt-cloud for you. Use your distribution's package manager to install the `salt-cloud` package from the same repo that you used to install Salt. These repos will automatically be setup by Salt Bootstrap.

If there is no salt-cloud package, install with `pip install salt-cloud`.

This quickstart walks you through the basic steps of setting up a cloud host and defining some virtual machines to create.

---

**Note:** Salt Cloud has its own process and does not rely on the Salt Master, so it can be installed on a standalone minion instead of your Salt Master.

---

### Define a Provider

The first step is to add the credentials for your cloud host. Credentials and other settings provided by the cloud host are stored in provider configuration files. Provider configurations contain the details needed to connect to a cloud host such as EC2, GCE, Rackspace, etc., and any global options that you want set on your cloud minions (such as the location of your Salt Master).
On your Salt Master, browse to `/etc/salt/cloud.providers.d/` and create a file called `<provider>.conf`, replacing `<provider>` with `ec2`, `softlayer`, and so on. The name helps you identify the contents, and is not important as long as the file ends in `.conf`.

Next, browse to the Provider specifics and add any required settings for your cloud host to this file. Here is an example for Amazon EC2:

```yaml
my-ec2:
  driver: ec2
  # Set the EC2 access credentials (see below)
  #
  id: 'HJGRYCIJLLKJYG'
  key: 'kdjgfsmg;woormgl/asrigjksjdasdfgn'
  # Make sure this key is owned by root with permissions 0400.
  #
  private_key: /etc/salt/my_test_key.pem
  keyname: my_test_key
  securitygroup: default
  # Optional: Set up the location of the Salt Master
  #
  minion:
    master: saltmaster.example.com
```

The required configuration varies between cloud hosts so make sure you read the provider specifics.

### List Cloud Provider Options

You can now query the cloud provider you configured for available locations, images, and sizes. This information is used when you set up VM profiles.

```
salt-cloud --list-locations <provider_name>   # my-ec2 in the previous example
salt-cloud --list-images <provider_name>
salt-cloud --list-sizes <provider_name>
```

Replace `<provider_name>` with the name of the provider configuration you defined.

### Create VM Profiles

On your Salt Master, browse to `/etc/salt/cloud.profiles.d/` and create a file called `<profile>.conf`, replacing `<profile>` with `ec2`, `softlayer`, and so on. The file must end in `.conf`.

You can now add any custom profiles you’d like to define to this file. Here are a few examples:

```yaml
micro_ec2:
  provider: my-ec2
  image: ami-d514f291
  size: t1.micro

medium_ec2:
  provider: my-ec2
  image: ami-d514f291
  size: m3.medium

large_ec2:
  provider: my-ec2
  image: ami-d514f291
  size: m3.large
```
Notice that the provider in our profile matches the provider name that we defined? That is how Salt Cloud knows how to connect to a cloud host to create a VM with these attributes.

**Create VMs**

VMs are created by calling `salt-cloud` with the following options:

```
salt-cloud -p <profile> <name1> <name2> ...
```

For example:

```
salt-cloud -p micro_ec2 minion1 minion2
```

**Destroy VMs**

Add a `-d` and the minion name you provided to destroy:

```
salt-cloud -d minion1 minion2
```

**Query VMs**

You can view details about the VMs you've created using `--query`:

```
salt-cloud --query
```

**Cloud Map**

Now that you know how to create and destroy individual VMs, next you should learn how to use a cloud map to create a number of VMs at once.

Cloud maps let you define a map of your infrastructure and quickly provision any number of VMs. On subsequent runs, any VMs that do not exist are created, and VMs that are already configured are left unmodified.

See [Cloud Map File](#).

### 9.13.2 Using Salt Cloud with the Event Reactor

One of the most powerful features of the Salt framework is the Event Reactor. As the Reactor was in development, Salt Cloud was regularly updated to take advantage of the Reactor upon completion. As such, various aspects of both the creation and destruction of instances with Salt Cloud fire events to the Salt Master, which can be used by the Event Reactor.

#### Event Structure

As of this writing, all events in Salt Cloud have a tag, which includes the ID of the instance being managed, and a payload which describes the task that is currently being handled. A Salt Cloud tag looks like:

```
salt/cloud/<minion_id>/<task>
```
For instance, the first event fired when creating an instance named `web1` would look like:

```
salt/cloud/web1/creating
```

Assuming this instance is using the `ec2-centos` profile, which is in turn using the `ec2-config` provider, the payload for this tag would look like:

```
{
    'name': 'web1',
    'profile': 'ec2-centos',
    'provider': 'ec2-config:ec2'
}
```

### Available Events

When an instance is created in Salt Cloud, whether by map, profile, or directly through an API, a minimum of five events are normally fired. More may be available, depending upon the cloud provider being used. Some of the common events are described below.

#### `salt/cloud/<minion_id>/creating`

This event states simply that the process to create an instance has begun. At this point in time, no actual work has begun. The payload for this event includes:

- name
- profile
- provider

#### `salt/cloud/<minion_id>/requesting`

Salt Cloud is about to make a request to the cloud provider to create an instance. At this point, all of the variables required to make the request have been gathered, and the payload of the event will reflect those variables which do not normally pose a security risk. What is returned here is dependent upon the cloud provider. Some common variables are:

- name
- image
- size
- location

#### `salt/cloud/<minion_id>/querying`

The instance has been successfully requested, but the necessary information to log into the instance (such as IP address) is not yet available. This event marks the beginning of the process to wait for this information.

The payload for this event normally only includes the `instance_id`.

#### `salt/cloud/<minion_id>/waiting_for_ssh`

The information required to log into the instance has been retrieved, but the instance is not necessarily ready to be accessed. Following this event, Salt Cloud will wait for the IP address to respond to a ping, then wait for the specified port (usually 22) to respond to a connection, and on Linux systems, for SSH to become available. Salt Cloud will attempt to issue the `date` command on the remote system, as a means to check for availability. If no `ssh_username` has been specified, a list of usernames (starting with `root`) will be attempted. If one or more usernames was configured for `ssh_username`, they will be added to the beginning of the list, in order.

The payload for this event normally only includes the `ip_address`.
salt/cloud/<minion_id>/deploying

The necessary port has been detected as available, and now Salt Cloud can log into the instance, upload any files used for deployment, and run the deploy script. Once the script has completed, Salt Cloud will log back into the instance and remove any remaining files.

A number of variables are used to deploy instances, and the majority of these will be available in the payload. Any keys, passwords or other sensitive data will be scraped from the payload. Most of the variables returned will be related to the profile or provider config, and any default values that could have been changed in the profile or provider, but weren't.

salt/cloud/<minion_id>/created

The deploy sequence has completed, and the instance is now available, Salted, and ready for use. This event is the final task for Salt Cloud, before returning instance information to the user and exiting.

The payload for this event contains little more than the initial creating event. This event is required in all cloud providers.

Configuring the Event Reactor

The Event Reactor is built into the Salt Master process, and as such is configured via the master configuration file. Normally this will be a YAML file located at /etc/salt/master. Additionally, master configuration items can be stored, in YAML format, inside the /etc/salt/master.d/ directory.

These configuration items may be stored in either location; however, they may only be stored in one location. For organizational and security purposes, it may be best to create a single configuration file, which contains only Event Reactor configuration, at /etc/salt/master.d/reactor.

The Event Reactor uses a top-level configuration item called reactor. This block contains a list of tags to be watched for, each of which also includes a list of sls files. For instance:

```
reactor:
  - 'salt/minion/*/start':
    - '/srv/reactor/custom-reactor.sls'
  - 'salt/cloud/*/created':
    - '/srv/reactor/cloud-alert.sls'
  - 'salt/cloud/*/destroyed':
    - '/srv/reactor/cloud-destroy-alert.sls'
```

The above configuration configures reactors for three different tags: one which is fired when a minion process has started and is available to receive commands, one which is fired when a cloud instance has been created, and one which is fired when a cloud instance is destroyed.

Note that each tag contains a wildcard (*) in it. For each of these tags, this will normally refer to a minion_id. This is not required of event tags, but is very common.

Reactor SLS Files

Reactor sls files should be placed in the /srv/reactor/ directory for consistency between environments, but this is not currently enforced by Salt.

Reactor sls files follow a similar format to other sls files in Salt. By default they are written in YAML and can be templated using Jinja, but since they are processed through Salt's rendering system, any available renderer (JSON, Mako, Cheetah, etc.) can be used.
As with other sls files, each stanza will start with a declaration ID, followed by the function to run, and then any arguments for that function. For example:

```bash
# /srv/reactor/cloud-alert.sls
new_instance_alert:
  cmd.pagerduty.create_event:
    - tgt: alertserver
    - kwarg:
      description: "New instance: {{ data['name'] }}"
      details: "New cloud instance created on {{ data['provider'] }}"
      service_key: 1626dead5ecafe46231e968eb1be29c4
      profile: my-pagerduty-account
```

When the Event Reactor receives an event notifying it that a new instance has been created, this sls will create a new incident in PagerDuty, using the configured PagerDuty account.

The declaration ID in this example is `new_instance_alert`. The function called is `cmd.pagerduty.create_event`. The `cmd` portion of this function specifies that an execution module and function will be called, in this case, the `pagerduty.create_event` function.

Because an execution module is specified, a target (tgt) must be specified on which to call the function. In this case, a minion called `alertserver` has been used. Any arguments passed through to the function are declared in the `kwarg` block.

**Example: Reactor-Based Highstate**

When Salt Cloud creates an instance, by default it will install the Salt Minion onto the instance, along with any specified minion configuration, and automatically accept that minion’s keys on the master. One of the configuration options that can be specified is `startup_states`, which is commonly set to `highstate`. This will tell the minion to immediately apply a `highstate`, as soon as it is able to do so.

This can present a problem with some system images on some cloud hosts. For instance, Salt Cloud can be configured to log in as either the `root` user, or a user with `sudo` access. While some hosts commonly use images that lock out remote `root` access and require a user with `sudo` privileges to log in (notably EC2, with their `ec2-user` login), most cloud hosts fall back to `root` as the default login on all images, including for operating systems (such as Ubuntu) which normally disallow remote `root` login.

For users of these operating systems, it is understandable that a `highstate` would include configuration to block remote `root` logins again. However, Salt Cloud may not have finished cleaning up its deployment files by the time the minion process has started, and kicked off a `highstate` run. Users have reported errors from Salt Cloud getting locked out while trying to clean up after itself.

The goal of a startup state may be achieved using the Event Reactor. Because a minion fires an event when it is able to receive commands, this event can effectively be used inside the reactor system instead. The following will point the reactor system to the right sls file:

```bash
reactor:
  - 'salt/cloud/*/created':
    - '/srv/reactor/startup_highstate.sls'
```

And the following sls file will start a `highstate` run on the target minion:

```bash
# /srv/reactor/startup_highstate.sls
reactor_highstate:
  cmd.state.apply:
    - tgt: {{ data['name'] }}
```
Because this event will not be fired until Salt Cloud has cleaned up after itself, the `highstate` run will not step on salt-cloud’s toes. And because every file on the minion is configurable, including `/etc/salt/minion`, the `startup_states` can still be configured for future minion restarts, if desired.
Proxy minions are a developing Salt feature that enables controlling devices that, for whatever reason, cannot run a standard salt-minion. Examples include network gear that has an API but runs a proprietary OS, devices with limited CPU or memory, or devices that could run a minion, but for security reasons, will not.

Proxy minions are not an `out of the box` feature. Because there are an infinite number of controllable devices, you will most likely have to write the interface yourself. Fortunately, this is only as difficult as the actual interface to the proxied device. Devices that have an existing Python module (PyUSB for example) would be relatively simple to interface. Code to control a device that has an HTML REST-based interface should be easy. Code to control your typical housecat would be excellent source material for a PhD thesis.

Salt proxy-minions provide the `plumbing` that allows device enumeration and discovery, control, status, remote execution, and state management.

See the Proxy Minion Walkthrough for an end-to-end demonstration of a working REST-based proxy minion.

See the Proxy Minion SSH Walkthrough for an end-to-end demonstration of a working SSH proxy minion.

See Proxyminion States to configure and run salt-proxy on a remote minion. Specify all your master side proxy (pillar) configuration and use this state to remotely configure proxies on one or more minions.

See Proxyminion Beacon to help with easy configuration and management of salt-proxy processes.

### 10.1 New in 2016.3

The deprecated config option enumerate_proxy_minions has been removed.

As mentioned in earlier documentation, the add_proxymodule_to_opts configuration variable defaults to False in this release. This means if you have proxymodules or other code looking in __opts__['proxymodule'] you will need to set this variable in your /etc/salt/proxy file, or modify your code to use the __proxy__ injected variable.

The __proxyenabled__ directive now only applies to grains and proxy modules themselves. Standard execution modules and state modules are not prevented from loading for proxy minions.

Enhancements in grains processing have made the __proxyenabled__ directive somewhat redundant in dynamic grains code. It is still required, but best practices for the __virtual__ function in grains files have changed. It is now recommended that the __virtual__ functions check to make sure they are being loaded for the correct proxitype, example below:

```python
def __virtual__():
    # Only work on proxy
```
try:
    if salt.utils.is_proxy() and \
    __opts__['proxy']['proxytype'] == 'ssh_sample':
        return __virtualname__
except KeyError:
    pass
return False

The try/except block above exists because grains are processed very early in the proxy minion startup process, sometimes earlier than the proxy key in the __opts__ dictionary is populated.

Grains are loaded so early in startup that no dunder dictionaries are present, so __proxy__, __salt__, etc. are not available. Custom grains located in /srv/salt/_grains and in the salt install grains directory can now take a single argument, proxy, that is identical to __proxy__. This enables patterns like

def get_ip(proxy):
    '''
    Ask the remote device what IP it has
    '''
    return {'ip':proxy['proxymodulename.get_ip']()}

Then the grain ip will contain the result of calling the get_ip() function in the proxymodule called proxymodulename.

Proxy modules now benefit from including a function called initialized(). This function should return True if the proxy's init() function has been successfully called. This is needed to make grains processing easier.

Finally, if there is a function called grains in the proxymodule, it will be executed on proxy-minion startup and its contents will be merged with the rest of the proxy's grains. Since older proxy-minions might have used other methods to call such a function and add its results to grains, this is config-gated by a new proxy configuration option called proxy_merge_grains_in_module. This defaults to False in this release. It will default to True in the release after next. The next release is codenamed Carbon, the following is Nitrogen.

10.2 New in 2015.8.2

BREAKING CHANGE: Adding the proxymodule variable to __opts__ is deprecated. The proxymodule variable has been moved a new globally-injected variable called __proxy__. A related configuration option called add_proxymodule_to_opts has been added and defaults to True. In the next major release, 2016.3.0, this variable will default to False.

In the meantime, proxies that functioned under 2015.8.0 and .1 should continue to work under 2015.8.2. You should rework your proxy code to use __proxy__ as soon as possible.

The rest_sample example proxy minion has been updated to use __proxy__.

This change was made because proxymodules are a LazyLoader object, but LazyLoaders cannot be serialized. __opts__ gets serialized, and so things like saltutil.sync_all and state.highstate would throw exceptions.

Support has been added to Salt's loader allowing custom proxymodules to be placed in salt://_proxy. Proxy minions that need these modules will need to be restarted to pick up any changes. A corresponding utility function, saltutil.sync_proxymodules, has been added to sync these modules to minions.

In addition, a salt.utils helper function called is_proxy() was added to make it easier to tell when the running minion is a proxy minion.
10.3 New in 2015.8

Starting with the 2015.8 release of Salt, proxy processes are no longer forked off from a controlling minion. Instead, they have their own script salt-proxy which takes mostly the same arguments that the standard Salt minion does with the addition of --proxyid. This is the id that the salt-proxy will use to identify itself to the master. Proxy configurations are still best kept in Pillar and their format has not changed.

This change allows for better process control and logging. Proxy processes can now be listed with standard process management utilities (ps from the command line). Also, a full Salt minion is no longer required (though it is still strongly recommended) on machines hosting proxies.

10.4 Getting Started

The following diagram may be helpful in understanding the structure of a Salt installation that includes proxy-minions:
The key thing to remember is the left-most section of the diagram. Salt’s nature is to have a minion connect to a master, then the master may control the minion. However, for proxy minions, the target device cannot run a minion. After the proxy minion is started and initiates its connection to the ‘dumb’ device, it connects back to the salt-master and for all intents and purposes looks like just another minion to the Salt master.

To create support for a proxied device one needs to create four things:

1. The `proxy_connection_module` (located in salt/proxy).
2. The `grains support code` (located in salt/grains).
3. Salt modules specific to the controlled device.
4. `Salt states` specific to the controlled device.
## 10.4.1 Configuration parameters

Proxy minions require no configuration parameters in `/etc/salt/master`.

Salt's Pillars system is ideally suited for configuring proxy-minions. Proxies can either be designated via a pillar file in `pillar_roots`, or through an external pillar. External pillars afford the opportunity for interfacing with a configuration management system, database, or other knowledgeable system that that may already contain all the details of proxy targets. To use static files in `pillar_roots`, pattern your files after the following examples, which are based on the diagram above:

/srv/pillar/top.sls

```
base:
    dumbdevice1:
    - dumbdevice1
    dumbdevice2:
    - dumbdevice2
    dumbdevice3:
    - dumbdevice3
    dumbdevice4:
    - dumbdevice4
    dumbdevice5:
    - dumbdevice5
    dumbdevice6:
    - dumbdevice6
    dumbdevice7:
    - dumbdevice7
```

/srv/pillar/dumbdevice1.sls

```
proxy:
    proxytype: networkswitch
    host: 172.23.23.5
    username: root
    passwd: letmein
```

/srv/pillar/dumbdevice2.sls

```
proxy:
    proxytype: networkswitch
    host: 172.23.23.6
    username: root
    passwd: letmein
```

/srv/pillar/dumbdevice3.sls

```
proxy:
    proxytype: networkswitch
    host: 172.23.23.7
    username: root
    passwd: letmein
```

/srv/pillar/dumbdevice4.sls

```
proxy:
    proxytype: i2c_lightshow
    i2c_address: 1
```

/srv/pillar/dumbdevice5.sls
Note the contents of each minioncontroller key may differ widely based on the type of device that the proxy-minion is managing.

In the above example

- dumbdevices 1, 2, and 3 are network switches that have a management interface available at a particular IP address.
- dumbdevices 4 and 5 are very low-level devices controlled over an i2c bus. In this case the devices are physically connected to machine `minioncontroller2', and are addressable on the i2c bus at their respective i2c addresses.
- dumbdevice 6 is a 433 MHz wireless transmitter, also physically connected to minioncontroller 2
- dumbdevice 7 is an SMS gateway connected to machine minioncontroller 3 via a serial port.

Because of the way pillar works, each of the salt-proxy processes that fork off the proxy minions will only see the keys specific to the proxies it will be handling.

Also, in general, proxy-minions are lightweight, so the machines that run them could conceivably control a large number of devices. To run more than one proxy from a single machine, simply start an additional proxy process with --proxyid set to the id to which you want the proxy to bind. It is possible for the proxy services to be spread across many machines if necessary, or intentionally run on machines that need to control devices because of some physical interface (e.g. i2c and serial above). Another reason to divide proxy services might be security. In more secure environments only certain machines may have a network path to certain devices.

### 10.4.2 Proxymodules

A proxy module encapsulates all the code necessary to interface with a device. Proxymodules are located inside the salt.proxy module, or can be placed in the _proxy directory in your file_roots (default is /srv/salt/_proxy).

At a minimum a proxymodule object must implement the following functions:

- **__virtual__()**: This function performs the same duty that it does for other types of Salt modules. Logic goes here to determine if the module can be loaded, checking for the presence of Python modules on which the proxy depends. Returning False will prevent the module from loading.

- **init(opts)**: Perform any initialization that the device needs. This is a good place to bring up a persistent connection to a device, or authenticate to create a persistent authorization token.

- **initialized()**: Returns True if init() was successfully called.

- **shutdown()**: Code to cleanly shut down or close a connection to a controlled device goes here. This function must exist, but can contain only the keyword pass if there is no shutdown logic required.

- **ping()**: While not required, it is highly recommended that this function also be defined in the proxymodule. The code for ping should contact the controlled device and make sure it is really available.
grains(): Rather than including grains in /srv/salt/_grains or in the standard install directories for grains, grains can be computed and returned by this function. This function will be called automatically if proxy_merge_grains_in_module is set to True in /etc/salt-proxy. This variable defaults to False in 2016.3 but will default to True in the release code-named Nitrogen.

Pre 2015.8 the proxymodule also must have an id() function. 2015.8 and following don't use this function because the proxy's id is required on the command line.

Here is an example proxymodule used to interface to a very simple REST server. Code for the server is in the salt-contrib GitHub repository

This proxymodule enables `service` enumeration, starting, stopping, restarting, and status; `package` installation, and a ping.

```python
# -*- coding: utf-8 -*-

# This is a simple proxy-minion designed to connect to and communicate with
# the bottle-based web service contained in https://github.com/saltstack/salt-contrib/
# ---tree/master/proxyminion_rest_example
#
from __future__ import absolute_import

# Import python libs
import logging
import salt.utils.http

HAS_REST_EXAMPLE = True

# This must be present or the Salt loader won't load this module
__proxyenabled__ = ['rest_sample']

# Variables are scoped to this module so we can have persistent data
# across calls to fns in here.
GRAINS_CACHE = {}
DETAILS = {}

# Want logging!
log = logging.getLogger(__file__)

# This does nothing, it's here just as an example and to provide a log
# entry when the module is loaded.
def __virtual__():
    """Only return if all the modules are available"
    ""
    log.debug('rest_sample proxy __virtual__() called...')
    return True

# Every proxy module needs an 'init', though you can
# just put DETAILS['initialized'] = True here if nothing
# else needs to be done.
def init(opts):
    log.debug('rest_sample proxy init() called...')
    DETAILS['initialized'] = True
```
# Save the REST URL
DETAILS['url'] = opts['proxy']['url']

# Make sure the REST URL ends with a '/'
if not DETAILS['url'].endswith('/ '):
    DETAILS['url'] += '/ '

def initialized():
    '''
    Since grains are loaded in many different places and some of those
    places occur before the proxy can be initialized, return whether
    our init() function has been called
    '''
    return DETAILS.get('initialized', False)

def grains():
    '''
    Get the grains from the proxied device
    '''
    if not DETAILS.get('grains_cache', {}):
        r = salt.utils.http.query(DETAILS['url']+'info', decode_type='json',
                                decode=True)
        DETAILS['grains_cache'] = r['dict']
    return DETAILS['grains_cache']

def grains_refresh():
    '''
    Refresh the grains from the proxied device
    '''
    DETAILS['grains_cache'] = None
    return grains()

def fns():
    return {'details': 'This key is here because a function in ' +
            'grains/rest_sample.py called fns() here in the proxymodule.'}

def service_start(name):
    '''
    Start a "service" on the REST server
    '''
    r = salt.utils.http.query(DETAILS['url']+'service/start/'+name, decode_type='json',
                              decode=True)
    return r['dict']

def service_stop(name):
    '''
    Stop a "service" on the REST server
    '''
    r = salt.utils.http.query(DETAILS['url']+'service/stop/'+name, decode_type='json',
                              decode=True)
    return r['dict']
def service_restart(name):
    '''
    Restart a "service" on the REST server
    '''
    r = salt.utils.http.query(DETAILS['url']+'service/restart/' + name, decode_type='json', decode=True)
    return r['dict']

def service_list():
    '''
    List "services" on the REST server
    '''
    r = salt.utils.http.query(DETAILS['url']+'service/list', decode_type='json', decode=True)
    return r['dict']

def service_status(name):
    '''
    Check if a service is running on the REST server
    '''
    r = salt.utils.http.query(DETAILS['url']+'service/status/' + name, decode_type='json', decode=True)
    return r['dict']

def package_list():
    '''
    List "packages" installed on the REST server
    '''
    r = salt.utils.http.query(DETAILS['url']+'package/list', decode_type='json', decode=True)
    return r['dict']

def package_install(name, **kwargs):
    '''
    Install a "package" on the REST server
    '''
    cmd = DETAILS['url']+'package/install/' + name
    if kwargs.get('version', False):
        cmd += '/'+kwargs['version']
    else:
        cmd += '/1.0'
    r = salt.utils.http.query(cmd, decode_type='json', decode=True)
    return r['dict']

def fix_outage():
    r = salt.utils.http.query(DETAILS['url']+'fix_outage')
    return r

def upodate(name):
    ...
Call the REST endpoint to see if the packages on the "server" are up to date.

```python
r = salt.utils.http.query(DETAILS['url']+'package/remove/'+name, decode_type='json', decode=True)
return r['dict']
```

```python
def package_remove(name):
    """
    Remove a "package" on the REST server
    """
    r = salt.utils.http.query(DETAILS['url']+'package/remove/'+name, decode_type='json', decode=True)
    return r['dict']
```

```python
def package_status(name):
    """
    Check the installation status of a package on the REST server
    """
    r = salt.utils.http.query(DETAILS['url']+'package/status/'+name, decode_type='json', decode=True)
    return r['dict']
```

```python
def ping():
    """
    Is the REST server up?
    """
    r = salt.utils.http.query(DETAILS['url']+'ping', decode_type='json', decode=True)
    try:
        return r['dict'].get('ret', False)
    except Exception:
        return False
```

```python
def shutdown(opts):
    """
    For this proxy shutdown is a no-op
    """
    log.debug('rest_sample proxy shutdown() called...')
```

Grains are data about minions. Most proxied devices will have a paltry amount of data as compared to a typical Linux server. By default, a proxy minion will have several grains taken from the host. Salt core code requires values for `kernel`, `os`, and `os_family`--all of these are forced to be `proxy` for proxy-minions.

To add others to your proxy minion for a particular device, create a file in `salt/grains` named `[proxytype]_.py` and place inside it the different functions that need to be run to collect the data you are interested in. Here's an example. Note the function below called `proxy_functions`. It demonstrates how a grains function can take a single argument, which will be set to the value of `__proxy__`. Dunder variables are not yet injected into Salt processes at the time grains are loaded, so this enables us to get a handle to the proxymodule so we can cross-call the functions therein used to communicate with the controlled device.

Note that as of 2016.3, grains values can also be calculated in a function called `grains()` in the proxymodule itself. This might be useful if a proxymodule author wants to keep all the code for the proxy interface in the same place instead of splitting it between the proxy and grains directories.
This function will only be called automatically if the configuration variable `proxy_merge_grains_in_module` is set to True in the proxy configuration file (default `/etc/salt/proxy`). This variable will default to True in the release code-named Nitrogen.

## 10.5 The `__proxyenabled__` directive

In previous versions of Salt the `__proxyenabled__` directive controlled loading of all Salt modules for proxies (e.g. grains, execution modules, state modules). From 2016.3 on, the only modules that respect `__proxyenabled__` are grains and proxy modules. These modules need to be told which proxy they work with.

`__proxyenabled__` is a list, and can contain a single `'*'` to indicate a grains module works with all proxies.

Example from `salt/grains/rest_sample.py`:

```python
# -*- coding: utf-8 -*-

'''
Generate baseline proxy minion grains
'''

from __future__ import absolute_import
import salt.utils

__proxyenabled__ = ['rest_sample']
__virtualname__ = 'rest_sample'

def __virtual__():
    try:
        if salt.utils.is_proxy() and __opts__['proxy']=['proxytype'] == 'rest_sample':
            return __virtualname__
    except KeyError:
        pass

    return False
```

## 10.5.1 Salt Proxy Minion End-to-End Example

The following is walkthrough that documents how to run a sample REST service and configure one or more proxy minions to talk to and control it.

1. Ideally, create a Python virtualenv in which to run the REST service. This is not strictly required, but without a virtualenv you will need to install bottle via pip globally on your system.

2. Clone [https://github.com/saltstack/salt-contrib](https://github.com/saltstack/salt-contrib) and copy the contents of the directory `proxyminion_rest_example` somewhere on a machine that is reachable from the machine on which you want to run the salt-proxy. This machine needs Python 2.7 or later.

3. Install bottle version 0.12.8 via pip or easy_install

```
pip install bottle==0.12.8
```

4. Run python `rest.py --help` for usage

5. Start the REST API on an appropriate port and IP.

6. Load the REST service's status page in your browser by going to the IP/port combination (e.g. `http://127.0.0.1:8000`)

```
```
7. You should see a page entitled "Salt Proxy Minion" with two sections, one for "services" and one for "packages" and you should see a log entry in the terminal where you started the REST process indicating that the index page was retrieved.

![SaltStack Proxy Minion]

Now, configure your salt-proxy.

1. Edit /etc/salt/proxy and add an entry for your master's location

```
master: localhost
```

2. On your salt-master, ensure that pillar is configured properly. Select an ID for your proxy (in this example we will name the proxy with the letter 'p' followed by the port the proxy is answering on). In your pillar topfile, place an entry for your proxy:

```
base:
  'p8000':
    - p8000
```

This says that Salt's pillar should load some values for the proxy p8000 from the file /srv/pillar/p8000.sls (if you have not changed your default pillar_roots)

3. In the pillar root for your base environment, create this file:

```
p8000.sls
--------
proxy:
  proxytype: rest_sample
  url: http://<IP your REST listens on>:port
```

In other words, if your REST service is listening on port 8000 on 127.0.0.1 the 'url' key above should say `url: http://127.0.0.1:8000`

4. Make sure your salt-master is running.

5. Start the salt-proxy in debug mode

```
salt-proxy --proxyid=p8000 -l debug
```

6. Accept your proxy's key on your salt-master

```
salt-key -y -a p8000
```

The following keys are going to be accepted:

Unaccepted Keys:
7. Now you should be able to ping your proxy. When you ping, you should see a log entry in the terminal where the REST service is running.

```
salt p8000 test.ping
```

8. The REST service implements a degenerately simple pkg and service provider as well as a small set of grains. To `install` a package, use a standard `pkg.install`. If you pass `==` and a version number after the package name then the service will parse that and accept that as the package's version.

9. Try running `salt p8000 grains.items` to see what grains are available. You can target proxies via grains if you like.

10. You can also start and stop the available services (apache, redbull, and postgresql with `service.start`, etc.

11. States can be written to target the proxy. Feel free to experiment with them.

### 10.6 SSH Proxymodules

See above for a general introduction to writing proxy modules. All of the guidelines that apply to REST are the same for SSH. This sections specifically talks about the SSH proxy module and explains the working of the example proxy module `ssh_sample`.

Here is a simple example proxymodule used to interface to a device over SSH. Code for the SSH shell is in the salt-contrib GitHub repository

This proxymodule enables `package` installation.

```python
# -*- coding: utf-8 -*-

'''
This is a simple proxy-minion designed to connect to and communicate with
a server that exposes functionality via SSH.
This can be used as an option when the device does not provide
an api over HTTP and doesn't have the python stack to run a minion.
'''

from __future__ import absolute_import

# Import python libs
import json
import logging

# Import Salt's libs
from salt.utils.vt_helper import SSHConnection
from salt.utils.vt import TerminalException

# This must be present or the Salt loader won't load this module
__proxyenabled__ = ['ssh_sample']

DETAILS = {}

# Want logging!
log = logging.getLogger(__file__)
```

# This does nothing, it's here just as an example and to provide a log
# entry when the module is loaded.
def __virtual__():
    '''
    Only return if all the modules are available
    '''
    log.info(\'ssh_sample proxy __virtual__() called...\')
    return True

def init(opts):
    '''
    Required.
    Can be used to initialize the server connection.
    '''
    try:
        DETAILS[\'server\'] = SSHConnection(host=\_opts__[\'proxy\'][\'host\'],
                                           username=\_opts__[\'proxy\'][\'username\'],
                                           password=\_opts__[\'proxy\'][\'password\'])
        # connected to the SSH server
        out, err = DETAILS[\'server\'].sendline(\'help\')
    except TerminalException as e:
        log.error(e)
    return False

def shutdown(opts):
    '''
    Disconnect
    '''
    DETAILS[\'server\'].close_connection()

def parse(out):
    '''
    Extract json from out.
    
    Parameter
    out: Type string. The data returned by the ssh command.
    '''
    jsonret = []
    in_json = False
    for ln in out.split(\'\n\'):
        if '{' in ln:  
            in_json = True
        if in_json:
            jsonret.append(ln_)
        if '}' in ln_:
            in_json = False
    return json.loads(\'\n\'.join(jsonret))

def package_list():
    '''
    List "packages" by executing a command via ssh
    This function is called in response to the salt command
    '''

```bash
.. code-block:: bash
    salt target_minion pkg.list_pkgs

    # Send the command to execute
    out, err = DETAILS['server'].sendline('pkg_list')

    # "scrape" the output and return the right fields as a dict
    return parse(out)

def package_install(name, **kwargs):
    
    # Install a "package" on the REST server
    cmd = 'pkg_install ' + name
    if 'version' in kwargs:
        cmd += '/'+kwargs['version']
    else:
        cmd += '/1.0'

    # Send the command to execute
    out, err = DETAILS['server'].sendline(cmd)

    # "scrape" the output and return the right fields as a dict
    return parse(out)

def package_remove(name):
    
    # Remove a "package" on the REST server
    cmd = 'pkg_remove ' + name

    # Send the command to execute
    out, err = DETAILS['server'].sendline(cmd)

    # "scrape" the output and return the right fields as a dict
    return parse(out)
```

## 10.6.1 Connection Setup

The `init()` method is responsible for connection setup. It uses the `host`, `username` and `password` config variables defined in the pillar data. The `prompt` kwarg can be passed to `SSHConnection` if your SSH server’s prompt differs from the example’s prompt (Cmd). Instantiating the `SSHConnection` class establishes an SSH connection to the ssh server (using Salt VT).

## 10.6.2 Command execution

The `package_*` methods use the SSH connection (established in `init()`) to send commands out to the SSH server. The `sendline()` method of `SSHConnection` class can be used to send commands out to the server. In the above example we send commands like `pkg_list` or `pkg_install`. You can send any SSH command via this utility.
10.6.3 Output parsing

Output returned by `sendline()` is a tuple of strings representing the stdout and the stderr respectively. In the toy example shown we simply scrape the output and convert it to a python dictionary, as shown in the `parse` method. You can tailor this method to match your parsing logic.

10.6.4 Connection teardown

The `shutdown` method is responsible for calling the `close_connection()` method of `SSHConnection` class. This ends the SSH connection to the server.

For more information please refer to class `SSHConnection`.

Salt Proxy Minion SSH End-to-End Example

The following is walkthrough that documents how to run a sample SSH service and configure one or more proxy minions to talk to and control it.

1. This walkthrough uses a custom SSH shell to provide an end to end example. Any other shells can be used too.
2. Setup the proxy command shell as shown https://github.com/saltstack/salt-contrib/tree/master/proxyminion_ssh_example

Now, configure your salt-proxy.

1. Edit `/etc/salt/proxy` and add an entry for your master's location

```yaml
master: localhost
add_proxymodule_to_opts: False
multiprocessing: False
```

2. On your salt-master, ensure that pillar is configured properly. Select an ID for your proxy (in this example we will name the proxy with the letter 'p' followed by the port the proxy is answering on). In your pillar topfile, place an entry for your proxy:

```yaml
base:
  'p8000':
    - p8000
```

This says that Salt's pillar should load some values for the proxy p8000 from the file /srv/pillar/p8000.sls (if you have not changed your default pillar_roots)

3. In the pillar root for your base environment, create this file:

```sls
---------
proxy:
  proxytype: ssh_sample
  host: saltyVM
  username: salt
  password: badpass
```

4. Make sure your salt-master is running.
5. Start the salt-proxy in debug mode
6. Accept your proxy's key on your salt-master

```
salt-proxy --proxyid=p8000 -l debug
```

```
salt-key -y -a p8000
The following keys are going to be accepted:
Unaccepted Keys:
p8000
Key for minion p8000 accepted.
```

7. Now you should be able to run commands on your proxy.

```
salt p8000 pkg.list_pkgs
```

8. The SSH shell implements a degenerately simple pkg. To ‘install’ a package, use a standard pkg. install.
If you pass ‘==’ and a version number after the package name then the service will parse that and accept that
as the package’s version.

New in version 2015.8.3.

**Proxy Minion Beacon**

The salt proxy beacon is meant to facilitate configuring multiple proxies on one or many minions. This should
simplify configuring and managing multiple salt-proxy processes.

1. On your salt-master, ensure that pillar is configured properly. Select an ID for your proxy (in this example we
will name the proxy ‘p8000’). In your pillar topfile, place an entry for your proxy:

```
base:
  'p8000':
    - p8000
```

This says that Salt’s pillar should load some values for the proxy p8000 from the file /srv/pillar/p8000.sls (if you
have not changed your default pillar_roots)

2. In the pillar root for your base environment, create this file:

```
p8000.sls
--------
proxy:
  # set proxotype for your proxymodule
  proxotype: ssh_sample
  host: saltyVM
  username: salt
  password: badpass
```

This should complete the proxy setup for p8000

3. **Configure** the salt_proxy beacon

```
beacons:
salt_proxy:
  - p8000: {}
```

Once this beacon is configured it will automatically start the salt-proxy process. If the salt-proxy process
is terminated the beacon will re-start it.
4. Accept your proxy’s key on your salt-master

```
salt-key -y -a p8000
The following keys are going to be accepted:
Unaccepted Keys:
p8000
Key for minion p8000 accepted.
```

5. Now you should be able to run commands on your proxy.

```
salt p8000 pkg.list_pkgs
```

New in version 2015.8.2.

**Proxy Minion States**

Salt proxy state can be used to deploy, configure and run a salt-proxy instance on your minion. Configure proxy settings on the master side and the state configures and runs salt-proxy on the remote end.

1. On your salt-master, ensure that pillar is configured properly. Select an ID for your proxy (in this example we will name the proxy `p8000`). In your pillar topfile, place an entry for your proxy:

```
base:
  'p8000':
    - p8000
```

This says that Salt’s pillar should load some values for the proxy p8000 from the file /srv/pillar/p8000.sls (if you have not changed your default pillar_roots)

2. In the pillar root for your base environment, create this file:

```
p8000.sls
--------
proxy:
  # set proxytype for your proxymodule
  proxytype: ssh_sample
  host: saltyVM
  username: salt
  password: badpass
```

3. Create the following state in your state tree (let’s name it salt_proxy.sls)

```
salt-proxy-configure:
salt_proxy.configure_proxy:
  - proxyname: p8000
  - start: True # start the process if it isn't running
```

4. Make sure your salt-master and salt-minion are running.

5. Run the state salt_proxy on the minion where you want to run salt-proxy

Example using state.sls to configure and run salt-proxy

```
# salt device_minion state.sls salt_proxy
```

This starts salt-proxy on device_minion

6. Accept your proxy’s key on your salt-master
salt-key -y -a p8000
The following keys are going to be accepted:
Unaccepted Keys:
p8000
Key for minion p8000 accepted.

7. Now you should be able to run commands on your proxy.
salt p8000 pkg.list_pkgs

ESXi Proxy Minion

New in version 2015.8.4.

Note: This tutorial assumes basic knowledge of Salt. To get up to speed, check out the Salt Walkthrough.
This tutorial also assumes a basic understanding of Salt Proxy Minions. If you’re unfamiliar with Salt’s Proxy Minion system, please read the Salt Proxy Minion documentation and the Salt Proxy Minion End-to-End Example tutorial.
The third assumption that this tutorial makes is that you also have a basic understanding of ESXi hosts. You can learn more about ESXi hosts on VMware’s various resources.

Salt’s ESXi Proxy Minion allows a VMware ESXi host to be treated as an individual Salt Minion, without installing a Salt Minion on the ESXi host.
Since an ESXi host may not necessarily run on an OS capable of hosting a Python stack, the ESXi host can’t run a regular Salt Minion directly. Therefore, Salt’s Proxy Minion functionality enables you to designate another machine to host a proxy process that ``proxies” communication from the Salt Master to the ESXi host. The master does not know or care that the ESXi target is not a “real” Salt Minion.
More in-depth conceptual reading on Proxy Minions can be found in the Proxy Minion section of Salt’s documentation.
Salt’s ESXi Proxy Minion was added in the 2015.8.4 release of Salt.

Note: Be aware that some functionality for the ESXi Proxy Minion may depend on the type of license attached the ESXi host(s).
For example, certain services are only available to manipulate service state or policies with a VMware vSphere Enterprise or Enterprise Plus license, while others are available with a Standard license. The ntpd service is restricted to an Enterprise Plus license, while ssh is available via the Standard license.
Please see the vSphere Comparison page for more information.

Dependencies

Manipulation of the ESXi host via a Proxy Minion requires the machine running the Proxy Minion process to have the ESXCLI package (and all of it’s dependencies) and the pyVmomi Python Library to be installed.
ESXi Password

The ESXi Proxy Minion uses VMware's API to perform tasks on the host as if it was a regular Salt Minion. In order to access the API that is already running on the ESXi host, the ESXi host must have a username and password that is used to log into the host. The username is usually root. Before Salt can access the ESXi host via VMware's API, a default password must be set on the host.

pyVmomi

The pyVmomi Python library must be installed on the machine that is running the proxy process. pyVmomi can be installed via pip:

```
pip install pyVmomi
```

**Note:** Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, the machine that you are running the proxy minion process from must have either Python 2.6, Python 2.7.9, or newer. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python version 2.7 to 2.7.8. If the version of Python running the proxy process is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the following:

```
pip install pyVmomi==5.5.0.2014.1.1
```

The 5.5.0.2014.1.1 is a known stable version that the original ESXi Proxy Minion was developed against.

ESXCLI

Currently, about a third of the functions used for the ESXi Proxy Minion require the ESXCLI package be installed on the machine running the Proxy Minion process.

The ESXCLI package is also referred to as the VMware vSphere CLI, or vCLI. VMware provides vCLI package installation instructions for vSphere 5.5 and vSphere 6.0.

Once all of the required dependencies are in place and the vCLI package is installed, you can check to see if you can connect to your ESXi host by running the following command:

```
esxcli -s <host-location> -u <username> -p <password> system syslog config get
```

If the connection was successful, ESXCLI was successfully installed on your system. You should see output related to the ESXi host's syslog configuration.

Configuration

There are several places where various configuration values need to be set in order for the ESXi Proxy Minion to run and connect properly.
Proxy Config File

On the machine that will be running the Proxy Minion process(es), a proxy config file must be in place. This file should be located in the `/etc/salt/` directory and should be named `proxy`. If the file is not there by default, create it.

This file should contain the location of your Salt Master that the Salt Proxy will connect to.

**Note:** If you're running your ESXi Proxy Minion on version of Salt that is 2015.8.2 or newer, you also need to set `add_proxymodule_to_opts: False` in your proxy config file. The need to specify this configuration will be removed with Salt 2016.3.0, the next major feature release. See the New in 2015.8.2 section of the Proxy Minion documentation for more information.

Example Proxy Config File:

```
# /etc/salt/proxy
master: <salt-master-location>
add_proxymodule_to_opts: False
```

Pillar Profiles

Proxy minions get their configuration from Salt's Pillar. Every proxy must have a stanza in Pillar and a reference in the Pillar top-file that matches the Proxy ID. At a minimum for communication with the ESXi host, the pillar should look like this:

```
proxy:
  proxytype: esxi
  host: <ip or dns name of esxi host>
  username: <ESXi username>
  passwords:
    - first_password
    - second_password
    - third_password
```

Some other optional settings are `protocol` and `port`. These can be added to the pillar configuration.

**proxytype**

The `proxytype` key and value pair is critical, as it tells Salt which interface to load from the `proxy` directory in Salt's install hierarchy, or from `/srv/salt/_proxy` on the Salt Master (if you have created your own proxy module, for example). To use this ESXi Proxy Module, set this to `esxi`.

**host**

The location, or ip/dns, of the ESXi host. Required.

**username**

The username used to login to the ESXi host, such as `root`. Required.
**passwords**

A list of passwords to be used to try and login to the ESXi host. At least one password in this list is required.

The proxy integration will try the passwords listed in order. It is configured this way so you can have a regular password and the password you may be updating for an ESXi host either via the `vsphere.update_host_password` execution module function or via the `esxi.password_present` state function. This way, after the password is changed, you should not need to restart the proxy minion—it should just pick up the new password provided in the list. You can then change pillar at will to move that password to the front and retire the unused ones.

Use-case/reasoning for using a list of passwords: You are setting up an ESXi host for the first time, and the host comes with a default password. You know that you'll be changing this password during your initial setup from the default to a new password. If you only have one password option, and if you have a state changing the password, any remote execution commands or states that run after the password change will not be able to run on the host until the password is updated in Pillar and the Proxy Minion process is restarted.

This allows you to use any number of potential fallback passwords.

**Note:** When a password is changed on the host to one in the list of possible passwords, the further down on the list the password is, the longer individual commands will take to return. This is due to the nature of pyVmomi's login system. We have to wait for the first attempt to fail before trying the next password on the list.

This scenario is especially true, and even slower, when the proxy minion first starts. If the correct password is not the first password on the list, it may take up to a minute for `test.ping` to respond with a `True` result. Once the initial authorization is complete, the responses for commands will be a little faster.

To avoid these longer waiting periods, SaltStack recommends moving the correct password to the top of the list and restarting the proxy minion at your earliest convenience.

**protocol**

If the ESXi host is not using the default protocol, set this value to an alternate protocol. Default is `https`. For example:

**port**

If the ESXi host is not using the default port, set this value to an alternate port. Default is `443`.

**Example Configuration Files**

An example of all of the basic configurations that need to be in place before starting the Proxy Minion processes includes the Proxy Config File, Pillar Top File, and any individual Proxy Minion Pillar files.

In this example, we'll assuming there are two ESXi hosts to connect to. Therefore, we'll be creating two Proxy Minion config files, one config for each ESXi host.

Proxy Config File:

```
# /etc/salt/proxy

master: <salt-master-location>
add_proxymodule_to_opts: False
```
Pillar Top File:

```
# /srv/pillar/top.sls

base:
  'esxi-1':
    - esxi-1
  'esxi-2':
    - esxi-2
```

Pillar Config File for the first ESXi host, esxi-1:

```
# /srv/pillar/esxi-1.sls

proxy:
  proxytype: esxi
  host: esxi-1.example.com
  username: 'root'
  passwords:
    - bad-password-1
    - backup-bad-password-1
```

Pillar Config File for the second ESXi host, esxi-2:

```
# /srv/pillar/esxi-2.sls

proxy:
  proxytype: esxi
  host: esxi-2.example.com
  username: 'root'
  passwords:
    - bad-password-2
    - backup-bad-password-2
```

**Starting the Proxy Minion**

Once all of the correct configuration files are in place, it is time to start the proxy processes!

1. First, make sure your Salt Master is running.

2. Start the first Salt Proxy, in debug mode, by giving the Proxy Minion process and ID that matches the config file name created in the **Configuration** section.

```
salt-proxy --proxyid='esxi-1' -l debug
```

   1. Accept the esxi-1 Proxy Minion’s key on the Salt Master:

```
# salt-key -L
Accepted Keys:
Denied Keys:
Unaccepted Keys:
esxi-1
Rejected Keys:
#
# salt-key -a esxi-1
The following keys are going to be accepted:
Unaccepted Keys:
```
1. Repeat for the second Salt Proxy, this time we'll run the proxy process as a daemon, as an example.

```
salt-proxy --proxyid='esxi-2' -d
```

1. Accept the `esxi-2` Proxy Minion's key on the Salt Master:

```
# salt-key -L
Accepted Keys:
esxi-1
Denied Keys:
Unaccepted Keys:
esxi-2
Rejected Keys:
#
# salt-key -a esxi-1
The following keys are going to be accepted:
Unaccepted Keys:
esxi-2
Proceed? [n/Y] y
Key for minion esxi-1 accepted.
```

1. Check and see if your Proxy Minions are responding:

```
# salt 'esxi-*' test.ping
esxi-1:
    True
esxi-3:
    True
```

## Executing Commands

Now that you've configured your Proxy Minions and have them responding successfully to a `test.ping`, we can start executing commands against the ESXi hosts via Salt.

It's important to understand how this particular proxy works, and there are a couple of important pieces to be aware of in order to start running remote execution and state commands against the ESXi host via a Proxy Minion: the `vSphere Execution Module`, the `ESXi Execution Module`, and the `ESXi State Module`.

### vSphere Execution Module

The `Salt.modules.vsphere` is a standard Salt execution module that does the bulk of the work for the ESXi Proxy Minion. If you pull up the docs for it you'll see that almost every function in the module takes credentials (`username` and `password`) and a target `host` argument. When credentials and a host aren't passed, Salt runs commands through `pyVmomi` or `ESXCLI` against the local machine. If you wanted, you could run functions from this module on any machine where an appropriate version of `pyVmomi` and `ESXCLI` are installed, and that machine would reach out over the network and communicate with the ESXi host.

You'll notice that most of the functions in the vSphere module require a `host`, `username`, and `password`. These parameters are contained in the Pillar files and passed through to the function via the proxy process that is already running. You don't need to provide these parameters when you execute the commands. See the `Running Remote Execution Commands` section below for an example.
ESXi Execution Module

In order for the Pillar information set up in the Configuration section above to be passed to the function call in the vSphere Execution Module, the `salt.modules.esxi` execution module acts as a "shim" between the vSphere execution module functions and the proxy process.

The "shim" takes the authentication credentials specified in the Pillar files and passes them through to the host, username, password, and optional protocol and port options required by the vSphere Execution Module functions.

If the function takes more positional, or keyword, arguments you can append them to the call. It's this shim that speaks to the ESXi host through the proxy, arranging for the credentials and hostname to be pulled from the Pillar section for the ESXi Proxy Minion.

Because of the presence of the shim, to lookup documentation for what functions you can use to interface with the ESXi host, you'll want to look in `salt.modules.vsphere` instead of `salt.modules.esxi`.

Running Remote Execution Commands

To run commands from the Salt Master to execute, via the ESXi Proxy Minion, against the ESXi host, you use the `esxi.cmd <vsphere-function-name>` syntax to call functions located in the vSphere Execution Module. Both args and kwargs needed for various vsphere execution module functions must be passed through in a kwargs-type manor. For example:

```
salt 'esxi-*' esxi.cmd system_info
salt 'esxi-*' esxi.cmd get_service_running service_name='ssh'
```

ESXi State Module

The ESXi State Module functions similarly to other state modules. The "shim" provided by the ESXi Execution Module passes the necessary host, username, and password credentials through, so those options don't need to be provided in the state. Other than that, state files are written and executed just like any other Salt state. See the `salt.modules.esxi` state for ESXi state functions.

The follow state file is an example of how to configure various pieces of an ESXi host including enabling SSH, uploading and SSH key, configuring a coredump network config, syslog, ntp, enabling VMotion, resetting a host password, and more.

```
# /srv/salt/configure-esxi.sls

configure-host-ssh:
    esxi.ssh_configured:
        - service_running: True
        - ssh_key_file: /etc/salt/ssh_keys/my_key.pub
        - service_policy: 'automatic'
        - service_restart: True
        - certificate_verify: True

configure-host-coredump:
    esxi.coredump_configured:
        - enabled: True
        - dump_ip: 'my-coredump-ip.example.com'

configure-host-syslog:
    esxi.syslog_configured:
```

10.6. SSH Proxymodules
- syslog_configs:
  - default-timeout: 120
- firewall: True
- reset_service: True
- reset_syslog_config: True
- reset_configs: loghost,default-timeout

configure-host-ntp:
  esxi.ntp_configured:
    - service_running: True
    - ntp_servers:
      - 192.174.1.100
      - 192.174.1.200
    - service_policy: 'automatic'
    - service_restart: True

configure-vmotion:
  esxi.vmotion_configured:
    - enabled: True

configure-host-vsan:
  esxi.vsan_configured:
    - enabled: True
    - add_disks_to_vsan: True

configure-host-password:
  esxi.password_present:
    - password: 'new-bad-password'

States are called via the ESXi Proxy Minion just as they would on a regular minion. For example:

```bash
salt 'esxi-*' state.sls configure-esxi test=true
salt 'esxi-*' state.sls configure-esxi
```

- **Salt Proxy Minion End-to-End Example**
- **vSphere Execution Module**
The Salt Virt cloud controller capability was initially added to Salt in version 0.14.0 as an alpha technology. The initial Salt Virt system supports core cloud operations:

- Virtual machine deployment
- Inspection of deployed VMs
- Virtual machine migration
- Network profiling
- Automatic VM integration with all aspects of Salt
- Image Pre-seeding

Many features are currently under development to enhance the capabilities of the Salt Virt systems.

**Note:** It is noteworthy that Salt was originally developed with the intent of using the Salt communication system as the backbone to a cloud controller. This means that the Salt Virt system is not an afterthought, simply a system that took the back seat to other development. The original attempt to develop the cloud control aspects of Salt was a project called butter. This project never took off, but was functional and proves the early viability of Salt to be a cloud controller.

**Warning:** Salt Virt does not work with KVM that is running in a VM. KVM must be running on the base hardware.

### 11.1 Salt Virt Tutorial

A tutorial about how to get Salt Virt up and running has been added to the tutorial section:  
*Cloud Controller Tutorial*

### 11.2 The Salt Virt Runner

The point of interaction with the cloud controller is the `virt` runner. The `virt` runner comes with routines to execute specific virtual machine routines.
Reference documentation for the virt runner is available with the runner module documentation:

*Virt Runner Reference*

## 11.3 Based on Live State Data

The Salt Virt system is based on using Salt to query live data about hypervisors and then using the data gathered to make decisions about cloud operations. This means that no external resources are required to run Salt Virt, and that the information gathered about the cloud is live and accurate.

## 11.4 Deploy from Network or Disk

### 11.4.1 Virtual Machine Disk Profiles

Salt Virt allows for the disks created for deployed virtual machines to be finely configured. The configuration is a simple data structure which is read from the `config.option` function, meaning that the configuration can be stored in the minion config file, the master config file, or the minion's pillar.

This configuration option is called `virt.disk`. The default `virt.disk` data structure looks like this:

```yaml
virt.disk:
  default:
    - system:
      size: 8192
      format: qcow2
      model: virtio
```

**Note:** The format and model does not need to be defined, Salt will default to the optimal format used by the underlying hypervisor, in the case of kvm this is qcow2 and virtio.

This configuration sets up a disk profile called default. The default profile creates a single system disk on the virtual machine.

### Define More Profiles

Many environments will require more complex disk profiles and may require more than one profile, this can be easily accomplished:

```yaml
virt.disk:
  default:
    - system:
      size: 8192
  database:
    - system:
      size: 8192
  data:
    - data:
      size: 30720
  web:
    - system:
      size: 1024
```
This configuration allows for one of three profiles to be selected, allowing virtual machines to be created with different storage needs of the deployed vm.

### 11.4.2 Virtual Machine Network Profiles

Salt Virt allows for the network devices created for deployed virtual machines to be finely configured. The configuration is a simple data structure which is read from the `config.option` function, meaning that the configuration can be stored in the minion config file, the master config file, or the minion's pillar.

This configuration option is called `virt.nic`. By default the `virt.nic` option is empty but defaults to a data structure which looks like this:

```yaml
virt.nic:
  default:
    eth0:
      bridge: br0
      model: virtio
```

**Note:** The model does not need to be defined, Salt will default to the optimal model used by the underlying hypervisor, in the case of kvm this model is `virtio`.

This configuration sets up a network profile called default. The default profile creates a single Ethernet device on the virtual machine that is bridged to the hypervisor's `br0` interface. This default setup does not require setting up the `virt.nic` configuration, and is the reason why a default install only requires setting up the `br0` bridge device on the hypervisor.

**Define More Profiles**

Many environments will require more complex network profiles and may require more than one profile, this can be easily accomplished:

```yaml
virt.nic:
  dual:
    eth0:
      bridge: service_br
    eth1:
      bridge: storage_br
  single:
    eth0:
      bridge: service_br
  triple:
    eth0:
      bridge: service_br
    eth1:
      bridge: storage_br
    eth2:
      bridge: dmz_br
  all:
    eth0:
      bridge: service_br
```
This configuration allows for one of six profiles to be selected, allowing virtual machines to be created which attach to different network depending on the needs of the deployed vm.

### 11.4.3 Salt as a Cloud Controller

In Salt 0.14.0, an advanced cloud control system were introduced, allow private cloud vms to be managed directly with Salt. This system is generally referred to as **Salt Virt**.

The Salt Virt system already exists and is installed within Salt itself, this means that besides setting up Salt, no additional salt code needs to be deployed.

---

**Note:** The libvirt python module and the certtool binary are required.

---

The main goal of Salt Virt is to facilitate a very fast and simple cloud. The cloud that can scale and is fully featured. Salt Virt comes with the ability to set up and manage complex virtual machine networking, powerful image and disk management, as well as virtual machine migration with and without shared storage.

This means that Salt Virt can be used to create a cloud from a blade center and a SAN, but can also create a cloud out of a swarm of Linux Desktops without a single shared storage system. Salt Virt can make clouds from truly commodity hardware, but can also stand up the power of specialized hardware as well.

---

**Setting up Hypervisors**

The first step to set up the hypervisors involves getting the correct software installed and setting up the hypervisor network interfaces.

---

**Installing Hypervisor Software**

Salt Virt is made to be hypervisor agnostic but currently the only fully implemented hypervisor is KVM via libvirt. The required software for a hypervisor is libvirt and kvm. For advanced features install libguestfs or qemu-nbd.

---

**Note:** Libguestfs and qemu-nbd allow for virtual machine images to be mounted before startup and get pre-seeded with configurations and a salt minion
This sls will set up the needed software for a hypervisor, and run the routines to set up the libvirt pki keys.

**Note:** Package names and setup used is Red Hat specific, different package names will be required for different platforms

```yaml
libvirt:
  pkg.installed: []
  file.managed:
    - name: /etc/sysconfig/libvirtd
    - contents: 'LIBVIRTD_ARGS="--listen"'
    - require:
      - pkg: libvirt
  virt.keys:
    - require:
      - pkg: libvirt
  service.running:
    - name: libvirtd
    - require:
      - pkg: libvirt
      - network: br0
      - libvirt: libvirt
    - watch:
      - file: libvirt

libvirt-python:
  pkg.installed: []

libguestfs:
  pkg.installed:
    - pkgs:
      - libguestfs
      - libguestfs-tools

Hypervisor Network Setup

The hypervisors will need to be running a network bridge to serve up network devices for virtual machines, this formula will set up a standard bridge on a hypervisor connecting the bridge to eth0:

```yaml
eth0:
  network.managed:
    - enabled: True
    - type: eth
    - bridge: br0

br0:
  network.managed:
    - enabled: True
    - type: bridge
    - proto: dhcp
    - require:
      - network: eth0
```
Virtual Machine Network Setup

Salt Virt comes with a system to model the network interfaces used by the deployed virtual machines; by default a single interface is created for the deployed virtual machine and is bridged to br0. To get going with the default networking setup, ensure that the bridge interface named br0 exists on the hypervisor and is bridged to an active network device.

Note: To use more advanced networking in Salt, read the Salt Virt Networking document:

Salt Virt Networking

Libvirt State

One of the challenges of deploying a libvirt based cloud is the distribution of libvirt certificates. These certificates allow for virtual machine migration. Salt comes with a system used to auto deploy these certificates. Salt manages the signing authority key and generates keys for libvirt clients on the master, signs them with the certificate authority and uses pillar to distribute them. This is managed via the libvirt state. Simply execute this formula on the minion to ensure that the certificate is in place and up to date:

Note: The above formula includes the calls needed to set up libvirt keys.

```
libvirt_keys:
  virt.keys
```

Getting Virtual Machine Images Ready

Salt Virt, requires that virtual machine images be provided as these are not generated on the fly. Generating these virtual machine images differs greatly based on the underlying platform.

Virtual machine images can be manually created using KVM and running through the installer, but this process is not recommended since it is very manual and prone to errors.

Virtual Machine generation applications are available for many platforms:

vm-builder: https://wiki.debian.org/VMBuilder

See also:

vmbuilder-formula

Once virtual machine images are available, the easiest way to make them available to Salt Virt is to place them in the Salt file server. Just copy an image into /srv/salt and it can now be used by Salt Virt.

For purposes of this demo, the file name centos.img will be used.

Existing Virtual Machine Images

Many existing Linux distributions distribute virtual machine images which can be used with Salt Virt. Please be advised that NONE OF THESE IMAGES ARE SUPPORTED BY SALTSTACK.
CentOS

These images have been prepared for OpenNebula but should work without issue with Salt Virt, only the raw qcow image file is needed: [http://wiki.centos.org/Cloud/OpenNebula](http://wiki.centos.org/Cloud/OpenNebula)

Fedora Linux

Images for Fedora Linux can be found here: [http://fedoraproject.org/en/get-fedora#clouds](http://fedoraproject.org/en/get-fedora#clouds)

Ubuntu Linux

Images for Ubuntu Linux can be found here: [http://cloud-images.ubuntu.com/](http://cloud-images.ubuntu.com/)

Using Salt Virt

With hypervisors set up and virtual machine images ready, Salt can start issuing cloud commands.

Start by running a Salt Virt hypervisor info command:

```
salt-run virt.hyper_info
```

This will query what the running hypervisor stats are and display information for all configured hypervisors. This command will also validate that the hypervisors are properly configured.

Now that hypervisors are available a virtual machine can be provisioned. The `virt.init` routine will create a new virtual machine:

```
salt-run virt.init centos1 2512 salt://centos.img
```

This command assumes that the CentOS virtual machine image is sitting in the root of the Salt fileserver. Salt Virt will now select a hypervisor to deploy the new virtual machine on and copy the virtual machine image down to the hypervisor.

Once the VM image has been copied down the new virtual machine will be seeded. Seeding the VMs involves setting pre-authenticated Salt keys on the new VM and if needed, will install the Salt Minion on the new VM before it is started.

**Note:** The biggest bottleneck in starting VMs is when the Salt Minion needs to be installed. Making sure that the source VM images already have Salt installed will GREATLY speed up virtual machine deployment.

Now that the new VM has been prepared, it can be seen via the `virt.query` command:

```
salt-run virt.query
```

This command will return data about all of the hypervisors and respective virtual machines.

Now that the new VM is booted it should have contacted the Salt Master, a `test.ping` will reveal if the new VM is running.
Migrating Virtual Machines

Salt Virt comes with full support for virtual machine migration, and using the libvirt state in the above formula makes migration possible.

A few things need to be available to support migration. Many operating systems turn on firewalls when originally set up, the firewall needs to be opened up to allow for libvirt and kvm to cross communicate and execution migration routines. On Red Hat based hypervisors in particular port 16514 needs to be opened on hypervisors:

```
iptables -A INPUT -m state --state NEW -m tcp -p tcp --dport 16514 -j ACCEPT
```

**Note:** More in-depth information regarding distribution specific firewall settings can read in:

*Opening the Firewall up for Salt*

Salt also needs an additional flag to be turned on as well. The `virt.tunnel` option needs to be turned on. This flag tells Salt to run migrations securely via the libvirt TLS tunnel and to use port 16514. Without `virt.tunnel` libvirt tries to bind to random ports when running migrations. To turn on `virt.tunnel` simple apply it to the master config file:

```
virt.tunnel: True
```

Once the master config has been updated, restart the master and send out a call to the minions to refresh the pillar to pick up on the change:

```
salt \* saltutil.refresh_modules
```

Now, migration routines can be run! To migrate a VM, simply run the Salt Virt migrate routine:

```
salt-run virt.migrate centos <new hypervisor>
```

VNC Consoles

Salt Virt also sets up VNC consoles by default, allowing for remote visual consoles to be opened up. The information from a `virt.query` routine will display the vnc console port for the specific vms:

```
centos
  CPU: 2
  Memory: 524288
  State: running
  Graphics: vnc - hyper6:5900
  Disk - vda:
    Size: 2.0G
    File: /srv/salt-images/ubuntu2/system.qcow2
    File Format: qcow2
  Nic - ac:de:48:98:08:77:
    Source: br0
    Type: bridge
```

The line `Graphics: vnc - hyper6:5900` holds the key. First the port named, in this case 5900, will need to be available in the hypervisor’s firewall. Once the port is open, then the console can be easily opened via vncviewer:

```
vncviewer hyper6:5900
```
By default there is no VNC security set up on these ports, which suggests that keeping them firewalled and mandating that SSH tunnels be used to access these VNC interfaces. Keep in mind that activity on a VNC interface that is accessed can be viewed by any other user that accesses that same VNC interface, and any other user logging in can also operate with the logged in user on the virtual machine.

**Conclusion**

Now with Salt Virt running, new hypervisors can be seamlessly added just by running the above states on new bare metal machines, and these machines will be instantly available to Salt Virt.
12.1 salt-call

12.1.1 salt-call

Synopsis

salt-call [options]

Description

The salt-call command is used to run module functions locally on a minion instead of executing them from the master. Salt-call is used to run a Standalone Minion, and was originally created for troubleshooting.

The Salt Master is contacted to retrieve state files and other resources during execution unless the --local option is specified.

Note: salt-call commands execute from the current user's shell context, while salt commands execute from the system's default context.

Options

--version
  Print the version of Salt that is running.

--versions-report
  Show program's dependencies and version number, and then exit

-h, --help
  Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_dir
  The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.

--hard-crash
  Raise any original exception rather than exiting gracefully Default: False
-g, --grains
Return the information generated by the Salt grains

-m MODULE_DIRS, --module-dirs=MODULE_DIRS
Specify an additional directory to pull modules from. Multiple directories can be provided by passing -m
|--module-dirs multiple times.

-d, --doc, --documentation
Return the documentation for the specified module or for all modules if none are specified

--master=MASTER
Specify the master to use. The minion must be authenticated with the master. If this option is omitted, the
master options from the minion config will be used. If multi masters are set up the first listed master that
responds will be used.

--return RETENDER
Set salt-call to pass the return data to one or many returner interfaces. To use many returner interfaces specify
a comma delimited list of returners.

--local
Run salt-call locally, as if there was no master running.

--file-root=FILE_ROOT
Set this directory as the base file root.

--pillar-root=PILLAR_ROOT
Set this directory as the base pillar root.

--retcode-passthrough
Exit with the salt call retcode and not the salt binary retcode

--metadata
Print out the execution metadata as well as the return. This will print out the outputter data, the return code,
etc.

--id=ID
Specify the minion id to use. If this option is omitted, the id option from the minion config will be used.

--skip-grains
Do not load grains.

--refresh-grains-cache
Force a refresh of the grains cache

Logging Options

Logging options which override any settings defined on the configuration files.

-1 LOG_LEVEL, --log-level=LOG_LEVEL
Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE
Log file path. Default: /var/log/salt/minion.

--log-file-level=LOG_LEVEL,LOGFILE
Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.
Output Options

--out
Pass in an alternative outputter to display the return of data. This outputter can be any of the available outputters:

    grains, highstate, json, key, overstatestage, pprint, raw, txt, yaml

Some outputters are formatted only for data returned from specific functions; for instance, the grains outputter will not work for non-grains data.

If an outputter is used that does not support the data passed into it, then Salt will fall back on the pprint outputter and display the return data using the Python pprint standard library module.

**Note:** If using --out=json, you will probably want --static as well. Without the static option, you will get a separate JSON string per minion which makes JSON output invalid as a whole. This is due to using an iterative outputter. So if you want to feed it to a JSON parser, use --static as well.

--out-indent OUTPUT_INDENT, --output-indent OUTPUT_INDENT
Print the output indented by the provided value in spaces. Negative values disable indentation. Only applicable in outputters that support indentation.

--out-file=OUTPUT_FILE, --output-file=OUTPUT_FILE
Write the output to the specified file.

--no-color
Disable all colored output

--force-color
Force colored output

**Note:** When using colored output the color codes are as follows:

green denotes success, red denotes failure, blue denotes changes and success and yellow denotes a expected future change in configuration.

salt(1) salt-master(1) salt-minion(1)

12.2 salt

12.2.1 salt

Synopsis

    salt `` [ options ] sys.doc
    salt -E `` [ options ] sys.doc cmd
    salt -G `os:Arch.* and webserv* or G@kernel:FreeBSD` [ options ] test.ping
    salt -C `G@os:Arch.* and webserv* or G@kernel:FreeBSD` [ options ] test.ping
Description

Salt allows for commands to be executed across a swath of remote systems in parallel. This means that remote systems can be both controlled and queried with ease.

Options

--version
Print the version of Salt that is running.

--versions-report
Show program's dependencies and version number, and then exit

-h, --help
Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_dir
The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.

-t TIMEOUT, --timeout=TIMEOUT
The timeout in seconds to wait for replies from the Salt minions. The timeout number specifies how long the command line client will wait to query the minions and check on running jobs. Default: 5

-s, --static
By default as of version 0.9.8 the salt command returns data to the console as it is received from minions, but previous releases would return data only after all data was received. Use the static option to only return the data with a hard timeout and after all minions have returned. Without the static option, you will get a separate JSON string per minion which makes JSON output invalid as a whole.

--async
Instead of waiting for the job to run on minions only print the job id of the started execution and complete.

--state-output=STATE_OUTPUT
New in version 0.17.
Override the configured state_output value for minion output. One of full, terse, mixed, changes or filter. Default: full.

--subset=SUBSET
Execute the routine on a random subset of the targeted minions. The minions will be verified that they have the named function before executing. The SUBSET argument is the count of the minions to target.

-v VERBOSE, --verbose
Turn on verbosity for the salt call, this will cause the salt command to print out extra data like the job id.

--hide-timeout
Instead of showing the return data for all minions. This option prints only the online minions which could be reached.

-b BATCH, --batch-size=BATCH
Instead of executing on all targeted minions at once, execute on a progressive set of minions. This option takes an argument in the form of an explicit number of minions to execute at once, or a percentage of minions to execute on.

-a EAUTH, --auth=EAUTH
Pass in an external authentication medium to validate against. The credentials will be prompted for. The options are auto, keystone, ldap, pam, and stormpath. Can be used with the -T option.
-T, --make-token
Used in conjunction with the -a option. This creates a token that allows for the authenticated user to send commands without needing to re-authenticate.

--return=RETURNER
Choose an alternative returner to call on the minion, if an alternative returner is used then the return will not come back to the command line but will be sent to the specified return system. The options are carbon, cassandra, couchbase, couchdb, elasticsearch, etcd, hipchat, local, local_cache, memcache, mongo, mysql, odbc, postgres, redis, sentry, slack, sms, smtp, sqlite3, syslog, and xmpp.

-d, --doc, --documentation
Return the documentation for the module functions available on the minions

--args-separator=ARGS_SEPARATOR
Set the special argument used as a delimiter between command arguments of compound commands. This is useful when one wants to pass commas as arguments to some of the commands in a compound command.

Logging Options

Logging options which override any settings defined on the configuration files.

-1 LOG_LEVEL, --log-level=LOG_LEVEL
Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE

--log-file-level=LOG_LEVEL_LOGFILE
Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

Target Selection

The default matching that Salt utilizes is shell-style globbing around the minion id. See https://docs.python.org/2/library/fnmatch.html#module-fnmatch.

-E, --pcre
The target expression will be interpreted as a PCRE regular expression rather than a shell glob.

-L, --list
The target expression will be interpreted as a comma-delimited list; example: server1.foo.bar,server2.foo.bar,example7.quo.qux

-G, --grain
The target expression matches values returned by the Salt grains system on the minions. The target expression is in the format of `<grain value>:<glob expression>`; example: `os:Arch*`

This was changed in version 0.9.8 to accept glob expressions instead of regular expression. To use regular expression matching with grains, use the --grain-pcre option.

--grain-pcre
The target expression matches values returned by the Salt grains system on the minions. The target expression is in the format of `<grain value>:< regular expression>`; example: `os:Arch.*`

-N, --nodegroup
Use a predefined compound target defined in the Salt master configuration file.
-R, --range
Instead of using shell globs to evaluate the target, use a range expression to identify targets. Range expressions look like %cluster.

Using the Range option requires that a range server is set up and the location of the range server is referenced in the master configuration file.

-C, --compound
Utilize many target definitions to make the call very granular. This option takes a group of targets separated by and or or. The default matcher is a glob as usual. If something other than a glob is used, preface it with the letter denoting the type; example: "webserv* and @os:Debian or @db*" Make sure that the compound target is encapsulated in quotes.

-I, --pillar
Instead of using shell globs to evaluate the target, use a pillar value to identify targets. The syntax for the target is the pillar key followed by a glob expression: "role:production*"

-S, --ipcidr
Match based on Subnet (CIDR notation) or IPv4 address.

Output Options

--out
Pass in an alternative outpuer to display the return of data. This outpuer can be any of the available outputers:

    grains, highstate, json, key, overstatestage, pprint, raw, txt, yaml

Some outputers are formatted only for data returned from specific functions; for instance, the grains outpuer will not work for non-grains data.

If an outpuer is used that does not support the data passed into it, then Salt will fall back on the pprint outpuer and display the return data using the Python pprint standard library module.

Note: If using --out=json, you will probably want --static as well. Without the static option, you will get a separate JSON string per minion which makes JSON output invalid as a whole. This is due to using an iterative outpuer. So if you want to feed it to a JSON parser, use --static as well.

--out-indent OUTPUT_INDENT, --output-indent OUTPUT_INDENT
Print the output indented by the provided value in spaces. Negative values disable indentation. Only applicable in outputers that support indentation.

--out-file=OUTPUT_FILE, --output-file=OUTPUT_FILE
Write the output to the specified file.

--no-color
Disable all colored output

--force-color
Force colored output

Note: When using colored output the color codes are as follows:

green denotes success, red denotes failure, blue denotes changes and success and yellow denotes a expected future change in configuration.

salt(7) salt-master(1) salt-minion(1)

12.3  salt-cloud

12.4  salt-cp

12.4.1  salt-cp

Copy a file or files to one or more minions

Synopsis

salt-cp  '*'  [ options ]  SOURCE  [SOURCE2  SOURCE3  ...]  DEST
salt-cp  -E  '*.'  [ options ]  SOURCE  [SOURCE2  SOURCE3  ...]  DEST
salt-cp  -G  'os:Arch.*'  [ options ]  SOURCE  [SOURCE2  SOURCE3  ...]  DEST

Description

salt-cp copies files from the master to all of the Salt minions matched by the specified target expression.

Note:  salt-cp uses Salt's publishing mechanism. This means the privacy of the contents of the file on the wire is completely dependent upon the transport in use. In addition, if the master or minion is running with debug logging, the contents of the file will be logged to disk.

In addition, this tool is less efficient than the Salt fileserver when copying larger files. It is recommended to instead use cp.get_file to copy larger files to minions. However, this requires the file to be located within one of the fileserver directories.

Options

--version  
Print the version of Salt that is running.

--versions-report  
Show program’s dependencies and version number, and then exit

-h,  --help  
Show the help message and exit

-c  CONFIG_DIR,  --config-dir=CONFIG_dir  
The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.
-t TIMEOUT, --timeout=TIMEOUT
The timeout in seconds to wait for replies from the Salt minions. The timeout number specifies how long the
command line client will wait to query the minions and check on running jobs. Default: 5

Logging Options

Logging options which override any settings defined on the configuration files.

-l LOG_LEVEL, --log-level=LOG_LEVEL
Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE

--log-file-level=LOG_LEVEL_LOGFILE
Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

Target Selection

The default matching that Salt utilizes is shell-style globbing around the minion id. See https://docs.python.org/2/
library/fnmatch.html#module-fnmatch.

-E, --pcre
The target expression will be interpreted as a PCRE regular expression rather than a shell glob.

-L, --list
The target expression will be interpreted as a comma-delimited list; example:
server1.foo.bar,server2.foo.bar,example7.quo.qux

-G, --grain
The target expression matches values returned by the Salt grains system on the minions. The target expression
is in the format of `<grain value>:<glob expression>'; example: `os:Arch`

This was changed in version 0.9.8 to accept glob expressions instead of regular expression. To use regular
expression matching with grains, use the --grain-pcre option.

--grain-pcre
The target expression matches values returned by the Salt grains system on the minions. The target expression
is in the format of `grain value>:< regular expression>'; example: `os:Arch`.

-N, --nodegroup
Use a predefined compound target defined in the Salt master configuration file.

-R, --range
Instead of using shell globs to evaluate the target, use a range expression to identify targets. Range expressions
look like %cluster.

Using the Range option requires that a range server is set up and the location of the range server is referenced
in the master configuration file.

-n, --no-compression
Disable gzip compression.

New in version 2016.3.7,2016.11.6,Nitrogen.

salt(1) salt-master(1) salt-minion(1)

12.5 salt-key

12.5.1 salt-key

Synopsis

```
salt-key [ options ]
```

Description

Salt-key executes simple management of Salt server public keys used for authentication.

On initial connection, a Salt minion sends its public key to the Salt master. This key must be accepted using the `salt-key` command on the Salt master.

Salt minion keys can be in one of the following states:

- **unaccepted**: key is waiting to be accepted.
- **accepted**: key was accepted and the minion can communicate with the Salt master.
- **rejected**: key was rejected using the `salt-key` command. In this state the minion does not receive any communication from the Salt master.
- **denied**: key was rejected automatically by the Salt master. This occurs when a minion has a duplicate ID, or when a minion was rebuilt or had new keys generated and the previous key was not deleted from the Salt master. In this state the minion does not receive any communication from the Salt master.

To change the state of a minion key, use `-d` to delete the key and then accept or reject the key.

Options

```
--version
   Print the version of Salt that is running.

--versions-report
   Show program's dependencies and version number, and then exit

-h, --help
   Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_dir
   The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.

-u USER, --user=USER
   Specify user to run salt-key

--hard-crash
   Raise any original exception rather than exiting gracefully. Default is False.
```
-q, --quiet
Suppress output

-y, --yes
Answer 'Yes' to all questions presented, defaults to False

--rotate-aes-key=ROTATE_AES_KEY
Setting this to False prevents the master from refreshing the key session when keys are deleted or rejected, this lowers the security of the key deletion/rejection operation. Default is True.

Logging Options

Logging options which override any settings defined on the configuration files.

--log-file=LOG_FILE
Log file path. Default: /var/log/salt/minion.

--log-file-level=LOG_LEVEL_LOGFILE
Log file logging level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

Output Options

--out
Pass in an alternative outputter to display the return of data. This outputter can be any of the available outputters:

grains, highstate, json, key, overstate, stage, pprint, raw, txt, yaml

Some outputters are formatted only for data returned from specific functions; for instance, the grains outputter will not work for non-grains data.

If an outputter is used that does not support the data passed into it, then Salt will fall back on the pprint outputter and display the return data using the Python pprint standard library module.

Note: If using --out=json, you will probably want --static as well. Without the static option, you will get a separate JSON string per minion which makes JSON output invalid as a whole. This is due to using an iterative outputter. So if you want to feed it to a JSON parser, use --static as well.

--out-indent OUTPUT_INDENT, --output-indent OUTPUT_INDENT
Print the output indented by the provided value in spaces. Negative values disable indentation. Only applicable in outputters that support indentation.

--out-file=OUTPUT_FILE, --output-file=OUTPUT_FILE
Write the output to the specified file.

--no-color
Disable all colored output

--force-color
Force colored output

Note: When using colored output the color codes are as follows:
green denotes success, red denotes failure, blue denotes changes and success and yellow denotes an expected future change in configuration.

Actions

-`l` ARG, `--list=ARG`
List the public keys. The args pre, un, and unaccepted will list unaccepted/unsigned keys. acc or accepted will list accepted/signed keys. rej or rejected will list rejected keys. Finally, all will list all keys.

-`L`, `--list-all`
List all public keys. (Deprecated: use `--list all`)

-`a` ACCEPT, `--accept=ACCEPT`
Accept the specified public key (use `--include-all` to match rejected keys in addition to pending keys). Globs are supported.

-`A`, `--accept-all`
Accepts all pending keys.

-`r` REJECT, `--reject=REJECT`
Reject the specified public key (use `--include-all` to match accepted keys in addition to pending keys). Globs are supported.

-`R`, `--reject-all`
Rejects all pending keys.

-`--include-all`
Include non-pending keys when accepting/rejecting.

-`p` PRINT, `--print=PRINT`
Print the specified public key.

-`P`, `--print-all`
Print all public keys

-`d` DELETE, `--delete=DELETE`
Delete the specified key. Globs are supported.

-`D`, `--delete-all`
Delete all keys.

-`f` FINGER, `--finger=FINGER`
Print the specified key's fingerprint.

-`F`, `--finger-all`
Print all keys' fingerprints.

Key Generation Options

-`--gen-keys=GEN_KEYS`
Set a name to generate a keypair for use with salt

-`--gen-keys-dir=GEN_KEYS_DIR`
Set the directory to save the generated keypair. Only works with `gen_keys_dir` option; default is the current directory.

12.5. salt-key

695
--keysize=KEYSIZE
Set the keysize for the generated key, only works with the `--gen-keys' option, the key size must be 2048 or higher, otherwise it will be rounded up to 2048. The default is 2048.

--gen-signature
Create a signature file of the master's public-key named master_pubkey_signature. The signature can be sent to a minion in the master's auth-reply and enables the minion to verify the master's public-key cryptographically. This requires a new signing-key-pair which can be auto-created with the --auto-create parameter.

--priv=PRIV
The private-key file to create a signature with

--signature-path=SIGNATURE_PATH
The path where the signature file should be written

--pub=PUB
The public-key file to create a signature for

--auto-create
Auto-create a signing key-pair if it does not yet exist

See also

salt(7) salt-master(1) salt-minion(1)

12.6 salt-master

12.6.1 salt-master

The Salt master daemon, used to control the Salt minions

Synopsis

```
salt-master [ options ]
```

Description

The master daemon controls the Salt minions

Options

--version
Print the version of Salt that is running.

--versions-report
Show program's dependencies and version number, and then exit

-h, --help
Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_dir
The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.
-u USER, --user=USER
  Specify user to run salt-master

-d, --daemon
  Run salt-master as a daemon

--pid-file PIDFILE
  Specify the location of the pidfile. Default: /var/run/salt-master.pid

Logging Options

Logging options which override any settings defined on the configuration files.

-l LOG_LEVEL, --log-level=LOG_LEVEL
  Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE

--log-file-level=LOG_LEVEL_LOGFILE
  Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

salt(1) salt(7) salt-minion(1)

12.7 salt-minion

12.7.1 salt-minion

The Salt minion daemon, receives commands from a remote Salt master.

Synopsis

salt-minion [ options ]

Description

The Salt minion receives commands from the central Salt master and replies with the results of said commands.

Options

--version
  Print the version of Salt that is running.

--versions-report
  Show program's dependencies and version number, and then exit
-h, --help
   Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_dir
   The location of the Salt configuration directory. This directory contains the configuration files for Salt master
   and minions. The default location on most systems is /etc/salt.

-u USER, --user=USER
   Specify user to run salt-minion

d, --daemon
   Run salt-minion as a daemon

--pid-file PIDFILE
   Specify the location of the pidfile. Default: /var/run/salt-minion.pid

Logging Options

Logging options which override any settings defined on the configuration files.

-l LOG_LEVEL, --log-level=LOG_LEVEL
   Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE
   Log file path. Default: /var/log/salt/minion.

--log-file-level=LOG_LEVEL_LOGFILE
   Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

12.8 salt-proxy

12.8.1 salt-proxy

Receives commands from a Salt master and proxies these commands to devices that are unable to run a full minion.

Synopsis

salt-proxy [ options ]

Description

The Salt proxy minion receives commands from a Salt master, transmits appropriate commands to devices that are unable to run a full minion, and replies with the results of said commands.
Options

--proxyid
The minion id that this proxy will assume. This is required.

--version
Print the version of Salt that is running.

--versions-report
Show program’s dependencies and version number, and then exit

-h, --help
Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_DIR
The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.

-u USER, --user=USER
Specify user to run salt-proxy

-d, --daemon
Run salt-proxy as a daemon

--pid-file PIDFILE
Specify the location of the pidfile. Default: /var/run/salt-proxy-<id>.pid

Logging Options

Logging options which override any settings defined on the configuration files.

-l LOG_LEVEL, --log-level=LOG_LEVEL
Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE
Log file path. Default: /var/log/salt/minion.

--log-file-level=LOG_LEVEL_LOGFILE
Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

salt(1) salt(7) salt-master(1) salt-minion(1)

12.9 salt-run

12.9.1 salt-run

Execute a Salt runner
Synopsis

```
salt-run RUNNER
```

Description

salt-run is the frontend command for executing Salt Runners. Salt runners are simple modules used to execute convenience functions on the master

Options

```
--version
  Print the version of Salt that is running.

--versions-report
  Show program's dependencies and version number, and then exit

-h, --help
  Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_dir
  The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.

-t TIMEOUT, --timeout=TIMEOUT
  The timeout in seconds to wait for replies from the Salt minions. The timeout number specifies how long the command line client will wait to query the minions and check on running jobs. Default: 1

--hard-crash
  Raise any original exception rather than exiting gracefully. Default is False.

-d, --doc, --documentation
  Display documentation for runners, pass a module or a runner to see documentation on only that module/runner.
```

Logging Options

Logging options which override any settings defined on the configuration files.

```
-l LOG_LEVEL, --log-level=LOG_LEVEL
  Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE

--log-file-level=LOG_LEVEL_LOGFILE
  Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.
```

12.10 salt-ssh

12.10.1 salt-ssh

Synopsis

salt-ssh 'x' [ options ] sys.doc
salt-ssh -E '.*' [ options ] sys.doc cmd

Description

Salt SSH allows for salt routines to be executed using only SSH for transport

Options

-r, --raw, --raw-shell
Execute a raw shell command.

--priv
Specify the SSH private key file to be used for authentication.

--roster
Define which roster system to use, this defines if a database backend, scanner, or custom roster system is used. Default is the flat file roster.

--roster-file
Define an alternative location for the default roster file location. The default roster file is called roster and is found in the same directory as the master config file.

--refresh, --refresh-cache
Force a refresh of the master side data cache of the target's data. This is needed if a target's grains have been changed and the auto refresh timeframe has not been reached.

--max-procs
Set the number of concurrent minions to communicate with. This value defines how many processes are opened up at a time to manage connections, the more running process the faster communication should be, default is 25.

-i, --ignore-host-keys
Disables StrictHostKeyChecking to relax acceptance of new and unknown host keys.

--no-host-keys
Fully ignores ssh host keys which by default are honored and connections would ask for approval. Useful if the host key of a remote server has changed and would still error with --ignore-host-keys.

--passwd
Set the default password to attempt to use when authenticating.

--key-deploy
Set this flag to attempt to deploy the authorized ssh key with all minions. This combined with --passwd can make initial deployment of keys very fast and easy.
**--version**

Print the version of Salt that is running.

**--versions-report**

Show program’s dependencies and version number, and then exit

**-h, --help**

Show the help message and exit

**--config-dir=CONFIG_dir**

The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is `/etc/salt`.

**Target Selection**

The default matching that Salt utilizes is shell-style globbing around the minion id. See [https://docs.python.org/2/library/fnmatch.html#module-fnmatch](https://docs.python.org/2/library/fnmatch.html#module-fnmatch).

**-E, --pcre**

The target expression will be interpreted as a PCRE regular expression rather than a shell glob.

**Logging Options**

Logging options which override any settings defined on the configuration files.

**-l LOG_LEVEL, --log-level=LOG_LEVEL**

Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

**--log-file=LOG_FILE**

**--log-file-level=LOG_LEVEL_LOGFILE**

Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

**Output Options**

**--out**

Pass in an alternative outpuoter to display the return of data. This outpuoter can be any of the available outputers:

grains, highstate, json, key, overstatestage, pprint, raw, txt, yaml

Some outputers are formatted only for data returned from specific functions; for instance, the grains outpuoter will not work for non-grains data.

If an outpuoter is used that does not support the data passed into it, then Salt will fall back on the pprint outpuoter and display the return data using the Python pprint standard library module.

**Note:** If using `--out=json`, you will probably want `--static` as well. Without the static option, you will get a separate JSON string per minion which makes JSON output invalid as a whole. This is due to using an iterative outpuoter. So if you want to feed it to a JSON parser, use `--static` as well.
--out-indent OUTPUT_INDENT, --output-indent OUTPUT_INDENT
Print the output indented by the provided value in spaces. Negative values disable indentation. Only applicable
in outputters that support indentation.

--out-file=OUTPUT_FILE, --output-file=OUTPUT_FILE
Write the output to the specified file.

--no-color
Disable all colored output

--force-color
Force colored output

Note: When using colored output the color codes are as follows:
green denotes success, red denotes failure, blue denotes changes and success and yellow denotes a
expected future change in configuration.

salt(7) salt-master(1) salt-minion(1)

12.11 salt-syndic

12.11.1 salt-syndic

The Salt syndic daemon, a special minion that passes through commands from a higher master

Synopsis

salt-syndic [ options ]

Description

The Salt syndic daemon, a special minion that passes through commands from a higher master.

Options

--version
Print the version of Salt that is running.

--versions-report
Show program's dependencies and version number, and then exit

-h, --help
Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_dir
The location of the Salt configuration directory. This directory contains the configuration files for Salt master
and minions. The default location on most systems is /etc/salt.
-u USER, --user=USER
    Specify user to run salt-syndic

-d, --daemon
    Run salt-syndic as a daemon

--pid-file PIDFILE
    Specify the location of the pidfile. Default: /var/run/salt-syndic.pid

Logging Options

Logging options which override any settings defined on the configuration files.

-l LOG_LEVEL, --log-level=LOG_LEVEL
    Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE

--log-file-level=LOG_LEVEL_LOGFILE
    Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

See also

salt(1) salt-master(1) salt-minion(1)

12.12 salt-api

12.12.1 salt-api

Start interfaces used to remotely connect to the salt master

Synopsis

salt-api

Description

The Salt API system manages network api connectors for the Salt Master

Options

--version
    Print the version of Salt that is running.

--versions-report
    Show program's dependencies and version number, and then exit
-h, --help
  Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_dir
  The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.

-d, --daemon
  Run the salt-api as a daemon

--pid-file=PIDFILE
  Specify the location of the pidfile. Default: /var/run/salt-api.pid

Logging Options

Logging options which override any settings defined on the configuration files.

-l LOG_LEVEL, --log-level=LOG_LEVEL
  Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE

--log-file-level=LOG_LEVEL_LOGFILE
  Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

salt-api(7) salt(7) salt-master(1)

12.13  spm

12.13.1  spm

Salt Package Manager

Synopsis

spm <command> [ <argument> ]

Description

spm is the frontend command for managing Salt packages. Packages normally only include formulas, meaning a group of SLS files that install into the file_roots on the Salt Master, but Salt modules can also be installed.
Options

-y, --assume-yes
Assume yes instead of prompting the other whether or not to proceed with a particular command. Default is False.

-f, --force
When presented with a course of action that spm would normally refuse to perform, that action will be performed anyway. This is often destructive, and should be used with caution.

Logging Options

Logging options which override any settings defined on the configuration files.

-l LOG_LEVEL, --log-level=LOG_LEVEL
Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE

--log-file-level=LOG_LEVEL_LOGFILE
Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

Commands

update_repo
Connect to remote repositories locally configured on the system and download their metadata.

install
Install a package from a configured SPM repository. Requires a package name.

remove
Remove an installed package from the system. Requires a package name.

info
List information about an installed package. Requires a package name.

files
List files belonging to an installed package. Requires a package name.

local
Perform one of the above options (except for remove) on a package file, instead of on a package in a repository, or an installed package. Requires a valid path to a local file on the system.

build
Build a package from a directory containing a FORMULA file. Requires a valid path to a local directory on the system.

create_repo
Scan a directory for valid SPM package files and build an SPM-METADATA file in that directory which describes them.
This section contains a list of the Python modules that are used to extend the various subsystems within Salt.

## 13.1 auth modules

<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>auto</code></td>
<td>An &quot;Always Approved&quot; eauth interface to test against, not intended for production use</td>

<td>Provide authentication using Stormpath</td>
</tr>
<tr>
<td><code>yubico</code></td>
<td>Provide authentication using YubiKey</td>
</tr>
</tbody>
</table>

### 13.1.1 salt.auth.auto

An "Always Approved" eauth interface to test against, not intended for production use

```
salt.auth.auto.auth(username, password)
```

Authenticate!

### 13.1.2 salt.auth.django

Provide authentication using Django Web Framework

```
depends
```

- Django Web Framework

Django authentication depends on the presence of the django framework in the `PYTHONPATH`, the Django project's `settings.py` file being in the `PYTHONPATH` and accessible via the `DJANGO_SETTINGS_MODULE` environment variable.

Django auth can be defined like any other eauth module:
external_auth:
django:
fred:
   - *
   - '@runner'

This will authenticate Fred via Django and allow him to run any execution module and all runners.

The authorization details can optionally be located inside the Django database. The relevant entry in the models.py file would look like this:

```python
class SaltExternalAuthModel(models.Model):
    user_fk = models.ForeignKey(auth.User)
    minion_matcher = models.CharField()
    minion_fn = models.CharField()
```

The `external_auth` clause in the master config would then look like this:

```yaml
external_auth:
django:
  ^model: <fully-qualified reference to model class>
```

When a user attempts to authenticate via Django, Salt will import the package indicated via the keyword `^model`. That model must have the fields indicated above, though the model DOES NOT have to be named `SaltExternalAuthModel`.

```python
salt.auth.django.auth(username, password)
```

Simple Django auth

```python
salt.auth.django.django_auth_setup()
```

Prepare the connection to the Django authentication framework

```python
salt.auth.django.retrieve_auth_entries(u=None)
```

Parameters `u` -- Username to filter for

Returns Dictionary that can be slotted into the `__opts__` structure for eauth that designates the user associated ACL.

Database records such as:

<table>
<thead>
<tr>
<th>username</th>
<th>minion_or_fn_matcher</th>
<th>minion_fn</th>
</tr>
</thead>
<tbody>
<tr>
<td>fred</td>
<td></td>
<td>test.ping</td>
</tr>
<tr>
<td>fred</td>
<td>server1</td>
<td>network.interfaces</td>
</tr>
<tr>
<td>fred</td>
<td>server1</td>
<td>raid.list</td>
</tr>
<tr>
<td>fred</td>
<td>server2</td>
<td>.*</td>
</tr>
<tr>
<td>guru</td>
<td>.*</td>
<td></td>
</tr>
<tr>
<td>smartadmin</td>
<td>server1</td>
<td>.*</td>
</tr>
</tbody>
</table>

Should result in an eauth config such as:

```yaml
fred:
  - test.ping
  - server1:
    - network.interfaces
    - raid.list
  - server2:
    - .*
guru:
  - .*
```
13.1.3 salt.auth.keystone

Provide authentication using OpenStack Keystone

depends
  • keystoneclient Python module

salt.auth.keystone.auth(username, password)
  Try and authenticate
	salt.auth.keystone.get_auth_url()
  Try and get the URL from the config, else return localhost

13.1.4 salt.auth.ldap

Provide authentication using simple LDAP binds

depends
  • ldap Python module
	salt.auth.ldap.auth(username, password)
    Simple LDAP auth
	salt.auth.ldap.expand_ldap_entries(entries, opts=None)
    Parameters
      • entries -- ldap subtree in external_auth config option
      • opts -- Opts to use when __opts__ not defined
    Returns Dictionary with all allowed operations

Takes the ldap subtree in the external_auth config option and expands it with actual minion names

webadmins%: <all users in the AD `webadmins' group>
  • server1
    - .*
  • ldap(OU=webservers,dc=int,dc=bigcompany,dc=com) - test.ping - service.restart
  • ldap(OU=Domain Controllers,dc=int,dc=bigcompany,dc=com) - allowed_fn_list_attribute

This function only gets called if auth.ldap.activedirectory = True
	salt.auth.ldap.groups(username, **kwargs)
  Authenticate against an LDAP group

  Behavior is highly dependent on if Active Directory is in use.

  AD handles group membership very differently than OpenLDAP. See the External Authentication documentation for a thorough discussion of available parameters for customizing the search.

  OpenLDAP allows you to search for all groups in the directory and returns members of those groups. Then we check against the username entered.
13.1.5 salt.auth.mysql

Provide authentication using MySQL.

When using MySQL as an authentication backend, you will need to create or use an existing table that has a username and a password column.

To get started, create a simple table that holds just a username and a password. The password field will hold a SHA256 checksum.

```
CREATE TABLE `users` (
    `id` int(11) NOT NULL AUTO_INCREMENT,
    `username` varchar(25) DEFAULT NULL,
    `password` varchar(70) DEFAULT NULL,
    PRIMARY KEY (`id`) ) ENGINE=InnoDB AUTO_INCREMENT=2 DEFAULT CHARSET=latin1;
```

To create a user within MySQL, execute the following statement.

```
INSERT INTO users VALUES (NULL, 'diana', SHA2('secret', 256))
```

The auth_sql contains the SQL that will validate a user to ensure they are correctly authenticated. This is where you can specify other SQL queries to authenticate users.

Enable MySQL authentication.

```
external_auth:
  mysql:
    damian:
      - test.*
```

depends

- MySQL-python Python module

```
salt.auth.mysql.auth(username, password)
```

Authenticate using a MySQL user table

13.1.6 salt.auth.pam

Authenticate against PAM

Provides an authenticate function that will allow the caller to authenticate a user against the Pluggable Authentication Modules (PAM) on the system.

Implemented using ctypes, so no compilation is necessary.

There is one extra configuration option for pam. The pam_service that is authenticated against. This defaults to login

```
auth.pam.service: login
```
Note: PAM authentication will not work for the `root` user.
The Python interface to PAM does not support authenticating as `root`.

Note: Using PAM groups with SSSD groups on python2.
To use sssd with the PAM eauth module and groups the `pysss` module is needed. On RedHat/CentOS this is `python-sss`.
This should not be needed with python >= 3.3, because the `os` modules has the `getgrouplist` function.

class salt.auth.pam.PamConv
    Wrapper class for pam_conv structure
    appdata_ptr
        Structure/Union member
    conv
        Structure/Union member
class salt.auth.pam.PamHandle
    Wrapper class for pam_handle_t
    handle
        Structure/Union member
class salt.auth.pam.PamMessage
    Wrapper class for pam_message structure
    msg
        Structure/Union member
    msg_style
        Structure/Union member
class salt.auth.pam.PamResponse
    Wrapper class for pam_response structure
    resp
        Structure/Union member
    resp_retcode
        Structure/Union member
salt.auth.pam.auth(username, password, **kwargs)
    Authenticate via pam
salt.auth.pam.authenticate(username, password)
    Returns True if the given username and password authenticate for the given service. Returns False otherwise
    username: the username to authenticate
    password: the password in plain text
salt.auth.pam.groups(username, **kwargs)
    Retrieve groups for a given user for this auth provider
    Uses system groups
13.1.7 salt.auth.pki

Authenticate via a PKI certificate.

Note: This module is Experimental and should be used with caution

Provides an authenticate function that will allow the caller to authenticate a user via their public cert against a pre-defined Certificate Authority.

TODO: Add a `ca_dir' option to configure a directory of CA files, a la Apache.

depends
    • pyOpenSSL module

salt.auth.pki.auth(username, password, **kwargs)
    Returns True if the given user cert (password is the cert contents) was issued by the CA and if cert's Common Name is equal to username.
    Returns False otherwise.

username: we need it to run the auth function from CLI/API; it should be in master config auth/acl
password: contents of user certificate (pem-encoded user public key); why `password'? For CLI, it's the only available name

Configure the CA cert in the master config file:

```yaml
external_auth:
    pki:
        ca_file: /etc/pki/tls/ca_certs/trusted-ca.crt
    your_user:
        - .*
```

13.1.8 salt.auth.rest module

Provide authentication using a REST call

Django auth can be defined like any other eauth module:

```yaml
external_auth:
    rest:
        ^url: https://url/for/rest/call
        fred:
            - .*
            - '@runner'
```

If there are entries underneath the `^url entry then they are merged with any responses from the REST call. In the above example, assuming the REST call does not return any additional ACLs, this will authenticate Fred via a REST call and allow him to run any execution module and all runners.

The REST call should return a JSON object that maps to a regular eauth YAML structure as above.

salt.auth.rest.auth(username, password)
    REST authentication

salt.auth.rest.rest_auth_setup()
13.1.9  salt.auth.sharedsecret

Provide authentication using configured shared secret

```python
external_auth:
    sharedsecret:
        fred:
            - .*
            - '@jobs'
```

The shared secret should be added to the master configuration, for example in `/etc/salt/master.d/sharedsecret.conf` (make sure that file is only readable by the user running the master):

```python
sharedsecret: OIUHF_CHANGE_THIS_12h88
```

This auth module should be used with caution. It was initially designed to work with a frontal that takes care of authentication (for example kerberos) and places the shared secret in the HTTP headers to the salt-api call. This salt-api call should really be done on localhost to avoid someone eavesdropping on the shared secret.

See the documentation for cherrypy to setup the headers in your frontal.

New in version Beryllium.

```python
salt.auth.sharedsecret.auth(username, sharedsecret, **kwargs)
```

Shared secret authentication

13.1.10  salt.auth.stormpath

Provide authentication using Stormpath.

This driver requires some extra configuration beyond that which Stormpath normally requires.

```python
stormpath:
    apiid: 1234567890
    apikey: 1234567890/ABCDEF
    # Can use an application ID
    application: 6789012345
    # Or can use a directory ID
    directory: 3456789012
    # But not both
```

New in version 2015.8.0.

```python
salt.auth.stormpath.auth(username, password)
```

Authenticate using a Stormpath directory or application

13.1.11  salt.auth.yubico

Provide authentication using YubiKey.

New in version 2015.5.0.

```python
depends  yubico-client Python module
```

To get your YubiKey API key you will need to visit the website below.

https://upgrade.yubico.com/getapikey/
The resulting page will show the generated Client ID (aka AuthID or API ID) and the generated API key (Secret Key). Make a note of both and use these two values in your /etc/salt/master configuration.

```
/etc/salt/master

yubico_users:
damian:
id: 12345
key: ABCDEFGHIJKLMNOPQRSTUVWXYZ

external_auth:
yubico:
damian:
  - test.*
```

Please wait five to ten minutes after generating the key before testing so that the API key will be updated on all the YubiCloud servers.

```
salt.auth.yubico.auth(username, password)
   Authenticate against yubico server

salt.auth.yubico.groups(username, *args, **kwargs)
```

### 13.2 beacon modules

<table>
<thead>
<tr>
<th>Trap</th>
<th>Description</th>
</tr>
</thead>
<tbody>

<tr>
<td>wtmp</td>
<td>Beacon to fire events at login of users as registered in the wtmp file</td>
</tr>
</tbody>
</table>

### 13.2.1 salt.beacons.adb module

Beacon to emit adb device state changes for Android devices

New in version 2016.3.0.
salt.beacons.adb.beacon(config)
Emit the status of all devices returned by adb

Specify the device states that should emit an event, there will be an event for each device with the event type and device specified.

```yaml
beacons:
adb:
  states:
    - offline
    - unauthorized
    - missing
  no_devices_event: True
  battery_low: 25
```

salt.beacons.adb.validate(config)
Validate the beacon configuration

13.2.2 salt.beacons.btmp

Beacon to fire events at failed login of users

```yaml
beacons:
btmp: {}
```

salt.beacons.btmp.beacon(config)
Read the last btmp file and return information on the failed logins

```yaml
beacons:
btmp: {}
```

salt.beacons.btmp.validate(config)
Validate the beacon configuration

13.2.3 salt.beacons.diskusage

Beacon to monitor disk usage.
New in version 2015.5.0.

```yaml
depends python-psutil
```

salt.beacons.diskusage.beacon(config)
Monitor the disk usage of the minion

Specify thresholds for each disk and only emit a beacon if any of them are exceeded.

```yaml
beacons:
diskusage:
  - /: 63%
  - /mnt/nfs: 50%
```

Windows drives must be quoted to avoid yaml syntax errors

```yaml
beacons:
diskusage:
  - interval: 120
```
salt.beacons.diskusage.validate(config)
    Validate the beacon configuration

13.2.4 salt.beacons.glxinfo module

Beacon to emit when a display is available to a linux machine

New in version 2016.3.0.

salt.beacons.glxinfo.beacon(config)
    Emit the status of a connected display to the minion

    Mainly this is used to detect when the display fails to connect for whatever reason.

    beacons:
        glxinfo:
            user: frank
            screen_event: True

salt.beacons.glxinfo.validate(config)
    Validate the beacon configuration

13.2.5 salt.beacons.inotify

Watch files and translate the changes into salt events

    depends
        - pyinotify Python module >= 0.9.5

    Caution Using generic mask options like open, access, ignored, and closed_nowrite with reactors can easily cause the reactor to loop on itself. To mitigate this behavior, consider setting the disable_during_state_run flag to True in the beacon configuration.

    note The inotify beacon only works on OSes that have inotify kernel support. Currently this excludes FreeBSD, Mac OS X, and Windows.

salt.beacons.inotify.beacon(config)
    Watch the configured files

Example Config

    beacons:
        inotify:
            /path/to/file/or/dir:
                mask:
                    - open
                    - create
                    - close_write
                recurse: True
                auto_add: True
                exclude:
                    - /path/to/file/or/dir/exclude1
                    - /path/to/file/or/dir/exclude2
The mask list can contain the following events (the default mask is create, delete, and modify):

- access - File accessed
- attrib - File metadata changed
- close_nowrite - Unwritable file closed
- close_write - Writable file closed
- create - File created in watched directory
- delete - File deleted from watched directory
- delete_self - Watched file or directory deleted
- modify - File modified
- moved_from - File moved out of watched directory
- moved_to - File moved into watched directory
- move_self - Watched file moved
- open - File opened

The mask can also contain the following options:

- dont_follow - Don't dereference symbolic links
- excl_unlink - Omit events for children after they have been unlinked
- oneshot - Remove watch after one event
- onlydir - Operate only if name is directory

**recurse:** Recursively watch files in the directory

**auto_add:** Automatically start watching files that are created in the watched directory

**exclude:** Exclude directories or files from triggering events in the watched directory

```
salt.beacons.inotify.close(config)
salt.beacons.inotify.validate(config)
```

**13.2.6 salt.beacons.journald**

A simple beacon to watch journald for specific entries

```
salt.beacons.journald.beacon(config)

The journald beacon allows for the systemd journal to be parsed and linked objects to be turned into events.

This beacons config will return all sshd journal entries
```

```
beacons:
    journald:
        sshd:
            SYSLOG_IDENTIFIER: sshd
            PRIORITY: 6
```

```
salt.beacons.journald.validate(config)
Validate the beacon configuration
```

**13.2. beacon modules**
**13.2.7 salt.beacons.load**

Beacon to emit system load averages

```python
salt.beacons.load.beacon(config)
```

Emit the load averages of this host.

Specify thresholds for each load average and only emit a beacon if any of them are exceeded.

*onchangeonly*: when *onchangeonly* is True the beacon will fire events only when the load average pass one threshold. Otherwise, it will fire an event at each beacon interval. The default is False.

*emitatstartup*: when *emitatstartup* is False the beacon will not fire event when the minion is reload. Applicable only when *onchangeonly* is True. The default is True.

```python
beacons:
    load:
        1m:
            - 0.0
            - 2.0
        5m:
            - 0.0
            - 1.5
        15m:
            - 0.1
            - 1.0
    emitatstartup: True
    onchangeonly: False
```

```python
salt.beacons.load.validate(config)
```

Validate the beacon configuration

**13.2.8 salt.beacons.memusage module**

Beacon to monitor memory usage.

New in version 2016.3.0.

```python
depends python-psutil
```

```python
salt.beacons.memusage.beacon(config)
```

Monitor the memory usage of the minion

Specify thresholds for percent used and only emit a beacon if it is exceeded.

```python
beacons:
    memusage:
        - percent: 63%
```

```python
salt.beacons.memusage.validate(config)
```

Validate the beacon configuration

**13.2.9 salt.beacons.network_info**

Beacon to monitor statistics from ethernet adapters

New in version 2015.5.0.
salt.beacons.network_info.beacon(config)

Emit the network statistics of this host.

Specify thresholds for each network stat and only emit a beacon if any of them are exceeded.

Emit beacon when any values are equal to configured values.

```yaml
beacons:
  network_info:
    eth0:
      - type: equal
      - bytes_sent: 100000
      - bytes_recv: 100000
      - packets_sent: 100000
      - packets_recv: 100000
      - errin: 100
      - errout: 100
      - dropin: 100
      - dropout: 100
```

Emit beacon when any values are greater than configured values.

```yaml
beacons:
  network_info:
    eth0:
      - type: greater
      - bytes_sent: 100000
      - bytes_recv: 100000
      - packets_sent: 100000
      - packets_recv: 100000
      - errin: 100
      - errout: 100
      - dropin: 100
      - dropout: 100
```

salt.beacons.network_info.validate(config)

Validate the beacon configuration

### 13.2.10 salt.beacons.network_settings

Beacon to monitor network adapter setting changes on Linux

New in version 2016.3.0.

class salt.beacons.network_settings.Hashabledict

Helper class that implements a hash function for a dictionary

salt.beacons.network_settings.beacon(config)

Watch for changes on network settings

By default, the beacon will emit when there is a value change on one of the settings on watch. The config also support the onvalue parameter for each setting, which instruct the beacon to only emit if the setting changed to the value defined.

Example Config

```yaml
beacons:
  network_settings:
    eth0:
```

13.2. beacon modules
The config above will check for value changes on eth0 ipaddr and eth1 linkmode. It will also emit if the promiscuity value changes to 1.

Beacon items can use the * wildcard to make a definition apply to several interfaces. For example an eth* would apply to all ethernet interfaces.

Setting the argument coalesce = True will combine all the beacon results on a single event. The example below shows how to trigger coalesced results:

```yaml
beacons:
    network_settings:
        coalesce: True
        eth0:
            ipaddr:
            promiscuity:
```

```
salt.beacons.network_settings.validate(config)
Validate the beacon configuration
```

### 13.2.11 salt.beacons.pkg

Watch for pkgs that have upgrades, then fire an event.

New in version 2016.3.0.

```
salt.beacons.pkg.beacon(config)
Check if installed packages are the latest versions and fire an event for those that have upgrades.
```

```yaml
beacons:
    pkg:
        pkgs:
            - zsh
            - apache2
            - refresh: True
```

```
salt.beacons.pkg.validate(config)
Validate the beacon configuration
```

### 13.2.12 salt.beacons.proxy_example module

Example beacon to use with salt-proxy

```yaml
beacons:
    proxy_example:
        endpoint: beacon
```

```
salt.beacons.proxy_example.beacon(config)
Called several times each second https://docs.saltstack.com/en/latest/topics/beacons/#the-beacon-function
```
```python
beacons:
    proxy_example:
      endpoint: beacon
```

salt.beacons.proxy_example.validate(config)
Validate the beacon configuration

### 13.2.13 salt.beacons.ps module

Send events covering service status
salties.beacons.ps.beacon(config)
Scan for processes and fire events

Example Config
```python
beacons:
    ps:
      salt-master: running
      mysql: stopped
```

The config above sets up beacons to check that processes are running or stopped.
salties.beacons.ps.validate(config)
Validate the beacon configuration

### 13.2.14 salt.beacons.salt_proxy module

Beacon to manage and report the status of one or more salt proxy processes

New in version 2015.8.3.
salties.beacons.salt_proxy.beacon(proxies)
Handle configured proxies

```python
beacons:
    salt_proxy:
      - p8000: {}
      - p8001: {}
```

### 13.2.15 salt.beacons.service

Send events covering service status
salt.beacons.service.beacon(config)
Scan for the configured services and fire events

Example Config
```python
beacons:
    service:
      salt-master:
      mysql:
```

13.2. beacon modules
The config above sets up beacons to check for the salt-master and mysql services.

The config also supports two other parameters for each service:

- **onchangeonly**: when `onchangeonly` is True the beacon will fire events only when the service status changes. Otherwise, it will fire an event at each beacon interval. The default is False.

- **emitatstartup**: when `emitatstartup` is False the beacon will not fire event when the minion is reload. Applicable only when `onchangeonly` is True. The default is True.

- **uncleanshutdown**: If `uncleanshutdown` is present it should point to the location of a pid file for the service. Most services will not clean up this pid file if they are shutdown uncleanly (e.g. via `kill -9`) or if they are terminated through a crash such as a segmentation fault. If the file is present, then the beacon will add `uncleanshutdown: True` to the event. If not present, the field will be False. The field is only added when the service is NOT running. Omitting the configuration variable altogether will turn this feature off.

Please note that some init systems can remove the pid file if the service registers as crashed. One such example is nginx on CentOS 7, where the service unit removes the pid file when the service shuts down (IE: the pid file is observed as removed when kill -9 is sent to the nginx master process). The `uncleanshutdown` option might not be of much use there, unless the unit file is modified.

Here is an example that will fire an event whenever the state of nginx changes and report an uncleanshutdown. This example is for Arch, which places nginx's pid file in `/run`.

```yaml
beacons:
  service:
    nginx:
      onchangeonly: True
      uncleanshutdown: /run/nginx.pid
```

**salt.beacons.service.validate(config)**

Validate the beacon configuration

### 13.2.16 salt.beacons.sh

Watch the shell commands being executed actively. This beacon requires strace.

**salt.beacons.sh.beacon(config)**

Scan the shell execve routines. This beacon will convert all login shells

```yaml
beacons:
  sh: {}
```

**salt.beacons.sh.validate(config)**

Validate the beacon configuration

### 13.2.17 salt.beacons.twilio_txt_msg

Beacon to emit Twilio text messages

**salt.beacons.twilio_txt_msg.beacon(config)**

Emit a dict name `texts` whose value is a list of texts.

```yaml
beacons:
  twilio_txt_msg:
    account_sid: "<account sid>"
    auth_token: "<auth token>"
```
twilio_number: "+15555555555"
interval: 10

salt.beacons.twilio_txt_msg.validate(config)
   Validate the beacon configuration

13.2.18 salt.beacons.wtmp

Beacon to fire events at login of users as registered in the wtmp file

beacons:
   wtmp: {}

salt.beacons.wtmp.beacon(config)
   Read the last wtmp file and return information on the logins

beacons:
   wtmp: {}

salt.beacons.wtmp.validate(config)
   Validate the beacon configuration

13.3 engine modules

<table>
<thead>
<tr>
<th>engine module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>docker_events</td>
<td>Send events from Docker events</td>
</tr>
<tr>
<td>logentries</td>
<td>An engine that sends events to the Logentries logging service.</td>
</tr>
<tr>
<td>logstash</td>
<td>An engine that reads messages from the salt event bus and pushes them onto a logstash endpoint.</td>
</tr>
<tr>
<td>redis_sentinel</td>
<td>An engine that reads messages from the redis sentinel pub-sub and sends reactor events based on the channels they are subscribed to.</td>
</tr>
<tr>
<td>slack</td>
<td>An engine that reads messages from Slack and sends them to the Salt event bus.</td>
</tr>
<tr>
<td>sqs_events</td>
<td>An engine that continuously reads messages from SQS and fires them as events.</td>
</tr>
<tr>
<td>test</td>
<td>A simple test engine, not intended for real use but as an example</td>
</tr>
<tr>
<td>thorium</td>
<td>Manage the Thorium complex event reaction system</td>
</tr>
</tbody>
</table>

13.3.1 salt.engines.docker_events module

Send events from Docker events

salt.engines.docker_events.start(docker_url='unix://var/run/docker.sock',
tag='salt/engines/docker_events')
   timeout=60,
   tag='salt/engines/docker_events')
   Example Config
engines:

```
docker_events:
    docker_url: unix:///var/run/docker.sock
```

The config above sets up engines to listen for events from the Docker daemon and publish them to the Salt event bus.

### 13.3.2 salt.engines.logentries

An engine that sends events to the Logentries logging service.

- **Maintainer:** Jimmy Tang (jimmy_tang@rapid7.com)
- **Maturity:** New
- **Depends:** ssl, certifi
- **Platform:** all

To enable this engine the master and/or minion will need the following python libraries

- ssl
- certifi

If you are running a new enough version of python then the ssl library will be present already.

You will also need the following values configured in the minion or master config.

- **Configuration**
  - **Example configuration**
  
  ```
  engines:
    - logentries: endpoint: data.logentries.com port: 10000 token: 057af3e2-1c05-47c5-882a-5cd644655dbf
  
  The `token' can be obtained from the Logentries service.
  ```

To test this engine

```salt '*' test.ping cmd.run uptime```

```
close_connection()
open_connection()
put(data)
reopen_connection()
```

class `salt.engines.logentries.SocketAppender` alias of `TLSSocketAppender`

class `salt.engines.logentries.TLSSocketAppender` (*verbose*=True, *LE_API*=`data.logentries.com`, *LE_PORT*=80, *LE_TLS_PORT*=443)

```
open_connection()
```
salt.engines.logentries.start(endpoint='data.logentries.com', port=10000, token=None, tag='salt/engines/logentries')

Listen to salt events and forward them to Logentries

13.3.3 salt.engines.logstash

An engine that reads messages from the salt event bus and pushes them onto a logstash endpoint.

collection

Example configuration

engines:

- logstash: host: log.my_network.com port: 5959

depends logstash

salt.engines.logstash.start(host, port=5959, tag='salt/engine/logstash')

Listen to salt events and forward them to logstash

13.3.4 salt.engines.redis_sentinel module

An engine that reads messages from the redis sentinel pubsub and sends reactor events based on the channels they are subscribed to.

configuration

Example configuration

engines:

- redis_sentinel:

  hosts: matching: `board*' port: 26379 interface: eth2

  channels:

  - `+switch-master`
  - `+odown`
  - `-odown`

depends redis

class salt.engines.redis_sentinel.Listener(host=None, port=None, channels=None, tag=None)

  run()

  work(item)

salt.engines.redis_sentinel.start(hosts, channels, tag=None)

13.3.5 salt.engines.slack module

An engine that reads messages from Slack and sends them to the Salt event bus. Alternatively Salt commands can be sent to the Salt master via Slack by setting the control parameter to True and using command prefaced with a !.

configuration

Example configuration

configuration
```python
engines:
    - slack:
        token: 'xoxb-xxxxxxxx-xxxxxxxxxxxxxxxxxxxxxxxx'
        control: True
        valid_users:
            - garethgreenaway
        valid_commands:
            - test.ping
            - cmd.run
            - list_jobs
            - list_command
        aliases:
            list_jobs:
                cmd: jobs.list_jobs
            list_command:
                cmd: pillar.get salt:engines:slack:valid_commands
        target=saltmaster

depends slackclient

salt.engines.slack.start(token, aliases=None, valid_users=None, valid_commands=None, control=False, tag='salt/engines/slack')

Listen to Slack events and forward them to Salt

13.3.6 salt.engines.sqs_events

An engine that continuously reads messages from SQS and fires them as events.
Note that long polling is utilized to avoid excessive CPU usage.

New in version 2015.8.0.

depends boto

Configuration

This engine can be run on the master or on a minion.

Example Config:

```py
engines:
    - sqs_events:
        queue: test
        profile: my-sqs-profile # optional
```

Explicit sqs credentials are accepted but this engine can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not (or for boto version < 2.5.1) used you need to specify them either in a pillar or in the config file of the master or minion, as appropriate:

```py
sqs.keyid: GKTADJGHEIQSXMKKRBJ08H
sqs.key: askdjghsdfsdfgWwUpUjasdfklkdfkljsdfjajkgsh
```
A region may also be specified in the configuration:

```yaml
sqs.region: us-east-1
```

If a region is not specified, the default is `us-east-1`.

It's also possible to specify key, keyid and region via a profile:

```yaml
myprofile:
  keyid: GKTADJGHEIQXSXMKKBRJ08H
  key: askdjghsdfjkgwupUjasdfkldflgjsdfjajkghs
  region: us-east-1
```

Additionally you can define cross account sqs:

```yaml
engines:
  - sqs_events:
      queue: prod
      owner_acct_id: 111111111111
```

```python
salt.engines.sqs_events.start(queue, profile=None, tag='salt/engine/sqs', owner_acct_id=None)
```

Listen to sqs and fire message on event bus.

### 13.3.7 salt.engines.test

A simple test engine, not intended for real use but as an example

```python
salt.engines.test.start()
```

Listen to events and write them to a log file.

### 13.3.8 salt.engines.thorium module

Manage the Thorium complex event reaction system

```python
salt.engines.thorium.start(grains=False, grain_keys=None, pillar=False, pillar_keys=None)
```

Execute the Thorium runtime.

### 13.4 fileserver modules

<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>azurefs</td>
<td>The backend for serving files from the Azure blob storage service.</td>
</tr>
<tr>
<td>gitfs</td>
<td>Git Fileserver Backend</td>
</tr>
<tr>
<td>hgfs</td>
<td>Mercurial Fileserver Backend</td>
</tr>
<tr>
<td>minionfs</td>
<td>Fileserver backend which serves files pushed to the Master</td>
</tr>
<tr>
<td>roots</td>
<td>The default file server backend</td>
</tr>
<tr>
<td>s3fs</td>
<td>Amazon S3 Fileserver Backend</td>
</tr>
<tr>
<td>svnfs</td>
<td>Subversion Fileserver Backend</td>
</tr>
</tbody>
</table>

#### 13.4.1 salt.fileserver.azurefs

The backend for serving files from the Azure blob storage service.
To enable, add `azurefs` to the `fileserver_backend` option in the Master config file.

```yaml
fileserver_backend:
  - azurefs
```

Each environment is configured as a storage container. The name of the container must match the name of the environment. The `storage_account` is the name of the storage account inside Azure where the container lives, and the `storage_key` is the access key used for that storage account:

```yaml
azurefs_envs:
  base:
    storage_account: my_storage
    storage_key: frehgfw34fwGefG07fwsfw343tGFDSDFGDFG==
```

With this configuration, multiple storage accounts can be used with a single salt infrastructure.

### 13.4.2 salt.fileserver.gitfs

Git Fileserver Backend

With this backend, branches and tags in a remote git repository are exposed to salt as different environments.

To enable, add `git` to the `fileserver_backend` option in the Master config file.

```yaml
fileserver_backend:
  - git
```

As of Salt 2014.7.0, the Git fileserver backend supports `GitPython`, `pygit2`, and `dulwich` to provide the Python interface to git. If more than one of these are present, the order of preference for which one will be chosen is the same as the order in which they were listed: `pygit2`, `GitPython`, `dulwich` (keep in mind, this order is subject to change).

An optional master config parameter (`gitfs_provider`) can be used to specify which provider should be used.

More detailed information on how to use gitfs can be found in the [Gitfs Walkthrough](#).

**Note:** Minimum requirements

To use `GitPython` for gitfs requires a minimum `GitPython` version of 0.3.0, as well as the `git` CLI utility. Instructions for installing `GitPython` can be found [here](#).

To use `pygit2` for gitfs requires a minimum `pygit2` version of 0.20.3. `pygit2` 0.20.3 requires `libgit2` 0.20.0. `pygit2` and `libgit2` are developed alongside one another, so it is recommended to keep them both at the same major release to avoid unexpected behavior. For example, `pygit2` 0.21.x requires `libgit2` 0.21.x, `pygit2` 0.22.x will require `libgit2` 0.22.x, etc.

To find stale refs, `pygit2` additionally requires the `git` CLI utility to be installed.

### 13.4.3 salt.fileserver.hgfs

Mercurial Fileserver Backend

To enable, add `hg` to the `fileserver_backend` option in the Master config file.

```yaml
fileserver_backend:
  - hg
```
After enabling this backend, branches, bookmarks, and tags in a remote mercurial repository are exposed to salt as different environments. This feature is managed by the `fileserver_backend` option in the salt master config file.

This fileserver has an additional option `hgfs_branch_method` that will set the desired branch method. Possible values are: branches, bookmarks, or mixed. If using branches or mixed, the default branch will be mapped to base.

Changed in version 2014.1.0: The `hgfs_base` master config parameter was added, allowing for a branch other than default to be used for the base environment, and allowing for a base environment to be specified when using an `hgfs_branch_method` of bookmarks.

```
depends
  - mercurial
  - python bindings for mercurial (python-hglib)
```

### 13.4.4 salt.fileserver.minionfs

Fileserver backend which serves files pushed to the Master

The `cp.push` function allows Minions to push files up to the Master. Using this backend, these pushed files are exposed to other Minions via the Salt fileserver.

To enable minionfs, `file_recv` needs to be set to `True` in the master config file (otherwise `cp.push` will not be allowed to push files to the Master), and `minion` must be added to the `fileserver_backends` list.

```
fileserver_backend:
  - minion
```

Other minionfs settings include: `minionfs_whitelist`, `minionfs_blacklist`, `minionfs_mountpoint`, and `minionfs_env`.

See also:

* MinionFS Backend Walkthrough

### 13.4.5 salt.fileserver.roots

The default file server backend

This fileserver backend serves files from the Master's local filesystem. If `fileserver_backend` is not defined in the Master config file, then this backend is enabled by default. If it is defined then `roots` must be in the `fileserver_backend` list to enable this backend.

```
fileserver_backend:
  - roots
```

Fileserver environments are defined using the `file_roots` configuration option.

### 13.4.6 salt.fileserver.s3fs

Amazon S3 Fileserver Backend

This backend exposes directories in S3 buckets as Salt environments. To enable this backend, add `s3fs` to the `fileserver_backend` option in the Master config file.
filesrv_backend:
  - s3fs

S3 credentials must also be set in the master config file:

s3.keyid: GKTADJGHEIQSXMKKRBJ08H
s3.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs

Alternatively, if on EC2 these credentials can be automatically loaded from instance metadata.

This fileserver supports two modes of operation for the buckets:

1. A single bucket per environment

   s3.buckets:
   production:
     - bucket1
     - bucket2
   staging:
     - bucket3
     - bucket4

2. Multiple environments per bucket

   s3.buckets:
   - bucket1
   - bucket2
   - bucket3
   - bucket4

Note that bucket names must be all lowercase both in the AWS console and in Salt, otherwise you may encounter SignatureDoesNotMatch errors.

A multiple-environment bucket must adhere to the following root directory structure:

s3://<bucket name>/<environment>/<files>

Note: This fileserver back-end requires the use of the MD5 hashing algorithm. MD5 may not be compliant with all security policies.

13.4.7 salt.fileserver.svnfs

Subversion Fileserver Backend

After enabling this backend, branches, and tags in a remote subversion repository are exposed to salt as different environments. To enable this backend, add svn to the fileserver_backend option in the Master config file.

filesrv_backend:
  - svn

This backend assumes a standard svn layout with directories for branches, tags, and trunk, at the repository root.

  depends
  * subversion
• pysvn

Changed in version 2014.7.0: The paths to the trunk, branches, and tags have been made configurable, via the config options `svnfs_trunk`, `svnfs_branches`, and `svnfs_tags`. `svnfs_mountpoint` was also added. Finally, support for per-remote configuration parameters was added. See the documentation for more information.

## 13.5 grains modules

<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>chronos</td>
<td>Generate chronos proxy minion grains.</td>
</tr>
<tr>
<td>core</td>
<td>The static grains, these are the core, or built in grains.</td>
</tr>
<tr>
<td>disks</td>
<td>Detect disks</td>
</tr>
<tr>
<td>esxi</td>
<td>Generate baseline proxy minion grains for ESXi hosts.</td>
</tr>
<tr>
<td>extra</td>
<td></td>
</tr>
<tr>
<td>fx2</td>
<td>Generate baseline proxy minion grains for Dell FX2 chassis.</td>
</tr>
<tr>
<td>junos</td>
<td>Grains for junos.</td>
</tr>
<tr>
<td>marathon</td>
<td>Generate marathon proxy minion grains.</td>
</tr>
<tr>
<td>mdadm</td>
<td>Detect MDADM RAIDs</td>
</tr>
<tr>
<td>opts</td>
<td>Simple grain to merge the opts into the grains directly if the <code>grain_opts</code></td>
</tr>
<tr>
<td>philips_hue</td>
<td>Static grains for the Philips HUE lamps</td>
</tr>
<tr>
<td>rest_sample</td>
<td>Generate baseline proxy minion grains</td>
</tr>
</tbody>
</table>

### 13.5.1 salt.grains.chronos

Generate chronos proxy minion grains.

New in version 2015.8.2.

- `salt.grains.chronos.kernel()`
- `salt.grains.chronos.os()`
- `salt.grains.chronos.os_data()`
- `salt.grains.chronos.os_family()`

### 13.5.2 salt.grains.core

The static grains, these are the core, or built in grains.

When grains are loaded they are not loaded in the same way that modules are loaded, grain functions are detected and executed, the functions MUST return a dict which will be applied to the main grains dict. This module will always be executed first, so that any grains loaded here in the core module can be overwritten just by returning dict keys with the same value as those returned here.

- `salt.grains.core.append_domain()`
  Return append_domain if set

- `salt.grains.core.dns()`
  Parse the resolver configuration file
  New in version 2016.3.0.

- `salt.grains.core.get_machine_id()`
  Provide the machine-id
salt.grains.core.get_master()
Provides the minion with the name of its master. This is useful in states to target other services running on the master.

salt.grains.core.get_server_id()
Provides an integer based on the FQDN of a machine. Useful as server-id in MySQL replication or anywhere else you'll need an ID like this.

salt.grains.core.hostname()
Return fqdn, hostname, domainname

salt.grains.core.hwaddr_interfaces()
Provide a dict of the connected interfaces and their hw addresses (Mac Address)

salt.grains.core.id_()
Return the id

salt.grains.core.ip4_interfaces()
Provide a dict of the connected interfaces and their ip4 addresses The addresses will be passed as a list for each interface

salt.grains.core.ip6_interfaces()
Provide a dict of the connected interfaces and their ip6 addresses The addresses will be passed as a list for each interface

salt.grains.core.ip_fqdn()
Return ip address and FQDN grains

salt.grains.core.ip_interfaces()
Provide a dict of the connected interfaces and their ip addresses The addresses will be passed as a list for each interface

salt.grains.core.locale_info()
Provides defaultlanguage defaultencoding

salt.grains.core.os_data()
Return grains pertaining to the operating system

salt.grains.core.path()
Return the path

salt.grains.core.pythonexecutable()
Return the python executable in use

salt.grains.core.pythonpath()
Return the Python path

salt.grains.core.pythonversion()
Return the Python version

salt.grains.core.saltpath()
Return the path of the salt module

salt.grains.core.saltversion()
Return the version of salt

salt.grains.core.saltversioninfo()
Return the version_info of salt
New in version 0.17.0.

salt.grains.core.zmqversion()
Return the zeromq version
13.5.3 salt.grains.disks

Detect disks

salt.grains.disks.disks()

Return list of disk devices

13.5.4 salt.grains.esxi

Generate baseline proxy minion grains for ESXi hosts.

.. versionadded:: 2015.8.4

salt.grains.esxi.esxi()
salt.grains.esxi.kernel()
salt.grains.esxi.os()
salt.grains.esxi.os_family()

13.5.5 salt.grains.extra

salt.grains.extra.config()

Return the grains set in the grains file

salt.grains.extra.shell()

Return the default shell to use on this system

13.5.6 salt.grains.fx2

Generate baseline proxy minion grains for Dell FX2 chassis. The challenge is that most of Salt isn't bootstrapped yet, so we need to repeat a bunch of things that would normally happen in proxy/fx2.py--just enough to get data from the chassis to include in grains.

salt.grains.fx2.fx2()
salt.grains.fx2.kernel()
salt.grains.fx2.location()
salt.grains.fx2.os_data()
salt.grains.fx2.os_family()

13.5.7 salt.grains.junos

Grains for junos. NOTE this is a little complicated--junos can only be accessed via salt-proxy-minion. Thus, some grains make sense to get them from the minion (PYTHONPATH), but others don't (ip_interfaces)

salt.grains.junos.defaults()
salt.grains.junos.facts()
salt.grains.junos.os_family()
13.5.8 salt.grains.marathon

Generate marathon proxy minion grains.
New in version 2015.8.2.
salt.grains.marathon.kernel()
salt.grains.marathon.marathon()
salt.grains.marathon.os()
salt.grains.marathon.os_data()
salt.grains.marathon.os_family()

13.5.9 salt.grains.mdadm

Detect MDADM RAIDs
salt.grains.mdadm.mdadm()
    Return list of mdadm devices

13.5.10 salt.grains.opts

Simple grain to merge the opts into the grains directly if the grain_opts configuration value is set
salt.grains.opts.opts()
    Return the minion configuration settings

13.5.11 salt.grains.philips_hue

Static grains for the Philips HUE lamps
New in version 2015.8.3.
salt.grains.philips_hue.kernel()
salt.grains.philips_hue.os()
salt.grains.philips_hue.os_family()
salt.grains.philips_hue.product()
salt.grains.philips_hue.vendor()

13.5.12 salt.grains.rest_sample

Generate baseline proxy minion grains
salt.grains.rest_sample.kernel()
salt.grains.rest_sample.location()
salt.grains.rest_sample.os()
salt.grains.rest_sample.os_data()
salt.grains.rest_sample.os_family()
salt.grains.rest_sample.proxy_functions(proxy)

The loader will execute functions with one argument and pass a reference to the proxymodules LazyLoader object. However, grains sometimes get called before the LazyLoader object is setup so proxy might be None.

### 13.6 execution modules

#### Virtual modules

#### 13.6.1 salt.modules.pkg

pkg is a virtual module that is fulfilled by one of the following modules:

<table>
<thead>
<tr>
<th>Execution Module</th>
<th>Used for</th>
</tr>
</thead>
<tbody>
<tr>
<td>aptpkg</td>
<td>Debian/Ubuntu-based distros which use <code>apt-get(8)</code> for package management</td>
</tr>
<tr>
<td>brew</td>
<td>Mac OS software management using Homebrew</td>
</tr>
<tr>
<td>ebuild</td>
<td>Gentoo-based systems (utilizes the <code>portage</code> python module as well as <code>emerge(1)</code>)</td>
</tr>
<tr>
<td>freebsdpkg</td>
<td>FreeBSD-based OSes using <code>pkg_add(1)</code></td>
</tr>
<tr>
<td>openbsdpkg</td>
<td>OpenBSD-based OSes using <code>pkg_add(1)</code></td>
</tr>
<tr>
<td>pacman</td>
<td>Arch Linux-based distros using <code>pacman(8)</code></td>
</tr>
<tr>
<td>pkgng</td>

<tr>
<td><strong>inspectlib.query</strong></td>
<td>Module for low-level interaction with JbossAS7 through CLI</td>
</tr>
<tr>
<td><strong>introspect</strong></td>
<td>Functions to perform introspection on a minion, and return data in a format</td>
</tr>
<tr>
<td><strong>ipmi</strong></td>
<td>Support IPMI commands over LAN</td>
</tr>
<tr>
<td><strong>ipset</strong></td>
<td>Support for ipset</td>
</tr>
<tr>
<td><strong>iptables</strong></td>
<td>Support for iptables</td>
</tr>
<tr>
<td><strong>iwtools</strong></td>
<td>Support for Wireless Tools for Linux</td>
</tr>
<tr>
<td><strong>jboss7</strong></td>
<td>Module for managing JBoss AS 7 through the CLI interface.</td>
</tr>
<tr>
<td><strong>jboss7_cli</strong></td>
<td>Module for low-level interaction with JbossAS7 through CLI</td>
</tr>
<tr>
<td><strong>jenkins</strong></td>
<td>Module for controlling Jenkins</td>
</tr>
<tr>
<td><strong>junos</strong></td>
<td>Module for interfacing to Junos devices</td>
</tr>
<tr>
<td><strong>kerberos</strong></td>
<td>Manage Kerberos KDC</td>
</tr>
<tr>
<td><strong>key</strong></td>
<td>Functions to view the minion’s public key information</td>
</tr>
<tr>
<td><strong>keyboard</strong></td>
<td>Module for managing keyboards on supported POSIX-like systems using systemd, or such as Redhat, Debian and Gentoo.</td>
</tr>
<tr>
<td><strong>keystone</strong></td>
<td>Module for handling openstack keystone calls.</td>
</tr>
<tr>
<td><strong>kmod</strong></td>
<td>Module to manage Linux kernel modules</td>
</tr>
<tr>
<td><strong>launchctl</strong></td>
<td>Module for the management of MacOS systems that use launchd-launchctl</td>
</tr>
<tr>
<td>Module</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>layman</strong></td>
<td>Support for Layman</td>
</tr>
<tr>
<td><strong>ldap3</strong></td>
<td>Query and modify an LDAP database (alternative interface)</td>
</tr>
<tr>
<td><strong>ldapmod</strong></td>
<td>Salt interface to LDAP commands</td>
</tr>
<tr>
<td><strong>linux_acl</strong></td>
<td>Support for Linux File Access Control Lists</td>
</tr>
<tr>
<td><strong>linux_ip</strong></td>
<td>The networking module for Non-RH/Deb Linux distros</td>
</tr>
<tr>
<td><strong>linux_lvm</strong></td>
<td>Support for Linux LVM2</td>
</tr>
<tr>
<td><strong>linux_sysctl</strong></td>
<td>Module for viewing and modifying sysctl parameters</td>
</tr>
<tr>
<td><strong>localemod</strong></td>
<td>Module for managing locales on POSIX-like systems.</td>
</tr>
<tr>
<td><strong>locate</strong></td>
<td>Module for using the locate utilities</td>
</tr>
<tr>
<td><strong>logadm</strong></td>
<td>Module for managing Solaris logadm based log rotations.</td>
</tr>
<tr>
<td><strong>logrotate</strong></td>
<td>Module for managing logrotate.</td>
</tr>
<tr>
<td><strong>lvs</strong></td>
<td>Support for LVS (Linux Virtual Server)</td>
</tr>
<tr>
<td><strong>lxc</strong></td>
<td>Control Linux Containers via Salt</td>
</tr>
<tr>
<td><strong>mac_assistive</strong></td>
<td>Mac OS X implementations of various commands in the <code>desktop</code> interface</td>
</tr>
<tr>
<td><strong>mac_brew</strong></td>
<td>Homebrew for Mac OS X</td>
</tr>
<tr>
<td><strong>mac_defaults</strong></td>
<td>Set defaults on Mac OS</td>
</tr>
<tr>
<td><strong>mac_desktop</strong></td>
<td>Mac OS X implementations of various commands in the <code>desktop</code> interface</td>
</tr>
<tr>
<td><strong>mac_group</strong></td>
<td>Manage groups on Mac OS 10.7+</td>
</tr>
<tr>
<td><strong>mac_keychain</strong></td>
<td>Install certificates into the keychain on Mac OS</td>
</tr>
<tr>
<td><strong>mac_pkutil</strong></td>
<td>Installer support for OS X.</td>
</tr>
<tr>
<td><strong>mac_ports</strong></td>
<td>Support for MacPorts under Mac OSX.</td>
</tr>
<tr>
<td><strong>mac_power</strong></td>
<td>Module for editing power settings on Mac OS X</td>
</tr>
<tr>
<td><strong>mac_service</strong></td>
<td>The service module for Mac OS X ..</td>
</tr>
<tr>
<td><strong>mac_shadow</strong></td>
<td>New in version 2016.3.0.</td>
</tr>
<tr>
<td><strong>mac_softwareupdate</strong></td>
<td>Support for the softwareupdate command on MacOS.</td>
</tr>
<tr>
<td><strong>mac_user</strong></td>
<td>Manage users on Mac OS 10.7+</td>
</tr>
<tr>
<td><strong>mac_sysctl</strong></td>
<td>Module for viewing and modifying sysctl parameters</td>
</tr>
<tr>
<td><strong>mac_system</strong></td>
<td>New in version 2016.3.0.</td>

<tr>
<td><strong>mac_timezone</strong></td>
<td>Manage users on Mac OS 10.7+</td>
</tr>
<tr>
<td><strong>mac_xattr</strong></td>
<td>This module allows you to manage extended attributes on files or directories</td>
</tr>
<tr>
<td><strong>makeconf</strong></td>
<td>Support for modifying make.conf under Gentoo</td>
</tr>
<tr>
<td><strong>marathon</strong></td>
<td>Module providing a simple management interface to a marathon cluster.</td>
</tr>
<tr>
<td><strong>match</strong></td>
<td>The match module allows for match routines to be run and determine target specs</td>
</tr>
<tr>
<td><strong>mdadm</strong></td>
<td>Salt module to manage RAID arrays with mdadm</td>
</tr>
<tr>
<td><strong>mdata</strong></td>
<td>Module for managing metadata in SmartOS Zones</td>
</tr>
<tr>
<td><strong>memcached</strong></td>
<td>Module for Management of Memcached Keys</td>
</tr>
<tr>
<td><strong>mine</strong></td>
<td>The function cache system allows for data to be stored on the master so it can be easily read by other minions</td>
</tr>
<tr>
<td><strong>minion</strong></td>
<td>Module to provide information about minions</td>
</tr>
<tr>
<td><strong>mod_random</strong></td>
<td>Provides access to randomness generators.</td>
</tr>
<tr>
<td><strong>modjk</strong></td>
<td>Control Modjk via the Apache Tomcat <code>Status</code> worker</td>
</tr>

<tr>
<td>zpool</td>
<td>Module for running ZFS zpool command</td>
</tr>
<tr>
<td>zypper</td>
<td>Package support for openSUSE via the zypper package manager</td>
</tr>
</tbody>
</table>

### 13.6.2 salt.modules.aliases

Manage the information in the aliases file

```python
salt.modules.aliases.get_target(alias)
```

Return the target associated with an alias
CLI Example:
```
salt '*' aliases.get_target alias
```

`salt.modules.aliases.has_target(alias, target)`
Return true if the alias/target is set

CLI Example:
```
salt '*' aliases.has_target alias target
```

`salt.modules.aliases.list_aliases()`
Return the aliases found in the aliases file in this format:
```
{'alias': 'target'}
```

CLI Example:
```
salt '*' aliases.list_aliases
```

`salt.modules.aliases.rm_alias(alias)`
Remove an entry from the aliases file

CLI Example:
```
salt '*' aliases.rm_alias alias
```

`salt.modules.aliases.set_target(alias, target)`
Set the entry in the aliases file for the given alias, this will overwrite any previous entry for the given alias or create a new one if it does not exist.

CLI Example:
```
salt '*' aliases.set_target alias target
```

### 13.6.3 `salt.modules.alternatives`

Support for Alternatives system

`codeauthor` Radek Rada <radek.rada@gmail.com>

`salt.modules.alternatives.auto(name)`
Trigger alternatives to set the path for `<name>` as specified by priority.

CLI Example:
```
salt '*' alternatives.auto name
```

`salt.modules.alternatives.check_exists(name, path)`
Check if the given path is an alternative for a name.

New in version 2015.8.4.

CLI Example:
```
salt '*' alternatives.check_exists name path
```
salt.modules.alternatives.check_installed(name, path)
Check if the current highest-priority match for a given alternatives link is set to the desired path

CLI Example:

```
salt '*' alternatives.check_installed name path
```

salt.modules.alternatives.display(name)
Display alternatives settings for defined command name

CLI Example:

```
salt '*' alternatives.display editor
```

salt.modules.alternatives.install(name, link, path, priority)
Install symbolic links determining default commands

CLI Example:

```
salt '*' alternatives.install editor /usr/bin/editor /usr/bin/emacs23 50
```

salt.modules.alternatives.remove(name, path)
Remove symbolic links determining the default commands.

CLI Example:

```
salt '*' alternatives.remove name path
```

salt.modules.alternatives.set(name, path)
Manually set the alternative <path> for <name>.

CLI Example:

```
salt '*' alternatives.set name path
```

salt.modules.alternatives.show_current(name)
Display the current highest-priority alternative for a given alternatives link

CLI Example:

```
salt '*' alternatives.show_current editor
```

salt.modules.alternatives.show_link(name)
Display master link for the alternative

New in version 2015.8.13,2016.3.4,2016.11.0.

CLI Example:

```
salt '*' alternatives.show_link editor
```

### 13.6.4 salt.modules.apache

Support for Apache

Note: The functions in here are generic functions designed to work with all implementations of Apache. Debian-specific functions have been moved into deb_apache.py, but will still load under the apache namespace when a Debian-based system is detected.
salt.modules.apache.config(name, config, edit=True)
Create VirtualHost configuration files
name File for the virtual host
config VirtualHost configurations

Note: This function is not meant to be used from the command line. Config is meant to be an ordered dict of all of the apache configs.

CLI Example:
salt '*' apache.config /etc/httpd/conf.d/ports.conf config="[{'Listen': '22'}]"

salt.modules.apache.directives()
Return list of directives together with expected arguments and places where the directive is valid (apachectl -L)

CLI Example:
salt '*' apache.directives

salt.modules.apache.fullversion()
Return server version (apachectl -V)

CLI Example:
salt '*' apache.fullversion

salt.modules.apache.modules()
Return list of static and shared modules (apachectl -M)

CLI Example:
salt '*' apache.modules

salt.modules.apache.server_status(profile='default')
Get Information from the Apache server-status handler

Note: The server-status handler is disabled by default. In order for this function to work it needs to be enabled. See [http://httpd.apache.org/docs/2.2/mod/mod_status.html](http://httpd.apache.org/docs/2.2/mod/mod_status.html)

The following configuration needs to exists in pillar/grains. Each entry nested in apache.server-status is a profile of a vhost/server. This would give support for multiple apache servers/vhosts.

apache.server-status:
    default:
        url: http://localhost/server-status
        user: someuser
        pass: password
        realm: 'authentication realm for digest passwords'
        timeout: 5

CLI Examples:
salt '*' apache.server_status
salt '*' apache.server_status other-profile
salt.modules.apache.servermods()
    Return list of modules compiled into the server (apachectl -l)

    CLI Example:
    ```
salt '*' apache.servermods
    ```

salt.modules.apache.signal(signal=None)
    Signals httpd to start, restart, or stop.

    CLI Example:
    ```
salt '*' apache.signal restart
    ```

salt.modules.apache.useradd(pwfile, user, password, opts='')
    Add HTTP user using the htpasswd command. If the htpasswd file does not exist, it will be created. Valid options that can be passed are:

    n  Don't update file; display results on stdout.
    m  Force MD5 hashing of the password (default).
    d  Force CRYPT(3) hashing of the password.
    p  Do not hash the password (plaintext).
    s  Force SHA1 hashing of the password.

    CLI Examples:
    ```
salt '*' apache.useradd /etc/httpd/htpasswd larry badpassword
    salt '*' apache.useradd /etc/httpd/htpasswd larry badpass opts=ns
    ```

salt.modules.apache.userdel(pwfile, user)
    Delete HTTP user from the specified htpasswd file.

    CLI Example:
    ```
salt '*' apache.userdel /etc/httpd/htpasswd larry
    ```

salt.modules.apache.version()
    Return server version (apachectl -v)

    CLI Example:
    ```
salt '*' apache.version
    ```

salt.modules.apache.vhosts()
    Show the settings as parsed from the config file (currently only shows the virtualhost settings) (apachectl -S). Because each additional virtual host adds to the execution time, this command may require a long timeout be specified by using `-t 10`.

    CLI Example:
    ```
salt -t 10 '*' apache.vhosts
    ```

13.6.5 salt.modules.aptpkg

    Support for APT (Advanced Packaging Tool)
**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install` is not available), see [here](#).

**Note:** For virtual package support, either the `python-apt` or `dctrl-tools` package must be installed.

For repository management, the `python-apt` package must be installed.

```python
salt.modules.aptpkg.autoremove(list_only=False, purge=False)
```

New in version 2015.5.0.

Remove packages not required by another package using `apt-get autoremove`.

- `list_only` [False] Only retrieve the list of packages to be auto-removed, do not actually perform the auto-removal.
- `purge` [False] Also remove package config data when autoremoving packages.

New in version 2015.8.0.

CLI Example:

```
salt '*' pkg.autoremove
salt '*' pkg.autoremove list_only=True
salt '*' pkg.autoremove purge=True
```

```python
salt.modules.aptpkg.del_repo(repo, **kwargs)
```

Delete a repo from the sources.list / sources.list.d

If the .list file is in the sources.list.d directory and the file that the repo exists in does not contain any other repo configuration, the file itself will be deleted.

The repo passed in must be a fully formed repository definition string.

CLI Examples:

```
salt '*' pkg.del_repo "myrepo definition"
```

```python
salt.modules.aptpkg.del_repo_key(name=None, **kwargs)
```

New in version 2015.8.0.

Remove a repo key using `apt-key del`

- `name` Repo from which to remove the key. Unnecessary if `keyid` is passed.
- `keyid` The KeyID of the GPG key to remove
- `keyid_ppa` [False] If set to True, the repo's GPG key ID will be looked up from ppa.launchpad.net and removed.

**Note:** Setting this option to `True` requires that the `name` param also be passed.

CLI Examples:

```
salt '*' pkg.del_repo_key keyid=0123ABCD
salt '*' pkg.del_repo_key name='ppa:foo/bar' keyid_ppa=True
```

```python
salt.modules.aptpkg.expand_repo_def(**kwargs)
```

Take a repository definition and expand it to the full pkg repository dict that can be used for comparison. This is a helper function to make the Debian/Ubuntu apt sources sane for comparison in the pkgrepo states.

This is designed to be called from pkgrepo states and will have little use being called on the CLI.
salt.modules.aptpkg.file_dict(*packages)
List the files that belong to a package, grouped by package. Not specifying any packages will return a list of every file on the system's package database (not generally recommended).

CLI Examples:

```
salt '*' pkg.file_dict httpd
salt '*' pkg.file_dict httpd postfix
salt '*' pkg.file_dict
```

salt.modules.aptpkg.file_list(*packages)
List the files that belong to a package. Not specifying any packages will return a list of every file on the system's package database (not generally recommended).

CLI Examples:

```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

salt.modules.aptpkg.get_repo(repo, **kwargs)
Display a repo from the sources.list / sources.list.d
The repo passed in needs to be a complete repo entry.

CLI Examples:

```
salt '*' pkg.get_repo "myrepo definition"
```

salt.modules.aptpkg.get_selections(pattern=None, state=None)
View package state from the dpkg database.

Returns a dict of dicts containing the state, and package names:

```
{'<host>':
 {'<state>': ['pkg1',
 ...]
 },
 ...}
```

CLI Example:

```
salt '*' pkg.get_selections
salt '*' pkg.get_selections 'python-*'
salt '*' pkg.get_selections state=hold
salt '*' pkg.get_selections 'openssh*' state=hold
```

salt.modules.aptpkg.hold(name=None, pkgs=None, sources=None, **kwargs)
New in version 2014.7.0.

Set package in `hold` state, meaning it will not be upgraded.

name  The name of the package, e.g., `tmux`

CLI Example:

```
salt '*' pkg.hold <package name>
```
**pkgs** A list of packages to hold. Must be passed as a python list.

CLI Example:
```
salt '*' pkg.hold pkgs='["foo", "bar"]'
```

salt.modules.aptpkg.info_installed(*names*)

Return the information of the named package(s) installed on the system.

**names** The names of the packages for which to return information.

CLI example:
```
salt '*' pkg.info_installed <package1>
salt '*' pkg.info_installed <package1> <package2> <package3> ...
```

salt.modules.aptpkg.install(*name=None, refresh=False, fromrepo=None, skip_verify=False, debconf=None, pkgs=None, sources=None, reinstall=False, **kwargs*)

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any apt-get/dpkg commands spawned by Salt when the salt-minion service is restarted. (see `KillMode` in the `systemd.kill(5)` manpage for more information). If desired, usage of `systemd-run(1)` can be suppressed by setting a config option called `systemd.scope`, with a value of `False` (no quotes).

Install the passed package, add `refresh=True` to update the dpkg database.

**name** The name of the package to be installed. Note that this parameter is ignored if either `"pkgs"` or `"sources"` is passed. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the `"sources"` option.

32-bit packages can be installed on 64-bit systems by appending the architecture designation (`:i386`, etc.) to the end of the package name.

CLI Example:
```
salt '*' pkg.install <package name>
```

**refresh** Whether or not to refresh the package database before installing.

**fromrepo** Specify a package repository to install from (e.g., `apt-get -t unstable install somepackage`)

**skip_verify** Skip the GPG verification check (e.g., `--allow-unauthenticated`, or `--force-bad-verify` for install from package file).

**debconf** Provide the path to a debconf answers file, processed before installation.

**version** Install a specific version of the package, e.g. `1.2.3-0ubuntu0`. Ignored if `"pkgs"` or `"sources"` is passed.

**reinstall** [False] Specifying `reinstall=True` will use `apt-get install --reinstall` rather than simply `apt-get install` for requested packages that are already installed.

If a version is specified with the requested package, then `apt-get install --reinstall` will only be used if the installed version matches the requested version.

New in version 2015.8.0.

Multiple Package Installation Options:

**pkgs** A list of packages to install from a software repository. Must be passed as a python list.

CLI Example:
```
salt '*' pkg.install pkgs='["foo", "bar"]'
salt '*' pkg.install pkgs='["foo", {"bar": "1.2.3-0ubuntu0"}]'
```
**sources** A list of DEB packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package. Dependencies are automatically resolved and marked as auto-installed.

32-bit packages can be installed on 64-bit systems by appending the architecture designation (:i386, etc.) to the end of the package name.

Changed in version 2014.7.0.

**force_yes** Passes --force-yes to the apt-get command. Don't use this unless you know what you're doing.

New in version 0.17.4.

**install_recommends** Whether to install the packages marked as recommended. Default is True.

New in version 2015.5.0.

**only_upgrade** Only upgrade the packages, if they are already installed. Default is False.

New in version 2015.5.0.

**force_conf_new** Always install the new version of any configuration files.

New in version 2015.8.0.

Returns a dict containing the new package names and versions:

```python
{'<package>': {'old': '<old-version>', 'new': '<new-version>'}}
```

salt.modules.aptpkg.latest_version(*names*, **kwargs)

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

A specific repo can be requested using the fromrepo keyword argument.

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package name> fromrepo=unstable
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

salt.modules.aptpkg.list_pkgs(*versions_as_list=False, removed=False, purge_desired=False, **kwargs)

List the packages currently installed in a dict:

```python
{'<package_name>': '<version>'}
```

removed If True, then only packages which have been removed (but not purged) will be returned.

purge_desired If True, then only packages which have been marked to be purged, but can't be purged due to their status as dependencies for other installed packages, will be returned. Note that these packages will appear in installed

Changed in version 2014.1.1: Packages in this state now correctly show up in the output of this function.

**Note:** External dependencies
Virtual package resolution requires the `dctrl-tools` package to be installed. Virtual packages will show a version of 1.

---

CLI Example:

```
salt '*' pkg.list_pkgs
salt '*' pkg.list_pkgs versions_as_list=True
```

```
salt.modules.aptpkg.list_repos()
```

Lists all repos in the sources.list (and sources.lists.d) files

CLI Example:

```
salt '*' pkg.list_repos
disable=True
```

```
salt.modules.aptpkg.list_upgrades(refresh=True, dist_upgrade=True, **kwargs)
```

List all available package upgrades.

- `refresh` Whether to refresh the package database before listing upgrades. Default: True.
- `dist_upgrade` Whether to list the upgrades using dist-upgrade vs upgrade. Default is to use dist-upgrade.

CLI Example:

```
salt '*' pkg.list_upgrades
```

```
salt.modules.aptpkg.mod_repo(repo, saltenv='base', **kwargs)
```

Modify one or more values for a repo. If the repo does not exist, it will be created, so long as the definition is well formed. For Ubuntu the `ppa:<project>/repo` format is acceptable. `ppa:` format can only be used to create a new repository.

The following options are available to modify a repo definition:

- `comps` a comma separated list of components for the repo, e.g. `main`
- `file` a file name to be used
- `keyserver` keyserver to get gpg key from
- `keyid` key id to load with the keyserver argument
- `key_url` URL to a GPG key to add to the APT GPG keyring
- `consolidate` if True, will attempt to de-dup and consolidate sources
- `comments` Sometimes you want to supply additional information, but not as enabled configuration. All comments provided here will be joined into a single string and appended to the repo configuration with a comment marker (#) before it.

**New in version 2015.8.9.**

**Note:** Due to the way keys are stored for APT, there is a known issue where the key won't be updated unless another change is made at the same time. Keys should be properly added on initial configuration.

CLI Examples:

```
salt '*' pkg.mod_repo 'myrepo definition' uri=http://new/uri
salt '*' pkg.mod_repo 'myrepo definition' comps=main,universe
```

```
salt.modules.aptpkg.owner(*paths)
```

New in version 2014.7.0.
Return the name of the package that owns the file. Multiple file paths can be passed. Like `pkg.version`, if a single path is passed, a string will be returned, and if multiple paths are passed, a dictionary of file/package name pairs will be returned.

If the file is not owned by a package, or is not present on the minion, then an empty string will be returned for that path.

CLI Example:

```
salt '*' pkg.owner /usr/bin/apachectl
salt '*' pkg.owner /usr/bin/apachectl /usr/bin/basename
```

**`salt.modules.aptpkg.purge(name=None, pkgs=None, **kwargs)`**

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running `systemd>=205`, `systemd-run(1)` is now used to isolate commands which modify installed packages from the salt-minion daemon’s control group. This is done to keep systemd from killing any apt-get/dpkg commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the `systemd.kill(5)` manpage for more information). If desired, usage of `systemd-run(1)` can be suppressed by setting a config option called `systemd.scope`, with a value of `False` (no quotes).

Remove packages via `apt-get purge` along with all configuration files.

**name** The name of the package to be deleted.

**Multiple Package Options:**

**pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'
```

**`salt.modules.aptpkg.refresh_db()`**

Updates the APT database to latest packages based upon repositories

Returns a dict, with the keys being package databases and the values being the result of the update attempt. Values can be one of the following:

- **True**: Database updated successfully
- **False**: Problem updating database
- **None**: Database already up-to-date

CLI Example:

```
salt '*' pkg.refresh_db
```

**`salt.modules.aptpkg.remove(name=None, pkgs=None, **kwargs)`**

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running `systemd>=205`, `systemd-run(1)` is now used to isolate commands which modify installed packages from the salt-minion daemon’s control group. This is done to keep systemd from killing any apt-get/dpkg commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the `systemd.kill(5)` manpage for more information). If desired, usage of `systemd-run(1)` can be suppressed by setting a config option called `systemd.scope`, with a value of `False` (no quotes).

Remove packages using `apt-get remove`.

**name** The name of the package to be deleted.

**Multiple Package Options:**
pkgs  A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.
New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs=['"foo", "bar"]
```

**salt.modules.aptpkg.set_selections** (*path=None, selection=None, clear=False, saltenv='base'*)

Change package state in the dpkg database.

The state can be any one of, documented in dpkg(1):

- install
- hold
- deinstall
- purge

This command is commonly used to mark specific packages to be held from being upgraded, that is, to be kept at a certain version. When a state is changed to anything but being held, then it is typically followed by apt-get -u dselect-upgrade.

Note: Be careful with the clear argument, since it will start with setting all packages to deinstall state.

Returns a dict of dicts containing the package names, and the new and old versions:

```
{'<host>':
    {'<package>': {'new': '<new-state>', 'old': '<old-state>'},
    ...}
}
```

CLI Example:

```
salt '*' pkg.set_selections selection={"install": ["netcat"]}
salt '*' pkg.set_selections selection={"hold": ["openssh-server", "openssh-client"]}
salt '*' pkg.set_selections salt://path/to/file
salt '*' pkg.set_selections salt://path/to/file clear=True
```

**salt.modules.aptpkg.unhold** (*name=None, pkgs=None, sources=None, **kwargs*)

New in version 2014.7.0.

Set package current in 'hold' state to install state, meaning it will be upgraded.

name  The name of the package, e.g., `tmux`

CLI Example:

```
salt '*' pkg.unhold <package name>
```

pkgs  A list of packages to hold. Must be passed as a python list.

CLI Example:

```
salt '*' pkg.unhold pkgs=['"foo", "bar"]'
```

**salt.modules.aptpkg.upgrade** (*refresh=True, dist_upgrade=False, **kwargs*)

Changed in version 2015.8.12,2016.3.3,2016.11.0: On minions running systemd>=205, systemd-run(1) is now
used to isolate commands which modify installed packages from the salt-minion daemon’s control group. This is done to keep systemd from killing any apt-get/dpkg commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Upgrades all packages via apt-get upgrade or apt-get dist-upgrade if dist_upgrade is True.

Returns a dict containing the changes:

```plaintext
{'<package>': {'old': '<old-version>', 'new': '<new-version>'}}
```

**dist_upgrade**  Whether to perform the upgrade using dist-upgrade vs upgrade. Default is to use upgrade.

  New in version 2014.7.0.

**force_conf_new**  Always install the new version of any configuration files.

  New in version 2015.8.0.

### CLI Example:

```
salt '*' pkg.upgrade
```

**salt.modules.aptpkg.upgrade_available(name)**

Check whether or not an upgrade is available for a given package

### CLI Example:

```
salt '*' pkg.upgrade_available <package name>
```

**salt.modules.aptpkg.version(*names, **kwargs)**

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

### CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

**salt.modules.aptpkg.version_cmp(pkg1, pkg2, ignore_epoch=False)**

Do a cmp-style comparison on two packages. Return -1 if pkg1 < pkg2, 0 if pkg1 == pkg2, and 1 if pkg1 > pkg2. Return None if there was a problem making the comparison.

**ignore_epoch**  [False] Set to True to ignore the epoch when comparing versions

  New in version 2015.8.10,2016.3.2.

### CLI Example:

```
salt '*' pkg.version_cmp '0.2.4-0ubuntu1' '0.2.4.1-0ubuntu1'
```

### 13.6.6 salt.modules.archive

A module to wrap (non-Windows) archive calls

New in version 2014.1.0.

**salt.modules.archive.cmd_unzip(zip_file, dest, excludes=None, template=None, options=None, runas=None, trim_output=False)**

  New in version 2015.5.0: In versions 2014.7.x and earlier, this function was known as archive.unzip.
Uses the `unzip` command to unpack zip files. This command is part of the Info-ZIP suite of tools, and is typically packaged as simply `unzip`.

**zip_file** Path of zip file to be unpacked

**dest** The destination directory into which the file should be unpacked

**excludes** [None] Comma-separated list of files not to unpack. Can also be passed in a Python list.

**template** [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:

```
salt '*' archive.cmd_unzip template=jinja /tmp/zipfile.zip /tmp/{{grains.id}}/
  -- excludes=file_1,file_2
```

**options** [None] Additional command-line options to pass to the `unzip` binary.

   Changed in version 2015.8.0: The mandatory `-prefixing has been removed. An options string beginning with a --long-option, would have uncharacteristically needed its first - removed under the former scheme.

**runas** [None] Unpack the zip file as the specified user. Defaults to the user under which the minion is running.

New in version 2015.5.0.

**trim_output** [False] The number of files we should output on success before the rest are trimmed, if this is set to True then it will default to 100

**CLI Example:**

```
salt '*' archive.cmd_unzip /tmp/zipfile.zip /home/strongbad/ excludes=file_1,file_2
```

```
salt.modules.archive.cmd_zip(zip_file, sources, template=None, cwd=None, runas=None)
```

New in version 2015.5.0: In versions 2014.7.x and earlier, this function was known as `archive.zip`.

Uses the `zip` command to create zip files. This command is part of the Info-ZIP suite of tools, and is typically packaged as simply `zip`.

**zip_file** Path of zip file to be created

**sources** Comma-separated list of sources to include in the zip file. Sources can also be passed in a Python list.

**template** [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:

```
salt '*' archive.cmd_zip template=jinja /tmp/zipfile.zip /tmp/sourcefile1,/
  tmp/{{grains.id}}.txt
```

**cwd** [None] Use this argument along with relative paths in sources to create zip files which do not contain the leading directories. If not specified, the zip file will be created as if the cwd was /, and creating a zip file of /foo/bar/baz.txt will contain the parent directories foo and bar. To create a zip file containing just baz.txt, the following command would be used:

```
salt '*' archive.cmd_zip /tmp/baz.zip baz.txt cwd=/foo/bar
```

New in version 2014.7.1.

**runas** [None] Create the zip file as the specified user. Defaults to the user under which the minion is running.

New in version 2015.5.0.

**CLI Example:**

```
salt '*' archive.cmd_zip /tmp/zipfile.zip /tmp/sourcefile1,/tmp/sourcefile2
```

```
salt.modules.archive.gunzip(gzipfile, template=None, runas=None, options=None)
```

Uses the gunzip command to unpack gzip files

**template** [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:
salt.modules.archive.gzip(sourcefile, template=None, runas=None, options=None)

Uses the gzip command to create gzip files

**template** [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:

```shell
salt '*' archive.gzip template=jinja /tmp/{{grains.id}}.txt
```

**runas** [None] The user with which to run the gzip command line
**options** [None] Pass any additional arguments to gzip

New in version 2016.3.4.

CLI Example:

```shell
# Create /tmp/sourcefile.txt
salt '*' archive.gzip /tmp/sourcefile.txt
salt '*' archive.gzip /tmp/sourcefile.txt options='--verbose'
```

salt.modules.archive.tar(options, tarfile, sources=None, dest=None, cwd=None, template=None, runas=None)

**Note:** This function has changed for version 0.17.0. In prior versions, the `cwd` and `template` arguments must be specified, with the source directories/files coming as a space-separated list at the end of the command. Beginning with 0.17.0, `sources` must be a comma-separated list, and the `cwd` and `template` arguments are optional.

Uses the tar command to pack, unpack, etc. tar files
**options** Options to pass to the tar command

Changed in version 2015.8.0: The mandatory -p prefixing has been removed. An options string beginning with a `--long-option`, would have uncharacteristically needed its first - removed under the former scheme.

Also, tar will parse its options differently if short options are used with or without a preceding -, so it is better to not confuse the user into thinking they’re using the non-- format, when really they are using the with-- format.

**tarfile** The filename of the tar archive to pack/unpack

**sources** Comma delimited list of files to pack into the tarfile. Can also be passed as a Python list.

**dest** The destination directory into which to unpack the tarfile

**cwd** [None] The directory in which the tar command should be executed. If not specified, will default to the home directory of the user under which the salt minion process is running.

**template** [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:

```bash
salt '*' archive.tar -cjvf /tmp/salt.tar.bz2 {{grains.saltpath}}
```

CLI Examples:

```bash
# Create a tarfile
salt '*' archive.tar -cjvf /tmp/tarfile.tar.bz2 /tmp/file_1,/tmp/file_2
# Unpack a tarfile
salt '*' archive.tar xf foo.tar dest=/target/directory
```

salt.modules.archive.unrar(rarfile, dest, excludes=None, template=None, runas=None, trim_output=False)

Uses rar for Linux to unpack rar files

**rarfile** Name of rar file to be unpacked

**dest** The destination directory into which to unpack the rar file

**template** [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:

```bash
salt '*' archive.unrar template=jinja /tmp/rarfile.rar /tmp/{{grains.id}}/
```

**trim_output** [False] The number of files we should output on success before the rest are trimmed, if this is set to True then it will default to 100

CLI Example:

```bash
salt '*' archive.unrar /tmp/rarfile.rar /home/strongbad/ excludes=file_1,file_2
```

salt.modules.archive.unzip(zip_file, dest, excludes=None, template=None, runas=None, trim_output=False, password=None)

Uses the zipfile Python module to unpack zip files

Changed in version 2015.5.0: This function was rewritten to use Python's native zip file support. The old functionality has been preserved in the new function `archive.cmd_unzip`. For versions 2014.7.x and earlier, see the `archive.cmd_zip` documentation.

**zip_file** Path of zip file to be unpacked

**dest** The destination directory into which the file should be unpacked

**excludes** [None] Comma-separated list of files not to unpack. Can also be passed in a Python list.

**template** [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:

```bash
salt '*' archive.unzip template=jinja /tmp/zipfile.zip /tmp/{{grains.id}}/
```

CLI Example:

```bash
salt '*' archive.unzip /tmp/zipfile.zip /home/strongbad/ excludes=file_1,file_2
```
**runas** [None] Unpack the zip file as the specified user. Defaults to the user under which the minion is running.

**trim_output** [False] The number of files we should output on success before the rest are trimmed, if this is set to True then it will default to 100

CLI Example:

```
salt '*' archive.unzip /tmp/zipfile.zip /home/strongbad/ excludes=file_1,file_2
```

**password**: None  Password to use with password protected zip files

New in version 2016.3.0.

CLI Example:

```
salt '*' archive.unzip /tmp/zipfile.zip /home/strongbad/ password='BadPassword'
```

salt.modules.archive.zip(zip_file, sources, template=None, cwd=None, runas=None)

Uses the zipfile Python module to create zip files

Changed in version 2015.5.0: This function was rewritten to use Python's native zip file support. The old functionality has been preserved in the new function `archive.cmd_zip`. For versions 2014.7.x and earlier, see the `archive.cmd_zip` documentation.

**zip_file** Path of zip file to be created

**sources** Comma-separated list of sources to include in the zip file. Sources can also be passed in a Python list.

**template** [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:

```
salt '*' archive.zip template=jinja /tmp/zipfile.zip /tmp/sourcefile1,/tmp/\n\n~{grains.id}).txt
```

**cwd** [None] Use this argument along with relative paths in `sources` to create zip files which do not contain the leading directories. If not specified, the zip file will be created as if the cwd was `/`, and creating a zip file of `/foo/bar/baz.txt` will contain the parent directories `foo` and `bar`. To create a zip file containing just `baz.txt`, the following command would be used:

```
salt '*' archive.zip /tmp/baz.zip baz.txt cwd=/foo/bar
```

**runas** [None] Create the zip file as the specified user. Defaults to the user under which the minion is running.

CLI Example:

```
salt '*' archive.zip /tmp/zipfile.zip /tmp/sourcefile1,/tmp/sourcefile2
```

### 13.6.7 salt.modules.artifactory

Module for fetching artifacts from Artifactory

**exception** `salt.modules.artifactory.ArtifactoryError`(*value*)

salt.modules.artifactory.get_latest_release(*artifactory_url, repository, group_id, artifact_id, packaging, target_dir='/tmp', target_file=None, classifier=None, username=None, password=None*)

Gets the latest release of the artifact

**artifactory_url** URL of artifactory instance

**repository** Release repository in artifactory to retrieve artifact from, for example: `libs-releases`

**group_id** Group Id of the artifact

**artifact_id** Artifact Id of the artifact

**packaging** Packaging type (jar, war, ear, etc)

**target_dir** Target directory to download artifact to (default: `/tmp`)
**target_file**  Target file to download artifact to (by default it is `target_dir/artifact_id-version.packaging`)

**classifier**  Artifact classifier name (ex: sources,javadoc,etc). Optional parameter.

**username**  Artifactory username. Optional parameter.

**password**  Artifactory password. Optional parameter.

```python
salt.modules.artifactory.get_latest_snapshot(artifactory_url, repository, group_id, artifact_id, packaging, target_dir="/tmp", target_file=None, classifier=None, username=None, password=None)
```

Gets latest snapshot of the given artifact

**artifactory_url**  URL of artifactory instance

**repository**  Snapshot repository in artifactory to retrieve artifact from, for example: `libs-snapshots`

**group_id**  Group Id of the artifact

**artifact_id**  Artifact Id of the artifact

**packaging**  Packaging type (jar,war,ear,etc)

**target_dir**  Target directory to download artifact to (default: `/tmp`)

**target_file**  Target file to download artifact to (by default it is `target_dir/artifact_id-snapshot_version.packaging`)

**classifier**  Artifact classifier name (ex: sources,javadoc,etc). Optional parameter.

**username**  Artifactory username. Optional parameter.

**password**  Artifactory password. Optional parameter.

```python
salt.modules.artifactory.get_release(artifactory_url, repository, group_id, artifact_id, packaging, version, target_dir="/tmp", target_file=None, classifier=None, username=None, password=None)
```

Gets the specified release of the artifact

**artifactory_url**  URL of artifactory instance

**repository**  Release repository in artifactory to retrieve artifact from, for example: `libs-releases`

**group_id**  Group Id of the artifact

**artifact_id**  Artifact Id of the artifact

**packaging**  Packaging type (jar,war,ear,etc)

**version**  Version of the artifact

**target_dir**  Target directory to download artifact to (default: `/tmp`)

**target_file**  Target file to download artifact to (by default it is `target_dir/artifact_id-version.packaging`)

**classifier**  Artifact classifier name (ex: sources,javadoc,etc). Optional parameter.

**username**  Artifactory username. Optional parameter.

**password**  Artifactory password. Optional parameter.

```python
salt.modules.artifactory.get_snapshot(artifactory_url, repository, group_id, artifact_id, packaging, version, snapshot_version=None, target_dir="/tmp", target_file=None, classifier=None, username=None, password=None)
```

Gets snapshot of the desired version of the artifact

**artifactory_url**  URL of artifactory instance

**repository**  Snapshot repository in artifactory to retrieve artifact from, for example: `libs-snapshots`

**group_id**  Group Id of the artifact

**artifact_id**  Artifact Id of the artifact

**packaging**  Packaging type (jar,war,ear,etc)

**version**  Version of the artifact

**target_dir**  Target directory to download artifact to (default: `/tmp`)

**target_file**  Target file to download artifact to (by default it is `target_dir/artifact_id-snapshot_version.packaging`)

**classifier**  Artifact classifier name (ex: sources,javadoc,etc). Optional parameter.

**username**  Artifactory username. Optional parameter.

**password**  Artifactory password. Optional parameter.
13.6.8 salt.modules.at

Wrapper module for at(1)
Also, a 'tag' feature has been added to more easily tag jobs.
salt.modules.at(**kwargs)
    Add a job to the queue.
The 'timespec' follows the format documented in the at(1) manpage.

CLI Example:

    salt '*' at.at <timespec> <cmd> [tag=<tag>] [runas=<user>]
salt '*' at.at 12:05am '/sbin/reboot' tag=reboot
salt '*' at.at '3:05am +3 days' 'bin/myscript' tag=nightly runas=jim

salt.modules.at.atc(jobid)
    Print the at(1) script that will run for the passed job id. This is mostly for debugging so the output will just be text.

CLI Example:

    salt '*' at.atc <jobid>

salt.modules.at.atq(tag=None)
    List all queued and running jobs or only those with an optional 'tag'.

CLI Example:

    salt '*' at.atq
salt '*' at.atq [tag]
salt '*' at.atq [job number]

salt.modules.at.atrm(*args)
    Remove jobs from the queue.

CLI Example:

    salt '*' at.atrm <jobid> <jobid> .. <jobid>
salt '*' at.atrm all
salt '*' at.atrm all [tag]

salt.modules.at.jobcheck(**kwargs)
    Check the job from queue. The kwargs dict include 'hour minute day month year tag runas' Other parameters will be ignored.

CLI Example:

    salt '*' at.jobcheck runas=jam day=13
salt '*' at.jobcheck day=13 month=12 year=13 tag=rose

13.6.9 salt.modules.augeas_cfg

Manages configuration files via augeas
This module requires the augeas Python module.
**Warning:** Minimal installations of Debian and Ubuntu have been seen to have packaging bugs with python-augeas, causing the augeas module to fail to import. If the minion has the augeas module installed, but the functions in this execution module fail to run due to being unavailable, first restart the salt-minion service. If the problem persists past that, the following command can be run from the master to determine what is causing the import to fail:

```
salt minion-id cmd.run 'python -c "from augeas import Augeas"'
```

For affected Debian/Ubuntu hosts, installing `libpython2.7` has been known to resolve the issue.

```python
salt.modules.augeas_cfg.execute(context=None, lens=None, commands=(), load_path=None)
```

**Execute Augeas commands**

New in version 2014.7.0.

**CLI Example:**

```
salt '*' augeas.execute /files/etc/redis/redis.conf \\ commands=\'["set bind 0.0.0.0", "set maxmemory 1G"]'\n```

- `context` The Augeas context
- `lens` The Augeas lens to use
- `commands` The Augeas commands to execute

New in version 2016.3.0.

**load_path** A colon-separated list of directories that modules should be searched in. This is in addition to the standard load path and the directories in `AUGEAS_LENS_LIB`.

```python
salt.modules.augeas_cfg.get(path, value='`, load_path=None)
```

**Get a value for a specific augeas path**

**CLI Example:**

```
salt '*' augeas.get /files/etc/hosts/1/ ipaddr
```

- `path` The path to get the value of
- `value` The optional value to get

New in version 2016.3.0.

**load_path** A colon-separated list of directories that modules should be searched in. This is in addition to the standard load path and the directories in `AUGEAS_LENS_LIB`.

```python
salt.modules.augeas_cfg.ls(path, load_path=None)
```

**List the direct children of a node**

**CLI Example:**

```
salt '*' augeas.ls /files/etc/passwd
```

- `path` The path to list

New in version 2016.3.0.

**load_path** A colon-separated list of directories that modules should be searched in. This is in addition to the standard load path and the directories in `AUGEAS_LENS_LIB`.

```python
salt.modules.augeas_cfg.match(path, value='`, load_path=None)
```

**Get matches for path expression**

**CLI Example:**

---

13.6. execution modules
salt '*' augeas.match /files/etc/services/service-name ssh

**path**  The path to match
**value**  The value to match on

New in version 2016.3.0.

**load_path**  A colon-spearated list of directories that modules should be searched in. This is in addition to the standard load path and the directories in AUGEAS_LENS_LIB.

```python
salt.modules.augeas_cfg.remove(path, load_path=None)
```

Get matches for path expression

CLI Example:

```
salt '*' augeas.remove /files/etc/sysctl.conf/net.ipv4.conf.all.log_martians
```

**path**  The path to remove

New in version 2016.3.0.

**load_path**  A colon-spearated list of directories that modules should be searched in. This is in addition to the standard load path and the directories in AUGEAS_LENS_LIB.

```python
salt.modules.augeas_cfg.setvalue(*args)
```

Set a value for a specific augeas path

CLI Example:

```
salt '*' augeas.setvalue /files/etc/hosts/1/canonical localhost
```

This will set the first entry in /etc/hosts to localhost

CLI Example:

```
salt '*' augeas.setvalue /files/etc/hosts/01/ipaddr 192.168.1.1 /files/etc/hosts/01/canonical test
```

Adds a new host to /etc/hosts the ip address 192.168.1.1 and hostname test

CLI Example:

```
salt '*' augeas.setvalue prefix=/files/etc/sudoers/ "spec[user = '%wheel']/host_group/host" 'ALL' "spec[user = '%wheel']/host_group/command[1]" 'ALL' "spec[user = '%wheel']/host_group/command[1]/tag" 'PASSWD' "spec[user = '%wheel']/host_group/command[2]" '/usr/bin/apt-get' "spec[user = '%wheel']/host_group/command[2]/tag" NOPASSWD
```

Ensures that the following line is present in /etc/sudoers:

```
%wheel ALL = PASSWD : ALL , NOPASSWD : /usr/bin/apt-get , /usr/bin/aptitude
```

```python
salt.modules.augeas_cfg.tree(path, load_path=None)
```

Returns recursively the complete tree of a node

CLI Example:

```
salt '*' augeas.tree /files/etc/
```
**path**  The base of the recursive listing

New in version 2016.3.0.

**load_path**  A colon-separated list of directories that modules should be searched in. This is in addition to the standard load path and the directories in AUGEAS_LENS_LIB.

### 13.6.10  `salt.modules.aws_sqs`

Support for the Amazon Simple Queue Service.

```python
salt.modules.aws_sqs.create_queue(name, region, opts=None, user=None)
```

Creates a queue with the correct name.

- **name**  Name of the SQS queue to create
- **region**  Region to create the SQS queue in
- **opts**  [None] Any additional options to add to the command line
- **user**  [None] Run hg as a user other than what the minion runs as

CLI Example:
```
salt '*' aws_sqs.create_queue <sqs queue> <region>
```

```python
salt.modules.aws_sqs.delete_message(queue, region, receipthandle, opts=None, user=None)
```

Delete one or more messages from a queue in a region.

- **queue**  The name of the queue to delete messages from
- **region**  Region where SQS queues exists
- **receipthandle**  The ReceiptHandle of the message to delete. The ReceiptHandle is obtained in the return from `receive_message`
- **opts**  [None] Any additional options to add to the command line
- **user**  [None] Run as a user other than what the minion runs as

CLI Example:
```
salt '*' aws_sqs.delete_message <sqs queue> <region> receipthandle='<sqs ReceiptHandle>'
```

New in version 2014.7.0.

```python
salt.modules.aws_sqs.delete_queue(name, region, opts=None, user=None)
```

Deletes a queue in the region.

- **name**  Name of the SQS queue to deletes
- **region**  Name of the region to delete the queue from
- **opts**  [None] Any additional options to add to the command line
- **user**  [None] Run hg as a user other than what the minion runs as

CLI Example:
```
salt '*' aws_sqs.delete_queue <sqs queue> <region>
```

```python
salt.modules.aws_sqs.list_queues(region, opts=None, user=None)
```

List the queues in the selected region.

- **region**  Region to list SQS queues for
- **opts**  [None] Any additional options to add to the command line
- **user**  [None] Run hg as a user other than what the minion runs as

CLI Example:
```
salt '*' aws_sqs.list_queues <region>
```

```python
salt.modules.aws_sqs.queue_exists(name, region, opts=None, user=None)
```

Returns True or False on whether the queue exists in the region.

- **name**  Name of the SQS queue to search for
- **region**  Name of the region to search for the queue in
- **opts**  [None] Any additional options to add to the command line
user  [None] Run hg as a user other than what the minion runs as
CLI Example:
salt '*' aws_sqs.queue_exists <sqs queue> <region>
salt.modules.aws_sqs.receive_message(queue, region, num=1, opts=None, user=None)
    Receive one or more messages from a queue in a region
    queue  The name of the queue to receive messages from
    region  Region where SQS queues exists
    num  [1] The max number of messages to receive
    opts  [None] Any additional options to add to the command line
    user  [None] Run as a user other than what the minion runs as
CLI Example:
salt '*' aws_sqs.receive_message <sqs queue> <region> num=10

New in version 2014.7.0.

13.6.11 salt.modules.bamboohr

Support for BambooHR
New in version 2015.8.0.
Requires a subdomain and an apikey in /etc/salt/minion:
salt.modules.bamboohr.list_employees(order_by='id')
    Show all employees for this company.
    CLI Example:
salt myminion bamboohr.list_employees
    By default, the return data will be keyed by ID. However, it can be ordered by any other field. Keep in mind that if the field that is chosen contains duplicate values (i.e., location is used, for a company which only has one location), then each duplicate value will be overwritten by the previous. Therefore, it is advisable to only sort by fields that are guaranteed to be unique.
    CLI Examples:
salt myminion bamboohr.list_employees order_by=id salt myminion bamboohr.list_employees order_by=displayName salt myminion bamboohr.list_employees order_by=workEmail
salt.modules.bamboohr.list_meta_fields()
    Show all meta data fields for this company.
    CLI Example:
salt myminion bamboohr.list_meta_fields
salt.modules.bamboohr.list_users(order_by='id')
    Show all users for this company.
    CLI Example:
salt myminion bamboohr.list_users
    By default, the return data will be keyed by ID. However, it can be ordered by any other field. Keep in mind that if the field that is chosen contains duplicate values (i.e., location is used, for a company which only has one location), then each duplicate value will be overwritten by the previous. Therefore, it is advisable to only sort by fields that are guaranteed to be unique.
    CLI Examples:
salt myminion bamboohr.list_users order_by=id salt myminion bamboohr.list_users order_by=email
salt.modules.bamboohr.show_employee

Show all employees for this company.

CLI Example:
salt myminion bamboohr.show_employee 1138

By default, the fields normally returned from bamboohr.list_employees are returned. These fields are:
- canUploadPhoto
- department
- displayName
- firstName
- id
- jobTitle
- lastName
- location
- mobilePhone
- nickname
- photoUploaded
- photoUrl
- workEmail
- workPhone
- workPhoneExtension

If needed, a different set of fields may be specified, separated by commas:

CLI Example:
salt myminion bamboohr.show_employee 1138 displayName,dateOfBirth

A list of available fields can be found at http://www.bamboohr.com/api/documentation/employees.php

salt.modules.bamboohr.update_employee

Update one or more items for this employee. Specifying an empty value will clear it for that employee.

CLI Examples:
salt myminion bamboohr.update_employee 1138 nickname Curly
salt myminion bamboohr.update_employee 1138 nickname ''
salt myminion bamboohr.update_employee 1138 items='{``nickname'': ``Curly''}''
salt myminion bamboohr.update_employee 1138 items='{``nickname'': ``''}''

13.6.12 salt.modules.bcache module

Module for managing BCache sets

BCache is a block-level caching mechanism similar to ZFS L2ARC/ZIL, dm-cache and fscache. It works by formatting one block device as a cache set, then adding backend devices (which need to be formatted as such) to the set and activating them.

It’s available in Linux mainline kernel since 3.10

https://www.kernel.org/doc/Documentation/bcache.txt

This module needs the bcache userspace tools to function.

salt.modules.bcache.attach

Attach a backing devices to a cache set If no dev is given, all backing devices will be attached.

CLI example:
salt '*' bcache.attach sdc
salt '*' bcache.attach /dev/bcache1
Returns bool or None if nuttin’ happened

salt.modules.bcache.back_make(dev, cache_mode='writeback', force=False, attach=True,
bucket_size=None)

Create a backing device for attachment to a set. Because the block size must be the same, a cache set already
needs to exist.

CLI example:

salt '*' bcache.back_make sdc cache_mode=writeback attach=True

Parameters

- cache_mode -- writethrough, writeback, writearound or none.
- force -- Overwrite existing baches
- attach -- Immediately attach the backing device to the set
- bucket_size -- Size of a bucket (see kernel doc)

salt.modules.bcache.cache_make(dev, reserved=None, force=False, block_size=None,
bucket_size=None, attach=True)

Create BCache cache on a block device. If blkdiscard is available the entire device will be properly cleared in
advance.

CLI example:

salt '*' bcache.cache_make sdb reserved=10% block_size=4096

Parameters

- reserved -- if dev is a full device, create a partition table with this size empty.

Note: this increases the amount of reserved space available to SSD garbage collectors,
potentially (vastly) increasing performance

- block_size -- Block size of the cache; defaults to devices' logical block size
- force -- Overwrite existing BCache sets
- attach -- Attach all existing backend devices immediately

salt.modules.bcache.config(dev=None, **kwargs)

Show or update config of a bcache device.

If no device is given, operate on the cache set itself.

CLI example:

salt '*' bcache.config
salt '*' bcache.config bcache1
salt '*' bcache.config errors=panic journal_delay_ms=150
salt '*' bcache.config bcache1 cache_mode=writeback writeback_percent=15

Returns config or True/False

salt.modules.bcache.detach(dev=None)

Detach a backing device(s) from a cache set If no dev is given, all backing devices will be attached.

Detaching a backing device will flush it’s write cache. This should leave the underlying device in a consistent
state, but might take a while.
salt.modules.bcache.device(dev, stats=False, config=False, internals=False, superblock=False)
Check the state of a single bcache device

CLI example:
```
salt '*' bcache.device bcache0
salt '*' bcache.device /dev/sdc stats=True
```

Parameters
- **stats** -- include statistics
- **settings** -- include all settings
- **internals** -- include all internals
- **superblock** -- include superblock info

salt.modules.bcache.start()
Trigger a start of the full bcache system through udev.

CLI example:
```
salt '*' bcache.start
```

salt.modules.bcache.status(stats=False, config=False, internals=False, superblock=False, alldevs=False)
Show the full status of the BCache system and optionally all it’s involved devices

CLI example:
```
salt '*' bcache.status
salt '*' bcache.status stats=True
salt '*' bcache.status internals=True alldevs=True
```

Parameters
- **stats** -- include statistics
- **config** -- include settings
- **internals** -- include internals
- **superblock** -- include superblock

salt.modules.bcache.stop(dev=None)
Stop a bcache device If no device is given, all backing devices will be detached from the cache, which will subsequently be stopped.

**Warning:** `Stop` on an individual backing device means hard-stop; no attempt at flushing will be done and the bcache device will seemingly `disappear` from the device lists

CLI example:
```
salt '*' bcache.stop
```
salt.modules.bcache.super(dev)
Read out BCache SuperBlock

CLI example:

```
salt '*' bcache.device bcache0
salt '*' bcache.device /dev/sdc
```

salt.modules.bcache.uuid(dev=\texttt{None})
Return the bcache UUID of a block device. If no device is given, the Cache UUID is returned.

CLI example:

```
salt '*' bcache.uuid
salt '*' bcache.uuid /dev/sda
salt '*' bcache.uuid bcache0
```

### 13.6.13 salt.modules.beacons

Module for managing the Salt beacons on a minion

New in version 2015.8.0.

salt.modules.beacons.add(name, beacon_data, **kwargs)
Add a beacon on the minion

\textbf{Parameters}

- \texttt{name} -- Name of the beacon to configure
- \texttt{beacon_data} -- Dictionary or list containing configuration for beacon.

\textbf{Returns} Boolean and status message on success or failure of add.

\textbf{CLI Example:}

```
salt '*' beacons.add ps "\{'salt-master': 'stopped', 'apache2': 'stopped'\}"
```

salt.modules.beacons.delete(name, **kwargs)
Delete a beacon item

\textbf{Parameters} \texttt{name} -- Name of the beacon to delete

\textbf{Returns} Boolean and status message on success or failure of delete.

\textbf{CLI Example:}

```
salt '*' beacons.delete ps
salt '*' beacons.delete load
```

salt.modules.beacons.disable(**kwargs)
Disable all beaconsd jobs on the minion

\textbf{Returns} Boolean and status message on success or failure of disable.

\textbf{CLI Example:}

```
salt '*' beacons.disable
```

salt.modules.beacons.disable_beacon(name, **kwargs)
Disable beacon on the minion

\textbf{Name} Name of the beacon to disable.

\textbf{Returns} Boolean and status message on success or failure of disable.
CLI Example:

```
salt '*' beacons.disable_beacon ps
```

```
salt.modules.beacons.enable('**kwargs')
   Enable all beacons on the minion
   Returns Boolean and status message on success or failure of enable.
CLI Example:

```
salt '*' beacons.enable
```

```
salt.modules.beacons.enable_beacon(name, '**kwargs')
   Enable beacon on the minion
   Name Name of the beacon to enable.
   Returns Boolean and status message on success or failure of enable.
CLI Example:

```
salt '*' beacons.enable_beacon ps
```

```
salt.modules.beacons.list(return_yaml=True)
   List the beacons currently configured on the minion
   Parameters return_yaml -- Whether to return YAML formatted output, default True
   Returns List of currently configured Beacons.
CLI Example:

```
salt '*' beacons.list
```

```
salt.modules.beacons.modify(name, beacon_data, '**kwargs')
   Modify an existing beacon
   Parameters
   • name -- Name of the beacon to configure
   • beacon_data -- Dictionary or list containing updated configuration for beacon.
   Returns Boolean and status message on success or failure of modify.
CLI Example:

```
salt '*' beacons.modify ps "{"salt-master": 'stopped', 'apache2': 'stopped'}"
```

```
salt.modules.beacons.save()
   Save all beacons on the minion
   Returns Boolean and status message on success or failure of save.
CLI Example:

```
salt '*' beacons.save
```

### 13.6.14 salt.modules.bigip

An execution module which can manipulate an f5 bigip via iControl REST

maturity develop

platform f5_bigip_11.6
salt.modules.bigip.add_pool_member(hostname, username, password, name, member)
A function to connect to a bigip device and add a new member to an existing pool.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the pool to modify
member The name of the member to add i.e. 10.1.1.2:80
CLI Example:
```bash
salt '*' bigip.add_pool_member bigip admin admin my-pool 10.2.2.1:80
```

salt.modules.bigip.commit_transaction(hostname, username, password, label)
A function to connect to a bigip device and commit an existing transaction.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
label The label of this transaction stored within the grain: bigip_f5_trans:<label>
CLI Example:
```bash
salt '*' bigip.commit_transaction bigip admin admin my_transaction
```

salt.modules.bigip.create_monitor(hostname, username, password, monitor_type, name, **kwargs)
A function to connect to a bigip device and create a monitor.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
monitor_type The type of monitor to create
name The name of the monitor to create
kwargs Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.
CLI Example:
```bash
salt '*' bigip.create_monitor bigip admin admin http my-http-monitor timeout=10 interval=5
```

salt.modules.bigip.create_node(hostname, username, password, name, address, trans_label=None)
A function to connect to a bigip device and create a node.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the node
address The address of the node
trans_label The label of the transaction stored within the grain: bigip_f5_trans:<label>
CLI Example:
```bash
salt '*' bigip.create_node bigip admin admin 10.1.1.2
```
**salt.modules.bigip.create_pool**

A function to connect to a bigip device and create a pool.

- **hostname**: The host/address of the bigip device
- **username**: The iControl REST username
- **password**: The iControl REST password
- **name**: The name of the pool to create.
- **members**: List of comma delimited pool members to add to the pool. i.e. `10.1.1.1:80,10.1.1.2:80,10.1.1.3:80`
- **allow_nat**: [yes | no]
- **allow_snat**: [yes | no]
- **description**: [string]
- **gateway_failsafe_device**: [string]
- **ignore_persisted_weight**: [enabled | disabled]
- **ip_tos_to_client**: [pass-through | [integer]]
- **ip_tos_to_server**: [pass-through | [integer]]
- **link_qos_to_client**: [pass-through | [integer]]
- **link_qos_to_server**: [pass-through | [integer]]
- **load_balancing_mode**: [dynamic-ratio-member | dynamic-ratio-node | fastest-app-response | fastest-node | least-connections-members | least-connections-node | least-sessions | observed-member | observed-node | predictive-member | predictive-node | ratio-least-connections-member | ratio-least-connections-node | ratio-member | ratio-node | ratio-session | round-robin | weighted-least-connections-member | weighted-least-connections-node]
- **min_active_members**: [integer]
- **min_up_members**: [integer]
- **min_up_members_action**: [failover | reboot | restart-all]
- **min_up_members_checking**: [enabled | disabled]
- **monitor**: [name]
- **profiles**: [none | profile_name]
- **queue_depth_limit**: [integer]
- **queue_on_connection_limit**: [enabled | disabled]
- **queue_time_limit**: [integer]
- **reselect_tries**: [integer]
- **service_down_action**: [drop | none | reselect | reset]
- **slow_ramp_time**: [integer]

**CLI Example:**

```bash
salt '*' bigip.create_pool bigip admin admin my-pool 10.1.1.1:80,10.1.1.2:80,10.1.1.3:80
```

**salt.modules.bigip.create_profile**

A function to connect to a bigip device and create a profile.

- **hostname**: The host/address of the bigip device
- **username**: The iControl REST username
- **password**: The iControl REST password
- **profile_type**: The type of profile to create
- **name**: The name of the profile to create
- ****kwargs**: Additional keyword arguments

**CLI Example:**

```bash
salt '*' bigip.create_profile bigip admin admin my-profile 10.1.1.1:80,10.1.1.2:80,10.1.1.3:80
```
name  The name of the profile to create
kwarg [ arg=val ] ... [arg=key1=val1,key2=val2] ...

Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

**Creating Complex Args** Profiles can get pretty complicated in terms of the amount of possible config options. Use the following shorthand to create complex arguments such as lists, dictionaries, and lists of dictionaries. An option is also provided to pass raw json as well.

**lists** 

[i,i,i]: param='item1,item2,item3'

**Dictionary** 

[k:v,k:v,k:v]: param='key-1:val-1,key-2:val2,key-3:va-3'

**List of Dictionaries** 

[k:v,k:v|k:v,k:v|k:v,k:v]: param='key-1:val-1,key-2:val-2|key-1:val-1,key-2:val-2|key-1:val-1,key-2:val-2'

**JSON:**  

'j{ ... }j': cert-key-chain='j{ "default": { "cert": "default.crt","chain": "default.crt","key": "default.key" } }j'

**Escaping Delimiters:** Use \, or \: or \| to escape characters which shouldn't be treated as delimiters i.e. ciphers='DEFAULT\:\::\!SSLv3'

**CLI Examples:**

```
salt '*' bigip.create_profile bigip admin admin http my-http-profile defaultsFrom=/Common/http
salt '*' bigip.create_profile bigip admin admin http my-http-profile defaultsFrom=/Common/http \ enforcement=maxHeaderCount:3200,maxRequests:10
```

dsalt.modules.bigip.create_virtual(hostname, username, password, name, destination, 
pool=None, address_status=None, auto_lasthop=None, 
bwc_policy=None, cmp_enabled=None, connection_limit=None, dhcp_relay=None, description=None, 
fallback_persistence=None, flow_eviction_policy=None, 
gtm_score=None, ip_forward=None, ip_protocol=None, 
internal=None, twelve_forward=None, last_hop_pool=None, 
mask=None, mirror=None, nat64=None, persist=None, profiles=None, policies=None, rate_class=None, rate_limit=None,

source_port=None, state=None, traffic_classes=None, translate_address=None, translate_port=None, vlans=None)

A function to connect to a bigip device and create a virtual server.

**hostname**  The host/address of the bigip device
**username**  The iControl REST username
**password**  The iControl REST password
**name**  The name of the virtual to create

**destination**  

[[virtual_address_name:port] | [ipv4:port] | [ipv6:port]]

**pool**  

[[pool_name] | none]

**address_status**  [yes | no]

**auto_lasthop**  [default | enabled | disabled ]

**bwc_policy**  [none] | [string]

**cmp_enabled**  [yes | no]

**dhcp_relay**  [yes | no]

**connection_limit**  [integer]

**description**  [string]

**state**  [disabled | enabled]
**Salt Documentation, Release 2016.3.6**

- `fallback_persistence` [none | [profile name]]
- `flow_eviction_policy` [none | [eviction policy name]]
- `gtm_score` [integer]
- `ip_forward` [yes | no]
- `ip_protocol` [any | protocol]
- `internal` [yes | no]
- `twelve_forward` (12-forward) [yes | no]
- `last_hop-pool` [[pool_name] | none]
- `mask` { [ipv4] | [ipv6] }
- `mirror` { [disabled | enabled | none] }

**CLI Examples:**

```bash
salt '*' bigip.create_virtual bigip admin admin my-virtual-3 26.2.2.5:80 \ pool=my-http-pool-http profiles=http,tcp

salt '*' bigip.create_virtual bigip admin admin my-virtual-3 43.2.2.5:80 \ pool=test-http-pool-http profiles=http,websecurity persist=cookie,hash \ policies=asm_auto_l7_policy_http_virtual \ rules=_sys_APM_ExchangeSupport_helper,_sys_https_redirect \ related_rules=_sys_APM_ExchangeSupport_helper \ source_translation=snat:my-snat-pool \ translate_address=enabled translate_port=enabled \ traffic_classes=my-class,other-class \ vlans=enabled:external,internal
```

**salt.modules.bigip.delete_monitor** (hostname, username, password, monitor_type, name)

A function to connect to a bigip device and delete an existing monitor.

- `hostname` The host/address of the bigip device
- `username` The iControl REST username
- `password` The iControl REST password
- `monitor_type` The type of monitor to delete
- `name` The name of the monitor to delete

**CLI Example:**

```bash
salt '*' bigip.delete_monitor hostname='192.168.1.1' username='admin' password='secretpassword' monitor_type='tcp' name='MyMonitor'
```
salt 's' bigip.delete_monitor bigip admin admin http my-http-monitor

```
salt.modules.bigip.delete_node(hostname, username, password, name, trans_label=None)
```

A function to connect to a bigip device and delete a specific node.

- **hostname** The host/address of the bigip device
- **username** The iControl REST username
- **password** The iControl REST password
- **name** The name of the node which will be deleted.
- **trans_label** The label of the transaction stored within the grain: bigip_f5_trans:<label>

CLI Example:
```
salt 's' bigip.delete_node bigip admin admin my-node
```

```
salt.modules.bigip.delete_pool(hostname, username, password, name)
```

A function to connect to a bigip device and delete a specific pool.

- **hostname** The host/address of the bigip device
- **username** The iControl REST username
- **password** The iControl REST password
- **name** The name of the pool which will be deleted

CLI Example:
```
salt 's' bigip.delete_pool bigip admin admin my-pool
```

```
salt.modules.bigip.delete_pool_member(hostname, username, password, name, member)
```

A function to connect to a bigip device and delete a specific pool member.

- **hostname** The host/address of the bigip device
- **username** The iControl REST username
- **password** The iControl REST password
- **name** The name of the pool to modify
- **member** The name of the pool member to delete

CLI Example:
```
salt 's' bigip.delete_pool_member bigip admin admin my-pool 10.2.2.80
```

```
salt.modules.bigip.delete_profile(hostname, username, password, profile_type, name)
```

A function to connect to a bigip device and delete an existing profile.

- **hostname** The host/address of the bigip device
- **username** The iControl REST username
- **password** The iControl REST password
- **profile_type** The type of profile to delete
- **name** The name of the profile to delete

CLI Example:
```
salt 's' bigip.delete_profile bigip admin admin http my-http-profile
```

```
salt.modules.bigip.delete_transaction(hostname, username, password, label)
```

A function to connect to a bigip device and delete an existing transaction.

- **hostname** The host/address of the bigip device
- **username** The iControl REST username
- **password** The iControl REST password
- **label** The label of this transaction stored within the grain: bigip_f5_trans:<label>

CLI Example:
```
salt 's' bigip.delete_transaction bigip admin admin my_transaction
```
salt.modules.bigip.delete_virtual(hostname, username, password, name)
    A function to connect to a bigip device and delete a specific virtual.
    hostname  The host/address of the bigip device
    username  The iControl REST username
    password  The iControl REST password
    name      The name of the virtual to delete
    CLI Example:
    salt '*' bigip.delete_virtual bigip admin admin my-virtual

salt.modules.bigip.list_monitor(hostname, username, password, monitor_type, name=None)
    A function to connect to a bigip device and list an existing monitor. If no name is provided than all monitors
    of the specified type will be listed.
    hostname  The host/address of the bigip device
    username  The iControl REST username
    password  The iControl REST password
    monitor_type  The type of monitor(s) to list
    name      The name of the monitor to list
    CLI Example:
    salt '*' bigip.list_monitor bigip admin admin http my-http-monitor

salt.modules.bigip.list_node(hostname, username, password, name=None, trans_label=None)
    A function to connect to a bigip device and list all nodes or a specific node.
    hostname  The host/address of the bigip device
    username  The iControl REST username
    password  The iControl REST password
    name      The name of the node to list. If no name is specified than all nodes will be listed.
    trans_label  The label of the transaction stored within the grain: bigip_f5_trans:<label>
    CLI Example:
    salt '*' bigip.list_node bigip admin admin my-node

salt.modules.bigip.list_pool(hostname, username, password, name=None)
    A function to connect to a bigip device and list all pools or a specific pool.
    hostname  The host/address of the bigip device
    username  The iControl REST username
    password  The iControl REST password
    name      The name of the pool to list. If no name is specified then all pools will be listed.
    CLI Example:
    salt '*' bigip.list_pool bigip admin admin my-pool

salt.modules.bigip.list_profile(hostname, username, password, profile_type, name=None)
    A function to connect to a bigip device and list an existing profile. If no name is provided than all profiles of
    the specified type will be listed.
    hostname  The host/address of the bigip device
    username  The iControl REST username
    password  The iControl REST password
    profile_type  The type of profile(s) to list
    name      The name of the profile to list
    CLI Example:
    salt '*' bigip.list_profile bigip admin admin http my-http-profile
salt.modules.bigip.list_transaction(hostname, username, password, label)
A function to connect to a bigip device and list an existing transaction.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
label the label of this transaction stored within the grain: bigip_f5_trans:<label>
CLI Example:
```
salt '*' bigip.list_transaction bigip admin admin my_transaction
```

salt.modules.bigip.list_virtual(hostname, username, password, name=None)
A function to connect to a bigip device and list all virtuals or a specific virtual.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the virtual to list. If no name is specified than all virtuals will be listed.
CLI Example:
```
salt '*' bigip.list_virtual bigip admin admin my-virtual
```

salt.modules.bigip.modify_monitor(hostname, username, password, monitor_type, name, **kwargs)
A function to connect to a bigip device and modify an existing monitor.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
monitor_type The type of monitor to modify
name The name of the monitor to modify
kwargs Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.
CLI Example:
```
salt '*' bigip.modify_monitor bigip admin admin http my-http-monitor timeout=16 interval=6
```

salt.modules.bigip.modify_node(hostname, username, password, name, connection_limit=None, description=None, dynamic_ratio=None, logging=None, monitor=None, rate_limit=None, ratio=None, session=None, state=None, trans_label=None)
A function to connect to a bigip device and modify an existing node.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the node to modify
connection_limit [integer]
description [string]
dynamic_ratio [integer]
logging [enabled | disabled]
monitor [[name] | none | default]
rate_limit [integer]
ratio [integer]
session [user-enabled | user-disabled]
state [user-down | user-up ]
trans_label The label of the transaction stored within the grain: bigip_f5_trans:<label>
CLI Example:
salt 'localhost' bigip.modify_node bigip admin admin 10.1.1.2 ratio=2 logging=enabled

salt.modules.bigip.modify_pool(hostname, username, password, name, allow_nat=None, allow_snat=None, description=None, gateway_failsafe_device=None, ignore_persisted_weight=None, ip_tos_to_client=None, ip_tos_to_server=None, link_qos_to_client=None, link_qos_to_server=None, load_balancing_mode=None, min_active_members=None, min_up_members=None, min_up_members_action=None, min_up_members_checking=None, monitor=None, profiles=None, queue_depth_limit=None, queue_on_connection_limit=None, queue_time_limit=None, reselect_tries=None, service_down_action=None, slow_ramp_time=None)

A function to connect to a bigip device and modify an existing pool.

hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
name  The name of the pool to modify.
allow_nat  [yes | no]
allow_snat  [yes | no]
description  [string]
gateway_failsafe_device  [string]
ignore_persisted_weight  [yes | no]
ip_tos_to_client  [pass-through | [integer]]
ip_tos_to_server  [pass-through | [integer]]
link_qos_to_client  [pass-through | [integer]]
link_qos_to_server  [pass-through | [integer]]
load_balancing_mode  [dynamic-ratio-member | dynamic-ratio-node | fastest-app-response | fastest-node | least-connections-members | least-connections-node | least-sessions | observed-member | observed-node | predictive-member | predictive-node | ratio-least-connections-member | ratio-least-connections-node | ratio-member | ratio-node | ratio-session | round-robin | weighted-least-connections-member | weighted-least-connections-node]
min_active_members  [integer]
min_up_members  [integer]
min_up_members_action  [failover | reboot | restart-all]
min_up_members_checking  [enabled | disabled]
monitor  [name]
profiles  [none | profile_name]
queue_on_connection_limit  [enabled | disabled]
queue_depth_limit  [integer]
queue_time_limit  [integer]
reselect_tries  [integer]
service_down_action  [drop | none | reselect | reset]
slow_ramp_time  [integer]

CLI Example:

salt 'localhost' bigip.modify_pool bigip admin admin my-pool 10.1.1.1:80,10.1.1.2:80,10.1.1.3:80 min_active_members=1
salt.modules.bigip.modify_pool_member

A function to connect to a bigip device and modify an existing member of a pool.

hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
name     The name of the pool to modify
member   The name of the member to modify i.e. 10.1.1.2:80
connection_limit  [integer]
description  [string]
dynamic_ratio  [integer]
inherit_profile  [enabled | disabled]
logging  [enabled | disabled]
monitor  [name]
priority_group  [integer]
profiles  [none | profile_name]
ratio  [integer]
session  [user-enabled | user-disabled]
state  [ user-up | user-down ]

CLI Example:

```
salt '!' bigip.modify_pool_member bigip admin admin my-pool 10.2.1.80 state=use-down session=user-disabled
```

salt.modules.bigip.modify_profile

A function to connect to a bigip device and create a profile.

hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
profile_type  The type of profile to create
name     The name of the profile to create
**kwargs

Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

Creating Complex Args

Profiles can get pretty complicated in terms of the amount of possible config options. Use the following shorthand to create complex arguments such as lists, dictionaries, and lists of dictionaries. An option is also provided to pass raw json as well.

```
lists [i,i,i]: param='item1,item2,item3'
Dictionary [k:v,k:v,k:v]: param='key-1:val-1,key-2:val2,key-3:val3'
List of Dictionaries [k:v,k:v] [k:v,k:v]: param='key-1:val-1,key-2:val2,key-1:val-1,key-2:val2'
JSON: 'j{ ... }': cert-key-chain='j{ "default": { "cert": "default.crt","chain": "default.crt","key": "default.key" } }'
```
Escaping Delimiters: Use `,`, or `:` or `|` to escape characters which shouldn't be treated as delimiters i.e. `ciphers='DEFAULT::!SSLv3'`

CLI Examples:

```
salt '*' bigip.modify_profile bigip admin admin http my-http-profile defaultsFrom= '/Common/http'

salt '*' bigip.modify_profile bigip admin admin http my-http-profile defaultsFrom= '/Common/http' \
  enforcement=maxHeaderCount:3200,maxRequests:10

salt '*' bigip.modify_profile bigip admin admin client-ssl my-client-ssl-10 \
  retainCertificate=false \ 
  ciphers='DEFAULT::!SSLv3' \
  cert_key_chain='j{ "default": { "cert": "default.crt", "chain": "default.crt" }, "key": "default.key" } j'
```

```
salt.modules.bigip.modify_virtual(hostname, username, password, name, destination=None, pool=None, address_status=None, auto_lasthop=None, bwc_policy=None, cmp_enabled=None, connection_limit=None, dhcp_relay=None, description=None, fallback_persistence=None, flow_eviction_policy=None, gtm_score=None, ip_forward=None, ip_protocol=None, internal=None, twelve_forward=None, last_hop_pool=None, mask=None, mirror=None, nat64=None, persist=None, profiles=None, policies=None, rate_class=None, rate_limit=None, rate_limit_mode=None, rate_limit_dst=None, rate_limit_src=None, rules=None, related_rules=None, reject=None, source=None, source_address_translation=None, source_port=None, state=None, traffic_classes=None, translate_address=None, translate_port=None, vlans=None)
```

A function to connect to a bigip device and modify an existing virtual server.

**hostname** The host/address of the bigip device

**username** The iControl REST username

**name** The name of the virtual to modify

**destination** [ [virtual_address_name:port] | [ipv4:port] | [ipv6:port] ]

**pool** [ [pool_name] | none]

**address_status** [yes | no]

**auto_lasthop** [default | enabled | disabled ]

**bwc_policy** [none] | string]

**cmp_enabled** [yes | no]

**dhcp_relay** [yes | no]

**connection_limit** [integer]

**description** [string]

**state** [disabled | enabled]

**fallback_persistence** [none | [profile name] ]

**flow_eviction_policy** [none | [eviction policy name] ]

**gtm_score** [integer]

**ip_forward** [yes | no]

**ip_protocol** [any | protocol]

**internal** [yes | no]

**twelve_forward** (12-forward) [yes | no]

**last_hop_pool** [ [pool_name] | none]

**mask** [ [ipv4] | [ipv6] ]
mirror [{disabled | enabled | none}]
nat64 [enabled | disabled]
persist [none | profile1,profile2,profile3 ... ]
profiles [none | default | profile1,profile2,profile3 ... ]
policies [none | default | policy1,policy2,policy3 ... ]
rate_class [name]
rate_limit [integer]
rate_limit_mode [destination | object | object-destination | object-source | object-source-destination | source | source-destination]
rate_limit_dst [integer]
rate_limit_src [integer]
rules [none | [rule_one,rule_two ... ] ]
related_rules [none | [rule_one,rule_two ... ] ]
reject [yes | no]
source { [ipv4[/prefixlen]] | [ipv6[/prefixlen]]}
source_address_translation [none | snat:pool_name | lsn | automap ]
source_port [change | preserve | preserve-strict]
state [enabled | disable]
traffic_classes [none | default | class_one,class_two ... ]
translate_address [enabled | disabled]
translate_port [enabled | disabled]
vlan [none | default | [enabled|disabled]:vlan1,vlan2,vlan3 ... ]

CLI Example:

```
salt '*' bigip.modify_virtual bigip admin admin my-virtual source_address_translation=none
salt '*' bigip.modify_virtual bigip admin admin my-virtual rules=my-rule,my-other
```

```
salt.modules.bigip.replace_pool_members( hostname, username, password, name, members )
A function to connect to a bigip device and replace members of an existing pool with new members.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the pool to modify
members List of comma delimited pool members to replace existing members with. i.e. 10.1.1.1:80,10.1.1.2:80,10.1.1.3:80

CLI Example:

```
salt '*' bigip.replace_pool_members bigip admin admin my-pool 10.2.2.1:80,10.2.2.2:80,10.2.2.3:80
```

```
salt.modules.bigip.start_transaction( hostname, username, password, label )
A function to connect to a bigip device and start a new transaction.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
label The name / alias for this transaction. The actual transaction id will be stored within a grain named bigip_f5_trans:<label>

CLI Example:

```
salt '*' bigip.start_transaction bigip admin admin my-pool 10.2.2.1:80,10.2.2.2:80,10.2.2.3:80
```
salt 'bigip' start_transaction bigip admin admin my_transaction

13.6.15 salt.modules.blockdev

Module for managing block devices

New in version 2014.7.0.

Deprecated since version Carbon: Merged to disk module

salt.modules.blockdev.dump(device, args=None)

Return all contents of dumpe2fs for a specified device

Deprecated since version 2016.3.0: Use disk.dump

args a list containing only the desired arguments to return

CLI Example:

salt '*' blockdev.dump /dev/sdX1

salt.modules.blockdev.format(device, fs_type='ext4', inode_size=None, lazy_itable_init=None)

Format a filesystem onto a block device

New in version 2015.8.2.

device The block device in which to create the new filesystem

fs_type The type of filesystem to create

inode_size Size of the inodes

lazy_itable_init If enabled and the uninit_bg feature is enabled, the inode table will not be fully initialized by mke2fs. This speeds up filesystem initialization noticeably, but it requires the kernel to finish initializing the filesystem in the background when the filesystem is first mounted. If the option value is omitted, it defaults to 1 to enable lazy inode table zeroing.

This option is only enabled for ext filesystems

CLI Example:

salt '*' blockdev.format /dev/sdX1

salt.modules.blockdev.fstype(device)

Return the filesystem name of a block device

New in version 2015.8.2.

device The name of the block device

CLI Example:

salt '*' blockdev.fstype /dev/sdX1

salt.modules.blockdev.resize2fs(device)

Resizes the filesystem.

Deprecated since version 2016.3.0: Use disk.resize2fs

CLI Example: .. code-block:: bash

    salt '*' blockdev.resize2fs /dev/sdX1

salt.modules.blockdev.tune(device, **kwargs)

Set attributes for the specified device

Deprecated since version 2016.3.0: Use disk.tune
CLI Example:
```
salt '*' blockdev.tune /dev/sdX1 read-ahead=1024 read-write=True
```

Valid options are: read-ahead, filesystem-read-ahead, read-only, read-write.
See the `blockdev(8)` manpage for a more complete description of these options.

**salt.modules.blockdev.wipe**(device)
Remove the filesystem information

Depreciated since version 2016.3.0: Use `disk.tune`

CLI Example:
```
salt '*' blockdev.wipe /dev/sdX1
```

### 13.6.16 salt.modules.bluez

Support for Bluetooth (using BlueZ in Linux).

The following packages are required packages for this module:
```
bluez >= 5.7 bluez-libs >= 5.7 bluez-utils >= 5.7 pybluez >= 0.18
```

**salt.modules.bluez.address()**
Get the many addresses of the Bluetooth adapter

CLI Example:
```
salt '*' bluetooth.address
```

**salt.modules.bluez.block**(bdaddr)
Block a specific bluetooth device by BD Address

CLI Example:
```
```

**salt.modules.bluez.discoverable**(dev)
Enable this bluetooth device to be discoverable.

CLI Example:
```
salt '*' bluetooth.discoverable hci0
```

**salt.modules.bluez.noscan**(dev)
Turn off scanning modes on this device.

CLI Example:
```
salt '*' bluetooth.noscan hci0
```

**salt.modules.bluez.pair**(address, key)
Pair the bluetooth adapter with a device

CLI Example:
```
salt '*' bluetooth.pair DE:AD:BE:EF:CA:FE 1234
```
Where DE:AD:BE:EF:CA:FE is the address of the device to pair with, and 1234 is the passphrase.

TODO: This function is currently broken, as the bluez-simple-agent program no longer ships with BlueZ >= 5.0. It needs to be refactored.

```
salt.modules.bluez.power(dev, mode)
    Power a bluetooth device on or off

    CLI Examples:
    salt '*' bluetooth.power hci0 on
    salt '*' bluetooth.power hci0 off
```

```
salt.modules.bluez.scan()
    Scan for bluetooth devices in the area

    CLI Example:
    salt '*' bluetooth.scan
```

```
salt.modules.bluez.start()
    Start the bluetooth service.

    CLI Example:
    salt '*' bluetooth.start
```

```
salt.modules.bluez.stop()
    Stop the bluetooth service.

    CLI Example:
    salt '*' bluetooth.stop
```

```
salt.modules.bluez.unblock(bdaddr)
    Unblock a specific bluetooth device by BD Address

    CLI Example:
```

```
salt.modules.bluez.unpair(address)
    Unpair the bluetooth adapter from a device

    CLI Example:
```

Where DE:AD:BE:EF:CA:FE is the address of the device to unpair.

TODO: This function is currently broken, as the bluez-simple-agent program no longer ships with BlueZ >= 5.0. It needs to be refactored.

```
salt.modules.bluez.version()
    Return Bluez version from bluetoothd -v

    CLI Example:
    salt '*' bluetoothd.version
```
13.6.17 salt.modules.boto_asg

Connection module for Amazon Autoscale Groups

New in version 2014.7.0.

configuration This module accepts explicit autoscale credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
asg.keyid: GKTADJGHEIQSXMKKRBJ08H
asg.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```
asg.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

depends boto

salt.modules.boto_asg.create(name, launch_config_name, availability_zones, min_size, max_size, desired_capacity=None, load_balancers=None, default_cooldown=None, health_check_type=None, health_check_period=None, placement_group=None, vpc_zone_identifier=None, tags=None, termination_policies=None, suspended_processes=None, scaling_policies=None, scheduled_actions=None, region=None, notification_arn=None, notification_types=None, key=None, keyid=None, profile=None)

Create an autoscale group.

CLI example:

```
salt myminion boto_asg.create myasg mylc ['"us-east-1a", "us-east-1e"] 1 10 load_balancers=['"myelb", "myelb2"] tags=['{"key": "Name", value="myasg", propagate_at_launch": True}']
```
salt.modules.boto_asg.create_launch_configuration(name, image_id, key_name=None, security_groups=None, user_data=None, instance_type='m1.small', kernel_id=None, ramdisk_id=None, block_device_mappings=None, instance_monitoring=False, spot_price=None, instance_profile_name=None, ebs_optimized=False, associate_public_ip_address=None, volume_type=None, delete_on_termination=True, iops=None, use_block_device_types=False, region=None, key=None, keyid=None, profile=None)

Create a launch configuration.

CLI example:

```
salt myminion boto_asg.create_launch_configuration mylc image_id=ami-0b9c9f62 key_name='mykey' security_groups=['mygroup'] instance_type='c3.2xlarge'
```

salt.modules.boto_asg.delete(name, force=False, region=None, key=None, keyid=None, profile=None)

Delete an autoscale group.

CLI example:

```
salt myminion boto_asg.delete myasg region=us-east-1
```

salt.modules.boto_asg.delete_launch_configuration(name, region=None, key=None, keyid=None, profile=None)

Delete a launch configuration.

CLI example:

```
salt myminion boto_asg.delete_launch_configuration mylc
```

salt.modules.boto_asg.exists(name, region=None, key=None, keyid=None, profile=None)

Check to see if an autoscale group exists.

CLI example:

```
salt myminion boto_asg.exists myasg region=us-east-1
```

salt.modules.boto_asg.get_cloud_init_mime(cloud_init)

Get a mime multipart encoded string from a cloud-init dict. Currently supports scripts and cloud-config.

CLI Example:

```
salt myminion boto.get_cloud_init_mime <cloud_init>
```

salt.modules.boto_asg.get_config(name, region=None, key=None, keyid=None, profile=None)

Get the configuration for an autoscale group.

CLI example:
salt myminion boto_asg.get_config myasg region=us-east-1

salt.modules.boto_asg.get_instances(name, lifecycle_state='InService', health_status='Healthy', attribute='private_ip_address', attributes=None, region=None, key=None, keyid=None, profile=None)

return attribute of all instances in the named autoscale group.

CLI example:
salt-call boto_asg.get_instances my_autoscale_group_name

salt.modules.boto_asg.get_scaling_policy_arn(as_group, scaling_policy_name, region=None, key=None, keyid=None, profile=None)

Return the arn for a scaling policy in a specific autoscale group or None if not found. Mainly used as a helper method for boto_cloudwatch_alarm, for linking alarms to scaling policies.

CLI Example:
salt '*' boto_asg.get_scaling_policy_arn mygroup mypolicy

salt.modules.boto_asg.launch_configuration_exists(name, region=None, key=None, keyid=None, profile=None)

Check for a launch configuration's existence.

CLI example:
salt myminion boto_asg.launch_configuration_exists mylc

salt.modules.boto_asg.update(name, launch_config_name, availability_zones, min_size, max_size, desired_capacity=None, load_balancers=None, default_cooldown=None, health_check_type=None, health_check_period=None, placement_group=None, vpc_zone_identifier=None, tags=None, termination_policies=None, suspended_processes=None, scaling_policies=None, scheduled_actions=None, notification_arn=None, notification_types=None, region=None, key=None, keyid=None, profile=None)

Update an autoscale group.

CLI example:
salt myminion boto_asg.update myasg mylc ']["us-east-1a", "us-east-1e"]' 1 10 load_balancers=['"myelb", "myelb2"]' tags='[{"key": "Name", value="myasg", "propagate_at_launch": True}]'

13.6.18 salt.modules.boto_cfn

Connection module for Amazon Cloud Formation

New in version 2015.5.0.

configuration This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:
If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```python
cfn.keyid: GKTADJGHEIQSXMKKRBJ08H
cfn.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```python
cfn.region: us-east-1
```

depends boto

```python
salt.modules.boto_cfn.create(name, template_body=None, template_url=None, parameters=None, notification_arns=None, disable_rollback=None, timeout_in_minutes=None, capabilities=None, tags=None, on_failure=None, stack_policy_body=None, stack_policy_url=None, region=None, key=None, keyid=None, profile=None)
```

Create a CFN stack.

CLI example to create a stack:

```bash
salt myminion boto_cfn.create mystack template_url='https://s3.amazonaws.com/bucket/template.cft' region=us-east-1
```

```python
salt.modules.boto_cfn.delete(name, region=None, key=None, keyid=None, profile=None)
```

Delete a CFN stack.

CLI example to delete a stack:

```bash
salt myminion boto_cfn.delete mystack region=us-east-1
```

```python
salt.modules.boto_cfn.describe(name, region=None, key=None, keyid=None, profile=None)
```

Describe a stack.

New in version 2015.8.0.

CLI example:

```bash
salt myminion boto_cfn.describe mystack region=us-east-1
```

```python
salt.modules.boto_cfn.exists(name, region=None, key=None, keyid=None, profile=None)
```

Check to see if a stack exists.

CLI example:

```bash
salt myminion boto_cfn.exists mystack region=us-east-1
```

```python
salt.modules.boto_cfn.get_template(name, region=None, key=None, keyid=None, profile=None)
```

Check to see if attributes are set on a CFN stack.

CLI example:

```bash
salt myminion boto_cfn.get_template mystack
```
salt.modules.boto_cfn.update_stack(name, template_body=None, template_url=None, parameters=None, notification_arns=None, disable_rollback=False, timeout_in_minutes=None, capabilities=None, tags=None, use_previous_template=None, stack_policy_during_update_body=None, stack_policy_during_update_url=None, stack_policy_body=None, stack_policy_url=None, region=None, key=None, keyid=None, profile=None)

Update a CFN stack.
New in version 2015.8.0.
CLI example to update a stack:

```bash
salt myminion boto_cfn.update_stack mystack template_url='https://s3.amazonaws.com/bucket/template.cft' region=us-east-1
```

salt.modules.boto_cfn.validate_template(template_body=None, template_url=None, region=None, key=None, keyid=None, profile=None)

Validate cloudformation template
New in version 2015.8.0.
CLI example:

```bash
salt myminion boto_cfn.validate_template mystack
```

### 13.6.19 salt.modules.boto_cloudtrail module

Connection module for Amazon CloudTrail
New in version 2016.3.0.

**depends**

- boto
- boto3

The dependencies listed above can be installed via package or pip.

**configuration**

This module accepts explicit Lambda credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```yaml
cloudtrail.keyid: GKTADJGHEIQSXMKKRBJ08H
cloudtrail.key: askdjghsdfjkghWupUjasdflkdfsljgjsdfjajkghs
```

A region may also be specified in the configuration:

```yaml
cloudtrail.region: us-east-1
```

If a region is not specified, the default is us-east-1.
It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgshWupUjasdfldfkjgjsdfajkghs
  region: us-east-1
```

```python
salt.modules.boto_cloudtrail.add_tags(Name, region=None, key=None, keyid=None, profile=None, **kwargs)
```

Add tags to a trail

Returns {tagged: true} if the trail was tagged and returns {tagged: False} if the trail was not tagged.

CLI Example:

```bash
salt myminion boto_cloudtrail.add_tags my_trail tag_a=tag_value tag_b=tag_value
```

```python
salt.modules.boto_cloudtrail.create(Name, S3BucketName, S3KeyPrefix=None, SnsTopicName=None, IncludeGlobalServiceEvents=None, EnableLogFileValidation=None, CloudWatchLogsLogGroupArn=None, CloudWatchLogsRoleArn=None, KmsKeyId=None, region=None, key=None, keyid=None, profile=None)
```

Given a valid config, create a trail.

Returns {created: true} if the trail was created and returns {created: False} if the trail was not created.

CLI Example:

```bash
salt myminion boto_cloudtrail.create my_trail my_bucket
```

```python
salt.modules.boto_cloudtrail.delete(Name, region=None, key=None, keyid=None, profile=None)
```

Given a trail name, delete it.

Returns {deleted: true} if the trail was deleted and returns {deleted: false} if the trail was not deleted.

CLI Example:

```bash
salt myminion boto_cloudtrail.delete mytrail
```

```python
salt.modules.boto_cloudtrail.describe(Name, region=None, key=None, keyid=None, profile=None)
```

Given a trail name describe its properties.

Returns a dictionary of interesting properties.

CLI Example:

```bash
salt myminion boto_cloudtrail.describe mytrail
```

```python
salt.modules.boto_cloudtrail.exists(Name, region=None, key=None, keyid=None, profile=None)
```

Given a trail name, check to see if the given trail exists.

Returns True if the given trail exists and returns False if the given trail does not exist.

CLI Example:
salt myminion boto_cloudtrail.exists mytrail

salt.modules.boto_cloudtrail.list(region=None, key=None, keyid=None, profile=None)
List all trails
Returns list of trails
CLI Example:

```
policies:
  - {...}
  - {...}
```

salt.modules.boto_cloudtrail.list_tags(Name, region=None, key=None, keyid=None, profile=None)
List tags of a trail
Returns:
```
tags:
  - {...}
  - {...}
```
CLI Example:
```
salt myminion boto_cloudtrail.list_tags my_trail
```

salt.modules.boto_cloudtrail.remove_tags(Name, region=None, key=None, keyid=None, profile=None, **kwargs)
Remove tags from a trail
Returns {tagged: true} if the trail was tagged and returns {tagged: False} if the trail was not tagged.
CLI Example:
```
salt myminion boto_cloudtrail.remove_tags my_trail tag_a=tag_value tag_b=tag_value
```

salt.modules.boto_cloudtrail.start_logging(Name, region=None, key=None, keyid=None, profile=None)
Start logging for a trail
Returns {started: true} if the trail was started and returns {started: False} if the trail was not started.
CLI Example:
```
salt myminion boto_cloudtrail.start_logging my_trail
```

salt.modules.boto_cloudtrail.status(Name, region=None, key=None, keyid=None, profile=None)
Given a trail name describe its properties.
Returns a dictionary of interesting properties.
CLI Example:
```
salt myminion boto_cloudtrail.describe mytrail
```

salt.modules.boto_cloudtrail.stop_logging(Name, region=None, key=None, keyid=None, profile=None)
Stop logging for a trail
Returns {stopped: true} if the trail was stopped and returns {stopped: False} if the trail was not stopped.
**CLI Example:**

```
salt myminion boto_cloudtrail.stop_logging my_trail
```

```
salt.modules.boto_cloudtrail.update(Name, S3BucketName, S3KeyPrefix=None, SnsTopicName=None, IncludeGlobalServiceEvents=None, EnableLogFileValidation=None, CloudWatchLogsLogGroupArn=None, CloudWatchLogsRoleArn=None, KmsKeyId=None, region=None, key=None, keyid=None, profile=None)
```

Given a valid config, update a trail.

Returns `{created: True}` if the trail was created and returns `{created: False}` if the trail was not created.

**CLI Example:**

```
salt myminion boto_cloudtrail.update my_trail my_bucket
```

---

**13.6.20 salt.modules.boto_cloudwatch**

Connection module for Amazon CloudWatch

New in version 2014.7.0.

**configuration**

This module accepts explicit credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
cloudwatch.keyid: GKTADJGHEIQSXMKKRBJ08H
cloudwatch.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```
cloudwatch.region: us-east-1
```

If a region is not specified, the default is `us-east-1`.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

**depends** boto

```
salt.modules.boto_cloudwatch.convert_to_arn(arns, region=None, key=None, keyid=None, profile=None)
```

Convert a list of strings into actual arns. Converts convenience names such as `scaling_policy:...`

**CLI Example:**
salt '*' convert_to_arn 'scaling_policy:'

salt.modules.boto_cloudwatch.create_or_update_alarm(connection=None, name=None, metric=None, namepace=None, statistic=None, comparison=None, threshold=None, period=None, evaluation_periods=None, unit=None, description=None, dimensions=None, alarm_actions=None, insufficient_data_actions=None, ok_actions=None, region=None, key=None, keyid=None, profile=None)

Create or update a cloudwatch alarm.

**Params are the same as:** http://boto.readthedocs.org/en/latest/ref/cloudwatch.html#boto.ec2.cloudwatch.alarm.MetricAlarm

Dimensions must be a dict. If the value of Dimensions is a string, it will be json decoded to produce a dict. alarm_actions, insufficient_data_actions, and ok_actions must be lists of string. If the passed-in value is a string, it will be split on "," to produce a list. The strings themselves for alarm_actions, insufficient_data_actions, and ok_actions must be Amazon resource names (ARN's); however, this method also supports an arn lookup notation, as follows:

```python
arn:aws:... ARN as per http://docs.aws.amazon.com/general/latest/gr/aws-arns-and-namespaces.html
scaling_policy:<as_name> Scaling policy, for the named group (e.g. scaling_policy:my-asg:ScaleDown)
```

This is convenient for setting up autoscaling as follows. First specify a boto_asg.present state for an ASG with scaling_policies, and then set up boto_cloudwatch_alarm.present states which have alarm_actions that reference the scaling_policy.

CLI example:

```
salt myminion boto_cloudwatch.create_alarm name=myalarm ... region=us-east-1
```

salt.modules.boto_cloudwatch.delete_alarm(name, region=None, key=None, keyid=None, profile=None)

Delete a cloudwatch alarm

CLI example to delete a queue:

```
salt myminion boto_cloudwatch.delete_alarm myalarm region=us-east-1
```

salt.modules.boto_cloudwatch.get_alarm(name, region=None, key=None, keyid=None, profile=None)

Get alarm details. Also can be used to check to see if an alarm exists.

CLI example:

```
salt myminion boto_cloudwatch.get_alarm myalarm region=us-east-1
```

salt.modules.boto_cloudwatch.get_all_alarms(region=None, prefix=None, key=None, keyid=None, profile=None)

Get all alarm details. Produces results that can be used to create an sls file.

If prefix parameter is given, alarm names in the output will be prepended with the prefix; alarms that have the prefix will be skipped. This can be used to convert existing alarms to be managed by salt, as follows:

1. Make a "backup" of all existing alarms

```
$ salt-call boto_cloudwatch.get_all_alarms --out=txt | sed "s/local: //" > legacy_alarms.sls
```

Chapter 13. Salt Module Reference
2. Get all alarms with new prefixed names

   $ salt-call boto_cloudwatch.get_all_alarms "prefix="MANAGED BY SALT"" --out=txt | sed "s/local: //" > managed_alarms.sls

3. Insert the managed alarms into cloudwatch

   $ salt-call state.template managed_alarms.sls

4. Manually verify that the new alarms look right

5. Delete the original alarms

   $ sed s/present/absent/ legacy_alarms.sls > remove_legacy_alarms.sls
   $ salt-call state.template remove_legacy_alarms.sls

6. Get all alarms again, verify no changes

   $ salt-call boto_cloudwatch.get_all_alarms --out=txt | sed "s/local: //" > final_alarms.sls
   $ diff final_alarms.sls managed_alarms.sls

 CLI example:

```
salt myminion boto_cloudwatch.get_all_alarms region=us-east-1 --out=txt
```

13.6.21 salt.modules.boto_datapipeline module

Connection module for Amazon Data Pipeline

New in version 2016.3.0.

```
depends boto3
```

**salt.modules.boto_datapipeline.activate_pipeline**

```
activate_pipeline(pipeline_id, region=None, key=None,
keyid=None, profile=None)
```

Start processing pipeline tasks. This function is idempotent.

 CLI example:

```
salt myminion boto_datapipeline.activate_pipeline my_pipeline_id
```

**salt.modules.boto_datapipeline.create_pipeline**

```
create_pipeline(name, unique_id, description='',
region=None, key=None, keyid=None,
profile=None)
```

Create a new, empty pipeline. This function is idempotent.

 CLI example:

```
salt myminion boto_datapipeline.create_pipeline my_name my_unique_id
```

**salt.modules.boto_datapipeline.delete_pipeline**

```
delete_pipeline(pipeline_id, region=None, key=None,
keyid=None, profile=None)
```

Delete a pipeline, its pipeline definition, and its run history. This function is idempotent.

 CLI example:

```
salt myminion boto_datapipeline.delete_pipeline my_pipeline_id
```

**salt.modules.boto_datapipeline.describe_pipelines**

```
describe_pipelines(pipeline_ids, region=None,
key=None, keyid=None, profile=None)
```

Retrieve metadata about one or more pipelines.

 CLI example:

```
salt myminion boto_datapipeline.describe_pipelines ['my_pipeline_id']
```

**salt.modules.boto_datapipeline.get_pipeline_definition**

```
get_pipeline_definition(pipeline_id, version='latest',
region=None, key=None, keyid=None, profile=None)
```

Get the definition of the specified pipeline.
CLI example:

```bash
salt myminion boto_datapipeline.get_pipeline_definition my_pipeline_id
```

Function `salt.modules.boto_datapipeline.list_pipelines`  
Get a list of pipeline ids and names for all pipelines.  
CLI Example:

```bash
salt myminion boto_datapipeline.list_pipelines profile=myprofile
```

Function `salt.modules.boto_datapipeline.pipeline_id_from_name`  
Get the pipeline id, if it exists, for the given name.  
CLI example:

```bash
salt myminion boto_datapipeline.pipeline_id_from_name my_pipeline_name
```

Function `salt.modules.boto_datapipeline.put_pipeline_definition`  
Add tasks, schedules, and preconditions to the specified pipeline. This function is idempotent and will replace an existing definition.  
CLI example:

```bash
salt myminion boto_datapipeline.put_pipeline_definition my_pipeline_id my_pipeline_objects
```

### 13.6.22 salt.modules.boto_dynamodb

Connection module for Amazon DynamoDB  
New in version 2015.5.0.  

**configuration**  
This module accepts explicit DynamoDB credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:  

If IAM roles are not used you need to specify them either in a pillar or in the minion’s config file:  

```
keyid: GKTADJGHEIQSXMKKRBJ08H  
key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:  

```
region: us-east-1
```

If a region is not specified, the default is us-east-1.
It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkgshWupUjasdflkdfklgjsdfjajkghs
    region: us-east-1
```

depends boto

```python
salt.modules.boto_dynamodb.create_table(table_name, region=None, key=None, keyid=None, profile=None, read_capacity_units=None, write_capacity_units=None, hash_key=None, hash_key_data_type=None, range_key=None, range_key_data_type=None, local_indexes=None, global_indexes=None)
```

Creates a DynamoDB table.

CLI Example:
```
salt myminion boto_dynamodb.create_table table_name /
    region=us-east-1 /
    hash_key=id /
    hash_key_data_type=N /
    range_key=created_at /
    range_key_data_type=N /
    read_capacity_units=1 /
    write_capacity_units=1
```

```python
salt.modules.boto_dynamodb.delete(table_name, region=None, key=None, keyid=None, profile=None)
```

Delete a DynamoDB table.

CLI Example:
```
salt myminion boto_dynamodb.delete table_name region=us-east-1
```

```python
salt.modules.boto_dynamodb.describe(table_name, region=None, key=None, keyid=None, profile=None)
```

Describe a DynamoDB table.

CLI example:
```
salt myminion boto_dynamodb.describe table_name region=us-east-1
```

```python
salt.modules.boto_dynamodb.exists(table_name, region=None, key=None, keyid=None, profile=None)
```

Check to see if a table exists.

CLI Example:
```
salt myminion boto_dynamodb.exists table_name region=us-east-1
```

```python
salt.modules.boto_dynamodb.update(table_name, throughput=None, global_indexes=None, region=None, key=None, keyid=None, profile=None)
```

Update a DynamoDB table.

CLI example:
13.6.23 salt.modules.boto_ec2

Connection module for Amazon EC2

New in version 2015.8.0.

configuration This module accepts explicit EC2 credentials but can also utilize IAM roles assigned to
the instance through Instance Profiles. Dynamic credentials are then automatically obtained from
AWS API and no further configuration is necessary. More Information available at:

http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-
-ec2.html

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

ec2.keyid: GKTADJGHEIQSXMKKRBJ08H
ec2.key: askdjghsdfjdkgHupUjasdlfdkflgjdsdjajkghs

A region may also be specified in the configuration:

ec2.region: us-east-1

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid, and region via a profile, either as a passed in dict, or as a
string to pull from pillars or minion config:

myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjdkgHupUjasdlfdkflgjdsdjajkghs
  region: us-east-1

depends boto

salt.modules.boto_ec2.allocate_eip_address(domain=None, region=None, key=None,
keyid=None, profile=None)

Allocate a new Elastic IP address and associate it with your account.

domain (string) Optional param - if set to exactly 'vpc', the address will be allocated to the VPC. The default
simply maps the EIP to your account container.

returns (dict) dict of `interesting` information about the newly allocated EIP, with probably the most inter-
esting keys being `public_ip`; and `allocation_id` iff `domain=vpc` was passed.

CLI Example:
salt-call boto_ec2.allocate_eip_address domain=vpc

New in version 2016.3.0.

salt.modules.boto_ec2.associate_eip_address(instance_id=None, instance_name=None,
public_ip=None, allocation_id=None,
network_interface_id=None, network_interface_name=None,
private_ip_address=None, allow_reassociation=False, region=None,
key=None, keyid=None, profile=None)

Associate an Elastic IP address with a currently running instance or a network interface. This requires exactly
Salt Documentation, Release 2016.3.6

one of either `public_ip' or `allocation_id', depending on whether you’re associating a VPC address or a plain
EC2 address.
instance_id (string) – ID of the instance to associate with (exclusive with `instance_name')
instance_name (string) – Name tag of the instance to associate with (exclusive with `instance_id')
public_ip (string) – Public IP address, for standard EC2 based allocations.
allocation_id (string) – Allocation ID for a VPC-based EIP.
network_interface_id (string) - ID of the network interface to associate the EIP with
network_interface_name (string) - Name of the network interface to associate the EIP with
private_ip_address (string) – e primary or secondary private IP address to associate with the Elastic IP
address.
allow_reassociation (bool) – Allow a currently associated EIP to be re-associated with the new instance or
interface.
returns (bool) - True on success, False otherwise
CLI Example:
salt myminion boto_ec2.associate_eip_address instance_name=bubba.ho.tep
,→allocation_id=eipalloc-ef382c8a

New in version 2016.3.0.
salt.modules.boto_ec2.attach_network_interface(device_index,
name=None,
network_interface_id=None,
instance_name=None, instance_id=None,
region=None, key=None, keyid=None,
proﬁle=None)
Aach an Elastic Network Interface.
New in version 2016.3.0.
CLI Example:
salt myminion boto_ec2.attach_network_interface my_eni instance_name=salt-master
,→device_index=0

salt.modules.boto_ec2.create_image(ami_name,
instance_id=None,
instance_name=None,
tags=None,
region=None,
key=None,
keyid=None,
proﬁle=None,
description=None,
no_reboot=False,
dry_run=False)
Given instance properties that deﬁne exactly one instance, create AMI and return AMI-id.
CLI Examples:
salt myminion boto_ec2.create_image ami_name instance_name=myinstance
salt myminion boto_ec2.create_image another_ami_name tags='{"mytag": "value"}'
,→description='this is my ami'

salt.modules.boto_ec2.create_key(key_name, save_path, region=None, key=None, keyid=None,
proﬁle=None)
Creates a key and saves it to a given path. Returns the private key.
CLI Example:
salt myminion boto_ec2.create_key mykey /root/

salt.modules.boto_ec2.create_network_interface(name,
subnet_id=None,
subnet_name=None,
private_ip_address=None,
description=None, groups=None, region=None,
key=None, keyid=None, proﬁle=None)
13.6. execution modules

799


Create an Elastic Network Interface.
New in version 2016.3.0.
CLI Example:
```
salt myminion boto_ec2.create_network_interface my_eni subnet-12345
  description=my_eni groups=['my_group']
```

```
salt.modules.boto_ec2.delete_key(key_name, region=None, key=None, keyid=None, profile=None)
```
Deletes a key. Always returns True
CLI Example:
```
salt myminion boto_ec2.delete_key mykey
```

```
salt.modules.boto_ec2.delete_network_interface(name=None, network_interface_id=None, region=None, key=None, keyid=None, profile=None)
```
Create an Elastic Network Interface.
New in version 2016.3.0.
CLI Example:
```
salt myminion boto_ec2.create_network_interface my_eni subnet-12345
  description=my_eni groups=['my_group']
```

```
salt.modules.boto_ec2.detach_network_interface(name=None, network_interface_id=None, attachment_id=None, force=False, region=None, key=None, keyid=None, profile=None)
```
Detach an Elastic Network Interface.
New in version 2016.3.0.
CLI Example:
```
salt myminion boto_ec2.detach_network_interface my_eni
```

```
salt.modules.boto_ec2.disassociate_eip_address(public_ip=None, association_id=None, region=None, key=None, keyid=None, profile=None)
```
Disassociate an Elastic IP address from a currently running instance. This requires exactly one of either 'association_id' or 'public_ip', depending on whether you’re associating a VPC address or a plain EC2 address.
```
public_ip (string) – Public IP address, for standard EC2 based allocations.
association_id (string) – Association ID for a VPC-based EIP.
returns (bool) - True on success, False otherwise
```
CLI Example:
```
salt myminion boto_ec2.disassociate_eip_address association_id=eipassoc-e3ba2d16
```
New in version 2016.3.0.

```
salt.modules.boto_ec2.exists(instance_id=None, name=None, tags=None, region=None, key=None, keyid=None, profile=None, in_states=None)
```
Given a instance id, check to see if the given instance id exists.
Returns True if the given an instance with the given id, name, or tags exists; otherwise, False is returned.
Salt Documentation, Release 2016.3.6

CLI Example:
salt myminion boto_ec2.exists myinstance

salt.modules.boto_ec2.find_images(ami_name=None,
executable_by=None,
owners=None,
image_ids=None, tags=None, region=None, key=None,
keyid=None, proﬁle=None, return_objs=False)
Given image properties, ﬁnd and return matching AMI ids
CLI Examples:
salt myminion boto_ec2.find_instances tags='{"mytag": "value"}'

salt.modules.boto_ec2.find_instances(instance_id=None,
name=None,
tags=None,
region=None, key=None, keyid=None, proﬁle=None,
return_objs=False, in_states=None)
Given instance properties, ﬁnd and return matching instance ids
CLI Examples:
salt myminion boto_ec2.find_instances # Lists all instances
salt myminion boto_ec2.find_instances name=myinstance
salt myminion boto_ec2.find_instances tags='{"mytag": "value"}'

salt.modules.boto_ec2.get_all_eip_addresses(addresses=None,
allocation_ids=None,
region=None, key=None, keyid=None, proﬁle=None)
Get public addresses of some, or all EIPs associated with the current account.
addresses (list) - Optional list of addresses. If provided, only the addresses associated with those in the list
will be returned.
allocation_ids (list) - Optional list of allocation IDs. If provided, only the addresses associated with the given
allocation IDs will be returned.
returns (list) - A list of the requested EIP addresses
CLI Example:
salt-call boto_ec2.get_all_eip_addresses

New in version 2016.3.0.
salt.modules.boto_ec2.get_attribute(aribute, instance_name=None, instance_id=None, region=None, key=None, keyid=None, proﬁle=None)
Get an EC2 instance aribute.
CLI Example:
salt myminion boto_ec2.get_attribute sourceDestCheck instance_name=my_instance

Available attributes:
• instanceType
• kernel
• ramdisk
• userData
• disableApiTermination
• instanceInitiatedShutdownBehavior
• rootDeviceName
13.6. execution modules

801


- blockDeviceMapping
- productCodes
- sourceDestCheck
- groupSet
- ebsOptimized
- sriovNetSupport

salt.modules.boto_ec2.get_eip_address_info(addresses=None, allocation_ids=None, region=None, key=None, keyid=None, profile=None)

Get `interesting' info about some, or all EIPs associated with the current account.

addresses (list) - Optional list of addresses. If provided, only the addresses associated with those in the list will be returned.

allocation_ids (list) - Optional list of allocation IDs. If provided, only the addresses associated with the given allocation IDs will be returned.

returns (list of dicts) - A list of dicts, each containing the info for one of the requested EIPs.

CLI Example:

```
salt-call boto_ec2.get_eip_address_info addresses=52.4.2.15
```

New in version 2016.3.0.

salt.modules.boto_ec2.get_id(name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Given instance properties, return the instance id if it exist.

CLI Example:

```
salt myminion boto_ec2.get_id myinstance
```

salt.modules.boto_ec2.get_key(key_name, region=None, key=None, keyid=None, profile=None)

Check to see if a key exists. Returns fingerprint and name if it does and False if it doesn't

CLI Example:

```
salt myminion boto_ec2.get_key mykey
```

salt.modules.boto_ec2.get_keys(keynames=None, filters=None, region=None, key=None, keyid=None, profile=None)

Gets all keys or filters them by name and returns a list. keynames (list): A list of the names of keypairs to retrieve. If not provided, all key pairs will be returned. filters (dict) :: Optional filters that can be used to limit the results returned. Filters are provided in the form of a dictionary consisting of filter names as the key and filter values as the value. The set of allowable filter names/values is dependent on the request being performed. Check the EC2 API guide for details.

CLI Example:

```
salt myminion boto_ec2.get_keys
```

salt.modules.boto_ec2.get_network_interface(name=None, network_interface_id=None, region=None, key=None, keyid=None, profile=None)

Get an Elastic Network Interface.

New in version 2016.3.0.

CLI Example:
salt myminion boto_ec2.get_network_interface name=my_eni

salt.modules.boto_ec2.get_network_interface_id(name, region=None, key=None, keyid=None, profile=None)

Get an Elastic Network Interface id from its name tag.

New in version 2016.3.0.

CLI Example:

salt myminion boto_ec2.get_network_interface_id name=my_eni

salt.modules.boto_ec2.get_unassociated_eip_address(domain='standard', region=None, key=None, keyid=None, profile=None)

Return the first unassociated EIP

domain Indicates whether the address is a EC2 address or a VPC address (standard|vpc).

CLI Example:

salt-call boto_ec2.get_unassociated_eip_address

New in version 2016.3.0.

salt.modules.boto_ec2.get_zones(region=None, key=None, keyid=None, profile=None)

Get a list of AZs for the configured region.

CLI Example:

salt myminion boto_ec2.get_zones

salt.modules.boto_ec2.import_key(key_name, public_key_material, region=None, key=None, keyid=None, profile=None)

Imports the public key from an RSA key pair that you created with a third-party tool. Supported formats: - OpenSSH public key format (e.g., the format in ~/.ssh/authorized_keys) - Base64 encoded DER format - SSH public key file format as specified in RFC4716 - DSA keys are not supported. Make sure your key generator is set up to create RSA keys. Supported lengths: 1024, 2048, and 4096.

CLI Example:

salt myminion boto_ec2.import mykey publickey

salt.modules.boto_ec2.modify_network_interface_attribute(name=None, network_interface_id=None, attr=None, value=None, region=None, key=None, keyid=None, profile=None)

Modify an attribute of an Elastic Network Interface.

New in version 2016.3.0.

CLI Example:

salt myminion boto_ec2.modify_network_interface_attribute my_eni attr=description value='example description'

salt.modules.boto_ec2.release_eip_address(public_ip=None, allocation_id=None, region=None, key=None, keyid=None, profile=None)
Free an Elastic IP address. Pass either a public IP address to release a `standard` EC2 Elastic IP address, or an AllocationId to release a VPC Elastic IP address.

- **public_ip** (string) - The public IP address - for EC2 elastic IPs.
- **allocation_id** (string) - The Allocation ID - for VPC elastic IPs.
- **returns** (bool) - True on success, False on failure

CLI Example:
```shell
salt myminion boto_ec2.release_eip_address allocation_id=eipalloc-ef382c8a
```

New in version 2016.3.0.

**salt.modules.boto_ec2.run**

```python
salt.modules.boto_ec2.run(image_id=None, name=None, tags=None, key_name=None, security_groups=None, user_data=None, instance_type='m1.small', placement=None, kernel_id=None, ramdisk_id=None, monitoring_enabled=None, vpc_id=None, vpc_name=None, subnet_id=None, subnet_name=None, private_ip_address=None, block_device_map=None, disable_api_termination=None, instance_initiated_shutdown_behavior=None, placement_group=None, client_token=None, security_group_ids=None, security_group_names=None, additional_info=None, tenancy=None, instance_profile_arn=None, instance_profile_name=None, ebs_optimized=None, network_interface_id=None, network_interface_name=None, region=None, key=None, keyid=None, profile=None, networkInterfaces=None)
```

Create and start an EC2 instance.

Returns True if the instance was created; otherwise False.

CLI Example:
```shell
salt myminion boto_ec2.run ami-b80c2b87 name=myinstance
```

- **image_id** (string) – The ID of the image to run.
- **name** (string) - The name of the instance.
- **tags** (dict of key: value pairs) - tags to apply to the instance.
- **key_name** (string) – The name of the key pair with which to launch instances.
- **security_groups** (list of strings) – The names of the EC2 classic security groups with which to associate instances
- **user_data** (string) – The Base64-encoded MIME user data to be made available to the instance(s) in this reservation.
- **instance_type** (string) – The type of instance to run. Note that some image types (e.g. hvm) only run on some instance types.
- **placement** (string) – The Availability Zone to launch the instance into.
- **kernel_id** (string) – The ID of the kernel with which to launch the instances.
- **ramdisk_id** (string) – The ID of the RAM disk with which to launch the instances.
- **monitoring_enabled** (bool) – Enable detailed CloudWatch monitoring on the instance.
- **vpc_id** (string) - ID of a VPC to bind the instance to. Exclusive with vpc_name.
- **vpc_name** (string) - Name of a VPC to bind the instance to. Exclusive with vpc_id.
- **subnet_id** (string) – The subnet ID within which to launch the instances for VPC.
- **subnet_name** (string) – The name of a subnet within which to launch the instances for VPC.
- **private_ip_address** (string) – If you’re using VPC, you can optionally use this parameter to assign the instance a specific available IP address from the subnet (e.g. 10.0.0.25).
- **block_device_map** (boto ec2.blockdevicemapping.BlockDeviceMapping) – A BlockDeviceMapping data structure describing the EBS volumes associated with the Image.
- **disable_api_termination** (bool) – If True, the instances will be locked and will not be able to be terminated via the API.
instance_initiated_shutdown_behavior (string) – Specifies whether the instance stops or terminates on instance-initiated shutdown. Valid values are: stop, terminate
placement_group (string) – If specified, this is the name of the placement group in which the instance(s) will be launched.
client_token (string) – Unique, case-sensitive identifier you provide to ensure idempotency of the request. Maximum 64 ASCII characters.
security_group_ids (list of strings) – The ID(s) of the VPC security groups with which to associate instances.
security_group_names (list of strings) – The name(s) of the VPC security groups with which to associate instances.
additional_info (string) – Specifies additional information to make available to the instance(s).
tenancy (string) – The tenancy of the instance you want to launch. An instance with a tenancy of ‘dedicated’ runs on single-tenant hardware and can only be launched into a VPC. Valid values are: “default” or “dedicated”. NOTE: To use dedicated tenancy you MUST specify a VPC subnet-ID as well.
instance_profile_arn (string) – The Amazon resource name (ARN) of the IAM Instance Profile (IIP) to associate with the instances.
instance_profile_name (string) – The name of the IAM Instance Profile (IIP) to associate with the instances.
ebs_optimized (bool) – Whether the instance is optimized for EBS I/O. This optimization provides dedicated throughput to Amazon EBS and an optimized configuration stack to provide optimal EBS I/O performance. This optimization isn’t available with all instance types.
network_interfaces (boto.ec2.networkinterface.NetworkInterfaceCollection) – A NetworkInterfaceCollection data structure containing the ENI specifications for the instance.
network_interface_id (string) - ID of the network interface to attach to the instance
network_interface_name (string) - Name of the network interface to attach to the instance

salt.modules.boto_ec2.set_attribute(attribute, attribute_value, instance_name=None, instance_id=None, region=None, key=None, keyid=None, profile=None)

Set an EC2 instance attribute. Returns whether the operation succeeded or not.

CLI Example:

```
salt myminion boto_ec2.set_attribute sourceDestCheck False instance_name=my_instance
```

Available attributes:

- instanceType
- kernel
- ramdisk
- userData
- disableApiTermination
- instanceInitiatedShutdownBehavior
- rootDeviceName
- blockDeviceMapping
- productCodes
- sourceDestCheck
- groupSet
- ebsOptimized
- sriovNetSupport
salt.modules.boto_ec2.terminate(instance_id=None, name=None, region=None, key=None, keyid=None, profile=None)

Terminate the instance described by instance_id or name.

CLI Example:

```
salt myminion boto_ec2.terminate name=myinstance
salt myminion boto_ec2.terminate instance_id=i-a46b9f
```

13.6.24 salt.modules.boto_elasticache

Connection module for Amazon Elasticache

New in version 2014.7.0.

configuration This module accepts explicit elasticache credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
elasticache.keyid: GKTADJGHEIQSXMKKRBJ08H
elasticache.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```
elasticache.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile: keyid: GKTADJGHEIQSXMKKRBJ08H
          key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
          region: us-east-1
```

depends boto

salt.modules.boto_elasticache.authorize_cache_security_group_ingress(name, ec2_security_group_name, ec2_security_group_owner_id, region=None, key=None, keyid=None, profile=None)

Authorize network ingress from an ec2 security group to a cache security group.

CLI example:

```
salt myminion boto_elasticache.authorize_cache_security_group_ingress name=myec2sg ec2_security_group_name=myec2sg ec2_security_group_owner_id=879879
```
salt.modules.boto_elasticache.

```

salt.modules.boto_elasticache.create(name, num_cache_nodes=None, engine=None, cache_node_type=None, replication_group_id=None, cache_parameter_group_name=None, cache_subnet_group_name=None, cache_security_group_names=None, security_group_ids=None, snapshot_arns=None, preferred_availability_zone=None, preferred_maintenance_window=None, port=None, notification_topic_arn=None, auto_minor_version_upgrade=None, wait=None, region=None, key=None, keyid=None, profile=None)
```

Create a cache cluster.

CLI example:

```
salt myminion boto_elasticache.create myelasticache
```

```
cache_security_group_names=['"myelasticachesg"]
```

salt.modules.boto_elasticache.

```
salt.modules.boto_elasticache.create_cache_security_group(name, description, region=None, key=None, keyid=None, profile=None)
```

Create a cache security group.

CLI example:

```
salt myminion boto_elasticache.create_cache_security_group myelasticachesg 'My\n\n->Cache Security Group'
```

salt.modules.boto_elasticache.

```
salt.modules.boto_elasticache.create_replication_group(name, primary_cluster_id, replication_group_description, wait=None, region=None, key=None, keyid=None, profile=None)
```

Create replication group.

CLI example:

```
salt myminion boto_elasticache.create_replication_group myelasticache\n\n->myprimarycluster description
```

salt.modules.boto_elasticache.

```
salt.modules.boto_elasticache.create_subnet_group(name, description, subnet_ids, tags=None, region=None, key=None, keyid=None, profile=None)
```

Create an ElastiCache subnet group

CLI example to create an ElastiCache subnet group:

```
salt myminion boto_elasticache.create_subnet_group my-subnet-group
\n\n->group description "[subnet-12345678, subnet-87654321]" region=us-east-1
```

salt.modules.boto_elasticache.

```
salt.modules.boto_elasticache.delete(name, wait=False, region=None, key=None, keyid=None, profile=None)
```

Delete a cache cluster.

CLI example:
salt myminion boto_elasticache.delete myelasticache

salt.modules.boto_elasticache.delete_cache_security_group(name, region=None, key=None, keyid=None, profile=None)

Delete a cache security group.

CLI example:
```
salt myminion boto_elasticache.delete_cache_security_group myelasticachesg 'My Cache Security Group'
```

salt.modules.boto_elasticache.delete_subnet_group(name, region=None, key=None, keyid=None, profile=None)

Delete an ElastiCache subnet group.

CLI example:
```
salt myminion boto_elasticache.delete_subnet_group my-subnet-group --region=us-east-1
```

salt.modules.boto_elasticache.describe_replication_group(name, region=None, key=None, keyid=None, profile=None, parameter=None)

Get replication group information.

CLI example:
```
salt myminion boto_elasticache.describe_replication_group mygroup
```

salt.modules.boto_elasticache.exists(name, region=None, key=None, keyid=None, profile=None)

Check to see if a cache cluster exists.

CLI example:
```
salt myminion boto_elasticache.exists myelasticache
```

salt.modules.boto_elasticache.get_cache_subnet_group(name, region=None, key=None, keyid=None, profile=None)

Get information about a cache subnet group.

CLI example:
```
salt myminion boto_elasticache.get_cache_subnet_group mycache_subnet_group
```

salt.modules.boto_elasticache.get_config(name, region=None, key=None, keyid=None, profile=None)

Get the configuration for a cache cluster.

CLI example:
```
salt myminion boto_elasticache.get_config myelasticache
```

salt.modules.boto_elasticache.get_group_host(name, region=None, key=None, keyid=None, profile=None)

Get hostname from replication cache group

CLI example:
**salt**

```
salt myminion boto_elasticache.get_group_host myelasticachegroup
```

group

```python
salt.modules.boto_elasticache.get_node_host(name, region=None, key=None, keyid=None, profile=None)
```

Get hostname from cache node

CLI example:

```
salt myminion boto_elasticache.get_node_host myelasticache
```

group

```python
salt.modules.boto_elasticache.group_exists(name, region=None, key=None, keyid=None, profile=None)
```

Check to see if a replication group exists.

CLI example:

```
salt myminion boto_elasticache.group_exists myelasticache
```

group

```python
salt.modules.boto_elasticache.revoke_cache_security_group_ingress(name, ec2_security_group_name, ec2_security_group_owner_id, region=None, key=None, keyid=None, profile=None)
```

Revoke network ingress from an ec2 security group to a cache security group.

CLI example:

```
salt myminion boto_elasticache.revoke_cache_security_group_ingress
  ←myelasticachesg myec2sg
```

group

```python
salt.modules.boto_elasticache.subnet_group_exists(name, tags=None, region=None, key=None, keyid=None, profile=None)
```

Check to see if an ElastiCache subnet group exists.

CLI example:

```
salt myminion boto_elasticache.subnet_group_exists my-param-group
  ←region=us-east-1
```

13.6.25 **salt.modules.boto_elb**

Connection module for Amazon ELB

New in version 2014.7.0.

**configuration** This module accepts explicit elb credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
```
If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
elb.keyid: GKTADJGHEIQXSXMZRBJ08H
elb.key: askdjghsdfjkgwupujasdfsdlkdfkgjksdfjajkghs
```

A region may also be specified in the configuration:

```
elb.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQXSXMZRBJ08H
  key: askdjghsdfjkgwupujasdfsdlkdfkgjksdfjajkghs
  region: us-east-1
```

```
depends boto >= 2.33.0
```

```
salt.modules.boto_elb.apply_security_groups(name, security_groups, region=None, key=None, keyid=None, profile=None)
```

Apply security groups to ELB.

CLI example:

```
salt myminion boto_elb.apply_security_groups myelb ['"mysecgroup1"]
```

```
salt.modules.boto_elb.attach_subnets(name, subnets, region=None, key=None, keyid=None, profile=None)
```

Attach ELB to subnets.

CLI example:

```
salt myminion boto_elb.attach_subnets myelb ['"mysubnet"]
```

```
salt.modules.boto_elb.create(name, availability_zones, listeners, subnets=None, security_groups=None, scheme='internet-facing', region=None, key=None, keyid=None, profile=None)
```

Create an ELB.

CLI example to create an ELB:

```
salt myminion boto_elb.create myelb ['"us-east-1a", "us-east-1e"]' '{"elb_port":443, "elb_protocol": "HTTPS", ...}' region=us-east-1
```

```
salt.modules.boto_elb.create_listeners(name, listeners, region=None, key=None, keyid=None, profile=None)
```

Create listeners on an ELB.

CLI example:

```
salt myminion boto_elb.create_listeners myelb '['"HTTPS", "HTTP", 443, 80, "arn:aws:iam::11111:server-certificate/mycert"]'
```

```
salt.modules.boto_elb.create_policy(name, policy_name, policy_type, policy, region=None, key=None, keyid=None, profile=None)
```

Create an ELB policy.

New in version 2016.3.0.
CLI example:

```python
salt myminion boto_elb.create_policy myelb mypolicy LBCookieStickinessPolicyType {
  "CookieExpirationPeriod": 3600
}
```

dsalt.modules.boto_elb.delete(name, region=None, key=None, keyid=None, profile=None)
Delete an ELB.

CLI example to delete an ELB:

```python
salt myminion boto_elb.delete myelb region=us-east-1
```

dsalt.modules.boto_elb.delete_listeners(name, ports, region=None, key=None, keyid=None, profile=None)
Delete listeners on an ELB.

CLI example:

```python
salt myminion boto_elb.delete_listeners myelb ['80,443']
```

dsalt.modules.boto_elb.delete_policy(name, policy_name, region=None, key=None, keyid=None, profile=None)
Delete an ELB policy.
New in version 2016.3.0.

CLI example:

```python
salt myminion boto_elb.delete_policy myelb mypolicy
```

dsalt.modules.boto_elb.delete_tags(name, tags, region=None, key=None, keyid=None, profile=None)
Add the tags on an ELB.

name  name of the ELB
tags   list of tags to remove

CLI Example:

```python
salt myminion boto_elb.delete_tags my-elb-name ['TagToRemove1', 'TagToRemove2']
```

dsalt.modules.boto_elb.deregister_instances(name, instances, region=None, key=None, keyid=None, profile=None)
Deregister instances with an ELB. Instances is either a string instance id or a list of string instance id's.

Returns:
- True: instance(s) deregistered successfully
- False: instance(s) failed to be deregistered
- None: instance(s) not valid or not registered, no action taken

CLI example:

```python
salt myminion boto_elb.deregister_instances myelb instance_id
salt myminion boto_elb.deregister_instances myelb "[instance_id, instance_id]"
```

dsalt.modules.boto_elb.detach_subnets(name, subnets, region=None, key=None, keyid=None, profile=None)
Detach ELB from subnets.

CLI example:

```python
salt myminion boto_elb.detach_subnets myelb ['"mysubnet"]'
```
salt.modules.boto_elb.disable_availability_zones(name, availability_zones, region=None, key=None, keyid=None, profile=None)

Disable availability zones for ELB.

CLI example:

```
salt myminion boto_elb.disable_availability_zones myelb '"[us-east-1a]"'
```

salt.modules.boto_elb.enable_availability_zones(name, availability_zones, region=None, key=None, keyid=None, profile=None)

Enable availability zones for ELB.

CLI example:

```
salt myminion boto_elb.enable_availability_zones myelb '"[us-east-1a]"'
```

salt.modules.boto_elb.exists(name, region=None, key=None, keyid=None, profile=None)

Check to see if an ELB exists.

CLI example:

```
salt myminion boto_elb.exists myelb region=us-east-1
```

salt.modules.boto_elb.get_attributes(name, region=None, key=None, keyid=None, profile=None)

Check to see if attributes are set on an ELB.

CLI example:

```
salt myminion boto_elb.get_attributes myelb
```

salt.modules.boto_elb.get_elb_config(name, region=None, key=None, keyid=None, profile=None)

Get an ELB configuration.

CLI example:

```
salt myminion boto_elb.exists myelb region=us-east-1
```

salt.modules.boto_elb.get_health_check(name, region=None, key=None, keyid=None, profile=None)

Get the health check configured for this ELB.

CLI example:

```
salt myminion boto_elb.get_health_check myelb
```

salt.modules.boto_elb.get_instance_health(name, region=None, key=None, keyid=None, profile=None, instances=None)

Get a list of instances and their health state.

CLI example:

```
salt myminion boto_elb.get_instance_health myelb
salt myminion boto_elb.get_instance_health myelb region=us-east-1 instances="[instance_id,instance_id]"
```

salt.modules.boto_elb.listener_dict_to_tuple(listener)

Convert an ELB listener dict into a listener tuple used by certain parts of the AWS ELB API.
CLI example:

```python
salt myminion boto_elb.listener_dict_to_tuple '{"elb_port":80,"instance_port":80, 
←"elb_protocol":"HTTP"}'
```

salt.modules.boto_elb.register_instances(name, instances, region=None, key=None, 
keyid=None, profile=None)

Register instances with an ELB. Instances is either a string instance id or a list of string instance id's.

Returns:
- True: instance(s) registered successfully
- False: instance(s) failed to be registered

CLI example:

```python
salt myminion boto_elb.register_instances myelb instance_id
salt myminion boto_elb.register_instances myelb "[instance_id,instance_id]"
```

salt.modules.boto_elb.set_attributes(name, attributes, region=None, key=None, 
keyid=None, profile=None)

Set attributes on an ELB.

- name (string) Name of the ELB instance to set attributes for
- attributes A dict of attributes to set.

Valid attributes are:
- access_log (dict)
  - enabled (bool) Enable storage of access logs.
  - s3_bucket_name (string) The name of the S3 bucket to place logs.
  - s3_bucket_prefix (string) Prefix for the log file name.
  - emit_interval (int) Interval for storing logs in S3 in minutes. Valid values are 5 and 60.
- connection_draining (dict)
  - enabled (bool) Enable connection draining.
  - timeout (int) Maximum allowed time in seconds for sending existing connections to an instance 
    that is deregistering or unhealthy. Default is 300.
- cross_zone_load_balancing (dict)
  - enabled (bool) Enable cross-zone load balancing.

CLI example to set attributes on an ELB:

```python
salt myminion boto_elb.set_attributes myelb '{"access_log": {"enabled": "true", 
←"s3_bucket_name": "mybucket", "s3_bucket_prefix": "mylogs/", "emit_interval": "5 
←"}}', region=us-east-1
```

salt.modules.boto_elb.set_backend_policy(name, port, policies=None, region=None, 
key=None, keyid=None, profile=None)

Set the policies of an ELB backend server.

CLI example:

```python
salt myminion boto_elb.set_backend_policy myelb 443 `[policy1,policy2]`
```

salt.modules.boto_elb.set_health_check(name, health_check, region=None, key=None, 
keyid=None, profile=None)

Set attributes on an ELB.

CLI example to set attributes on an ELB:
Salt Documentation, Release 2016.3.6

```
salt myminion boto_elb.set_health_check myelb '{"target": "HTTP:80/"}'
```

salt.modules.boto_elb.set_listener_policy(name, port, policies=None, region=None, key=None, keyid=None, profile=None)

Set the policies of an ELB listener.
New in version 2016.3.0.
CLI example:
```
salt myminion boto_elb.set_listener_policy myelb 443 "[policy1,policy2]"
```

salt.modules.boto_elb.set_tags(name, tags, region=None, key=None, keyid=None, profile=None)

Add the tags on an ELB
New in version 2016.3.0.
name name of the ELB
tags dict of name/value pair tags
CLI Example:
```
salt myminion boto_elb.set_tags my-elb-name '{'Tag1': 'Value', 'Tag2': 'Another Value'}'
```

13.6.26 salt.modules.boto_iam

Connection module for Amazon IAM
New in version 2014.7.0.

configuration This module accepts explicit iam credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
iam.keyid: GKTADJGHEIQSXMKKRBJ08H
iam.key: askdjghsdfjghWupUjasdfsdlkdfklgjsdfjawjkghs
iam.region: us-east-1
```

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjghWupUjasdfsdlkdfklgjsdfjawjkghs
  region: us-east-1
```

depends boto

salt.modules.boto_iam.add_user_to_group(user_name, group_name, region=None, key=None, keyid=None, profile=None)

Add user to group.
New in version 2015.8.0.
CLI Example:
```bash
salt myminion boto_iam.add_user_to_group myuser mygroup
```

```
salt.modules.boto_iam.associate_profile_to_role(
    profile_name, role_name, region=None,
    key=None, keyid=None, profile=None)
```

Associate an instance profile with an IAM role.

CLI Example:
```bash
salt myminion boto_iam.associate_profile_to_role myirole myiprofile
```

```
salt.modules.boto_iam.build_policy(
    region=None, key=None, keyid=None, profile=None)
```

Build a default assume role policy.

New in version 2015.8.0.

CLI Example:
```bash
salt myminion boto_iam.build_policy
```

```
salt.modules.boto_iam.create_access_key(
    user_name, region=None, key=None, keyid=None,
    profile=None)
```

Create access key id for a user.

New in version 2015.8.0.

CLI Example:
```bash
salt myminion boto_iam.create_access_key myuser
```

```
salt.modules.boto_iam.create_group(
    group_name, path=None, region=None, key=None,
    keyid=None, profile=None)
```

Create a group.

New in version 2015.8.0.

CLI Example:
```bash
salt myminion boto_iam.create_group group
```

```
salt.modules.boto_iam.create_instance_profile(
    name, region=None, key=None,
    keyid=None, profile=None)
```

Create an instance profile.

CLI Example:
```bash
salt myminion boto_iam.create_instance_profile myiprofile
```

```
salt.modules.boto_iam.create_login_profile(
    user_name, password, region=None, key=None,
    keyid=None, profile=None)
```

Creates a login profile for the specified user, give the user the ability to access AWS services and the AWS Management Console.

New in version 2015.8.0.

CLI Example:
```bash
salt myminion boto_iam.create_login_profile user_name password
```
salt.modules.boto_iam.create_role(name, policy_document=None, path=None, region=None, key=None, keyid=None, profile=None)

Create an instance role.

CLI Example:
```
salt myminion boto_iam.create_role myrole
```

salt.modules.boto_iam.create_role_policy(role_name, policy_name, policy, region=None, key=None, keyid=None, profile=None)

Create or modify a role policy.

CLI Example:
```
salt myminion boto_iam.create_role_policy myirole mypolicy
```

```bash
dict = {
    "MyPolicy": {
        "Statement": [ {
            "Action": ["sqs:*"],
            "Effect": "Allow",
            "Resource": ["arn:aws:sqs:*:*:*"]
        } ],
        "Sid": "MyPolicySqs1"
    }
}
salt myminion boto_iam.create_role_policy myirole mypolicy {"MyPolicy":
dict}
```

salt.modules.boto_iam.create_user(user_name, path=None, region=None, key=None, keyid=None, profile=None)

Create a user.

New in version 2015.8.0.

CLI Example:
```
salt myminion boto_iam.create_user myuser
```

salt.modules.boto_iam.deactivate_mfa_device(user_name, serial, region=None, key=None, keyid=None, profile=None)

Deactivates the specified MFA device and removes it from association with the user.

New in version 2016.3.0.

CLI Example:
```
salt myminion boto_iam.deactivate_mfa_device user_name serial_num
```

salt.modules.boto_iam.delete_access_key(access_key_id, user_name=None, region=None, key=None, keyid=None, profile=None)

Delete access key id from a user.

New in version 2015.8.0.

CLI Example:
```
salt myminion boto_iam.delete_access_key myuser
```

salt.modules.boto_iam.delete_group_policy(group_name, policy_name, region=None, key=None, keyid=None, profile=None)

Delete a group policy.

CLI Example:
```
salt myminion boto_iam.delete_group_policy mygroup mypolicy
```

salt.modules.boto_iam.delete_instance_profile(name, region=None, key=None, keyid=None, profile=None)

Delete an instance profile.
CLI Example:
```
salt myminion boto_iam.delete_instance_profile myiprofile
```

`salt.modules.boto_iam.delete_login_profile(user_name, region=None, key=None, keyid=None, profile=None)`

Deletes a login profile for the specified user.

New in version 2016.3.0.

CLI Example:
```
salt myminion boto_iam.delete_login_profile user_name
```

`salt.modules.boto_iam.delete_role(name, region=None, key=None, keyid=None, profile=None)`

Delete an IAM role.

CLI Example:
```
salt myminion boto_iam.delete_role myirole
```

`salt.modules.boto_iam.delete_role_policy(role_name, policy_name, region=None, key=None, keyid=None, profile=None)`

Delete a role policy.

CLI Example:
```
salt myminion boto_iam.delete_role_policy myirole mypolicy
```

`salt.modules.boto_iam.delete_server_cert(cert_name, region=None, key=None, keyid=None, profile=None)`

Deletes a certificate from Amazon.

New in version 2015.8.0.

CLI Example:
```
salt myminion boto_iam.delete_server_cert mycert_name
```

`salt.modules.boto_iam.delete_user(user_name, region=None, key=None, keyid=None, profile=None)`

Delete a user.

New in version 2015.8.0.

CLI Example:
```
salt myminion boto_iam.delete_user myuser
```

`salt.modules.boto_iam.delete_user_policy(user_name, policy_name, region=None, key=None, keyid=None, profile=None)`

Delete a user policy.

CLI Example:
```
salt myminion boto_iam.delete_user_policy myuser mypolicy
```

`salt.modules.boto_iam.describe_role(name, region=None, key=None, keyid=None, profile=None)`

Get information for a role.

CLI Example:
salt myminion boto_iam.describe_role myrole

salt.modules.boto_iam.disassociate_profile_from_role(profile_name, role_name, region=None, key=None, keyid=None, profile=None)

Disassociate an instance profile from an IAM role.

CLI Example:
salt myminion boto_iam.disassociate_profile_from_role myirole myiprofile

salt.modules.boto_iam.export_users(path_prefix='/', region=None, key=None, keyid=None, profile=None)

Get all IAM user details. Produces results that can be used to create an sls file.

New in version 2016.3.0.

CLI Example:
salt-call boto_iam.export_users --out=txt | sed `s/local: //` > iam_users.sls

salt.modules.boto_iam.get_account_id(region=None, key=None, keyid=None, profile=None)

Get a the AWS account id associated with the used credentials.

CLI Example:
salt myminion boto_iam.get_account_id

salt.modules.boto_iam.get_account_policy(region=None, key=None, keyid=None, profile=None)

Get account policy for the AWS account.

New in version 2015.8.0.

CLI Example:
salt myminion boto_iam.get_account_policy

salt.modules.boto_iam.get_all_access_keys(user_name, marker=None, max_items=None, region=None, key=None, keyid=None, profile=None)

Get all access keys from a user.

New in version 2015.8.0.

CLI Example:
salt myminion boto_iam.get_all_access_keys myuser

salt.modules.boto_iam.get_all_group_policies(group_name, region=None, key=None, keyid=None, profile=None)

Get a list of policy names from a group.

CLI Example:
salt myminion boto_iam.get_all_group_policies mygroup

salt.modules.boto_iam.get_all_mfa_devices(user_name, region=None, key=None, keyid=None, profile=None)

Get all MFA devices associated with an IAM user.

New in version 2016.3.0.
CLI Example:

```
salt myminion boto_iam.get_all_mfa_devices user_name
```

```python
salt.modules.boto_iam.get_all_user_policies(user_name, marker=None, max_items=None, region=None, key=None, keyid=None, profile=None)
```

Get all user policies.
New in version 2015.8.0.

CLI Example:

```
salt myminion boto_iam.get_group mygroup
```

```python
salt.modules.boto_iam.get_group(group_name, region=None, key=None, keyid=None, profile=None)
```

Get group information.
New in version 2015.8.0.

CLI Example:

```
salt myminion boto_iam.get_group mygroup
```

```python
salt.modules.boto_iam.get_group_members(group_name, region=None, key=None, keyid=None, profile=None)
```

Get group information.
New in version 2016.3.0.

CLI Example:

```
salt myminion boto_iam.get_group mygroup
```

```python
salt.modules.boto_iam.get_group_policy(group_name, policy_name, region=None, key=None, keyid=None, profile=None)
```

Retrieves the specified policy document for the specified group.
New in version 2015.8.0.

CLI Example:

```
salt myminion boto_iam.get_group_policy mygroup policyman
```

```python
salt.modules.boto_iam.get_role_policy(role_name, policy_name, region=None, key=None, keyid=None, profile=None)
```

Get a role policy.

CLI Example:

```
salt myminion boto_iam.get_role_policy myirole mypolicy
```

```python
salt.modules.boto_iam.get_server_certificate(cert_name, region=None, key=None, keyid=None, profile=None)
```

Returns certificate information from Amazon
New in version 2015.8.0.

CLI Example:
salt myminion boto_iam.get_server_certificate mycert_name

salt.modules.boto_iam.get_user(
    user_name=None, region=None, key=None, keyid=None, profile=None
)

Get user information.
New in version 2015.8.0.
CLI Example:
salt myminion boto_iam.get_user myuser

salt.modules.boto_iam.get_user_policy(
    user_name, policy_name, region=None, key=None, keyid=None, profile=None
)

Retrieves the specified policy document for the specified user.
New in version 2015.8.0.
CLI Example:
salt myminion boto_iam.get_user_policy myuser mypolicyname

salt.modules.boto_iam.instance_profile_exists(
    name, region=None, key=None, keyid=None, profile=None
)

Check to see if an instance profile exists.
CLI Example:
salt myminion boto_iam.instance_profile_exists myiprofile

salt.modules.boto_iam.list_role_policies(
    role_name, region=None, key=None, keyid=None, profile=None
)

Get a list of policy names from a role.
CLI Example:
salt myminion boto_iam.list_role_policies myirole

salt.modules.boto_iam.profile_associated(
    role_name, profile_name, region, key, keyid, profile
)

Check to see if an instance profile is associated with an IAM role.
CLI Example:
salt myminion boto_iam.profile_associated myirole myiprofile

salt.modules.boto_iam.put_group_policy(
    group_name, policy_name, policy_json, region=None, key=None, keyid=None, profile=None
)

Adds or updates the specified policy document for the specified group.
New in version 2015.8.0.
CLI Example:
salt myminion boto_iam.put_group_policy mygroup policymap policymarules

salt.modules.boto_iam.put_user_policy(
    user_name, policy_name, policy_json, region=None, key=None, keyid=None, profile=None
)

Adds or updates the specified policy document for the specified user.
New in version 2015.8.0.
CLI Example:
```
salt myminion boto_iam.put_user_policy myuser policynname policyrules
```

```
salt.modules.boto_iam.remove_user_from_group(group_name, user_name, region=None, key=None, keyid=None, profile=None)
```

Remove user from group.
New in version 2015.8.0.

CLI Example:
```
salt myminion boto_iam.remove_user_from_group mygroup myuser
```

```
salt.modules.boto_iam.role_exists(name, region=None, key=None, keyid=None, profile=None)
```
Check to see if an IAM role exists.

CLI Example:
```
salt myminion boto_iam.role_exists myirole
```

```
salt.modules.boto_iam.update_account_password_policy(allow_users_to_change_password=None, hard_expiry=None, max_password_age=None, minimum_password_length=None, passwordReusePrevention=None, require_lowercase_characters=None, require_numbers=None, require_symbols=None, require_uppercase_characters=None, region=None, key=None, keyid=None, profile=None)
```

Update the password policy for the AWS account.
New in version 2015.8.0.

CLI Example:
```
salt myminion boto_iam.update_account_password_policy True
```

```
salt.modules.boto_iam.update_assume_role_policy(role_name, policy_document, region=None, key=None, keyid=None, profile=None)
```

Update an assume role policy for a role.
New in version 2015.8.0.

CLI Example:
```
salt myminion boto_iam.update_assume_role_policy myrole '{"Statement":"..."}"
```

```
salt.modules.boto_iam.upload_server_cert(cert_name, cert_body, private_key, cert_chain=None, path=None, region=None, key=None, keyid=None, profile=None)
```
Upload a certificate to Amazon.
New in version 2015.8.0.
CLI Example:

```
salt myminion boto_iam.upload_server_cert mycert_name crt priv_key
```

**Parameters**

- **cert_name** -- The name for the server certificate. Do not include the path in this value.
- **cert_body** -- The contents of the public key certificate in PEM-encoded format.
- **private_key** -- The contents of the private key in PEM-encoded format.
- **cert_chain** -- The contents of the certificate chain. This is typically a concatenation of the PEM-encoded public key certificates of the chain.
- **path** -- The path for the server certificate.
- **region** -- The name of the region to connect to.
- **key** -- The key to be used in order to connect
- **keyid** -- The keyid to be used in order to connect
- **profile** -- The profile that contains a dict of region, key, keyid

**Returns** True / False

```
salt.modules.boto_iam.user_exists_in_group(user_name, group_name, region=None, key=None, keyid=None, profile=None)
```

Check if user exists in group.

New in version 2015.8.0.

CLI Example:

```
salt myminion boto_iam.user_exists_in_group myuser mygroup
```

### 13.6.27 salt.modules.boto_iot module

Connection module for Amazon IoT

New in version 2016.3.0.

**depends**

- boto
- boto3

The dependencies listed above can be installed via package or pip.

**configuration** This module accepts explicit Lambda credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
iot.keyid: GKTADJGHEIQSXMKKRBJ08H
iot.key: askdjghsdfjdksfjgWupUjasdfklgjsdfajkghs
```
A region may also be specified in the configuration:

```yaml
iot.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a
string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdkflgjsdfajkghs
  region: us-east-1
```

salt.modules.boto_iot.attach_principal_policy(policyName, principal, region=None, key=None, keyid=None, profile=None)

Attach the specified policy to the specified principal (certificate or other credential.)

Returns {attached: true} if the policy was attached {attached: False} if the policy was not attached.

CLI Example:

```
salt myminion boto_iot.attach_principal_policy mypolicy mycognitoID
```

class.modules.boto_iot.create_policy(policyName, policyDocument, region=None, key=None, keyid=None, profile=None)

Given a valid config, create a policy.

Returns {created: true} if the policy was created and returns {created: False} if the policy was not created.

CLI Example:

```bash
salt myminion boto_iot.create_policy my_policy

```

class.modules.boto_iot.create_policy_version(policyName, policyDocument, setAsDefault=False, region=None, key=None, keyid=None, profile=None)

Given a valid config, create a new version of a policy.

Returns {created: true} if the policy version was created and returns {created: False} if the policy version was not created.

CLI Example:

```bash
salt myminion boto_iot.create_policy_version my_policy
```

class.modules.boto_iot.create_topic_rule(ruleName, sql, actions, description, ruleDisabled=False, region=None, key=None, keyid=None, profile=None)

Given a valid config, create a topic rule.

Returns {created: true} if the rule was created and returns {created: False} if the rule was not created.

CLI Example:
salt myminion boto_iot.create_topic_rule my_rule "SELECT * FROM 'some/thing'\n["lambda":{"functionArn":"arn::something"},"sns":{
 "targetArn":"arn::something","roleArn":"arn::something"}]

salt.modules.boto_iot.delete_policy(policyName, region=None, key=None, keyid=None, profile=None)

Given a policy name, delete it.
Returns [deleted: true] if the policy was deleted and returns [deleted: false] if the policy was not deleted.
CLI Example:
salt myminion boto_iot.delete_policy mypolicy

salt.modules.boto_iot.delete_policy_version(policyName, policyVersionId, region=None, key=None, keyid=None, profile=None)

Given a policy name and version, delete it.
Returns [deleted: true] if the policy version was deleted and returns [deleted: false] if the policy version was not deleted.
CLI Example:
salt myminion boto_iot.delete_policy_version mypolicy version

salt.modules.boto_iot.delete_topic_rule(ruleName, region=None, key=None, keyid=None, profile=None)

Given a rule name, delete it.
Returns [deleted: true] if the rule was deleted and returns [deleted: false] if the rule was not deleted.
CLI Example:
salt myminion boto_iot.delete_rule myrule

salt.modules.boto_iot.describe_policy(policyName, region=None, key=None, keyid=None, profile=None)

Given a policy name describe its properties.
Returns a dictionary of interesting properties.
CLI Example:
salt myminion boto_iot.describe_policy mypolicy

salt.modules.boto_iot.describe_policy_version(policyName, policyVersionId, region=None, key=None, keyid=None, profile=None)

Given a policy name and version describe its properties.
Returns a dictionary of interesting properties.
CLI Example:
salt myminion boto_iot.describe_policy_version mypolicy version

salt.modules.boto_iot.describe_topic_rule(ruleName, region=None, key=None, keyid=None, profile=None)

Given a topic rule name describe its properties.
Returns a dictionary of interesting properties.
CLI Example:
detach_principal_policy

```python
salt.myminion.boto_iot.detach_principal_policy(policyName, principal, region=None,
                                            key=None, keyid=None, profile=None)
```

Detach the specified policy from the specified principal (certificate or other credential.)

Returns {detached: true} if the policy was detached {detached: False} if the policy was not detached.

CLI Example:

```shell
salt myminion boto_iot.detach_principal_policy mypolicy mycognitoID
```

list_policies

```python
salt.modules.boto_iot.list_policies(region=None, key=None, keyid=None, profile=None)
```

List all policies

Returns list of policies

CLI Example:

```shell
salt myminion boto_iot.list_policies
```

Example Return:

```
policies:
 - {...}
 - {...}
```

list_policy_versions

```python
salt.modules.boto_iot.list_policy_versions(policyName, region=None, key=None, keyid=None, profile=None)
```

List the versions available for the given policy.

CLI Example:

```shell
salt myminion boto_iot.list_policy_versions mypolicy
```

Example Return:

```
policyVersions:
 - {...}
 - {...}
```

list_principal_policies

```python
salt.modules.boto_iot.list_principal_policies(principal, region=None, key=None, keyid=None, profile=None)
```

List the policies attached to the given principal.

CLI Example:

```shell
salt myminion boto_iot.list_principal_policies myprincipal
```

Example Return:

```
policies:
 - {...}
 - {...}
```

list_topic_rules

```python
salt.modules.boto_iot.list_topic_rules(topic=None, ruleDisabled=None, region=None,
                                      key=None, keyid=None, profile=None)
```

List all rules (for a given topic, if specified)

Returns list of rules
salt.modules.boto_iot.list_topic_rules

Example Return:

```
rules:
  - {...}
  - {...}
```

salt.modules.boto_iot.policy_exists(policyName, region=None, key=None, keyid=None, profile=None)

Given a policy name, check to see if the given policy exists.

Returns True if the given policy exists and returns False if the given policy does not exist.

CLI Example:

```text
salt myminion boto_iot.policy_exists mypolicy
```

salt.modules.boto_iot.policy_version_exists(policyName, policyVersionId, region=None, key=None, keyid=None, profile=None)

Given a policy name and version ID, check to see if the given policy version exists.

Returns True if the given policy version exists and returns False if the given policy version does not exist.

CLI Example:

```text
salt myminion boto_iot.policy_version_exists mypolicy versionid
```

salt.modules.boto_iot.replace_topic_rule(ruleName, sql, actions, description, ruleDisabled=False, region=None, key=None, keyid=None, profile=None)

Given a valid config, replace a topic rule with the new values.

Returns {created: true} if the rule was created and returns {created: False} if the rule was not created.

CLI Example:

```text
salt myminion boto_iot.replace_topic_rule my_rule 'SELECT * FROM some.thing' '[["lambda":"FunctionArn":"arn::::::something"],"sns":[] "targetArn":"arn::::::something","roleArn":"arn::::::something"}]
```

salt.modules.boto_iot.set_default_policy_version(policyName, policyVersionId, region=None, key=None, keyid=None, profile=None)

Sets the specified version of the specified policy as the policy’s default (operative) version. This action affects all certificates that the policy is attached to.

Returns {changed: true} if the policy version was set {changed: False} if the policy version was not set.

CLI Example:

```text
salt myminion boto_iot.set_default_policy_version mypolicy versionid
```

salt.modules.boto_iot.topic_rule_exists(ruleName, region=None, key=None, keyid=None, profile=None)

Given a rule name, check to see if the given rule exists.

Returns True if the given rule exists and returns False if the given rule does not exist.

CLI Example:
13.6.28 salt.modules.boto_kms

Connection module for Amazon KMS

New in version 2015.8.0.

**configuration**  This module accepts explicit kms credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```yaml
kms.keyid: GKTADJGHEIQSXMKKRBJ08H
kms.key: askdjghsdjfkgjWupUjasdfldkflgjsdfjajkgths
```

A region may also be specified in the configuration:

```yaml
kms.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```yaml
myprofile: keyid: GKTADJGHEIQSXMKKRBJ08H key: askdjghsdjfkgjWupUjasdfldkflgjsdfjajkgths region: us-east-1
```

**depends** boto

salt.modules.boto_kms.create_alias(*alias_name*, *target_key_id*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Create a display name for a key.

CLI example:

```bash
salt myminion boto_kms.create_alias 'alias/mykey' key_id
```

salt.modules.boto_kms.create_grant(*key_id*, *grantee_principal*, *retiring_principal=None*, *operations=None*, *constraints=None*, *grant_tokens=None*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Add a grant to a key to specify who can access the key and under what conditions.

CLI example:

```bash
salt myminion boto_kms.create_grant 'alias/mykey' 'arn:aws:iam::111111:/role/myrole' operations=['["Encrypt","Decrypt"]']
```

salt.modules.boto_kms.create_key(*policy=None*, *description=None*, *key_usage=None*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Creates a master key.

CLI example:
Salt myminion boto_kms.create_key '{"Statement":...}' "My master key"

```
salt.myminion.boto_kms.decrypt(ciphertext_blob, encryption_context=None, grant_tokens=None, region=None, key=None, keyid=None, profile=None)
```

Decrypt ciphertext.
CLI example:
```
salt.myminion.boto_kms.decrypt encrypted_ciphertext
```

```
salt.modules.boto_kms.describe_key(key_id, region=None, key=None, keyid=None, profile=None)
```

Get detailed information about a key.
CLI example:
```
salt.myminion.boto_kms.describe_key 'alias/mykey'
```

```
salt.modules.boto_kms.disable_key(key_id, region=None, key=None, keyid=None, profile=None)
```

Mark key as disabled.
CLI example:
```
salt.myminion.boto_kms.disable_key 'alias/mykey'
```

```
salt.modules.boto_kms.disable_key_rotation(key_id, region=None, key=None, keyid=None, profile=None)
```

Disable key rotation for specified key.
CLI example:
```
salt.myminion.boto_kms.disable_key_rotation 'alias/mykey'
```

```
salt.modules.boto_kms.enable_key(key_id, region=None, key=None, keyid=None, profile=None)
```

Mark key as enabled.
CLI example:
```
salt.myminion.boto_kms.enable_key 'alias/mykey'
```

```
salt.modules.boto_kms.enable_key_rotation(key_id, region=None, key=None, keyid=None, profile=None)
```

Disable key rotation for specified key.
CLI example:
```
salt.myminion.boto_kms.enable_key_rotation 'alias/mykey'
```

```
salt.modules.boto_kms.encrypt(key_id, plaintext, encryption_context=None, grant_tokens=None, region=None, key=None, keyid=None, profile=None)
```

Encrypt plaintext into cipher text using specified key.
CLI example:
```
salt.myminion.boto_kms.encrypt 'alias/mykey' 'myplaindata' '{"aws:username":"myuser"}'
salt.modules.boto_kms.generate_data_key(key_id, encryption_context=None, num-
ber_of_bytes=None, key_spec=None, grant_tokens=None, region=None, key=None,
keyid=None, profile=None)

Generate a secure data key.

CLI example:

```
salt myminion boto_kms.generate_data_key 'alias/mykey' number_of_bytes=1024 key_
->spec=AES_128
```

salt.modules.boto_kms.generate_data_key_without_plaintext(key_id, encryption_context=None,
number_of_bytes=None, key_spec=None, grant_tokens=None, region=None, key=None,
keyid=None, profile=None)

Generate a secure data key without a plaintext copy of the key.

CLI example:

```
salt myminion boto_kms.generate_data_key_without_plaintext 'alias/mykey' number_of_bytes=1024 key_spec=AES_128
```

salt.modules.boto_kms.generate_random(number_of_bytes=None, region=None, key=None,
keyid=None, profile=None)

Generate a random string.

CLI example:

```
salt myminion boto_kms.generate_random number_of_bytes=1024
```

salt.modules.boto_kms.get_key_policy(key_id, policy_name, region=None, key=None,
keyid=None, profile=None)

Get the policy for the specified key.

CLI example:

```
salt myminion boto_kms.get_key_policy 'alias/mykey' mypolicy
```

salt.modules.boto_kms.get_key_rotation_status(key_id, region=None, key=None,
keyid=None, profile=None)

Get status of whether or not key rotation is enabled for a key.

CLI example:

```
salt myminion boto_kms.get_key_rotation_status 'alias/mykey'
```

salt.modules.boto_kms.key_exists(key_id, region=None, key=None, keyid=None, profile=None)

Check for the existence of a key.

CLI example:

```
salt myminion boto_kms.key_exists 'alias/mykey'
```

salt.modules.boto_kms.list_grants(key_id, limit=None, marker=None, region=None, key=None,
keyid=None, profile=None)

List grants for the specified key.
CLI example:

```python
salt myminion boto_kms.list_grants 'alias/mykey'
```

**salt.modules.boto_kms.list_key_policies**(*key_id*, *limit=*, *marker=*, *region=*, *key=*, *keyid=*, *profile=* )

List key_policies for the specified key.

CLI example:

```python
salt myminion boto_kms.list_key_policies 'alias/mykey'
```

**salt.modules.boto_kms.put_key_policy**(*key_id*, *policy_name*, *policy*, *region=*, *key=*, *keyid=*, *profile=*)

Attach a key policy to the specified key.

CLI example:

```python
salt myminion boto_kms.put_key_policy 'alias/mykey' default '{"Statement":...}'
```

**salt.modules.boto_kms.re_encrypt**(*ciphertext_blob*, *destination_key_id*, *source_encryption_context=*, *destination_encryption_context=*, *grant_tokens=*, *region=*, *key=*, *keyid=*, *profile=*)

Reencrypt encrypted data with a new master key.

CLI example:

```python
salt myminion boto_kms.re_encrypt 'encrypted_data' 'alias/mynewkey' default '{"Statement":...}'
```

**salt.modules.boto_kms.revoke_grant**(*key_id*, *grant_id*, *region=*, *key=*, *keyid=*, *profile=*)

Revoke a grant from a key.

CLI example:

```python
salt myminion boto_kms.revoke_grant 'alias/mykey' 8u89hf-j09j...
```

**salt.modules.boto_kms.update_key_description**(*key_id*, *description*, *region=*, *key=*, *keyid=*, *profile=*)

Update a key’s description.

CLI example:

```python
salt myminion boto_kms.update_key_description 'alias/mykey' 'My key'
```

### 13.6.29 salt.modules.boto_lambda module

Connection module for Amazon Lambda

New in version 2016.3.0.

**depends**

- boto
- boto3

The dependencies listed above can be installed via package or pip.
configuration This module accepts explicit Lambda credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

lambda.keyid: GKTADJGHEIQSXMKKRBJ08H
lambda.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs

A region may also be specified in the configuration:

lambda.region: us-east-1

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

myprofile:
keyid: GKTADJGHEIQSXMKKRBJ08H
key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
region: us-east-1

Changed in version 2015.8.0: All methods now return a dictionary. Create and delete methods return:

created: true

or

created: false
error:
message: error message

Request methods (e.g., describe_function) return:

function:
- {...}
- {...}

or

error:
message: error message

salt.modules.boto_lambda.add_permission(FunctionName, StatementId, Action, Principal,
SourceArn=None, SourceAccount=None, Qualifier=None, region=None, key=None, keyid=None,
profile=None)

Add a permission to a lambda function.

Returns [added: true] if the permission was added and returns [added: False] if the permission was not added.

CLI Example:
salt.myminion.boto_lamba.add_permission my_function my_id "lambda:*" \  
s3.amazonaws.com aws:arn::::bucket-name \  
aws-account-id

salt.modules.boto_lambda.alias_exists(FunctionName, Name, region=None, key=None, keyid=None, profile=None)
Given a function name and alias name, check to see if the given alias exists.
Returns True if the given alias exists and returns False if the given alias does not exist.
CLI Example:
```
salt myminion boto_lambda.alias_exists myfunction myalias
```

salt.modules.boto_lambda.create_alias(FunctionName, Name, FunctionVersion, Description='', region=None, key=None, keyid=None, profile=None)
Given a valid config, create an alias to a function.
Returns {created: true} if the alias was created and returns {created: False} if the alias was not created.
CLI Example:
```
salt myminion boto_lamba.create_alias my_function my_alias $LATEST "An alias"
```

salt.modules.boto_lambda.create_event_source_mapping(EventSourceArn, FunctionName, StartingPosition, Enabled=True, BatchSize=100, region=None, key=None, keyid=None, profile=None)
Identifies a stream as an event source for a Lambda function. It can be either an Amazon Kinesis stream or an Amazon DynamoDB stream. AWS Lambda invokes the specified function when records are posted to the stream.
Returns {created: true} if the event source mapping was created and returns {created: False} if the event source mapping was not created.
CLI Example:
```
salt myminion boto_lamba.create_event_source_mapping arn::::eventsource myfunction LATEST
```

salt.modules.boto_lambda.create_function(FunctionName, Runtime, Role, Handler, ZipFile=None, S3Bucket=None, S3Key=None, S3ObjectVersion=None, Description=' ', Timeout=3, MemorySize=128, Publish=False, WaitForRole=False, RoleRetries=5, region=None, key=None, keyid=None, profile=None)
Given a valid config, create a function.
Returns {created: true} if the function was created and returns {created: False} if the function was not created.
CLI Example:
```
salt myminion boto_lamba.create_function my_function python2.7 my_role my_file.my_function my_function.zip
```

salt.modules.boto_lambda.delete_alias(FunctionName, Name, region=None, key=None, keyid=None, profile=None)
Given a function name and alias name, delete the alias.
Returns {deleted: true} if the alias was deleted and returns {deleted: false} if the alias was not deleted.

CLI Example:
```
salt myminion boto_lambda.delete_alias myfunction myalias
```

```python
salt.modules.boto_lambda.delete_event_source_mapping(UUID=None,
    EventSourceArn=None, FunctionName=None, region=None,
    key=None, keyid=None, profile=None)
```

Given an event source mapping ID or an event source ARN and FunctionName, delete the event source mapping.

Returns {deleted: true} if the mapping was deleted and returns {deleted: false} if the mapping was not deleted.

CLI Example:
```
salt myminion boto_lambda.delete_event_source_mapping 260c423d-e8b5-4443-8d6a-5e91b9ecd8fa
```

```python
salt.modules.boto_lambda.delete_function(FunctionName, Qualifier=None, region=None,
    key=None, keyid=None, profile=None)
```

Given a function name and optional version qualifier, delete it.

Returns {deleted: true} if the function was deleted and returns {deleted: false} if the function was not deleted.

CLI Example:
```
salt myminion boto_lambda.delete_function myfunction
```

```python
salt.modules.boto_lambda.describe_alias(FunctionName, Name=None, region=None,
    key=None, keyid=None, profile=None)
```

Given a function name and alias name describe the properties of the alias.

Returns a dictionary of interesting properties.

CLI Example:
```
salt myminion boto_lambda.describe_alias myalias
```

```python
salt.modules.boto_lambda.describe_event_source_mapping(UUID=None,
    EventSourceArn=None, FunctionName=None, region=None,
    key=None, keyid=None, profile=None)
```

Given an event source mapping ID or an event source ARN and FunctionName, obtain the current settings of that mapping.

Returns a dictionary of interesting properties.

CLI Example:
```
salt myminion boto_lambda.describe_event_source_mapping uuid
```

```python
salt.modules.boto_lambda.describe_function(FunctionName, region=None, key=None,
    keyid=None, profile=None)
```

Given a function name describe its properties.

Returns a dictionary of interesting properties.

CLI Example:
salt.modules.boto_lambda.describe_function myfunction

salt.modules.boto_lambda.event_source_mapping_exists(UUID=None, EventSourceArn=None, FunctionName=None, region=None, key=None, keyid=None, profile=None)

Given an event source mapping ID or an event source ARN and FunctionName, check whether the mapping exists.

Returns True if the given alias exists and returns False if the given alias does not exist.

CLI Example:
salt myminion boto_lambda.alias_exists myfunction myalias

salt.modules.boto_lambda.function_exists(FunctionName, region=None, key=None, keyid=None, profile=None)

Given a function name, check to see if the given function name exists.

Returns True if the given function exists and returns False if the given function does not exist.

CLI Example:
salt myminion boto_lambda.function_exists myfunction

salt.modules.boto_lambda.get_event_source_mapping_ids(EventSourceArn, FunctionName, region=None, key=None, keyid=None, profile=None)

Given an event source and function name, return a list of mapping IDs

CLI Example:
salt myminion boto_lambda.get_event_source_mapping_ids arn:::: myfunction

salt.modules.boto_lambda.get_permissions(FunctionName, Qualifier=None, region=None, key=None, keyid=None, profile=None)

Get resource permissions for the given lambda function

Returns dictionary of permissions, by statement ID

CLI Example:
salt myminion boto_lambda.get_permissions my_function

permissions: {...}

salt.modules.boto_lambda.list_function_versions(FunctionName, region=None, key=None, keyid=None, profile=None)

List the versions available for the given function.

Returns list of function versions

CLI Example:

versions:
- {...}
- {...}
salt.modules.boto_lambda.remove_permission(FunctionName, StatementId, Qualifier=None, region=None, key=None, keyid=None, profile=None)

Remove a permission from a lambda function.

Returns {removed: true} if the permission was removed and returns {removed: False} if the permission was not removed.

CLI Example:
```
salt myminion boto_lamba.remove_permission my_function my_id
```

salt.modules.boto_lambda.update_alias(FunctionName, Name, FunctionVersion=None, Description=None, region=None, key=None, keyid=None, profile=None)

Update the named alias to the configuration.

Returns {updated: true} if the alias was updated and returns {updated: False} if the alias was not updated.

CLI Example:
```
salt myminion boto_lamba.update_alias my_lambda my_alias $LATEST
```

salt.modules.boto_lambda.update_event_source_mapping(UUID, FunctionName=None, Enabled=None, BatchSize=None, region=None, key=None, keyid=None, profile=None)

Update the event source mapping identified by the UUID.

Returns {updated: true} if the alias was updated and returns {updated: False} if the alias was not updated.

CLI Example:
```
salt myminion boto_lamba.update_event_source_mapping uuid FunctionName=new_function
```

salt.modules.boto_lambda.update_function_code(FunctionName, ZipFile=None, S3Bucket=None, S3Key=None, S3ObjectVersion=None, Publish=False, region=None, key=None, keyid=None, profile=None)

Upload the given code to the named lambda function.

Returns {updated: true} if the function was updated and returns {updated: False} if the function was not updated.

CLI Example:
```
salt myminion boto_lamba.update_function_code my_function ZipFile=function.zip
```

salt.modules.boto_lambda.update_function_config(FunctionName, Role=None, Handler=None, Description=None, Timeout=None, MemorySize=None, region=None, key=None, keyid=None, profile=None)

Update the named lambda function to the configuration.

Returns {updated: true} if the function was updated and returns {updated: False} if the function was not updated.
CLI Example:

```
salt myminion boto_lamba.update_function_config my_function my_role my_file.my_
```

function "my lambda function"

### 13.6.30 salt.modules.boto_rds

Connection module for Amazon RDS

New in version 2015.8.0.

**configuration** This module accepts explicit rds credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-
```

ec2.html

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
rds.keyid: GKTADJGHEIQSXMKKRBJ08H
rds.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```
rds.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
    region: us-east-1
```

**depends** boto

```
salt.modules.boto_rds.create(name, allocated_storage, db_instance_class, engine, mas-
```

ter_username, master_user_password, db_name=None, 

db_security_groups=None, vpc_security_group_ids=None, 

availability_zone=None, db_subnet_group_name=None, 

preferred_maintenance_window=None, 

db_parameter_group_name=None, backup_retention_period=None, 

preferred_backup_window=None, port=None, multi_az=None, 

engine_version=None, auto_minor_version_upgrade=None, 

license_model=None, iops=None, option_group_name=None, character_set_name=None, 

publicly_accessible=None, wait_status=None, 

tags=None, region=None, key=None, keyid=None, profile=None)
```

Create an RDS

CLI example to create an RDS:

```
salt myminion boto_rds.create myrds 10 db.t2.micro MySQL sqlusr sqlpassw
```
salt.modules.boto_rds.create_option_group(name, engine_name, major_engine_version, option_group_description, tags=None, region=None, key=None, keyid=None, profile=None)

Create an RDS option group

CLI example to create an RDS option group:

```bash
salt myminion boto_rds.create_option_group my-opt-group mysql 5.6
->"group description"
```

salt.modules.boto_rds.create_parameter_group(name, db_parameter_group_family, description, tags=None, region=None, key=None, keyid=None, profile=None)

Create an RDS parameter group

CLI example to create an RDS parameter group:

```bash
salt myminion boto_rds.create_parameter_group my-param-group mysql5.6
->"group description"
```

salt.modules.boto_rds.create_read_replica(name, source_name, db_instance_class=None, availability_zone=None, port=None, auto_minor_version_upgrade=None, iops=None, option_group_name=None, publicly_accessible=None, tags=None, region=None, key=None, keyid=None, profile=None)

Create an RDS read replica

CLI example to create an RDS read replica:

```bash
salt myminion boto_rds.create_read_replica replicaname source_name
```

salt.modules.boto_rds.create_subnet_group(name, description, subnet_ids, tags=None, region=None, key=None, keyid=None, profile=None)

Create an RDS subnet group

CLI example to create an RDS subnet group:

```bash
salt myminion boto_rds.create_subnet_group my-subnet-group "group description" '[subnet-12345678, subnet-87654321]' region=us-east-1
```

salt.modules.boto_rds.delete(name, skip_final_snapshot=None, final_db_snapshot_identifier=None, region=None, key=None, keyid=None, profile=None, wait_for_deletion=True, timeout=180)

Delete an RDS instance.

CLI example:

```bash
salt myminion boto_rds.delete myrds skip_final_snapshot=True
->region=us-east-1
```

salt.modules.boto_rds.delete_option_group(name, region=None, key=None, keyid=None, profile=None)

Delete an RDS option group.

CLI example:
salt.modules.boto_rds.delete_option_group(name, region=None, key=None, keyid=None, profile=None)

Delete an RDS option group.

CLI example:

salt myminion boto_rds.delete_option_group my-opt-group region=us-east-1

salt.modules.boto_rds.delete_parameter_group(name, region=None, key=None, keyid=None, profile=None)

Delete an RDS parameter group.

CLI example:

salt myminion boto_rds.delete_parameter_group my-param-group region=us-east-1

salt.modules.boto_rds.delete_subnet_group(name, region=None, key=None, keyid=None, profile=None)

Delete an RDS subnet group.

CLI example:

salt myminion boto_rds.delete_subnet_group my-subnet-group region=us-east-1

salt.modules.boto_rds.describe(name, tags=None, region=None, key=None, keyid=None, profile=None)

Return RDS instance details.

CLI example:

salt myminion boto_rds.describe myrds

salt.modules.boto_rds.exists(name, tags=None, region=None, key=None, keyid=None, profile=None)

Check to see if an RDS exists.

CLI example:

salt myminion boto_rds.exists myrds region=us-east-1

salt.modules.boto_rds.get_endpoint(name, tags=None, region=None, key=None, keyid=None, profile=None)

Return the endpoint of an RDS instance.

CLI example:

salt myminion boto_rds.get_endpoint myrds

salt.modules.boto_rds.option_group_exists(name, tags=None, region=None, key=None, keyid=None, profile=None)

Check to see if an RDS option group exists.

CLI example:

salt myminion boto_rds.option_group_exists myoptiongr region=us-east-1

salt.modules.boto_rds.parameter_group_exists(name, tags=None, region=None, key=None, keyid=None, profile=None)

Check to see if an RDS parameter group exists.

CLI example:
**salt.myminion boto_rds.parameter_group_exists myparametergroup**

```
--region=us-east-1
```

**salt.modules.boto_rds.subnet_group_exists** *(name, tags=None, region=None, key=None, keyid=None, profile=None)*

Check to see if an RDS subnet group exists.

**CLI example:**

```
salt myminion boto_rds.subnet_group_exists my-param-group
--region=us-east-1
```

**salt.modules.boto_rds.update_parameter_group** *(name, parameters, apply_method='pending-reboot', tags=None, region=None, key=None, keyid=None, profile=None)*

Update an RDS parameter group.

**CLI example:**

```
salt myminion boto_rds.update_parameter_group my-param-group
--parameters='{"back_log":1, "binlog_cache_size":4096}'
--region=us-east-1
```

---

### 13.6.31 salt.modules.boto_route53

Connection module for Amazon Route53

**New in version 2014.7.0.**

**configuration** This module accepts explicit route53 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
route53.keyid: GKTADJGHEIQSXMKKRBJ08H
route53.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```
route53.region: us-east-1
```

If a region is not specified, the default is `universal`, which is what the boto_route53 library expects, rather than `None`.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

**depends** boto
salt.modules.boto_route53.add_record(name, value, zone, record_type, identifier=None, ttl=None, region=None, key=None, keyid=None, profile=None, wait_for_sync=True, split_dns=False, private_zone=False, retry_on_rate_limit=True, rate_limit_retries=5)

Add a record to a zone.

CLI example:

```
salt myminion boto_route53.add_record test.example.org 1.1.1.1 example.org A
```

salt.modules.boto_route53.create_zone(zone, private=False, vpc_id=None, vpc_region=None, region=None, key=None, keyid=None, profile=None)

Create a Route53 hosted zone.

New in version 2015.8.0.

zone DNZ zone to create
private True/False if the zone will be a private zone
vpc_id VPC ID to associate the zone to (required if private is True)
vpc_region VPC Region (required if private is True)
region region endpoint to connect to
key AWS key
keyid AWS keyid
profile AWS pillar profile

CLI Example:

```
salt myminion boto_route53.create_zone example.org
```

salt.modules.boto_route53.delete_record(name, zone, record_type, all_records=False, region=None, key=None, keyid=None, profile=None, wait_for_sync=True, split_dns=False, private_zone=False, retry_on_rate_limit=True, rate_limit_retries=5)

Modify a record in a zone.

CLI example:

```
salt myminion boto_route53.delete_record test.example.org example.org A
```

salt.modules.boto_route53.delete_zone(zone, region=None, key=None, keyid=None, profile=None)

Delete a Route53 hosted zone.

New in version 2015.8.0.

CLI Example:

```
salt myminion boto_route53.delete_zone example.org
```

salt.modules.boto_route53.get_record(name, zone, record_type, fetch_all=False, region=None, key=None, keyid=None, profile=None, split_dns=False, private_zone=False, retry_on_rate_limit=True, rate_limit_retries=5)

Get a record from a zone.

CLI example:

```
salt myminion boto_route53.get_record test.example.org example.org A
```
salt.modules.boto_route53.update_record(name, value, zone, record_type, identifier=None, ttl=None, region=None, key=None, keyid=None, profile=None, wait_for_sync=True, split_dns=False, private_zone=False, retry_on_rate_limit=True, rate_limit_retries=5)

Modify a record in a zone.

CLI example:
```
salt myminion boto_route53.modify_record test.example.org 1.1.1.1 example.org A
```

salt.modules.boto_route53.zone_exists(zone, region=None, key=None, keyid=None, profile=None, retry_on_rate_limit=True, rate_limit_retries=5)

Check for the existence of a Route53 hosted zone.

New in version 2015.8.0.

CLI Example:
```
salt myminion boto_route53.zone_exists example.org
```

### 13.6.32 salt.modules.boto_secgroup

Connection module for Amazon Security Groups

New in version 2014.7.0.

**configuration** This module accepts explicit ec2 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
secgroup.keyid: GKTADJGHEIQSXMKKRBJ08H
secgroup.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```
secgroup.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

**depends** boto
salt.modules.boto_secgroup.authorize(name=None, source_group_name=None, source_group_owner_id=None, ip_protocol=None, from_port=None, to_port=None, cidr_ip=None, group_id=None, source_group_group_id=None, region=None, key=None, keyid=None, profile=None, vpc_id=None, vpc_name=None, egress=False)

Add a new rule to an existing security group.

CLI example:

```
salt myminion boto_secgroup.authorize mysecgroup ip_protocol=tcp from_port=80 to_port=80 cidr_ip='[10.0.0.0/8', '192.168.0.0/24']'
```

salt.modules.boto_secgroup.convert_to_group_ids(groups, vpc_id, vpc_name=None, region=None, key=None, keyid=None, profile=None)

Given a list of security groups and a vpc_id, convert_to_group_ids will convert all list items in the given list to security group ids.

CLI example:

```
salt myminion boto_secgroup.convert_to_group_ids mysecgroup vpc-89yhh7h
```

salt.modules.boto_secgroup.create(name, description, vpc_id=None, vpc_name=None, region=None, key=None, keyid=None, profile=None)

Create a security group.

CLI example:

```
salt myminion boto_secgroup.create mysecgroup 'My Security Group'
```

salt.modules.boto_secgroup.delete(name=None, group_id=None, region=None, key=None, keyid=None, profile=None, vpc_id=None, vpc_name=None)

Delete a security group.

CLI example:

```
salt myminion boto_secgroup.delete mysecgroup
```

salt.modules.boto_secgroup.delete_tags(tags, name=None, group_id=None, vpc_name=None, vpc_id=None, region=None, key=None, keyid=None, profile=None)

deletes tags from a security group

New in version 2016.3.0.

tags a list of tags to remove

name the name of the security group

group_id the group id of the security group (in lie of a name/vpc combo)

vpc_name the name of the vpc to search the named group for

vpc_id the id of the vpc, in lieu of the vpc_name

region the amazon region

key amazon key

keyid amazon keyid

profile amazon profile

CLI example:

```
salt myminion boto_secgroup.delete_tags ['TAG_TO_DELETE1','TAG_TO_DELETE2']
        security_group_name vpc_id=vpc-13435 profile=my_aws_profile
```
salt.modules.boto_secgroup.exists(name=None, region=None, key=None, keyid=None, profile=None, vpc_id=None, vpc_name=None, group_id=None)

Check to see if a security group exists.

CLI example:
```
salt myminion boto_secgroup.exists mysecgroup
```

salt.modules.boto_secgroup.get_config(name=None, group_id=None, region=None, key=None, keyid=None, profile=None, vpc_id=None, vpc_name=None)

Get the configuration for a security group.

CLI example:
```
salt myminion boto_secgroup.get_config mysecgroup
```

salt.modules.boto_secgroup.get_group_id(name, vpc_id=None, vpc_name=None, region=None, key=None, keyid=None, profile=None)

Get a Group ID given a Group Name or Group Name and VPC ID

CLI example:
```
salt myminion boto_secgroup.get_group_id mysecgroup
```

salt.modules.boto_secgroup.revoke(name=None, source_group_name=None, source_group_owner_id=None, ip_protocol=None, from_port=None, to_port=None, cidr_ip=None, group_id=None, source_group_group_id=None, region=None, key=None, keyid=None, profile=None, vpc_id=None, vpc_name=None, egress=False)

Remove a rule from an existing security group.

CLI example:
```
salt myminion boto_secgroup.revoke mysecgroup ip_protocol=tcp from_port=80 to_port=80 cidr_ip='10.0.0.0/8'
```

salt.modules.boto_secgroup.set_tags(tags, name=None, group_id=None, vpc_name=None, vpc_id=None, region=None, key=None, keyid=None, profile=None)

sets tags on a security group

New in version 2016.3.0.

tags a dict of key:value pair of tags to set on the security group
name the name of the security group
group_id the group id of the security group (in lieu of a name/vpc combo)
vpc_name the name of the vpc to search the named group for
vpc_id the id of the vpc, in lieu of the vpc_name
region the amazon region
key amazon key
keyid amazon keyid
profile amazon profile

CLI example:
```
salt myminion boto_secgroup.set_tags "{"TAG1": 'Value1', "TAG2": 'Value2'}" security_group_name vpc_id=vpc-13435 profile=my_aws_profile
```
13.6.33 salt.modules.boto_sns

Connection module for Amazon SNS

**configuration** This module accepts explicit sns credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
sns.keyid: GKTADJGHEIQSXMKKRBJ08H
sns.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```
sns.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

depends boto

**salt.modules.boto_sns.create**(name, region=None, key=None, keyid=None, profile=None)

Create an SNS topic.

CLI example to create a topic:

```
salt myminion boto_sns.create mytopic region=us-east-1
```

**salt.modules.boto_sns.delete**(name, region=None, key=None, keyid=None, profile=None)

Delete an SNS topic.

CLI example to delete a topic:

```
salt myminion boto_sns.delete mytopic region=us-east-1
```

**salt.modules.boto_sns.exists**(name, region=None, key=None, keyid=None, profile=None)

Check to see if an SNS topic exists.

CLI example:

```
salt myminion boto_sns.exists mytopic region=us-east-1
```

**salt.modules.boto_sns.get_all_subscriptions_by_topic**(name, region=None, key=None, keyid=None, profile=None)

Get list of all subscriptions to a specific topic.

CLI example to delete a topic:
salt.myminion boto_sns.get_all_subscriptions_by_topic mytopic region=us-east-1

```
salt.modules.boto_sns.get_all_topics(region=None, key=None, keyid=None, profile=None)
```

Returns a list of the all topics.

CLI example:

```
salt myminion boto_sns.get_all_topics
```

```
salt.modules.boto_sns.get_arn(name, region=None, key=None, keyid=None, profile=None)
```

Returns the full ARN for a given topic name.

CLI example:

```
salt myminion boto_sns.get_arn mytopic
```

```
salt.modules.boto_sns.subscribe(topic, protocol, endpoint, region=None, key=None, keyid=None, profile=None)
```

Subscribe to a Topic.

CLI example to delete a topic:

```
salt myminion boto_sns.subscribe mytopic https https://www.example.com/sns-endpoint region=us-east-1
```

### 13.6.34 salt.modules.boto_sqs

Connection module for Amazon SQS

New in version 2014.7.0.

**configuration**

This module accepts explicit sqs credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
sqs.keyid: GKTADJGHEIQSXMKKRBJ08H
sqs.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```
sqs.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQXSXMRRB3B8H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

**depends** boto
salt.modules.boto_sqs.create(name, region=None, key=None, keyid=None, profile=None)
Create an SQS queue.
    CLI example to create a queue:
```
salt myminion boto_sqs.create myqueue region=us-east-1
```

salt.modules.boto_sqs.delete(name, region=None, key=None, keyid=None, profile=None)
Delete an SQS queue.
    CLI example to delete a queue:
```
salt myminion boto_sqs.delete myqueue region=us-east-1
```

salt.modules.boto_sqs.exists(name, region=None, key=None, keyid=None, profile=None)
Check to see if a queue exists.
    CLI example:
```
salt myminion boto_sqs.exists myqueue region=us-east-1
```

salt.modules.boto_sqs.get_attributes(name, region=None, key=None, keyid=None, profile=None)
Check to see if attributes are set on an SQS queue.
    CLI example:
```
salt myminion boto_sqs.get_attributes myqueue
```

salt.modules.boto_sqs.set_attributes(name, attributes, region=None, key=None, keyid=None, profile=None)
Set attributes on an SQS queue.
    CLI example to set attributes on a queue:
```
salt myminion boto_sqs.set_attributes myqueue '{ReceiveMessageWaitTimeSeconds: 20}' region=us-east-1
```

13.6.35 salt.modules.boto_vpc
Connection module for Amazon VPC
New in version 2014.7.0.

configuration This module accepts explicit VPC credentials but can also utilize IAM roles assigned to
the instance through Instance Profiles. Dynamic credentials are then automatically obtained from
AWS API and no further configuration is necessary. More Information available at:
```
http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-
_ec2.html
```
If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:
```
vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```
A region may also be specified in the configuration:
vpc.region: us-east-1

If a region is not specified, the default is us-east-1.

It’s also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfhjajkghs
  region: us-east-1

Changed in version 2015.8.0: All methods now return a dictionary. Create and delete methods return:

created: true

or

created: false
text
message: error message

Request methods (e.g., describe_vpc) return:

vpcs:
- {...}
- {...}

or

error:
  message: error message

depends boto

salt.modules.boto_vpc.associate_dhcp_options_to_vpc(dhcp_options_id=None, vpc_id=None, vpc_name=None, region=None, key=None, keyid=None, profile=None)

Given valid DHCP options id and a valid VPC id, associate the DHCP options record with the VPC.

Returns True if the DHCP options record were associated and returns False if the DHCP options record was not associated.

CLI Example:

salt myminion boto_vpc.associate_dhcp_options_to_vpc 'dhcp-a0bl34pp' 'vpc-6b1fe402'

salt.modules.boto_vpc.associate_network_acl_to_subnet(network_acl_id=None, subnet_id=None, network_acl_name=None, subnet_name=None, region=None, key=None, keyid=None, profile=None)

Given a network acl and subnet ids or names, associate a network acl to a subnet.

CLI Example:
salt minion boto_vpc.associate_network_acl_to_subnet
  network_acl_id='acl-5fb85d36' subnet_id='subnet-6a1fe403'

salt minion boto_vpc.associate_network_acl_to_subnet
  network_acl_id='myacl' subnet_id='mysubnet'

salt.modules.boto_vpc.associate_new_dhcp_options_to_vpc(vpc_id, domain_name=None, domain_name_servers=None, ntp_servers=None, netbios_name_servers=None, netbios_node_type=None, region=None, key=None, keyid=None, profile=None)

.. deprecated:: Carbon
   This function has been deprecated in favor of boto_vpc.create_dhcp_options, which now takes vpc_id or vpc_name as kwargs.
   This function will be removed in the Salt Carbon release.

   Given valid DHCP options and a valid VPC id, create and associate the DHCP options record with the VPC.
   CLI Example:

   salt minion boto_vpc.associate_new_dhcp_options_to_vpc 'vpc-6b1fe402' domain_name='example.com' domain_name_servers='[1.2.3.4]' ntp_servers='[5.6.7.8]' netbios_name_servers='[10.0.0.1]' netbios_node_type=1

salt.modules.boto_vpc.associate_new_network_acl_to_subnet(vpc_id, subnet_id, network_acl_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

.. deprecated:: Carbon
   This function has been deprecated in favor of boto_vpc.create_network_acl, which now takes subnet_id or subnet_name as kwargs.
   This function will be removed in the Salt Carbon release.
   Given a vpc ID and a subnet ID, associates a new network act to a subnet.
   Returns a dictionary containing the network acl id and the new association id if successful. If unsuccessful, returns False.
   CLI Example:

   salt minion boto_vpc.associate_new_network_acl_to_subnet 'vpc-6b1fe402' 'subnet-6a1fe403'

salt.modules.boto_vpc.associate_route_table(route_table_id=None, subnet_id=None, route_table_name=None, subnet_name=None, region=None, key=None, keyid=None, profile=None)

Given a route table and subnet name or id, associates the route table with the subnet.
   CLI Example:

   salt minion boto_vpc.associate_route_table 'rtb-1f382e7d' 'subnet-6a1fe403'
   salt minion boto_vpc.associate_route_table route_table_name='myrtb' subnet_name='mysubnet'
salt.modules.boto_vpc.check_vpc(vpc_id=None, vpc_name=None, region=None, key=None, keyid=None, profile=None)

Check whether a VPC with the given name or id exists. Returns the vpc_id or None. Raises SaltInvocationError if both vpc_id and vpc_name are None. Optionally raise a CommandExecutionError if the VPC does not exist.

New in version 2016.3.0.

CLI Example:

```bash
salt myminion boto_vpc.check_vpc vpc_name=myvpc profile=awsprofile
```

salt.modules.boto_vpc.create(cidr_block, instance_tenancy=None, vpc_name=None, enable_dns_support=None, enable_dns_hostnames=None, tags=None, region=None, key=None, keyid=None, profile=None)

Given a valid CIDR block, create a VPC.

An optional instance_tenancy argument can be provided. If provided, the valid values are `default` or `dedicated`

An optional vpc_name argument can be provided.

Returns {created: true} if the VPC was created and returns {created: False} if the VPC was not created.

CLI Example:

```bash
salt myminion boto_vpc.create '10.0.0.0/24'
```

salt.modules.boto_vpc.create_customer_gateway(vpn_connection_type, ip_address, bgp_asn, customer_gateway_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Given a valid VPN connection type, a static IP address and a customer gateway’s Border Gateway Protocol (BGP) Autonomous System Number, create a customer gateway.

Returns the customer gateway id if the customer gateway was created and returns False if the customer gateway was not created.

CLI Example:

```bash
salt myminion boto_vpc.create_customer_gateway 'ipsec.1', '12.1.2.3', 65534
```

salt.modules.boto_vpc.create_dhcp_options(domain_name=None, domain_name_servers=None, ntp_servers=None, netbios_name_servers=None, netbios_node_type=None, dhcp_options_name=None, tags=None, vpc_id=None, vpc_name=None, region=None, key=None, keyid=None, profile=None)

Given valid DHCP options, create a DHCP options record, optionally associating it with an existing VPC.

Returns True if the DHCP options record was created and returns False if the DHCP options record was not deleted.

Changed in version 2015.8.0: Added vpc_name and vpc_id arguments

CLI Example:

```bash
salt myminion boto_vpc.create_dhcp_options domain_name='example.com' \ domain_name_servers=[1.2.3.4] ntp_servers=[5.6.7.8] \...
salt.modules.boto_vpc.create_internet_gateway(internet_gateway_name=None, vpc_id=None, vpc_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Create an Internet Gateway, optionally attaching it to an existing VPC.

Returns the internet gateway id if the internet gateway was created and returns False if the internet gateways was not created.

New in version 2015.8.0.

CLI Example:
```
salt myminion boto_vpc.create_internet_gateway
  internet_gateway_name=myigw vpc_name=myvpc
```

salt.modules.boto_vpc.create_network_acl(vpc_id=None, vpc_name=None, network_acl_name=None, subnet_id=None, subnet_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Given a vpc_id, creates a network acl.

Returns the network acl id if successful, otherwise returns False.

Changed in version 2015.8.0: Added vpc_name, subnet_id, and subnet_name arguments

CLI Example:
```
salt myminion boto_vpc.create_network_acl
  vpc-6b1fe402
```

salt.modules.boto_vpc.create_network_acl_entry(network_acl_id=None, rule_number=None, protocol=None, rule_action=None, cidr_block=None, egress=None, network_acl_name=None, icmp_code=None, icmp_type=None, port_range_from=None, port_range_to=None, region=None, key=None, keyid=None, profile=None)

Creates a network acl entry.

CLI Example:
```
salt myminion boto_vpc.create_network_acl_entry
  acl-5fb85d36 '32767' 'all' 'deny' '0.0.0.0/0' egress=true
```

salt.modules.boto_vpc.create_route(route_table_id=None, destination_cidr_block=None, route_table_name=None, gateway_id=None, internet_gateway_name=None, instance_id=None, interface_id=None, region=None, key=None, keyid=None, profile=None)

Creates a route.

CLI Example:
```
salt myminion boto_vpc.create_route
  rtb-1f382e7d '10.0.0.0/16' gateway_id=vgw-850
```

850 Chapter 13. Salt Module Reference
salt.modules.boto_vpc.create_route_table(vpc_id=None, vpc_name=None, route_table_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Creates a route table.
Changed in version 2015.8.0: Added vpc_name argument

CLI Examples:
```
salt myminion boto_vpc.create_route_table vpc_id='vpc-6b1fe402' \ route_table_name='myroutetable'
salt myminion boto_vpc.create_route_table vpc_name='myvpc' \ route_table_name='myroutetable'
```

salt.modules.boto_vpc.create_subnet(vpc_id=None, cidr_block=None, vpc_name=None, availability_zone=None, subnet_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Given a valid VPC ID or Name and a CIDR block, create a subnet for the VPC.
An optional availability zone argument can be provided.
Returns True if the VPC subnet was created and returns False if the VPC subnet was not created.
Changed in version 2015.8.0: Added vpc_name argument

CLI Examples:
```
salt myminion boto_vpc.create_subnet vpc_id='vpc-6b1fe402' \ subnet_name='mysubnet' cidr_block='10.0.0.0/25'
salt myminion boto_vpc.create_subnet vpc_name='myvpc' \ subnet_name='mysubnet', cidr_block='10.0.0.0/25'
```

salt.modules.boto_vpc.customer_gateway_exists(customer_gateway_id=None, customer_gateway_name=None, region=None, key=None, keyid=None, profile=None)

Given a customer gateway ID, check if the customer gateway ID exists.
Returns True if the customer gateway ID exists; Returns False otherwise.

CLI Example:
```
salt myminion boto_vpc.customer_gateway_exists cgw-b6a247df
salt myminion boto_vpc.customer_gateway_exists customer_gateway_name=mycgw
```

salt.modules.boto_vpc.delete(vpc_id=None, name=None, vpc_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Given a VPC ID or VPC name, delete the VPC.
Returns {deleted: true} if the VPC was deleted and returns {deleted: false} if the VPC was not deleted.

CLI Example:
```
salt myminion boto_vpc.delete vpc_id='vpc-6b1fe402'
salt myminion boto_vpc.delete name='myvpc'
```

salt.modules.boto_vpc.delete_customer_gateway(customer_gateway_id=None, customer_gateway_name=None, region=None, key=None, keyid=None, profile=None)

Given a customer gateway ID or name, delete the customer gateway.
Returns True if the customer gateway was deleted and returns False if the customer gateway was not deleted.

Changed in version 2015.8.0: Added customer_gateway_name argument

CLI Example:
```
salt myminion boto_vpc.delete_customer_gateway 'cgw-b6a247df'
```

```python
salt.modules.boto_vpc.delete_dhcp_options(dhcp_options_id=None, dhcp_options_name=None, region=None, key=None, keyid=None, profile=None)
```

Delete dhcp options by id or name.

New in version 2015.8.0.

CLI Example:
```
salt myminion boto_vpc.delete_dhcp_options 'dopt-b6a247df'
```

```python
salt.modules.boto_vpc.delete_internet_gateway(internet_gateway_id=None, internet_gateway_name=None, detach=False, region=None, key=None, keyid=None, profile=None)
```

Delete an internet gateway (by name or id).

Returns True if the internet gateway was deleted and otherwise False.

New in version 2015.8.0.

CLI Examples:
```
salt myminion boto_vpc.delete_internet_gateway internet_gateway_id='igw-1a2b3c'
salt myminion boto_vpc.delete_internet_gateway internet_gateway_name='myigw'
```

```python
salt.modules.boto_vpc.delete_network_acl(network_acl_id=None, network_acl_name=None, disassociate=False, region=None, key=None, keyid=None, profile=None)
```

Delete a network acl based on the network_acl_id or network_acl_name provided.

CLI Examples:
```
salt myminion boto_vpc.delete_network_acl network_acl_id='acl-5fb85d36' \ 
  disassociate=false
```
```
salt myminion boto_vpc.delete_network_acl network_acl_name='myacl' \ 
  disassociate=true
```

```python
salt.modules.boto_vpc.delete_network_acl_entry(network_acl_id=None, rule_number=None, egress=None, network_acl_name=None, region=None, key=None, keyid=None, profile=None)
```

Deletes a network acl entry.

CLI Example:
```
salt myminion boto_vpc.delete_network_acl_entry 'acl-5fb85d36' '32767'
```

```python
salt.modules.boto_vpc.delete_route(route_table_id=None, destination_cidr_block=None, route_table_name=None, region=None, key=None, keyid=None, profile=None)
```

Deletes a route.
CLI Example:
```
salt myminion boto_vpc.delete_route 'rtb-1f382e7d' '10.0.0.0/16'
```

```python
salt.modules.boto_vpc.delete_route_table(route_table_id=None, route_table_name=None, region=None, key=None, keyid=None, profile=None)
```
Deletes a route table.

CLI Examples:
```
salt myminion boto_vpc.delete_route_table route_table_id='rtb-1f382e7d'
salt myminion boto_vpc.delete_route_table route_table_name='myroutetable'
```

```python
salt.modules.boto_vpc.delete_subnet(subnet_id=None, subnet_name=None, region=None, key=None, keyid=None, profile=None)
```
Given a subnet ID or name, delete the subnet.
Returns True if the subnet was deleted and returns False if the subnet was not deleted.
Changed in version 2015.8.0: Added subnet_name argument

CLI Example:
```
salt myminion boto_vpc.delete_subnet 'subnet-6a1fe403'
```

```python
salt.modules.boto_vpc.describe(vpc_id=None, vpc_name=None, region=None, key=None, keyid=None, profile=None)
```
Given a VPC ID describe its properties.
Returns a dictionary of interesting properties.
Changed in version 2015.8.0: Added vpc_name argument

CLI Example:
```
salt myminion boto_vpc.describe vpc_id=vpc-123456
salt myminion boto_vpc.describe vpc_name=myvpc
```

```python
salt.modules.boto_vpc.describe_route_table(route_table_id=None, route_table_name=None, tags=None, region=None, key=None, keyid=None, profile=None)
```
Given route table properties, return route table details if matching table(s) exist.
New in version 2015.8.0.

CLI Example:
```
salt myminion boto_vpc.describe_route_table route_table_id='rtb-1f382e7d'
```

```python
salt.modules.boto_vpc.describe_subnet(subnet_id=None, subnet_name=None, region=None, key=None, keyid=None, profile=None)
```
Given a subnet ID or name, describe its properties.
Returns a dictionary of interesting properties.
New in version 2015.8.0.

CLI Examples:
```
salt myminion boto_vpc.describe_subnet subnet_id=subnet-123456
salt myminion boto_vpc.describe_subnet subnet_name=mysubnet
```
salt.modules.boto_vpc.describe_subnets(subnet_ids=None, subnet_names=None, vpc_id=None, cidr=None, region=None, key=None, keyid=None, profile=None)

Given a VPC ID or subnet CIDR, returns a list of associated subnets and their details. Return all subnets if VPC ID or CIDR are not provided. If a subnet id or CIDR is provided, only its associated subnet details will be returned.

New in version 2015.8.0.

CLI Examples:
salt myminion boto_vpc.describe_subnets
salt myminion boto_vpc.describe_subnets subnet_ids=['subnet-ba1987ab', 'subnet-ba1987cd']
salt myminion boto_vpc.describe_subnets vpc_id=vpc-123456
salt myminion boto_vpc.describe_subnets cidr=10.0.0.0/21

salt.modules.boto_vpc.describe_vpcs(vpc_id=None, name=None, cidr=None, tags=None, region=None, key=None, keyid=None, profile=None)

Describe all VPCs, matching the filter criteria if provided.

Returns a list of dictionaries with interesting properties.

New in version 2015.8.0.

CLI Example:
salt myminion boto_vpc.describe_vpcs

salt.modules.boto_vpc.dhcp_options_exists(dhcp_options_id=None, name=None, dhcp_options_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Check if a dhcp option exists.

Returns True if the dhcp option exists; Returns False otherwise.

CLI Example:
salt myminion boto_vpc.dhcp_options_exists dhcp_options_id='dhcp-a0bl34pp'

salt.modules.boto_vpc.disassociate_network_acl(subnet_id=None, vpc_id=None, subnet_name=None, vpc_name=None, region=None, key=None, keyid=None, profile=None)

Given a subnet ID, disassociates a network acl.

CLI Example:
salt myminion boto_vpc.disassociate_network_acl 'subnet-6a1fe403'

salt.modules.boto_vpc.disassociate_route_table(association_id, region=None, key=None, keyid=None, profile=None)

Dissociates a route table.

association_id The Route Table Association ID to dissociate

CLI Example:
salt.myminion.boto_vpc.disassociate_route_table 'rtbassoc-d8ccdbba'

salt.modules.boto_vpc.exists(vpc_id=None, name=None, cidr=None, tags=None, region=None, key=None, keyid=None, profile=None)

Given a VPC ID, check to see if the given VPC ID exists.

Returns True if the given VPC ID exists and returns False if the given VPC ID does not exist.

CLI Example:
salt myminion boto_vpc.exists myvpc

salt.modules.boto_vpc.get_dhcp_options(dhcp_options_name=None, dhcp_options_id=None, region=None, key=None, keyid=None, profile=None)

Return a dict with the current values of the requested DHCP options set

CLI Example:
salt myminion boto_vpc.get_dhcp_options 'myfunnydhcopptionsname'

New in version 2016.3.0.

salt.modules.boto_vpc.get_id(name=None, cidr=None, tags=None, region=None, key=None, keyid=None, profile=None)

Given VPC properties, return the VPC id if a match is found.

CLI Example:
salt myminion boto_vpc.get_id myvpc

salt.modules.boto_vpc.get_resource_id(resource, name=None, resource_id=None, region=None, key=None, keyid=None, profile=None)

Get an AWS id for a VPC resource by type and name.

New in version 2015.8.0.

CLI Example:
salt myminion boto_vpc.get_resource_id internet_gateway myigw

salt.modules.boto_vpc.get_subnet_association(subnets, region=None, key=None, keyid=None, profile=None)

Given a subnet (aka: a vpc zone identifier) or list of subnets, returns vpc association.

Returns a VPC ID if the given subnets are associated with the same VPC ID. Returns False on an error or if the given subnets are associated with different VPC IDs.

CLI Examples:
salt myminion boto_vpc.get_subnet_association subnet-61b47516

salt.myminion.boto_vpc.get_subnet_association [ 'subnet-61b47516', 'subnet-2cb9785b ...']

salt.modules.boto_vpc.network_acl_exists(network_acl_id=None, name=None, network_acl_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Checks if a network acl exists.

Returns True if the network acl exists or returns False if it doesn't exist.
CLI Example:

```
salt myminion boto_vpc.network_acl_exists network_acl_id='acl-5fb85d36'
```

```
salt.modules.boto_vpc.replace_network_acl_entry(network_acl_id=None,
    rule_number=None, protocol=None,
    rule_action=None, cidr_block=None,
    egress=None, network_acl_name=None,
    icmp_code=None, icmp_type=None,
    port_range_from=None, port_range_to=None,
    region=None, key=None, keyid=None, profile=None)
```

Replaces a network acl entry.

CLI Example:

```
salt myminion boto_vpc.replace_network_acl_entry 'acl-5fb85d36' '32767' \
    'all' 'deny' '0.0.0.0/0' egress=true
```

```
salt.modules.boto_vpc.replace_route(route_table_id=None, destination_cidr_block=None,
    route_table_name=None, gateway_id=None, instance_id=None, interface_id=None,
    region=None, key=None, keyid=None, profile=None)
```

Replaces a route.

CLI Example:

```
salt myminion boto_vpc.replace_route 'rtb-1f382e7d' '10.0.0.0/16' gateway_id='vgw--a1b2c3'
```

```
salt.modules.boto_vpc.replace_route_table_association(association_id, route_table_id,
    region=None, key=None, keyid=None, profile=None)
```

Replaces a route table association.

CLI Example:

```
salt myminion boto_vpc.replace_route_table_association 'rtbassoc-d8ccddba' 'rtb--1f382e7d'
```

```
salt.modules.boto_vpc.resource_exists(resource, name=None, resource_id=None, tags=None,
    region=None, key=None, keyid=None, profile=None)
```

Given a resource type and name, return {exists: true} if it exists, {exists: false} if it does not exist, or {error: {message: error text}} on error.

New in version 2015.8.0.

CLI Example:

```
salt myminion boto_vpc.resource_exists internet_gateway myigw
```

```
salt.modules.boto_vpc.route_exists(destination_cidr_block, route_table_name=None,
    route_table_id=None, gateway_id=None, instance_id=None, interface_id=None,
    tags=None, region=None, key=None, keyid=None, profile=None)
```

Checks if a route exists.

New in version 2015.8.0.

CLI Example:
salt myminion boto_vpc.route_exists destination_cidr_block='10.0.0.0/20' gateway_id='local' route_table_name='test'

salt.modules.boto_vpc.route_table_exists(route_table_id=None, name=None, route_table_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Checks if a route table exists.

CLI Example:
salt myminion boto_vpc.route_table_exists route_table_id='rtb-1f382e7d'

salt.modules.boto_vpc.subnet_exists(subnet_id=None, name=None, subnet_name=None, cidr=None, tags=None, zones=None, region=None, key=None, keyid=None, profile=None)

Check if a subnet exists.

Returns True if the subnet exists, otherwise returns False.

Changed in version 2015.8.0: Added subnet_name argument Deprecated name argument

CLI Example:
salt myminion boto_vpc.subnet_exists subnet_id='subnet-6a1fe403'

13.6.36  salt.modules.bower

Manage and query Bower packages

This module manages the installed packages using Bower. Note that npm, git and bower must be installed for this module to be available.

salt.modules.bower.install(pkg, dir, pkgs=None, runas=None, env=None)
Install a Bower package.

If no package is specified, the dependencies (from bower.json) of the package in the given directory will be installed.

pkg  A package name in any format accepted by Bower, including a version identifier
dir  The target directory in which to install the package
pkgs  A list of package names in the same format as the pkg parameter
runas  The user to run Bower with
env  Environment variables to set when invoking Bower. Uses the same env format as the cmd.run execution function.

CLI Example:
salt '*' bower.install underscore /path/to/project

salt '*' bower.install jquery#2.0 /path/to/project

salt.modules.bower.list(dir, runas=None, env=None)
List installed Bower packages.

dir  The directory whose packages will be listed
runas  The user to run Bower with
env  Environment variables to set when invoking Bower. Uses the same env format as the cmd.run execution function.

CLI Example:
salt '*' bower.list /path/to/project

salt.modules.bower.uninstall(pkg, dir, runas=None, env=None)
Uninstall a Bower package.
pkg  A package name in any format accepted by Bower
dir  The target directory from which to uninstall the package
runas  The user to run Bower with
env  Environment variables to set when invoking Bower. Uses the same env format as the cmd.run execution function.
CLI Example:
salt '*' bower.uninstall underscore /path/to/project

13.6.37 salt.modules.bridge

Module for gathering and managing bridging information
salt.modules.bridge.add(br=None)
Creates a bridge
CLI Example:
salt '*' bridge.add br0

salt.modules.bridge.addif(br=None, iface=None)
Adds an interface to a bridge
CLI Example:
salt '*' bridge.addif br0 eth0

salt.modules.bridge.delete(br=None)
Deletes a bridge
CLI Example:
salt '*' bridge.delete br0

salt.modules.bridge.delif(br=None, iface=None)
Removes an interface from a bridge
CLI Example:
salt '*' bridge.delif br0 eth0

salt.modules.bridge.find_interfaces(*args)
Returns the bridge to which the interfaces are bond to
CLI Example:
salt '*' bridge.find_interfaces eth0 [eth1...]

salt.modules.bridge.interfaces(br=None)
Returns interfaces attached to a bridge
CLI Example:
salt '*' bridge.interfaces br0

**salt.modules.bridge.list()**
Returns the machine’s bridges list

CLI Example:
salt '*' bridge.list

**salt.modules.bridge.show**(br=None)
Returns bridges interfaces along with enslaved physical interfaces. If no interface is given, all bridges are shown, else only the specified bridge values are returned.

CLI Example:
salt '*' bridge.show
salt '*' bridge.show br0

**salt.modules.bridge.stp**(br=None, state='disable', iface=None)
Sets Spanning Tree Protocol state for a bridge

CLI Example:
salt '*' bridge.stp br0 enable
salt '*' bridge.stp br0 disable

For BSD-like operating systems, it is required to add the interface on which to enable the STP.

CLI Example:
salt '*' bridge.stp bridge0 enable fxp0
salt '*' bridge.stp bridge0 disable fxp0

### 13.6.38 salt.modulesbsd_shadow

Manage the password database on BSD systems

**Important:** If you feel that Salt should be using this module to manage passwords on a minion, and it is using a different module (or gives an error similar to `shadow.info` is not available), see here.

**salt.modulesbsd_shadow.default_hash()**
Returns the default hash used for unset passwords

CLI Example:
salt '*' shadow.default_hash

**salt.modulesbsd_shadow.del_password**(name)
New in version 2015.8.2.
Delete the password from name user

CLI Example:
salt '*' shadow.del_password username
salt.modules.bsd_shadow.info(name)
Return information for the specified user

CLI Example:
salt '*' shadow.info someuser

salt.modules.bsd_shadow.set_change(name, change)
Sets the time at which the password expires (in seconds since the UNIX epoch). See man 8 usermod on NetBSD and OpenBSD or man 8 pw on FreeBSD.
A value of 0 sets the password to never expire.

CLI Example:
salt '*' shadow.set_change username 1419980400

salt.modules.bsd_shadow.set_expire(name, expire)
Sets the time at which the account expires (in seconds since the UNIX epoch). See man 8 usermod on NetBSD and OpenBSD or man 8 pw on FreeBSD.
A value of 0 sets the account to never expire.

CLI Example:
salt '*' shadow.set_expire username 1419980400

salt.modules.bsd_shadow.set_password(name, password)
Set the password for a named user. The password must be a properly defined hash. The password hash can be generated with this command:

```
python -c "import crypt; print crypt.crypt('password',ciphersalt)"
```

Note: When constructing the ciphersalt string, you must escape any dollar signs, to avoid them being interpolated by the shell.

'password' is, of course, the password for which you want to generate a hash.
ciphersalt is a combination of a cipher identifier, an optional number of rounds, and the cryptographic salt. The arrangement and format of these fields depends on the cipher and which flavor of BSD you are using. For more information on this, see the manpage for crypt(3). On NetBSD, additional information is available in passwd.conf(5).

It is important to make sure that a supported cipher is used.

CLI Example:
salt '*' shadow.set_password someuser '$1$UYCIxa628.9qXjpQCjM4a...'

13.6.39 salt.modules.btrfs

Module for managing BTRFS file systems.
salt.modules.btrfs.add(mountpoint, *devices, **kwargs)
Add a devices to a BTRFS filesystem.

General options:
- nodiscard: Do not perform whole device TRIM
**force**: Force overwrite existing filesystem on the disk

CLI Example:

```
salt '*' btrfs.add /mountpoint /dev/sda1 /dev/sda2
```

```salt.modules.btrfs.convert```

Convert ext2/3/4 to BTRFS. Device should be mounted.

Filesystem can be converted temporarily so the further processing and rollback is possible, or permanently, where previous extended filesystem image gets deleted. Please note, permanent conversion takes a while as BTRFS filesystem needs to be properly rebalanced afterwards.

General options:

- **permanent**: Specify if the migration should be permanent (false by default)
- **keeplf**: Keep *lost+found* of the partition (removed by default, but still in the image, if not permanent migration)

CLI Example:

```
salt '*' btrfs.convert /dev/sda1
salt '*' btrfs.convert /dev/sda1 permanent=True
```

```salt.modules.btrfs.defragment```

Defragment mounted BTRFS filesystem. In order to defragment a filesystem, device should be properly mounted and writable.

If passed a device name, then defragmented whole filesystem, mounted on. If passed a mountpoint of the filesystem, then only this mount point is defragmented.

CLI Example:

```
salt '*' btrfs.defragment /dev/sda1
salt '*' btrfs.defragment /path/on/filesystem
```

```salt.modules.btrfs.delete```

Remove devices from a BTRFS filesystem.

CLI Example:

```
salt '*' btrfs.delete /mountpoint /dev/sda1 /dev/sda2
```

```salt.modules.btrfs.devices```

Get known BTRFS formatted devices on the system.

CLI Example:

```
salt '*' btrfs.devices
```

```salt.modules.btrfs.features```

List currently available BTRFS features.

CLI Example:

```
salt '*' btrfs.mkfs_features
```

```salt.modules.btrfs.info```

Get BTRFS filesystem information.

CLI Example:
salt '(*' btrfs.info /dev/sda1

salt.modules.btrfs.mkfs('devices, **kwargs)
Create a file system on the specified device. By default wipes out with force.

General options:
- allocsize: Specify the BTRFS offset from the start of the device.
- bytecount: Specify the size of the resultant filesystem.
- nodest: Node size.
- leafsize: Specify the nodesize, the tree block size in which btrfs stores data.
- noforce: Prevent force overwrite when an existing filesystem is detected on the device.
- sectorsize: Specify the sectorsize, the minimum data block allocation unit.
- nodiscard: Do not perform whole device TRIM operation by default.
- uuid: Pass UUID or pass True to generate one.

Options:
- dto: (raid0|raid1|raid5|raid6|raid10|single|dup) Specify how the data must be spanned across the devices specified.
- mto: (raid0|raid1|raid5|raid6|raid10|single|dup) Specify how metadata must be spanned across the devices specified.
- nfs: Features (call salt <host> btrfs.features for full list of available features)

See the mkfs.btrfs(8) manpage for a more complete description of corresponding options description.

CLI Example:

salt '(*' btrfs.mkfs /dev/sda1
salt '(*' btrfs.mkfs /dev/sda1 noforce=True

salt.modules.btrfs.properties(obj, type=None, set=None)
List properties for given btrfs object. The object can be path of BTRFS device, mount point, or any directories/files inside the BTRFS filesystem.

General options:
- type: Possible types are s[ubvol], f[ilesystem], i[node] and d[evice].
- force: Force overwrite existing filesystem on the disk
- set: <key=value,key1=value1…> Options for a filesystem properties.

CLI Example:

salt '(*' btrfs.properties /mountpoint
salt '(*' btrfs.properties /dev/sda1 type=subvol set='ro=false,label="My Storage")

salt.modules.btrfs.resize(mountpoint, size)
Resize filesystem.

General options:
- mountpoint: Specify the BTRFS mountpoint to resize.
- size: ([+/-]<newsize>[kKmGtTpPeE]|max) Specify the new size of the target.

CLI Example:

salt '(*' btrfs.resize /mountpoint size=+1g
salt '(*' btrfs.resize /dev/sda1 size=max

salt.modules.btrfs.usage(path)
Show in which disk the chunks are allocated.

CLI Example:
salt 'ls' btrfs.usage /your/mountpoint

salt.modules.btrfs.version()

Return BTRFS version.

CLI Example:
salt 'ls' btrfs.version

13.6.40 salt.modules.cabal

Manage and query Cabal packages

New in version 2015.8.0.

salt.modules.cabal.install(pkg=None, pkgs=None, user=None, install_global=False, env=None)

Install a cabal package.

pkg A package name in format accepted by cabal-install. See: https://wiki.haskell.org/Cabal-Install
pkgs A list of packages names in same format as pkg
user The user to run cabal install with
install_global Install package globally instead of locally
env Environment variables to set when invoking cabal. Uses the same env format as the cmd.run execution function

CLI Example:
salt 'ls' cabal.install shellcheck
salt 'ls' cabal.install shellcheck-0.3.5

salt.modules.cabal.list(pkg=None, user=None, installed=False, env=None)

List packages matching a search string.

pkg Search string for matching package names
user The user to run cabal list with
installed If True, only return installed packages.
env Environment variables to set when invoking cabal. Uses the same env format as the cmd.run execution function

CLI example:
salt 'ls' cabal.list
salt 'ls' cabal.list ShellCheck

salt.modules.cabal.uninstall(pkg, user=None, env=None)

Uninstall a cabal package.

pkg The package to uninstall
user The user to run ghc-pkg unregister with
env Environment variables to set when invoking cabal. Uses the same env format as the cmd.run execution function

salt.modules.cabal.update(user=None, env=None)

Updates list of known packages.

13.6.41 salt.modules.cassandra

Cassandra NoSQL Database Module
depends
  • pycassa Cassandra Python adapter

configuration The location of the `nodetool' command, host, and thrift port needs to be specified via pillar:

| cassandra.nodetool: /usr/local/bin/nodetool |
| cassandra.host: localhost |
| cassandra.thrift_port: 9160 |

salt.modules.cassandra.column_families
  Return existing column families for all keyspaces or just the provided one.

  CLI Example:

  ```
salt '*' cassandra.column_families
salt '*' cassandra.column_families <keyspace>
```

salt.modules.cassandra.column_family_definition
  Return a dictionary of column family definitions for the given keyspace/column_family

  CLI Example:

  ```
salt '*' cassandra.column_family_definition <keyspace> <column_family>
```

salt.modules.cassandra.compactionstats
  Return compactionstats info

  CLI Example:

  ```
salt '*' cassandra.compactionstats
```

salt.modules.cassandra.info
  Return cassandra node info

  CLI Example:

  ```
salt '*' cassandra.info
```

salt.modules.cassandra.keyspaces
  Return existing keyspaces

  CLI Example:

  ```
salt '*' cassandra.keyspaces
```

salt.modules.cassandra.netstats
  Return netstats info

  CLI Example:

  ```
salt '*' cassandra.netstats
```

salt.modules.cassandra.ring
  Return cassandra ring info

  CLI Example:

  ```
salt '*' cassandra.ring
```
salt.modules.cassandra.tpstats()
Return tpstats info

CLI Example:
```
salt '*' cassandra.tpstats
```

salt.modules.cassandra.version()
Return the cassandra version

CLI Example:
```
salt '*' cassandra.version
```

### 13.6.42 salt.modules.cassandra_cql

Cassandra Database Module

New in version 2015.5.0.

- **depends**  DataStax Python Driver for Apache Cassandra https://github.com/datastax/python-driver pip install cassandra-driver
- **referenced by**  Salt’s cassandra_cql returner
- **configuration**  The Cassandra cluster members and connection port can either be specified in the master or minion config, the minion’s pillar or be passed to the module.

Example configuration in the config for a single node:
```
cassandra:
    cluster: 192.168.50.10
    port: 9000
```

Example configuration in the config for a cluster:
```
cassandra:
    cluster:
        - 192.168.50.10
        - 192.168.50.11
        - 192.168.50.12
    port: 9000
    username: cas_admin
```

Changed in version Carbon: Added support for `ssl_options` and `protocol_version`.

Example configuration with `ssl options`:

If `ssl_options` are present in cassandra config the cassandra_cql returner will use SSL. SSL isn’t used if `ssl_options` isn’t specified.
```
cassandra:
    cluster:
        - 192.168.50.10
        - 192.168.50.11
        - 192.168.50.12
    port: 9000
    username: cas_admin

ssl_options:
```

13.6. execution modules
ca_certs: /etc/ssl/certs/ca-bundle.trust.crt

# SSL version should be one from the ssl module
# This is an optional parameter
ssl_version: PROTOCOL_TLSv1

Additionally you can also specify the protocol_version to use.

cassandra:
  cluster:
    - 192.168.50.10
    - 192.168.50.11
    - 192.168.50.12
  port: 9000
  username: cas_admin

  # defaults to 4, if not set
  protocol_version: 3

salt.modules.cassandra_cql.cql_query(query, contact_points=None, port=None, cql_user=None, cql_pass=None)

Run a query on a Cassandra cluster and return a dictionary.

Parameters

- query (str) -- The query to execute.
- contact_points (str | list[str]) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- cql_user (str) -- The Cassandra user if authentication is turned on.
- cql_pass (str) -- The Cassandra user password if authentication is turned on.
- port (int) -- The Cassandra cluster port, defaults to None.
- params (str) -- The parameters for the query, optional.

Returns A dictionary from the return values of the query

Return type list[dict]

salt.modules.cassandra_cql.cql_query_with_prepare(query, statement_name, statement_arguments, async=False, callback_errors=None, contact_points=None, port=None, cql_user=None, cql_pass=None)

Run a query on a Cassandra cluster and return a dictionary.

This function should not be used asynchronously for SELECTs -- it will not return anything and we don't currently have a mechanism for handling a future that will return results.

Parameters

- query (str) -- The query to execute.
- statement_name (str) -- Name to assign the prepared statement in the __context__ dictionary
- statement_arguments (list[str]) -- Bind parameters for the SQL statement
- async (bool) -- Run this query in asynchronous mode
- callback_errors (Function callable) -- Function to call after query runs if there is an error
- **contact_points** *(str | list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql_user** *(str)* -- The Cassandra user if authentication is turned on.
- **cql_pass** *(str)* -- The Cassandra user password if authentication is turned on.
- **port** *(int)* -- The Cassandra cluster port, defaults to None.
- **params** *(str)* -- The parameters for the query, optional.

**Returns** A dictionary from the return values of the query

**Return type** list[dict]

```python
cassandra_cql.create_keyspace(keyspace, replication_strategy='SimpleStrategy', replication_factor=1, replication_datacenters=None, contact_points=None, port=None, cql_user=None, cql_pass=None)
```

Create a new keyspace in Cassandra.

**Parameters**

- **keyspace** *(str)* -- The keyspace name
- **replication_strategy** *(str)* -- either SimpleStrategy or NetworkTopologyStrategy
- **replication_factor** *(int)* -- number of replicas of data on multiple nodes. not used if using NetworkTopologyStrategy
- **replication_datacenters** *(str | dict[str, int]*) -- string or dict of datacenter names to replication factors, required if using NetworkTopologyStrategy (will be a dict if coming from state file).
- **contact_points** *(str | list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql_user** *(str)* -- The Cassandra user if authentication is turned on.
- **cql_pass** *(str)* -- The Cassandra user password if authentication is turned on.
- **port** *(int)* -- The Cassandra cluster port, defaults to None.

**Returns** The info for the keyspace or False if it does not exist.

**Return type** dict

```python
cassandra_cql.create_keyspace(keyspace=newkeyspace, replication_strategy='NetworkTopologyStrategy', replication_datacenters={'datacenter_1': 3, 'datacenter_2': 2})
```

Create a new cassandra user with credentials and superuser status.

**Parameters**

- **username** *(str)* -- The name of the new user.
- **password** *(str)* -- The password of the new user.
- **superuser** *(bool)* -- Is the new user going to be a superuser? default: False

```python
cassandra_cql.create_user(username, password, superuser=False, contact_points=None, port=None, cql_user=None, cql_pass=None)
```
- **contact_points** *(str | list[str])* -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql_user** *(str)* -- The Cassandra user if authentication is turned on.
- **cql_pass** *(str)* -- The Cassandra user password if authentication is turned on.
- **port** *(int)* -- The Cassandra cluster port, defaults to None.

Returns

Return type

```
salt 'minion1' cassandra_cql.create_user username=joe password=secret
salt 'minion1' cassandra_cql.create_user username=joe password=secret* superuser=True
salt 'minion1' cassandra_cql.create_user username=joe password=secret* superuser=True contact_points=minion1
```

salt.modules.cassandra_cql.drop_keyspace*(keyspace, contact_points=None, port=None, cql_user=None, cql_pass=None)*

Drop a keyspace if it exists in a Cassandra cluster.

Parameters

- **keyspace** *(str)* -- The keyspace to drop.
- **contact_points** *(str | list[str])* -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql_user** *(str)* -- The Cassandra user if authentication is turned on.
- **cql_pass** *(str)* -- The Cassandra user password if authentication is turned on.
- **port** *(int)* -- The Cassandra cluster port, defaults to None.

Returns

The info for the keyspace or False if it does not exist.

Return type **dict**

CLI Example:

```
salt 'minion1' cassandra_cql.drop_keyspace keyspace=test
salt 'minion1' cassandra_cql.drop_keyspace keyspace=test contact_points=minion1
```

salt.modules.cassandra_cql.grant_permission*(username, resource=None, resource_type='keyspace', permission=None, contact_points=None, port=None, cql_user=None, cql_pass=None)*

Grant permissions to a user.

Parameters

- **username** *(str)* -- The name of the user to grant permissions to.
- **resource** *(str)* -- The resource (keyspace or table), if None, permissions for all resources are granted.
- **resource_type** *(str)* -- The resource_type (keyspace or table), defaults to 'keyspace'.
- **permission** *(str)* -- A permission name (e.g. select), if None, all permissions are granted.
• **contact_points** *(str | list[str])* -- The Cassandra cluster addresses, can either be a string or a list of IPs.

• **cql_user** *(str)* -- The Cassandra user if authentication is turned on.

• **cql_pass** *(str)* -- The Cassandra user password if authentication is turned on.

• **port** *(int)* -- The Cassandra cluster port, defaults to None.

Returns

Return type

```python
salt 'minion1' cassandra_cql.grant_permission
salt 'minion1' cassandra_cql.grant_permission username=joe resource=test_keyspace
    ! permission=select
salt 'minion1' cassandra_cql.grant_permission username=joe resource=test_table
    ! resource_type=table permission=select contact_points=minion1
```

```
salt.modules.cassandra_cql.info(contact_points=None, port=None, cql_user=None, cql_pass=None)
```

Show the Cassandra information for this cluster.

Parameters

• **contact_points** *(str | list[str])* -- The Cassandra cluster addresses, can either be a string or a list of IPs.

• **cql_user** *(str)* -- The Cassandra user if authentication is turned on.

• **cql_pass** *(str)* -- The Cassandra user password if authentication is turned on.

• **port** *(int)* -- The Cassandra cluster port, defaults to None.

Returns

The information for this Cassandra cluster.

Return type

dict

CLI Example:

```python
salt 'minion1' cassandra_cql.info
salt 'minion1' cassandra_cql.info contact_points=minion1
```

```
salt.modules.cassandra_cql.keyspace_exists(keyspace, contact_points=None, port=None, cql_user=None, cql_pass=None)
```

Check if a keyspace exists in a Cassandra cluster.

:returns: The info for the keyspace or False if it does not exist.

CLI Example:

```python
salt 'minion1' cassandra_cql.keyspace_exists keyspace=system
salt 'minion1' cassandra_cql.list_keyspaces keyspace=system contact_points=minion1
```
salt.modules.cassandra_cql.list_column_families(keyspace=None, contact_points=None, port=None, cql_user=None, cql_pass=None)

List column families in a Cassandra cluster for all keyspaces or just the provided one.

Parameters

- **keyspace** *(str)* -- The keyspace to provide the column families for, optional.
- **contact_points** *(str | list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql_user** *(str)* -- The Cassandra user if authentication is turned on.
- **cql_pass** *(str)* -- The Cassandra user password if authentication is turned on.
- **port** *(int)* -- The Cassandra cluster port, defaults to None.

Returns
The column families in this Cassandra cluster.

Return type list[dict]

CLI Example:

```
salt 'minion1' cassandra_cql.list_column_families
salt 'minion1' cassandra_cql.list_column_families contact_points=minion1
salt 'minion1' cassandra_cql.list_column_families keyspace=system
```
	salt.modules.cassandra_cql.list_keyspaces(contact_points=None, port=None, cql_user=None, cql_pass=None)

List keyspaces in a Cassandra cluster.

Parameters

- **contact_points** *(str | list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql_user** *(str)* -- The Cassandra user if authentication is turned on.
- **cql_pass** *(str)* -- The Cassandra user password if authentication is turned on.
- **port** *(int)* -- The Cassandra cluster port, defaults to None.

Returns
The keyspaces in this Cassandra cluster.

Return type list[dict]

CLI Example:

```
salt 'minion1' cassandra_cql.list_keyspaces
salt 'minion1' cassandra_cql.list_keyspaces contact_points=minion1 port=9000
```
	salt.modules.cassandra_cql.list_permissions(username=None, resource=None, resource_type='keyspace', permission=None, contact_points=None, port=None, cql_user=None, cql_pass=None)

List permissions.

Parameters

- **username** *(str)* -- The name of the user to list permissions for.
- **resource** *(str)* -- The resource (keyspace or table), if None, permissions for all resources are listed.
- **resource_type** (*str*) -- The resource_type (keyspace or table), defaults to 'keyspace'.
- **permission** (*str*) -- A permission name (e.g. select), if None, all permissions are listed.
- **contact_points** (*str | list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql_user** (*str*) -- The Cassandra user if authentication is turned on.
- **cql_pass** (*str*) -- The Cassandra user password if authentication is turned on.
- **port** (*int*) -- The Cassandra cluster port, defaults to None.

Returns Dictionary of permissions.

Return type dict

```python
salt 'minion1' cassandra_cql.list_permissions
salt 'minion1' cassandra_cql.list_permissions username=joe resource=test_keyspace permission=select
salt 'minion1' cassandra_cql.list_permissions username=joe resource=test_table resource_type=table permission=select contact_points=minion1
```

**salt.modules.cassandra_cql.list_users** (*contact_points=None*, *port=None*, *cql_user=None*, *cql_pass=None*)

List existing users in this Cassandra cluster.

Parameters
- **contact_points** (*str | list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **port** (*int*) -- The Cassandra cluster port, defaults to None.
- **cql_user** (*str*) -- The Cassandra user if authentication is turned on.
- **cql_pass** (*str*) -- The Cassandra user password if authentication is turned on.

Returns The list of existing users.

Return type dict

```python
salt 'minion1' cassandra_cql.list_users
salt 'minion1' cassandra_cql.list_users contact_points=minion1
```

**salt.modules.cassandra_cql.version** (*contact_points=None*, *port=None*, *cql_user=None*, *cql_pass=None*)

Show the Cassandra version.

Parameters
- **contact_points** (*str | list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql_user** (*str*) -- The Cassandra user if authentication is turned on.
- **cql_pass** (*str*) -- The Cassandra user password if authentication is turned on.
- **port** (*int*) -- The Cassandra cluster port, defaults to None.

Returns The version for this Cassandra cluster.
Return type  str

CLI Example:

- `salt 'minion1' cassandra_cql.version`
- `salt 'minion1' cassandra_cql.version contact_points=minion1`

### 13.6.43 salt.modules.chassis

Glue execution module to link to the fx2 proxymodule.

Depends: `iDRAC Remote execution module (salt.modules.dracr)`

For documentation on commands that you can direct to a Dell chassis via proxy, look in the documentation for `salt.modules.dracr`.

This execution module calls through to a function in the fx2 proxy module called `chconfig`. That function looks up the function passed in the `cmd` parameter in `salt.modules.dracr` and calls it.

New in version 2015.8.2.

```python
salt.modules.chassis.chassis_credentials()
salt.modules.chassis.cmd(cmd, *args, **kwargs)
```

### 13.6.44 salt.modules.chef

Execute chef in server or solo mode

```python
salt.modules.chef.client(whyrun=False, localmode=False, logfile=None, **kwargs)
```

Execute a chef client run and return a dict with the stderr, stdout, return code, and pid.

CLI Example:

```bash
salt '*' chef.client server=https://localhost
```

- **server**  The chef server URL
- **client_key**  Set the client key file location
- **config**  The configuration file to use
- **config-file-jail**  Directory under which config files are allowed to be loaded (no client.rb or knife.rb outside this path will be loaded).
- **environment**  Set the Chef Environment on the node
- **group**  Group to set privilege to
- **json-attributes**  Load attributes from a JSON file or URL
- **localmode**  Point chef-client at local repository if True
- **log_level**  Set the log level (debug, info, warn, error, fatal)
- **logfile**  Set the log file location
- **node-name**  The node name for this client
- **override-runlist**  Replace current run list with specified items for a single run
- **pid**  Set the PID file location, defaults to /tmp/chef-client.pid
- **run-lock-timeout**  Set maximum duration to wait for another client run to finish, default is indefinitely.
- **runlist**  Permanently replace current run list with specified items
- **user**  User to set privilege to
- **validation_key**  Set the validation key file location, used for registering new clients
- **whyrun**  Enable whyrun mode when set to True
salt.modules.chef.solo(whyrun=False, logfile=None, **kwargs)

Execute a chef solo run and return a dict with the stderr, stdout, return code, and pid.

CLI Example:

```
salt '*' chef.solo override-runlist=test
```

cfg  The configuration file to use
evironment  Set the Chef Environment on the node
group  Group to set privilege to
json-attributes  Load attributes from a JSON file or URL
log_level  Set the log level (debug, info, warn, error, fatal)
logfile  Set the log file location
node-name  The node name for this client
override-runlist  Replace current run list with specified items for a single run
recipe-url  Pull down a remote gzipped tarball of recipes and untar it to the cookbook cache
run-lock-timeout  Set maximum duration to wait for another client run to finish, default is indefinitely.
user  User to set privilege to
whyrun  Enable whyrun mode when set to True

13.6.45  salt.modules.chocolatey

A dead simple module wrapping calls to the Chocolatey package manager (http://chocolatey.org)

New in version 2014.1.0.

salt.modules.chocolatey.add_source(name, source_location, username=None, password=None)

Instructs Chocolatey to add a source.

name  The name of the source to be added as a chocolatey repository.
source  Location of the source you want to work with.
username  Provide username for chocolatey sources that need authentication credentials.
password  Provide password for chocolatey sources that need authentication credentials.

CLI Example:

```
salt '*' chocolatey.add_source <source name> <source_location>
salt '*' chocolatey.add_source <source name> <source_location> user=<user> --password=<password>
```

salt.modules.chocolatey.bootstrap(force=False)

Download and install the latest version of the Chocolatey package manager via the official bootstrap.

Chocolatey requires Windows PowerShell and the .NET v4.0 runtime. Depending on the host's version of Windows, chocolatey.bootstrap will attempt to ensure these prerequisites are met by downloading and executing the appropriate installers from Microsoft.

Note that if PowerShell is installed, you may have to restart the host machine for Chocolatey to work.

force  Run the bootstrap process even if Chocolatey is found in the path.

CLI Example:

```
salt '*' chocolatey.bootstrap
salt '*' chocolatey.bootstrap force=True
```

salt.modules.chocolatey.chocolatey_version()

Returns the version of Chocolatey installed on the minion.

CLI Example:
salt '*' chocolatey.chocolatey_version

salt.modules.chocolatey.disable_source(name)
  Instructs Chocolatey to disable a source.
  name  Name of the source repository to disable.
  CLI Example:
  
salt '*' chocolatey.disable_source <name>

salt.modules.chocolatey.enable_source(name)
  Instructs Chocolatey to enable a source.
  name  Name of the source repository to enable.
  CLI Example:
  
salt '*' chocolatey.enable_source <name>

salt.modules.chocolatey.install(name, version=None, source=None, force=False,
  pre_versions=False, install_args=None, override_args=False,
  force_x86=False, package_args=None)
  Instructs Chocolatey to install a package.

  Args:
  name (str):  The name of the package to be installed. Only accepts a single argument.
  version (str):  Install a specific version of the package. Defaults to latest version.
  source (str):  Chocolatey repository (directory, share or remote URL feed) the package comes from. Defaults to the official Chocolatey feed.

  Alternative Sources:
  • cygwin
  • python
  • ruby
  • webpi
  • windowsfeatures
  force (bool):  Reinstall the current version of an existing package.
  pre_versions (bool):  Include pre-release packages. Defaults to False.
  install_args (str):  A list of install arguments you want to pass to the installation process i.e product key or feature list
  override_args (bool):  Set to true if you want to override the original install arguments (for the native installer) in the package and use your own. When this is set to False install_args will be appended to the end of the default arguments
  force_x86 (str):  Force x86 (32bit) installation on 64 bit systems. Defaults to false.
  package_args (str):  A list of arguments you want to pass to the package

  Returns:  str:  The output of the chocolatey command

  CLI Example:
  
salt '*' chocolatey.install <package name>
salt '*' chocolatey.install <package name> version=<package version>
salt '*' chocolatey.install <package name> install_args=<args> override_args=True
salt.modules.chocolatey.install_cygwin(name, install_args=None, override_args=False)

Instructs Chocolatey to install a package via Cygwin.

name The name of the package to be installed. Only accepts a single argument.
install_args A list of install arguments you want to pass to the installation process i.e product key or feature list
override_args

Set to true if you want to override the original install arguments (for the native installer) in the package and use your own. When this is set to False install_args will be appended to the end of the default arguments

CLI Example:

```
salt '*' chocolatey.install_cygwin <package name>
salt '*' chocolatey.install_cygwin <package name> install_args=<args> override_args=True
```

salt.modules.chocolatey.install_gem(name, version=None, install_args=None, override_args=False)

Instructs Chocolatey to install a package via Ruby's Gems.

name The name of the package to be installed. Only accepts a single argument.
version Install a specific version of the package. Defaults to latest version available.
install_args A list of install arguments you want to pass to the installation process i.e product key or feature list
override_args

Set to true if you want to override the original install arguments (for the native installer) in the package and use your own. When this is set to False install_args will be appended to the end of the default arguments

CLI Example:

```
salt '*' chocolatey.install_gem <package name>
salt '*' chocolatey.install_gem <package name> version=<package version>
salt '*' chocolatey.install_gem <package name> install_args=<args> override_args=True
```

salt.modules.chocolatey.install_missing(name, version=None, source=None)

Instructs Chocolatey to install a package if it doesn't already exist.

Changed in version 2014.7.0: If the minion has Chocolatey >= 0.9.8.24 installed, this function calls chocolatey.install instead, as installmissing is deprecated as of that version and will be removed in Chocolatey 1.0.

name The name of the package to be installed. Only accepts a single argument.
version Install a specific version of the package. Defaults to latest version available.
source Chocolatey repository (directory, share or remote URL feed) the package comes from. Defaults to the official Chocolatey feed.

CLI Example:

```
salt '*' chocolatey.install_missing <package name>
salt '*' chocolatey.install_missing <package name> version=<package version>
```

salt.modules.chocolatey.install_python(name, version=None, install_args=None, override_args=False)

Instructs Chocolatey to install a package via Python's easy_install.

name The name of the package to be installed. Only accepts a single argument.
version Install a specific version of the package. Defaults to latest version available.
install_args A list of install arguments you want to pass to the installation process i.e product key or feature list
override_args

Set to true if you want to override the original install arguments (for the native installer) in the package and use your own. When this is set to False install_args will be appended to the end of the default arguments.

CLI Example:

```bash
salt '*' chocolatey.install_python <package name>
salt '*' chocolatey.install_python <package name> version=<package version>
salt '*' chocolatey.install_python <package name> install_args=<args> override_args=True
```

salt.modules.chocolatey.install_webpi(name, install_args=None, override_args=False)

Instructs Chocolatey to install a package via the Microsoft Web PI service.

- **name** The name of the package to be installed. Only accepts a single argument.
- **install_args** A list of install arguments you want to pass to the installation process i.e product key or feature list
- **override_args**

    Set to true if you want to override the original install arguments (for the native installer) in the package and use your own. When this is set to False install_args will be appended to the end of the default arguments.

CLI Example:

```bash
salt '*' chocolatey.install_webpi <package name>
salt '*' chocolatey.install_webpi <package name> install_args=<args> override_args=True
```

salt.modules.chocolatey.install_windowsfeatures(name)

Instructs Chocolatey to install a Windows Feature via the Deployment Image Servicing and Management tool.

- **name** The name of the feature to be installed. Only accepts a single argument.

CLI Example:

```bash
salt '*' chocolatey.install_windowsfeatures <package name>
```

salt.modules.chocolatey.list(narrow=None, all_versions=False, pre_versions=False, source=None, local_only=False)

Instructs Chocolatey to pull a vague package list from the repository.

- **narrow** Term used to narrow down results. Searches against name/description/tag.
- **all_versions** Display all available package versions in results. Defaults to False.
- **pre_versions** Display pre-release packages in results. Defaults to False.
- **source** Chocolatey repository (directory, share or remote URL feed) the package comes from. Defaults to the official Chocolatey feed.
- **local_only** Display packages only installed locally

CLI Example:

```bash
salt '*' chocolatey.list <narrow>
salt '*' chocolatey.list <narrow> all_versions=True
```

salt.modules.chocolatey.list_webpi()

Instructs Chocolatey to pull a full package list from the Microsoft Web PI repository.

**Returns:** str: List of webpi packages

CLI Example:

```bash
salt '*' chocolatey.list_webpi
```

salt.modules.chocolatey.list_windowsfeatures()
Instructs Chocolatey to pull a full package list from the Windows Features list, via the Deployment Image Servicing and Management tool.

Returns: str: List of Windows Features

CLI Example:
```
salt '*' chocolatey.list_windowsfeatures
```

```python
salt.modules.chocolatey.uninstall(name, version=None, uninstall_args=None, override_args=False)
```

Instructs Chocolatey to uninstall a package.

**name** The name of the package to be uninstalled. Only accepts a single argument.

**version** Uninstalls a specific version of the package. Defaults to latest version installed.

**uninstall_args** A list of uninstall arguments you want to pass to the uninstallation process i.e product key or feature list

**override_args**

Set to true if you want to override the original uninstall arguments (for the native uninstaller) in the package and use your own. When this is set to False uninstall_args will be appended to the end of the default arguments

CLI Example:
```
salt '*' chocolatey.uninstall <package name>
salt '*' chocolatey.uninstall <package name> version=<package version>
salt '*' chocolatey.uninstall <package name> version=<package version> uninstall_-args=<args> override_args=True
```

```python
salt.modules.chocolatey.update(name, source=None, pre_versions=False)
```

Instructs Chocolatey to update packages on the system.

**name** The name of the package to update, or `''all''` to update everything installed on the system.

**source** Chocolatey repository (directory, share or remote URL feed) the package comes from. Defaults to the official Chocolatey feed.

**pre_versions** Include pre-release packages in comparison. Defaults to False.

CLI Example:
```
salt "*" chocolatey.update all
salt "*" chocolatey.update <package name> pre_versions=True
```

```python
salt.modules.chocolatey.upgrade(name, version=None, source=None, force=False, pre_versions=False, install_args=None, override_args=False, force_x86=False, package_args=None)
```

New in version 2016.3.4.

Instructs Chocolatey to upgrade packages on the system. (update is being deprecated)

**Args:**

name (str): The name of the package to update, or `''all''` to update everything installed on the system.

version (str): Install a specific version of the package. Defaults to latest version.

source (str): Chocolatey repository (directory, share or remote URL feed) the package comes from. Defaults to the official Chocolatey feed.

force (bool): Reinstall the same version already installed

pre_versions (bool): Include pre-release packages in comparison. Defaults to False.

install_args (str): A list of install arguments you want to pass to the installation process i.e product key or feature list
**override_args** (str): Set to true if you want to override the original install arguments (for the native installer) in the package and use your own. When this is set to False install_args will be appended to the end of the default arguments.

**force_x86**  Force x86 (32bit) installation on 64 bit systems. Defaults to false.

**package_args**  A list of arguments you want to pass to the package

**Returns:**  str: Results of the chocolatey command

CLI Example:

```sh
salt "*") chocolatey.upgrade all
salt "*") chocolatey.upgrade <package name> pre_versions=True
```

**salt.modules.chocolatey.version** (name, check_remote=False, source=None, pre_versions=False)

Instructs Chocolatey to check an installed package version, and optionally compare it to one available from a remote feed.

- **name**  The name of the package to check.
- **check_remote**  Get the version number of the latest package from the remote feed. Defaults to False.
- **source**  Chocolatey repository (directory, share or remote URL feed) the package comes from. Defaults to the official Chocolatey feed.
- **pre_versions**  Include pre-release packages in comparison. Defaults to False.

CLI Example:

```sh
salt "*") chocolatey.version <package name>
salt "*") chocolatey.version <package name> check_remote=True
```

### 13.6.46  salt.modules.chronos module

Module providing a simple management interface to a chronos cluster.

Currently this only works when run through a proxy minion.

New in version 2015.8.2.

**salt.modules.chronos.has_job** (name)

Return whether the given job is currently configured.

CLI Example:

```sh
salt chronos-minion-id chronos.has_job my-job
```

**salt.modules.chronos.job** (name)

Return the current server configuration for the specified job.

CLI Example:

```sh
salt chronos-minion-id chronos.job my-job
```

**salt.modules.chronos.jobs**

Return a list of the currently installed job names.

CLI Example:

```sh
salt chronos-minion-id chronos.jobs
```

**salt.modules.chronos.rm_job** (name)

Remove the specified job from the server.
CLI Example:
```
salt chronos-minion-id chronos.rm_job my-job
```

salt.modules.chronos.update_job(name, config)
Update the specified job with the given configuration.

CLI Example:
```
salt chronos-minion-id chronos.update_job my-job '<<config yaml>>'
```

### 13.6.47 salt.modules.cloud

Salt-specific interface for calling Salt Cloud directly

salt.modules.cloud.action(fun=None, cloudmap=None, names=None, provider=None, instance=None, **kwargs)
Execute a single action on the given provider/instance

CLI Example:
```
salt '*' cloud.action start instance=myinstance
salt '*' cloud.action stop instance=myinstance
salt '*' cloud.action show_image provider=my-ec2-config image=ami-1624987f
```

salt.modules.cloud.create(provider, names, **kwargs)
Create an instance using Salt Cloud

CLI Example:
```
salt minionname cloud.create my-ec2-config myinstance image=ami-1624987f size='t1.micro' ssh_username=ec2-user securitygroup=default delvol_on_destroy=True
```

salt.modules.cloud.destroy(names)
Destroy the named VM(s)

CLI Example:
```
salt '*' cloud.destroy myinstance
```

salt.modules.cloud.full_query(query_type='list_nodes_full')
List all available cloud provider data

CLI Example:
```
salt '*' cloud.full_query
```

salt.modules.cloud.get_instance(name, provider=None)
Return details on an instance.
Similar to the cloud action show_instance but returns only the instance details.

CLI Example:
```
salt '*' cloud.get_instance myinstance
```

SLS Example:
salt.modules.cloud.get_instance('myinstance')['mac_address']

salt.modules.cloud.has_instance(name, provider=None)
Return true if the instance is found on a provider

CLI Example:
salt '*' cloud.has_instance myinstance

salt.modules.cloud.list_images(provider='all')
List cloud provider images for the given providers

CLI Example:
salt '*' cloud.list_images my-gce-config

salt.modules.cloud.list_locations(provider='all')
List cloud provider locations for the given providers

CLI Example:
salt '*' cloud.list_locations my-gce-config

salt.modules.cloud.list_sizes(provider='all')
List cloud provider sizes for the given providers

CLI Example:
salt '*' cloud.list_sizes my-gce-config

salt.modules.cloud.network_create(provider, names, **kwargs)
Create private network

CLI Example:
salt minionname cloud.network_create my-nova names=['salt'] cidr='192.168.100.0/24'

salt.modules.cloud.network_list(provider)
List private networks

CLI Example:
salt minionname cloud.network_list my-nova

salt.modules.cloud.profile(profile, names, vm_overrides=None, **kwargs)
Spin up an instance using Salt Cloud

CLI Example:
salt '*' cloud.profile my-gce-config myinstance

salt.modules.cloud.query(query_type='list_nodes')
List cloud provider data for all providers

CLI Examples:
salt '*' cloud.query
salt '*' cloud.query list_nodes_full
salt '*' cloud.query list_nodes_select
salt.modules.cloud.select_query(query_type='list_nodes_select')

List selected nodes

CLI Example:
```
salt '*' cloud.select_query
```

salt.modules.cloud.virtual_interface_create(provider, names, **kwargs)

Attach private interfaces to a server

CLI Example:
```
salt minionname cloud.virtual_interface_create my-nova names=['salt-master'] net_name='salt'
```

salt.modules.cloud.virtual_interface_list(provider, names, **kwargs)

List virtual interfaces on a server

CLI Example:
```
salt minionname cloud.virtual_interface_list my-nova names=['salt-master']
```

salt.modules.cloud.volume_attach(provider, names, **kwargs)

Attach volume to a server

CLI Example:
```
salt minionname cloud.volume_attach my-nova myblock server_name=myserver device='/dev/xvdf'
```

salt.modules.cloud.volume_create(provider, names, **kwargs)

Create volume

CLI Example:
```
salt minionname cloud.volume_create my-nova myblock size=100 voltype=SSD
```

salt.modules.cloud.volume_delete(provider, names, **kwargs)

Delete volume

CLI Example:
```
salt minionname cloud.volume_delete my-nova myblock
```

salt.modules.cloud.volume_detach(provider, names, **kwargs)

Detach volume from a server

CLI Example:
```
salt minionname cloud.volume_detach my-nova myblock server_name=myserver
```

salt.modules.cloud.volume_list(provider)

List block storage volumes

CLI Example:
```
salt minionname cloud.volume_list my-nova
```

13.6. execution modules
13.6.48  salt.modules.cmdmod

A module for shelling out.

Keep in mind that this module is insecure, in that it can give whomever has access to the master root execution access to all salt minions.

```
salt.modules.cmdmod.exec_code(lang, code, cwd=None)
    Pass in two strings, the first naming the executable language, aka - python2, python3, ruby, perl, lua, etc. the second string containing the code you wish to execute. The stdout will be returned.
    CLI Example:
    salt '*' cmd.exec_code ruby 'puts "cheese"'
```

```
salt.modules.cmdmod.exec_code_all(lang, code, cwd=None)
    Pass in two strings, the first naming the executable language, aka - python2, python3, ruby, perl, lua, etc. the second string containing the code you wish to execute. All cmd artifacts (stdout, stderr, retcode, pid) will be returned.
    CLI Example:
    salt '*' cmd.exec_code_all ruby 'puts "cheese"'
```

```
salt.modules.cmdmod.has_exec(cmd)
    Returns true if the executable is available on the minion, false otherwise
    CLI Example:
    salt '*' cmd.has_exec cat
```

```
salt.modules.cmdmod.powershell(cmd, cwd=None, stdin=None, runas=None, shell='/bin/sh', env=None, clean_env=False, template=None, rstrip=True, umask=None, output_loglevel='debug', quiet=False, time_out=None, reset_system_locale=True, ignore_retcode=False, saltenv='base', use_vt=False, password=None, depth=None, **kwargs)
    Execute the passed PowerShell command and return the output as a dictionary.
    Other cmd.* functions return the raw text output of the command. This function appends | ConvertTo-JSON to the command and then parses the JSON into a Python dictionary. If you want the raw textual result of your PowerShell command you should use cmd.run with the shell=powershell option.
    For example:
    salt '*' cmd.run '$PSVersionTable.CLRVersion' shell=powershell
    salt '*' cmd.run 'Get-NetTCPConnection' shell=powershell
```

New in version 2016.3.0.

**Warning:** This passes the cmd argument directly to PowerShell without any further processing! Be absolutely sure that you have properly sanitized the command passed to this function and do not use untrusted inputs.

Note that env represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.
In addition to the normal `cmd.run` parameters, this command offers the `depth` parameter to change the Windows default depth for the `ConvertTo-JSON` powershell command. The Windows default is 2. If you need more depth, set that here.

**Note:** For some commands, setting the depth to a value greater than 4 greatly increases the time it takes for the command to return and in many cases returns useless data.

**Parameters**

- **cmd (str)** -- The powershell command to run.
- **cwd (str)** -- The current working directory to execute the command in
- **stdin (str)** -- A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input:
- **runas (str)** -- User to run script as. If running on a Windows minion you must also pass a password
- **password (str)** -- Windows only. Required when specifying `runas`. This parameter will be ignored on non-Windows platforms.
  
  New in version 2016.3.0.
- **shell (str)** -- Shell to execute under. Defaults to the system default shell.
- **python_shell (bool)** -- If False, let python handle the positional arguments. Set to True to use shell features, such as pipes or redirection
- **env (list)** -- A list of environment variables to be set prior to execution.

Example:

```
salt://scripts/foo.sh:
  cmd.script:
    - env:
      - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that **yes**, **no**, **on**, **off**, **true**, and **false** are all loaded as boolean **True** and **False** values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So `$PATH` in the following example is a literal `$PATH`:

```
salt://scripts/bar.sh:
  cmd.script:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing `$PATH` by using a bit of Jinja:

```
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
```
cmd.run:
- name: ls -l /
- env:
  - PATH: {{ [current_path, '/my/special/bin']|join(':') }}

- **clean_env** *(bool)* -- Attempt to clean out all other shell environment variables and set only those provided in the `env` argument to this function.
- **template** *(str)* -- If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported.
- **rstrip** *(bool)* -- Strip all whitespace off the end of output before it is returned.
- **umask** *(str)* -- The umask (in octal) to use when running the command.
- **output_loglevel** *(str)* -- Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless `quiet` is used for this value.
- **timeout** *(int)* -- A timeout in seconds for the executed process to return.
- **use_vt** *(bool)* -- Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.
- **reset_system_locale** *(bool)* -- Resets the system locale
- **ignore_retcode** *(bool)* -- Ignore the return code
- **saltenv** *(str)* -- The salt environment to use. Default is `base`
- **depth** *(int)* -- The number of levels of contained objects to be included. Default is 2. Values greater than 4 seem to greatly increase the time it takes for the command to complete for some commands. eg: `dir`

New in version 2016.3.4.

**Returns**

dict A dictionary of data returned by the powershell command.

**CLI Example:**

```
salt '*' cmd.powershell "$PSVersionTable.CLRVersion"
```
• **runas** *(str)* -- User to run script as. If running on a Windows minion you must also pass a password.

• **password** *(str)* -- Windows only. Required when specifying runas. This parameter will be ignored on non-Windows platforms.

  New in version 2016.3.0.

• **shell** *(str)* -- Shell to execute under. Defaults to the system default shell.

• **python_shell** *(bool)* -- If False, let python handle the positional arguments. Set to True to use shell features, such as pipes or redirection.

• **env** *(list)* -- A list of environment variables to be set prior to execution.

  Example:

  ```yaml
  salt://scripts/foo.sh:
  cmd.script:
  - env:
    - BATCH: 'yes'
  ```

  **Warning:** The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

  Variables as values are not evaluated. So $PATH in the following example is a literal `PATH`:

  ```yaml
  salt://scripts/bar.sh:
  cmd.script:
  - env: "PATH=/some/path:$PATH"
  ```

  One can still use the existing $PATH by using a bit of Jinja:

  ```bash
  {% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

  mycommand:
  cmd.run:
  - name: ls -l /
  - env:
    - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
  ```

• **clean_env** *(bool)* -- Attempt to clean out all other shell environment variables and set only those provided in the `env` argument to this function.

• **template** *(str)* -- If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported.

• **rstrip** *(bool)* -- Strip all whitespace off the end of output before it is returned.

• **umask** *(str)* -- The umask (in octal) to use when running the command.

• **output_loglevel** *(str)* -- Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.
- **timeout** *(int)* -- A timeout in seconds for the executed process to return.

- **use_vt** *(bool)* -- Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

**Note:** env represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

**Return type**  int

**Return type**  None

**Returns**  Return Code as an int or None if there was an exception.

CLI Example:

```bash
salt '*' cmd.retcode "file /bin/bash"
```

The template arg can be set to ‘jinja’ or another supported template engine to render the command arguments before execution. For example:

```bash
salt '*' cmd.retcode template=jinja "file {{grains.pythonpath[0]}}/python"
```

A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input:

```bash
salt '*' cmd.retcode "grep f" stdin='one
two
three
four
five'
```

salt.modules.cmdmod.run(*cmd*, *cwd=None*, *stdin=None*, *runas=None*, *shell=’/bin/sh’,* python_shell=None,* env=None,* clean_env=False,* template=None,* rstrip=True,* umask=None,* output_loglevel=’debug’,* log_callback=None,* timeout=None,* reset_system_locale=True,* ignore_retcode=False,* saltenv=’base’,* use_vt=False,* bg=False,* password=None,* **kwargs)

Execute the passed command and return the output as a string

Note that env represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

**Parameters**

- **cmd** *(str)* -- The command to run. ex: ls -lart /home

- **cwd** *(str)* -- The current working directory to execute the command in, defaults to /root (C:\ in windows)

- **stdin** *(str)* -- A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input.

- **runas** *(str)* -- User to run script as. If running on a Windows minion you must also pass a password.

- **password** *(str)* -- Windows only. Required when specifying runas. This parameter will be ignored on non-Windows platforms.

  New in version 2016.3.0.

- **shell** *(str)* -- Shell to execute under. Defaults to the system default shell.

- **python_shell** *(bool)* -- If False, let python handle the positional arguments. Set to True to use shell features, such as pipes or redirection.
• **bg (bool)** -- If True, run command in background and do not await or deliver it's results

New in version 2016.3.0.

• **env (list)** -- A list of environment variables to be set prior to execution.

Example:

```yaml
salt://scripts/foo.sh:
  cmd.script:
    - env:
        - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH`:

```yaml
salt://scripts/bar.sh:
  cmd.script:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```python
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

• **clean_env (bool)** -- Attempt to clean out all other shell environment variables and set only those provided in the `env` argument to this function.

• **template (str)** -- If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported.

• **rstrip (bool)** -- Strip all whitespace off the end of output before it is returned.

• **umask (str)** -- The umask (in octal) to use when running the command.

• **output_loglevel (str)** -- Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

• **timeout (int)** -- A timeout in seconds for the executed process to return.

• **use_vt (bool)** -- Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.
**Warning:** This function does not process commands through a shell unless the python_shell flag is set to True. This means that any shell-specific functionality such as `echo` or the use of pipes, redirection or `&&`, should either be migrated to cmd.shell or have the python_shell=True flag set here.

The use of python_shell=True means that the shell will accept _any_ input including potentially malicious commands such as `good_command;rm -rf /`. Be absolutely certain that you have sanitized your input prior to using python_shell=True

**CLI Example:**

```bash
salt '*' cmd.run "ls -l | awk '/foo/{print $2}""
```

The template arg can be set to `jinja` or another supported template engine to render the command arguments before execution. For example:

```bash
salt '*' cmd.run template=jinja "ls -l /tmp/{{grains.id}} | awk '/foo/{print $2}"
```

Specify an alternate shell with the shell parameter:

```bash
salt '*' cmd.run "Get-ChildItem C:\" shell='powershell'
```

A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input:

```bash
salt '*' cmd.run "grep f" stdin='one\ntwo\nthree\nfour\nfive\n'
```

If an equal sign (=) appears in an argument to a Salt command it is interpreted as a keyword argument in the format key=val. That processing can be bypassed in order to pass an equal sign through to the remote shell command by manually specifying the kwarg:

```bash
salt '*' cmd.run cmd='sed -e s/=/:/g'
```

salt.modules.cmdmod.run_all(cmd, cwd=None, stdin=None, runas=None, shell='/bin/sh', python_shell=None, env=None, clean_env=False, template=None, rstrip=True, umask=None, output_loglevel='debug', log_callback=None, timeout=None, reset_system_locale=True, ignore_retcode=False, saltenv='base', use_vt=False, redirect_stderr=False, password=None, **kwargs)

Execute the passed command and return a dict of return data

**Parameters**

- **cmd** *(str)* -- The command to run. ex: `ls -lart /home`
- **cwd** *(str)* -- The current working directory to execute the command in, defaults to /root
- **stdin** *(str)* -- A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input:
- **runas** *(str)* -- User to run script as. If running on a Windows minion you must also pass a password
- **password** *(str)* -- Windows only. Required when specifying runas. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.0.
- **shell** *(str)* -- Shell to execute under. Defaults to the system default shell.

- **python_shell** *(bool)* -- If False, let python handle the positional arguments. Set to True to use shell features, such as pipes or redirection

- **env** *(list)* -- A list of environment variables to be set prior to execution.

  Example:

  ```
salt://scripts/foo.sh:
  cmd.script:
  - env:
    - BATCH: 'yes'
  ```

  **Warning:** The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

  Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH':

  ```
salt://scripts/bar.sh:
  cmd.script:
  - env: "PATH=/some/path:$PATH"
  ```

  One can still use the existing $PATH by using a bit of Jinja:

  ```
  {% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}
  mycommand:
  cmd.run:
  - name: ls -l /
  - env:
    - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
  ```

- **clean_env** *(bool)* -- Attempt to clean out all other shell environment variables and set only those provided in the `env` argument to this function.

- **template** *(str)* -- If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported

- **rstrip** *(bool)* -- Strip all whitespace off the end of output before it is returned.

- **umask** *(str)* -- The umask (in octal) to use when running the command.

- **output_loglevel** *(str)* -- Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

- **timeout** *(int)* -- A timeout in seconds for the executed process to return.

- **use_vt** *(bool)* -- Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.
Note: env represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

Parameters

- **redirect_stderr (bool)** -- If set to True, then stderr will be redirected to stdout. This is helpful for cases where obtaining both the retcode and output is desired, but it is not desired to have the output separated into both stdout and stderr.
  
  New in version 2015.8.2.

- **password (str)** -- Windows only. Required when specifying runas. This parameter will be ignored on non-Windows platforms.
  
  New in version 2016.3.0.

- **bg (bool)** -- If True, run command in background and do not await or deliver it's results
  
  New in version 2016.3.6.

CLI Example:

```bash
salt '*' cmd.run_all "ls -l | awk '/foo/\{print \$2\}""
```

The template arg can be set to `jinja` or another supported template engine to render the command arguments before execution. For example:

```bash
salt '*' cmd.run_all template=jinja "ls -l /tmp/{{grains.id}} | awk '/foo/\{print \$2\}""
```

A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input:

```bash
salt '*' cmd.run_all "grep f" stdin='one
two
three
four
five
'
```

```

salt.modules.cmdmod.run_bg(cmd, cwd=None, runas=None, shell="/bin/sh", python_shell=None, env=None, clean_env=False, template=None, umask=None, timeout=None, output_loglevel='debug', log_callback=None, reset_system_locale=True, ignore_retcode=False, saltenv='base', password=None, **kwargs)
```

Execute the passed command in the background and return it's PID

Note that env represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

Parameters

- **cmd (str)** -- The command to run. ex: `ls -lart /home`

- **cwd (str)** -- The current working directory to execute the command in, defaults to `/root` (`C:` in windows)

- **output_loglevel (str)** -- Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

- **runas (str)** -- User to run script as. If running on a Windows minion you must also pass a password
- **password** *(str)* -- Windows only. Required when specifying `runas`. This parameter will be ignored on non-Windows platforms.

  New in version 2016.3.0.

- **shell** *(str)* -- Shell to execute under. Defaults to the system default shell.

- **python_shell** *(bool)* -- If False, let python handle the positional arguments. Set to True to use shell features, such as pipes or redirection

- **env** *(list)* -- A list of environment variables to be set prior to execution.

  Example:

  ```
salt://scripts/foo.sh:
  cmd.script:
    - env:
      - BATCH: 'yes'
  ```

  **Warning:** The above illustrates a common PyYAML pitfall, that `yes`, `no`, `on`, `off`, `true`, and `false` are all loaded as boolean `True` and `False` values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So `$PATH` in the following example is a literal `$PATH`:

```
salt://scripts/bar.sh:
  cmd.script:
    - env: "PATH=/some/path:$PATH"
```  

One can still use the existing $PATH by using a bit of Jinja:

```
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ current_path, '/my/special/bin'|join(':') }}
```  

- **clean_env** *(bool)* -- Attempt to clean out all other shell environment variables and set only those provided in the `env` argument to this function.

- **template** *(str)* -- If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported

- **umask** *(str)* -- The umask (in octal) to use when running the command.

- **timeout** *(int)* -- A timeout in seconds for the executed process to return.

  **Warning:** This function does not process commands through a shell unless the `python_shell` flag is set to True. This means that any shell-specific functionality such as `echo` or the use of pipes, redirection or `&&`, should either be migrated to `cmd.shell` or have the `python_shell=True` flag set here.
The use of python_shell=True means that the shell will accept _any_ input including potentially malicious commands such as `good_command;rm -rf /'. Be absolutely certain that you have sanitized your input prior to using python_shell=True

CLI Example:
```
salt '*' cmd.run_bg "fstrim-all"
```

The template arg can be set to `jinja` or another supported template engine to render the command arguments before execution. For example:
```
salt '*' cmd.run_bg template=jinja "ls -l /tmp/{{grains.id}} | awk '/foo/ {print $2}"
```

Specify an alternate shell with the shell parameter:
```
salt '*' cmd.run_bg "Get-ChildItem C:\" shell='powershell'
```

If an equal sign (=) appears in an argument to a Salt command it is interpreted as a keyword argument in the format key=val. That processing can be bypassed in order to pass an equal sign through to the remote shell command by manually specifying the kwarg:
```
salt '*' cmd.run_bg cmd='ls -lR / | sed -e s/=/:/g > /tmp/dontwait'
```

salt.modules.cmdmod.run_chroot(root, cmd, cwd=`, stdin=None, runas=None, shell='/bin/sh', python_shell=True, env=None, clean_env=False, template=None, rstrip=True, umask=None, output_loglevel='quiet', log_callback=None, quiet=False, timeout=None, reset_system_locale=True, ignore_retcode=False, saltenv='base', use_vt=False, bg=False, **kwargs)

New in version 2014.7.0.

This function runs cmd.run_all wrapped within a chroot, with dev and proc mounted in the chroot

**root** Path to the root of the jail to use.

**cmd** The command to run. ex: `ls -lart /home`

**cwd** The current working directory to execute the command in, defaults to /root

**stdin** A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input.:  

**runas** User to run script as.

**shell** Shell to execute under. Defaults to the system default shell.

**python_shell** If False, let python handle the positional arguments. Set to True to use shell features, such as pipes or redirection

**env**

A list of environment variables to be set prior to execution. Example:
```
salt://scripts/foo.sh:
  cmd.script:
    - env:
      - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in
quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH':

```
salt://scripts/bar.sh:
  cmd.script:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}
mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

clean_env: Attempt to clean out all other shell environment variables and set only those provided in the `env' argument to this function.

template If this setting is applied then the named templating engine will be used to render the downloaded file. Currently Jinja, mako, and Wempy are supported.

rstrip Strip all whitespace off the end of output before it is returned.

umask The umask (in octal) to use when running the command.

output_loglevel Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

timeout A timeout in seconds for the executed process to return.

use_vt Use VT utils (saltstack) to stream the command output more interactively to the console and the logs.

This is experimental.

CLI Example:

```
salt '*' cmd.run_chroot /var/lib/lxc/container_name/rootfs 'sh /tmp/bootstrap.sh'
```

```
salt.modules.cmdmod.run_stdout(cmd, cwd=None, stdin=None, runas=None, shell='/bin/sh',
  python_shell=None, env=None, clean_env=False, template=None, rstrip=True, umask=None, output_loglevel='debug',
  log_callback=None, timeout=None, reset_system_locale=True, ignore_retcode=False, saltenv='base', use_vt=False, password=None,
  **kwargs)
```

Execute a command and only return the standard error.

Parameters

- cmd (str) -- The command to run. ex: `ls -lart /home'
- cwd (str) -- The current working directory to execute the command in, defaults to /root
- stdin (str) -- A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input.
- runas (str) -- User to run script as. If running on a Windows minion you must also pass a password
- **password** *(str)* -- Windows only. Required when specifying `runas`. This parameter will be ignored on non-Windows platforms.

  New in version 2016.3.0.

- **shell** *(str)* -- Shell to execute under. Defaults to the system default shell.

- **python_shell** *(bool)* -- If False, let python handle the positional arguments. Set to True to use shell features, such as pipes or redirection.

- **env** *(list)* -- A list of environment variables to be set prior to execution.

  Example:

  ```
  salt://scripts/foo.sh:
  cmd.script:
  - env:
    - BATCH: 'yes'
  ```

  **Warning:** The above illustrates a common PyYAML pitfall, that `yes`, `no`, `on`, `off`, `true`, and `false` are all loaded as boolean `True` and `False` values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

  Variables as values are not evaluated. So `$PATH` in the following example is a literal `'$PATH'`:

  ```
  salt://scripts/bar.sh:
  cmd.script:
  - env: "PATH=/some/path:$PATH"
  ```

  One can still use the existing `$PATH` by using a bit of Jinja:

  ```
  {% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}
  
  mycommand:
  cmd.run:
  - name: ls -l /
  - env:
    - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
  ```

- **clean_env** *(bool)* -- Attempt to clean out all other shell environment variables and set only those provided in the `env` argument to this function.

- **template** *(str)* -- If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported.

- **rstrip** *(bool)* -- Strip all whitespace off the end of output before it is returned.

- **umask** *(str)* -- The umask (in octal) to use when running the command.

- **output_loglevel** *(str)* -- Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless `quiet` is used for this value.

- **timeout** *(int)* -- A timeout in seconds for the executed process to return.
- **use_vt**(bool) -- Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

**Note:** env represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

**CLI Example:**

```
salt '*' cmd.run_stderr "ls -l | awk '/foo/{print $2}""
```

The template arg can be set to `jinja` or another supported template engine to render the command arguments before execution. For example:

```
salt '*' cmd.run_stderr template=jinja "ls -l /tmp/{{grains.id}} | awk '/foo/ \{print $2}\""
```

A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input:

```
salt '*' cmd.run_stderr "grep f stdin='one
two
three
four
five'"
```

salt.modules.cmdmod.run_stdout(cmd, cwd=None, stdin=None, runas=None, password=None, shell=None, python_shell=None, env=None, clean_env=False, template=None, rstrip=True, umask=None, output_loglevel='debug', log_callback=None, timeout=None, reset_system_locale=True, ignore_retcode=False, saltenv='base', use_vt=False, **kwargs)

Execute a command, and only return the standard out

**Parameters**

- **cmd**(str) -- The command to run. ex: `ls -lart /home`
- **cwd**(str) -- The current working directory to execute the command in, defaults to /root
- **stdin**(str) -- A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input:
- **runas**(str) -- User to run script as. If running on a Windows minion you must also pass a password
- **password**(str) -- Windows only. Required when specifying runas. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.0.

- **shell**(str) -- Shell to execute under. Defaults to the system default shell.
- **python_shell**(bool) -- If False, let python handle the positional arguments. Set to True to use shell features, such as pipes or redirection
- **env**(list) -- A list of environment variables to be set prior to execution.

Example:

```
salt://scripts/foo.sh:
  cmd.script:
    - env:
      - BATCH: 'yes'
```
Warning: The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH`:

```
salt://scripts/bar.sh:
  cmd.script:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}
mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

- **clean_env (bool)** -- Attempt to clean out all other shell environment variables and set only those provided in the `env` argument to this function.
- **template (str)** -- If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported
- **rstrip (bool)** -- Strip all whitespace off the end of output before it is returned.
- **umask (str)** -- The umask (in octal) to use when running the command.
- **output_loglevel (str)** -- Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.
- **timeout (int)** -- A timeout in seconds for the executed process to return.
- **use_vt (bool)** -- Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

Note: env represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

CLI Example:

```
salt '*' cmd.run_stdout "ls -l | awk '/foo/{print \$2}"
```

The template arg can be set to `jinja` or another supported template engine to render the command arguments before execution. For example:

```
salt '*' cmd.run_stdout template=jinja "ls -l /tmp/\{grains.id\} | awk '/foo/ \{print \$2\}"
```
A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input:

```
salt '*' cmd.run_stdout "grep f" stdin='one\ntwo\nthree\nfour\nfive\n'
```

```
salt.modules.cmdmod.script(source, args=None, cwd=None, stdin=None, runas=None, shell='/bin/sh', python_shell=None, env=None, template=None, umask=None, output_loglevel='debug', log_callback=None, quiet=False, timeout=None, reset_system_locale=True, __env__=None, saltenv='base', use_vt=False, bg=False, password=None, **kwargs)
```

Download a script from a remote location and execute the script locally. The script can be located on the salt master file server or on an HTTP/FTP server.

The script will be executed directly, so it can be written in any available programming language.

**Parameters**

- **source (str)** -- The location of the script to download. If the file is located on the master in the directory named spam, and is called eggs, the source string is `salt://spam/eggs`
- **args (str)** -- String of command line args to pass to the script. Only used if no args are specified as part of the `name` argument. To pass a string containing spaces in YAML, you will need to doubly-quote it: `arg1 'arg two' arg3`
- **cwd (str)** -- The current working directory to execute the command in, defaults to `/root`
- **stdin (str)** -- A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input.
- **runas (str)** -- User to run script as. If running on a Windows minion you must also pass a password
- **password (str)** -- Windows only. Required when specifying `runas`. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.0.

- **shell (str)** -- Shell to execute under. Defaults to the system default shell.
- **python_shell (bool)** -- If False, let python handle the positional arguments. Set to True to use shell features, such as pipes or redirection
- **bg (bool)** -- If True, run script in background and do not await or deliver it's results
- **env (list)** -- A list of environment variables to be set prior to execution.

Example:

```
salt://scripts/foo.sh:
  cmd.script:
    - env:
      - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that `yes`, `no`, `on`, `off`, `true`, and `false` are all loaded as boolean `True` and `False` values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).
Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH':

```
salt://scripts/bar.sh:
  cmd.script:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}
mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ current_path, '/my/special/bin'|join(':' ) }}
```

- **template**(str) -- If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported

- **umask**(str) -- The umask (in octal) to use when running the command.

- **output_loglevel**(str) -- Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

- **quiet**(bool) -- The command will be executed quietly, meaning no log entries of the actual command or its return data. This is deprecated as of the 2014.1.0 release, and is being replaced with output_loglevel: quiet.

- **timeout**(int) -- If the command has not terminated after timeout seconds, send the subprocess sigterm, and if sigterm is ignored, follow up with sigkill

- **use_vt**(bool) -- Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

CLI Example:

```
salt '*' cmd.script salt://scripts/runme.sh
salt '*' cmd.script salt://scripts/runme.sh 'arg1 arg2 "arg 3"'
salt '*' cmd.script salt://scripts/windows_task.ps1 args=' -Input c:\tmp\infile.
  -txt' shell='powershell'
salt '*' cmd.script salt://scripts/runme.sh stdin='one
two
three
four
five
'
```

```
salt.modules.cmdmod.script_retcode(source, args=None, cwd=None, stdin=None, runas=None, shell='/bin/sh', python_shell=None, env=None, template='jinja', umask=None, timeout=None, reset_system_locale=True, __env__=None, saltenv='base', output_loglevel='debug', log_callback=None, use_vt=False, password=None, **kwargs)
```

Download a script from a remote location and execute the script locally. The script can be located on the salt master file server or on an HTTP/FTP server.

The script will be executed directly, so it can be written in any available programming language.

The script can also be formatted as a template, the default is jinja.

Only evaluate the script return code and do not block for terminal output
Parameters

- **source (str)** -- The location of the script to download. If the file is located on the master in the directory named spam, and is called eggs, the source string is `salt://spam/eggs`

- **args (str)** -- String of command line args to pass to the script. Only used if no args are specified as part of the `name` argument. To pass a string containing spaces in YAML, you will need to doubly-quote it: `"arg1 'arg two' arg3"

- **cwd (str)** -- The current working directory to execute the command in, defaults to `/root`

- **stdin (str)** -- A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input.

- **runas (str)** -- User to run script as. If running on a Windows minion you must also pass a password

- **password (str)** -- Windows only. Required when specifying `runas`. This parameter will be ignored on non-Windows platforms.

  New in version 2016.3.0.

- **shell (str)** -- Shell to execute under. Defaults to the system default shell.

- **python_shell (bool)** -- If False, let python handle the positional arguments. Set to True to use shell features, such as pipes or redirection.

- **env (list)** -- A list of environment variables to be set prior to execution.

  Example:

  ```yaml
  salt://scripts/foo.sh:
  cmd.script:
    - env:
      - BATCH: 'yes'
  ```

  **Warning:** The above illustrates a common PyYAML pitfall, that `yes`, `no`, `on`, `off`, `true`, and `false` are all loaded as boolean `True` and `False` values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](https://docs.python.org/3/library/yaml.html).

  Variables as values are not evaluated. So `$PATH` in the following example is a literal `"$PATH"`:

  ```yaml
  salt://scripts/bar.sh:
  cmd.script:
    - env: "PATH=/some/path:$PATH"
  ```

  One can still use the existing `$PATH` by using a bit of Jinja:

  ```jinja
  {% set current_path = salt['environ.get']('PATH', '/bin:!/usr/bin') %}
  mycommand:
    cmd.run:
      - name: ls -l /
  ```
- env:
  - PATH: {{ [current_path, '/my/special/bin']|join(':') }}

- **template**(str) -- If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported

- **umask**(str) -- The umask (in octal) to use when running the command.

- **output_loglevel**(str) -- Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

- **quiet**(bool) -- The command will be executed quietly, meaning no log entries of the actual command or its return data. This is deprecated as of the 2014.1.0 release, and is being replaced with output_loglevel: quiet.

- **timeout**(int) -- If the command has not terminated after timeout seconds, send the subprocess sigterm, and if sigterm is ignored, follow up with sigkill

- **use_vt**(bool) -- Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

CLI Example:

```
salt '*' cmd.script_retcode salt://scripts/runme.sh
salt '*' cmd.script_retcode salt://scripts/runme.sh 'arg1 arg2 "arg 3"'
salt '*' cmd.script_retcode salt://scripts/windows_task.ps1 args=' -Input c: \tmp\infile.txt! shell='powershell'
```

A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input:

```
salt '*' cmd.script_retcode salt://scripts/runme.sh stdin=
-\'one\ntwo\nthree\nfour\nfive\n\'
```

salt.modules.cmdmod.shell(cmd, cwd=None, stdin=None, runas=None, shell='/bin/sh', env=None, clean_env=False, template=None, rstrip=True, umask=None, output_loglevel='debug', log_callback=None, quiet=False, timeout=None, reset_system_locale=True, ignore_retcode=False, saltenv='base', use_vt=False, bg=False, password=None, **kwargs)

Execute the passed command and return the output as a string.

**Parameters**

- **cmd**(str) -- The command to run. ex: `ls -lart /home`

- **cwd**(str) -- The current working directory to execute the command in, defaults to /root

- **stdin**(str) -- A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input.

- **runas**(str) -- User to run script as. If running on a Windows minion you must also pass a password

- **password**(str) -- Windows only. Required when specifying runas. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.0.
- **shell** *(int)* -- Shell to execute under. Defaults to the system default shell.
- **bg** *(bool)* -- If True, run command in background and do not await or deliver its results.
- **env** *(list)* -- A list of environment variables to be set prior to execution.

Example:

```
salt://scripts/foo.sh:
  cmd.script:
    - env:
      - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that `yes`, `no`, `on`, `off`, `true`, and `false` are all loaded as boolean `True` and `False` values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So `$PATH` in the following example is a literal `$PATH`:

```
salt://scripts/bar.sh:
  cmd.script:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing `$PATH` by using a bit of Jinja:

```
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ current_path, '/my/special/bin'|join(':') }}
```

- **clean_env** *(bool)* -- Attempt to clean out all other shell environment variables and set only those provided in the `env` argument to this function.
- **template** *(str)* -- If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported.
- **rstrip** *(bool)* -- Strip all whitespace off the end of output before it is returned.
- **umask** *(str)* -- The umask (in octal) to use when running the command.
- **output_loglevel** *(str)* -- Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DE-BUG) regardless, unless `quiet` is used for this value.
- **timeout** *(int)* -- A timeout in seconds for the executed process to return.
- **use_vt** *(bool)* -- Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.
Warning: This passes the cmd argument directly to the shell without any further processing! Be absolutely sure that you have properly sanitized the command passed to this function and do not use untrusted inputs.

Note: env represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

CLI Example:

```
salt '*' cmd.shell "ls -l | awk '/foo/{print $2}"
```

The template arg can be set to 'jinja' or another supported template engine to render the command arguments before execution. For example:

```
salt '*' cmd.shell template=jinja "ls -l /tmp/{{grains.id}} | awk '/foo/{print \$2}""
```

Specify an alternate shell with the shell parameter:

```
salt '*' cmd.shell "Get-ChildItem C:\" shell='powershell'
```

A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input:

```
salt '*' cmd.shell "grep f" stdin='one	wo
three
four
five
'
```

If an equal sign (=) appears in an argument to a Salt command it is interpreted as a keyword argument in the format key=val. That processing can be bypassed in order to pass an equal sign through to the remote shell command by manually specifying the kwarg:

```
salt '*' cmd.shell cmd='sed -e s/=/:/g'
```

salt.modules.cmdmod.shells()
Lists the valid shells on this system via the /etc/shells file

New in version 2015.5.0.

CLI Example:

```
salt '*' cmd.shells
```

salt.modules.cmdmod.tty(device, echo=None)
Echo a string to a specific tty

CLI Example:

```
salt '*' cmd.tty tty0 'This is a test'
salt '*' cmd.tty pts3 'This is a test'
```

salt.modules.cmdmod.which(cmd)
Returns the path of an executable available on the minion, None otherwise

CLI Example:

```
salt '*' cmd.which cat
```
salt.modules.cmdmod.which_bin(cmds)

Returns the first command found in a list of commands

CLI Example:

```
salt '*' cmd.which_bin '[pip2, pip, pip-python]'```

13.6.49 salt.modules.composer

Use composer to install PHP dependencies for a directory

salt.modules.composer.did_composer_install(dir)

Test to see if the vendor directory exists in this directory

dir Directory location of the composer.json file

CLI Example:

```
salt '*' composer.did_composer_install /var/www/application```

salt.modules.composer.install(directory, composer=None, php=None, runas=None, prefer_source=None, prefer_dist=None, no_scripts=None, no_plugins=None, optimize=None, no_dev=None, quiet=False, composer_home='/root')

Install composer dependencies for a directory.

If composer has not been installed globally making it available in the system PATH & making it executable, the composer and php parameters will need to be set to the location of the executables.

directory Directory location of the composer.json file.
composer Location of the composer.phar file. If not set composer will just execute `composer` as if it is installed globally. (i.e. /path/to/composer.phar)
php Location of the php executable to use with composer. (i.e. /usr/bin/php)
runas Which system user to run composer as.
prefer_source --prefer-source option of composer.
prefer_dist --prefer-dist option of composer.
no_scripts --no-scripts option of composer.
no_plugins --no-plugins option of composer.
optimize --optimize-autoloader option of composer. Recommended for production.
no_dev --no-dev option for composer. Recommended for production.
quiet --quiet option for composer. Whether or not to return output from composer.
composer_home $COMPOSER_HOME environment variable

CLI Example:

```
salt '*' composer.install /var/www/application
salt '*' composer.install /var/www/application no_dev=True optimize=True```

salt.modules.composer.selfupdate(composer=None, php=None, runas=None, quiet=False, composer_home='/root')

Update composer itself.

If composer has not been installed globally making it available in the system PATH & making it executable, the composer and php parameters will need to be set to the location of the executables.

composer Location of the composer.phar file. If not set composer will just execute `composer` as if it is installed globally. (i.e. /path/to/composer.phar)
php Location of the php executable to use with composer. (i.e. /usr/bin/php)
runas Which system user to run composer as.
quiet --quiet option for composer. Whether or not to return output from composer.
**composer_home**  $COMPOSER_HOME environment variable

CLI Example:

```bash
salt '*' composer.selfupdate
```

**salt.modules.composer.update**(directory, composer=None, php=None, runas=None, prefer_source=None, prefer_dist=None, no_scripts=None, no_plugins=None, optimize=None, no_dev=None, quiet=False, composer_home='/root')

Update composer dependencies for a directory.

If composer install has not yet been run, this runs composer install instead.

If composer has not been installed globally making it available in the system PATH & making it executable, the composer and php parameters will need to be set to the location of the executables.

directory  Directory location of the composer.json file.

composer  Location of the composer.phar file. If not set composer will just execute `composer` as if it is installed globally. (i.e. /path/to/composer.phar)

php  Location of the php executable to use with composer. (i.e. /usr/bin/php)

runas  Which system user to run composer as.

prefer_source  --prefer-source option of composer.

prefer_dist  --prefer-dist option of composer.

no_scripts  --no-scripts option of composer.

no_plugins  --no-plugins option of composer.

optimize  --optimize-autoloader option of composer. Recommended for production.

no_dev  --no-dev option for composer. Recommended for production.

quiet  --quiet option for composer. Whether or not to return output from composer.

**composer_home**  $COMPOSER_HOME environment variable

CLI Example:

```bash
salt '*' composer.update /var/www/application
salt '*' composer.update /var/www/application no_dev=True optimize=True
```

### 13.6.50  salt.modules.config

Return config information

**salt.modules.config.backup_mode**(backup='')

Return the backup mode

CLI Example:

```bash
salt '*' config.backup_mode
```

**salt.modules.config.dot_vals**(value)

Pass in a configuration value that should be preceded by the module name and a dot, this will return a list of all read key/value pairs

CLI Example:

```bash
salt '*' config.dot_vals host
```

**salt.modules.config.gather_bootstrap_script**(bootstrap=None)

Download the salt-bootstrap script, and return its location

bootstrap  URL of alternate bootstrap script
CLI Example:

```
salt '*' config.gather_bootstrap_script
```

```python
salt.modules.config.get(key, default='`, delimiter=':', merge=None)
```

Attempt to retrieve the named value from the minion config file, pillar, grains or the master config. If the named value is not available, return the value specified by `default`. If not specified, the default is an empty string.

Values can also be retrieved from nested dictionaries. Assume the below data structure:

```python
{'pkg': {'apache': 'httpd'}}
```

To retrieve the value associated with the `apache` key, in the sub-dictionary corresponding to the `pkg` key, the following command can be used:

```
salt myminion config.get pkg:apache
```

The `:` (colon) is used to represent a nested dictionary level.

Changed in version 2015.5.0: The `delimiter` argument was added, to allow delimiters other than `:` to be used.

This function traverses these data stores in this order, returning the first match found:

- Minion configuration
- Minion's grains
- Minion's pillar data
- Master configuration (requires `pillar_opts` to be set to `True` in Minion config file in order to work)

This means that if there is a value that is going to be the same for the majority of minions, it can be configured in the Master config file, and then overridden using the grains, pillar, or Minion config file.

Adding config options to the Master or Minion configuration file is easy:

```python
my-config-option: value
cafe-menu:
  - egg and bacon
  - egg sausage and bacon
  - egg and spam
  - egg bacon and spam
  - egg bacon sausage and spam
  - spam bacon sausage and spam
  - spam egg spam spam bacon and spam
  - spam sausage spam spam bacon spam tomato and spam
```

**Note:** Minion configuration options built into Salt (like those defined here) will always be defined in the Minion configuration and thus cannot be overridden by grains or pillar data. However, additional (user-defined) configuration options (as in the above example) will not be in the Minion configuration by default and thus can be overridden using grains/pillar data by leaving the option out of the minion config file.

**Arguments**

- `delimiter` New in version 2015.5.0.
  
  Override the delimiter used to separate nested levels of a data structure.

- `merge` New in version 2015.5.0.
  
  If passed, this parameter will change the behavior of the function so that, instead of traversing each data store above in order and returning the first match, the data stores are first merged together and then...
searched. The pillar data is merged into the master config data, then the grains are merged, followed by the Minion config data. The resulting data structure is then searched for a match. This allows for configurations to be more flexible.

**Note:** The merging described above does not mean that grain data will end up in the Minion’s pillar data, or pillar data will end up in the master config data, etc. The data is just combined for the purposes of searching an amalgam of the different data stores.

The supported merge strategies are as follows:

- **recurse** - If a key exists in both dictionaries, and the new value is not a dictionary, it is replaced. Otherwise, the sub-dictionaries are merged together into a single dictionary, recursively on down, following the same criteria. For example:

```python
>>> dict1 = {'foo': {'bar': 1, 'qux': True},
            'hosts': ['a', 'b', 'c'],
            'only_x': None}
>>> dict2 = {'foo': {'baz': 2, 'qux': False},
            'hosts': ['d', 'e', 'f'],
            'only_y': None}
>>> merged = {'foo': {'bar': 1, 'baz': 2, 'qux': False},
              'hosts': ['d', 'e', 'f'],
              'only_dict1': None,
              'only_dict2': None}
```

- **overwrite** - If a key exists in the top level of both dictionaries, the new value completely overwrites the old. For example:

```python
>>> dict1 = {'foo': {'bar': 1, 'qux': True},
            'hosts': ['a', 'b', 'c'],
            'only_x': None}
>>> dict2 = {'foo': {'baz': 2, 'qux': False},
            'hosts': ['d', 'e', 'f'],
            'only_y': None}
>>> merged = {'foo': {'baz': 2, 'qux': False},
              'hosts': ['d', 'e', 'f'],
              'only_dict1': None,
              'only_dict2': None}
```

CLI Example:

```
salt '*' config.get pkg:apache
salt '*' config.get lxc.container_profile:centos merge=recurse
```

**salt.modules.config.manage_mode**(mode)

Return a mode value, normalized to a string

CLI Example:

```
salt '*' config.manage_mode
```

**salt.modules.config.merge**(value, default='', omit_opts=False, omit_master=False, omit_pillar=False)

Retrieves an option based on key, merging all matches. Same as option() except that it merges all matches, rather than taking the first match.
CLI Example:

```
salt '*' config.merge schedule
```

```python
salt.modules.config.option(value, default='`, omit_opts=False, omit_master=False, omit_pillar=False)
```
Pass in a generic option and receive the value that will be assigned

CLI Example:

```
salt '*' config.option redis.host
```

```python
salt.modules.config.valid_fileproto(uri)
```
Returns a boolean value based on whether or not the URI passed has a valid remote file protocol designation

CLI Example:

```
salt '*' config.valid_fileproto salt://path/to/file
```

### 13.6.51 `salt.modules.consul`

Interact with Consul

https://www.consul.io

```python
salt.modules.consul.acl_clone(consul_url=None, **kwargs)
```
Information about an ACL token.

**Parameters**

- `consul_url` -- The Consul server URL.
- `id` -- Unique identifier for the ACL to update.

**Returns**

Boolean, message of success or failure, and new ID of cloned ACL.

CLI Example:

```
salt '*' consul.acl_info id='c1c4d223-91cb-3d1f-1ee8-f2af9e7b6716'
```

```python
salt.modules.consul.acl_create(consul_url=None, **kwargs)
```
Create a new ACL token.

**Parameters**

- `consul_url` -- The Consul server URL.
- `name` -- Meaningful indicator of the ACL's purpose.
- `type` -- Type is either client or management. A management token is comparable to a root user and has the ability to perform any action including creating, modifying, and deleting ACLs.
- `rules` -- The Consul server URL.

**Returns**

Boolean & message of success or failure.

CLI Example:

```
salt '*' consul.acl_create
```

```python
salt.modules.consul.acl_delete(consul_url=None, **kwargs)
```
Delete an ACL token.

**Parameters**

13.6. execution modules
- **`consul_url`** -- The Consul server URL.
- **`id`** -- Unique identifier for the ACL to update.

**Returns** Boolean & message of success or failure.

CLI Example:
```
salt '*' consul.acl_delete id='c1c4d223-91cb-3d1f-1ee8-f2af9e7b6716'
```

```python
salt.modules.consul.acl_info(consul_url=None, **kwargs)
```
Information about an ACL token.

**Parameters**
- **`consul_url`** -- The Consul server URL.
- **`id`** -- Unique identifier for the ACL to update.

**Returns** Information about the ACL requested.

CLI Example:
```
salt '*' consul.acl_info id='c1c4d223-91cb-3d1f-1ee8-f2af9e7b6716'
```

```python
salt.modules.consul.acl_list(consul_url=None, **kwargs)
```
List the ACL tokens.

**Parameters** **`consul_url`** -- The Consul server URL.

**Returns** List of ACLs

CLI Example:
```
salt '*' consul.acl_list
```

```python
salt.modules.consul.acl_update(consul_url=None, **kwargs)
```
Update an ACL token.

**Parameters**
- **`consul_url`** -- The Consul server URL.
- **`name`** -- Meaningful indicator of the ACL's purpose.
- **`id`** -- Unique identifier for the ACL to update.
- **`type`** -- Type is either client or management. A management token is comparable to a root user and has the ability to perform any action including creating, modifying, and deleting ACLs.
- **`rules`** -- The Consul server URL.

**Returns** Boolean & message of success or failure.

CLI Example:
```
salt '*' consul.acl_update
```

```python
salt.modules.consul.agent_check_deregister(consul_url=None, checkid=None)
```
The agent will take care of deregistering the check from the Catalog.

**Parameters**
- **`consul_url`** -- The Consul server URL.
- **`checkid`** -- The ID of the check to deregister from Consul.

**Returns** Boolean and message indicating success or failure.

CLI Example:
salt '*' consul.agent_check_deregister checkid='Memory Utilization'

salt.modules.consul.agent_check_fail(consul_url=None, checkid=None, **kwargs)
This endpoint is used with a check that is of the TTL type. When this is called, the status of the check is set to critical and the TTL clock is reset.

Parameters
- consul_url -- The Consul server URL.
- checkid -- The ID of the check to deregister from Consul.
- note -- A human-readable message with the status of the check.

Returns Boolean and message indicating success or failure.

CLI Example:
salt '*' consul.agent_check_fail checkid='redis_check1'
    note='Forcing check into critical state.'

salt.modules.consul.agent_check_pass(consul_url=None, checkid=None, **kwargs)
This endpoint is used with a check that is of the TTL type. When this is called, the status of the check is set to passing and the TTL clock is reset.

Parameters
- consul_url -- The Consul server URL.
- checkid -- The ID of the check to mark as passing.
- note -- A human-readable message with the status of the check.

Returns Boolean and message indicating success or failure.

CLI Example:
salt '*' consul.agent_check_pass checkid='redis_check1'
    note='Forcing check into passing state.'

salt.modules.consul.agent_check_register(consul_url=None, **kwargs)
The register endpoint is used to add a new check to the local agent.

Parameters
- consul_url -- The Consul server URL.
- name -- The description of what the check is for.
- id -- The unique name to use for the check, if not provided `name` is used.
- notes -- Human readable description of the check.
- script -- If script is provided, the check type is a script, and Consul will evaluate that script based on the interval parameter.
- http -- Check will perform an HTTP GET request against the value of HTTP (expected to be a URL) based on the interval parameter.
- ttl -- If a TTL type is used, then the TTL update endpoint must be used periodically to update the state of the check.
- interval -- Interval at which the check should run.

Returns Boolean and message indicating success or failure.

CLI Example:
```
salt '*' consul.agent_check_register name='Memory Utilization'
    script='/usr/local/bin/check_mem.py' interval='15s'
```

salt.modules.consul.agent_check_warn(consul_url=None, checkid=None, **kwargs)

This endpoint is used with a check that is of the TTL type. When this is called, the status of the check is set to warning and the TTL clock is reset.

**Parameters**
- **consul_url** -- The Consul server URL.
- **checkid** -- The ID of the check to deregister from Consul.
- **note** -- A human-readable message with the status of the check.

**Returns**
Boolean and message indicating success or failure.

**CLI Example:**
```
salt '*' consul.agent_check_warn checkid='redis_check1'
    note='Forcing check into warning state.'
```

salt.modules.consul.agent_checks(consul_url=None)

Returns the checks the local agent is managing

**Parameters**
- **consul_url** -- The Consul server URL.

**Returns**
Returns the checks the local agent is managing

**CLI Example:**
```
salt '*' consul.agent_checks
```

salt.modules.consul.agent_join(consul_url=None, address=None, **kwargs)

Triggers the local agent to join a node

**Parameters**
- **consul_url** -- The Consul server URL.
- **address** -- The address for the agent to connect to.
- **wan** -- Causes the agent to attempt to join using the WAN pool.

**Returns**
Boolean and message indicating success or failure.

**CLI Example:**
```
salt '*' consul.agent_join address='192.168.1.1'
```

salt.modules.consul.agent_leave(consul_url=None, node=None)

Used to instruct the agent to force a node into the left state.

**Parameters**
- **consul_url** -- The Consul server URL.
- **node** -- The node the agent will force into left state

**Returns**
Boolean and message indicating success or failure.

**CLI Example:**
```
salt '*' consul.agent_leave node='web1.example.com'
```

salt.modules.consul.agent_maintenance(consul_url=None, **kwargs)

Manages node maintenance mode

**Parameters**
- **consul_url** -- The Consul server URL.
- **enable** -- The enable flag is required. Acceptable values are either true (to enter maintenance mode) or false (to resume normal operation).
- **reason** -- If provided, its value should be a text string explaining the reason for placing the node into maintenance mode.

**Returns**
Boolean and message indicating success or failure.

**CLI Example:**
```
salt '*' consul.agent_maintenance enable='False' reason='Upgrade in progress'
```

salt.modules.consul.agent_members(consul_url=None, **kwargs)
Returns the members as seen by the local serf agent

**Parameters**  
- **consul_url** -- The Consul server URL.

**Returns**
Returns the members as seen by the local serf agent

**CLI Example:**
```
salt '*' consul.agent_members
```

salt.modules.consul.agent_self(consul_url=None)
Returns the local node configuration

**Parameters**  
- **consul_url** -- The Consul server URL.

**Returns**
Returns the local node configuration

**CLI Example:**
```
salt '*' consul.agent_self
```

salt.modules.consul.agent_service_deregister(consul_url=None, serviceid=None)
Used to remove a service.

**Parameters**  
- **consul_url** -- The Consul server URL.
- **serviceid** -- A serviceid describing the service.

**Returns**
Boolean and message indicating success or failure.

**CLI Example:**
```
salt '*' consul.agent_service_deregister serviceid='redis'
```

salt.modules.consul.agent_service_maintenance(consul_url=None, serviceid=None, **kwargs)
Used to place a service into maintenance mode.

**Parameters**  
- **consul_url** -- The Consul server URL.
- **serviceid** -- A name of the service.
- **enable** -- Whether the service should be enabled or disabled.
- **reason** -- A human readable message of why the service was enabled or disabled.

**Returns**
Boolean and message indicating success or failure.

**CLI Example:**
```
salt '*' consul.agent_service_deregister serviceid='redis'  
    enable='True' reason='Down for upgrade'
```
salt.modules.consul.agent_service_register(consul_url=None, **kwargs)

The used to add a new service, with an optional health check, to the local agent.

Parameters

- `consul_url` -- The Consul server URL.
- `name` -- A name describing the service.
- `address` -- The address used by the service, defaults to the address of the agent.
- `port` -- The port used by the service.
- `id` -- Unique ID to identify the service, if not provided the value of the name parameter is used.
- `tags` -- Identifying tags for service, string or list.
- `script` -- If script is provided, the check type is a script, and Consul will evaluate that script based on the interval parameter.
- `http` -- Check will perform an HTTP GET request against the value of HTTP (expected to be a URL) based on the interval parameter.
- `check_ttl` -- If a TTL type is used, then the TTL update endpoint must be used periodically to update the state of the check.
- `check_interval` -- Interval at which the check should run.

Returns  Boolean and message indicating success or failure.

CLI Example:

```
salt '*' consul.agent_service_register name='redis'
  tags='["master", "v1"]' address='127.0.0.1' port='8080'
  check_script='"/usr/local/bin/check_redis.py" interval='10s"
```

salt.modules.consul.agent_services(consul_url=None)

Returns the services the local agent is managing

Parameters  consul_url -- The Consul server URL.

Returns  Returns the services the local agent is managing

CLI Example:

```
salt '*' consul.agent_services
```

salt.modules.consul.catalog_datacenters(consul_url=None)

Return list of available datacenters from catalog.

Parameters  consul_url -- The Consul server URL.

Returns  The list of available datacenters.

CLI Example:

```
salt '*' consul.catalog_datacenters
```

salt.modules.consul.catalog_deregister(consul_url=None, **kwargs)

Deregisters a node, service, or check

Parameters

- `consul_url` -- The Consul server URL.
- `node` -- The node to deregister.
- `datacenter` -- By default, the datacenter of the agent is queried; however, the dc can be provided using the ``dc`` parameter.
- `checkid` -- The ID of the health check to deregister.
- `serviceid` -- The ID of the service to deregister.

**Returns** Boolean & message of success or failure.

CLI Example:
```
salt '*' consul.catalog_register node='node1' serviceid='redis_server1' checkid='redis_check1'
```

salt.modules.consul.catalog_node (consul_url=None, node=None, **kwargs)

Information about the registered node.

**Parameters**
- `consul_url` -- The Consul server URL.
- `node` -- The node to request information about.
- `dc` -- By default, the datacenter of the agent is queried; however, the `dc` can be provided using the ``dc`` parameter.

**Returns** Information about the requested node.

CLI Example:
```
salt '*' consul.catalog_service service='redis'
```

salt.modules.consul.catalog_nodes (consul_url=None, **kwargs)

Return list of available nodes from catalog.

**Parameters**
- `consul_url` -- The Consul server URL.
- `dc` -- By default, the datacenter of the agent is queried; however, the `dc` can be provided using the ``dc`` parameter.

**Returns** The list of available nodes.

CLI Example:
```
salt '*' consul.catalog_nodes
```

salt.modules.consul.catalog_register (consul_url=None, **kwargs)

Registers a new node, service, or check.

**Parameters**
- `consul_url` -- The Consul server URL.
- `dc` -- By default, the datacenter of the agent is queried; however, the `dc` can be provided using the ``dc`` parameter.
- `node` -- The node to register.
- `address` -- The address of the node.
- `service` -- The service that will be registered.
- `service_address` -- The address that the service listens on.
- `service_port` -- The port for the service.
- `service_id` -- A unique identifier for the service, if this is not provided ``name`` will be used.
- `service_tags` -- Any tags associated with the service.
- **check** -- The name of the health check to register
- **check_status** -- The initial status of the check, must be one of unknown, passing, warning, or critical.
- **check_service** -- The service that the check is performed against.
- **check_id** -- Unique identifier for the service.
- **check_notes** -- An opaque field that is meant to hold human-readable text.

**Returns**  Boolean & message of success or failure.

**CLI Example:**
```
salt '*' consul.catalog_register node='node1' address='192.168.1.1'
    service='redis' service_address='127.0.0.1' service_port='8080'
    service_id='redis_server1'
```

```python
salt.modules.consul.catalog_service(consul_url=None, service=None, **kwargs)
```
Information about the registered service.

**Parameters**
- **consul_url** -- The Consul server URL.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the ``dc`` parameter.
- **tag** -- Filter returned services with tag parameter.

**Returns**  Information about the requested service.

**CLI Example:**
```
salt '*' consul.catalog_service service='redis'
```

```python
salt.modules.consul.catalog_services(consul_url=None, **kwargs)
```
Return list of available services rom catalog.

**Parameters**
- **consul_url** -- The Consul server URL.

**Returns**  The list of available services.

**CLI Example:**
```
salt '*' consul.catalog_services
```

```python
salt.modules.consul.delete(consul_url=None, key=None, **kwargs)
```
Delete values from Consul

**Parameters**
- **consul_url** -- The Consul server URL.
- **key** -- The key to use as the starting point for the list.
- **recurse** -- Delete values recursively beginning at the value of key.
- **cas** -- This flag is used to turn the DELETE into a Check-And-Set operation.

**Returns**  Boolean & message of success or failure.

**CLI Example:**
salt '*' consul.delete key='web'
salt '*' consul.delete key='web' recurse='True'

salt.modules.consul.event_fire(consul_url=None, name=None, **kwargs)
List the ACL tokens.

Parameters
- **consul_url** -- The Consul server URL.
- **name** -- The name of the event to fire.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the `"dc" parameter.
- **node** -- Filter by node name.
- **service** -- Filter by service name.
- **tag** -- Filter by tag name.

Returns List of ACLs

CLI Example:
salt '*' consul.event_fire name='deploy'

salt.modules.consul.event_list(consul_url=None, **kwargs)
List the recent events.

Parameters
- **consul_url** -- The Consul server URL.
- **name** -- The name of the event to fire.

Returns List of ACLs

CLI Example:
salt '*' consul.event_list

salt.modules.consul.get(consul_url=None, key=None, recurse=False, decode=False, raw=False)
Get key from Consul

Parameters
- **consul_url** -- The Consul server URL.
- **key** -- The key to use as the starting point for the list.
- **recurse** -- Return values recursively beginning at the value of key.
- **decode** -- By default values are stored as Base64 encoded values, decode will return the whole key with the value decoded.
- **raw** -- Simply return the decoded value of the key.

Returns The keys in Consul.

CLI Example:
salt '*' consul.get key='web/key1'
salt '*' consul.list key='web' recurse='True'
salt '*' consul.list key='web' recurse='True' decode='True'
By default values stored in Consul are base64 encoded, passing the decode option will show them as the decoded values.

```shell
salt '*' consul.list key='web' recurse='True' decode='True' raw='True'
```

By default Consult will return other information about the key, the raw option will return only the raw value.

```python
salt.modules.consul.health_checks(consul_url=None, service=None, **kwargs)
```

Health information about the registered service.

Parameters

- **consul_url** -- The Consul server URL.
- **service** -- The service to request health information about.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the ``dc`` parameter.

Returns

Health information about the requested node.

CLI Example:

```shell
salt '*' consul.health_checks service='redis1'
```

```python
salt.modules.consul.health_node(consul_url=None, node=None, **kwargs)
```

Health information about the registered node.

Parameters

- **consul_url** -- The Consul server URL.
- **node** -- The node to request health information about.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the ``dc`` parameter.

Returns

Health information about the requested node.

CLI Example:

```shell
salt '*' consul.health_node node='node1'
```

```python
salt.modules.consul.health_service(consul_url=None, service=None, **kwargs)
```

Health information about the registered service.

Parameters

- **consul_url** -- The Consul server URL.
- **service** -- The service to request health information about.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the ``dc`` parameter.
- **tag** -- Filter returned services with tag parameter.
- **passing** -- Filter results to only nodes with all checks in the passing state.

Returns

Health information about the requested node.

CLI Example:

```shell
salt '*' consul.health_service service='redis1'
salt '*' consul.health_service service='redis1' passing='True'
```

```python
salt.modules.consul.health_state(consul_url=None, state=None, **kwargs)
```

Returns the checks in the state provided on the path.
Parameters

- **consul_url** -- The Consul server URL.
- **state** -- The state to show checks for. The supported states are any, unknown, passing, warning, or critical. The any state is a wildcard that can be used to return all checks.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the ``dc`` parameter.

Returns The checks in the provided state.

CLI Example:

```
salt '*' consul.health_state state='redis1'
salt '*' consul.health_state service='redis1' passing='True'
```

salt.modules.consul.list(**kwargs)**

List keys in Consul

Parameters

- **consul_url** -- The Consul server URL.
- **key** -- The key to use as the starting point for the list.

Returns The list of keys.

CLI Example:

```
salt '*' consul.list
salt '*' consul.list key='web'
```

salt.modules.consul.put(**kwargs)**

Put values into Consul

Parameters

- **consul_url** -- The Consul server URL.
- **key** -- The key to use as the starting point for the list.
- **value** -- The value to set the key to.
- **flags** -- This can be used to specify an unsigned value between 0 and 2^64-1. Clients can choose to use this however makes sense for their application.
- **cas** -- This flag is used to turn the PUT into a Check-And-Set operation.
- **acquire** -- This flag is used to turn the PUT into a lock acquisition operation.
- **release** -- This flag is used to turn the PUT into a lock release operation.

Returns Boolean & message of success or failure.

CLI Example:

```
salt '*' consul.put key='web/key1' value='Hello there'
salt '*' consul.put key='web/key1' value='Hello there' acquire='d5d371f4-c380-5280-12fd-8810be175592'
salt '*' consul.put key='web/key1' value='Hello there' release='d5d371f4-c380-5280-12fd-8810be175592'
```
salt.modules.consul.session_create(consul_url=None, **kwargs)

Used to create a session.

Parameters

- **consul_url** -- The Consul server URL.
- **lockdelay** -- Duration string using a `s` suffix for seconds. The default is 15s.
- **node** -- Must refer to a node that is already registered, if specified. By default, the agent's own node name is used.
- **name** -- A human-readable name for the session
- **checks** -- A list of associated health checks. It is highly recommended that, if you override this list, you include the default `serfHealth`.
- **behavior** -- Can be set to either release or delete. This controls the behavior when a session is invalidated. By default, this is release, causing any locks that are held to be released. Changing this to delete causes any locks that are held to be deleted. delete is useful for creating ephemeral key/value entries.
- **ttl** -- Session is invalidated if it is not renewed before the TTL expires

Returns

Boolean and message indicating success or failure.

CLI Example:
```
salt '*' consul.session_create node='node1' name='my-session' behavior='delete' ttl='3600s'
```

salt.modules.consul.session_destroy(consul_url=None, session=None, **kwargs)

Destroy session

Parameters

- **consul_url** -- The Consul server URL.
- **session** -- The ID of the session to destroy.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the `dc` parameter.

Returns

Boolean & message of success or failure.

CLI Example:
```
salt '*' consul.session_destroy session='c1c4d223-91cb-3d1f-1ee8-f2af9e7b6716'
```

salt.modules.consul.session_info(consul_url=None, session=None, **kwargs)

Information about a session

Parameters

- **consul_url** -- The Consul server URL.
- **session** -- The ID of the session to return information about.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the `dc` parameter.

Returns

Boolean & message of success or failure.

CLI Example:
```
salt '*' consul.session_info session='c1c4d223-91cb-3d1f-1ee8-f2af9e7b6716'
```

salt.modules.consul.session_list(consul_url=None, return_list=False, **kwargs)

Used to list sessions.
Parameters

- **consul_url** -- The Consul server URL.
- **dc** -- By default, the datacenter of the agent is queried; however, the `dc` can be provided using the ``dc`` parameter.
- **return_list** -- By default, all information about the sessions is returned, using the `return_list` parameter will return a list of session IDs.

Returns
A list of all available sessions.

CLI Example:
```
salt '*' consul.session_list
```

```python
salt.modules.consul.status_leader(consul_url=None)
```
Returns the current Raft leader

**Parameters**
- **consul_url** -- The Consul server URL.

**Returns**
The address of the Raft leader.

CLI Example:
```
salt '*' consul.status_leader
```

```python
salt.modules.consul.status_peers(consul_url)
```
Returns the current Raft peer set

**Parameters**
- **consul_url** -- The Consul server URL.

**Returns**
Retrieves the Raft peers for the datacenter in which the agent is running.

CLI Example:
```
salt '*' consul.status_peers
```

### 13.6.52 salt.modules.container_resource

Common resources for LXC and systemd-nspawn containers

New in version 2015.8.0.

These functions are not designed to be called directly, but instead from the `lxc`, `nspawn`, and `docker` execution modules. They provide for common logic to be re-used for common actions.

```python
salt.modules.container_resource.cache_file(source)
```
Wrapper for cp.cache_file which raises an error if the file was unable to be cached.

CLI Example:
```
salt myminion container_resource.cache_file salt://foo/bar/baz.txt
```

```python
salt.modules.container_resource.copy_to(*args, **kwargs)
```
Common logic for copying files to containers

- **path** path to the container parent (for LXC only) default: /var/lib/lxc (system default)

CLI Example:
```
salt myminion container_resource.copy_to mycontainer /local/file/path /container/
```

```python
salt.modules.container_resource.run(*args, **kwargs)
```
Common logic for running shell commands in containers
**path**  path to the container parent (for LXC only) default: /var/lib/lxc (system default)

CLI Example:
```
salt myminion container_resource.run mycontainer 'ps aux' container_type=docker exec_driver=nsenter output=stdout
```

### 13.6.53 salt.modules.cp

Minion side functions for salt-cp

**salt.modules.cp.cache_dir**(path, saltenv='base', include_empty=False, include_pat=None, exclude_pat=None, env=None)

Download and cache everything under a directory from the master

- **include_pat**  [None] Glob or regex to narrow down the files cached from the given path. If matching with a regex, the regex must be prefixed with E@, otherwise the expression will be interpreted as a glob.

  New in version 2014.7.0.

- **exclude_pat**  [None] Glob or regex to exclude certain files from being cached from the given path. If matching with a regex, the regex must be prefixed with E@, otherwise the expression will be interpreted as a glob.

  Note: If used with **include_pat**, files matching this pattern will be excluded from the subset of files defined by **include_pat**.

  New in version 2014.7.0.

CLI Examples:
```
salt '*' cp.cache_dir salt://path/to/dir
salt '*' cp.cache_dir salt://path/to/dir include_pat='E@*.py$'
```

**salt.modules.cp.cache_file**(path, saltenv='base', env=None)

Used to cache a single file on the Minion

Returns the location of the new cached file on the Minion.

CLI Example:
```
salt '*' cp.cache_file salt://path/to/file
```

There are two ways of defining the fileserver environment (a.k.a. `saltenv`) from which to cache the file. One is to use the `saltenv` parameter, and the other is to use a querystring syntax in the `salt://` URL. The below two examples are equivalent:
```
salt '*' cp.cache_file salt://foo/bar.conf saltenv=config
salt '*' cp.cache_file salt://foo/bar.conf?saltenv=config
```

If the path being cached is a `salt://` URI, and the path does not exist, then `False` will be returned.

Note: It may be necessary to quote the URL when using the querystring method, depending on the shell being used to run the command.

**salt.modules.cp.cache_files**(paths, saltenv='base', env=None)

Used to gather many files from the Master, the gathered files will be saved in the minion cachedir reflective to the paths retrieved from the Master

CLI Example:
There are two ways of defining the fileserver environment (a.k.a. \texttt{saltenv}) from which to cache the files. One is to use the \texttt{saltenv} parameter, and the other is to use a querystring syntax in the \texttt{salt://} URL. The below two examples are equivalent:

```
salt '*' cp.cache_files salt://foo/bar.conf,salt://foo/baz.conf
```

```
 salt 's' cp.cache_files salt://foo/bar.conf?saltenv=config,salt://foo/baz.conf?
```

The querystring method is less useful when all files are being cached from the same environment, but is a good way of caching files from multiple different environments in the same command. For example, the below command will cache the first file from the \texttt{config1} environment, and the second one from the \texttt{config2} environment.

```
salt '*' cp.cache_files salt://foo/bar.conf?saltenv=config1,salt://foo/bar.conf?saltenv=config2
```

\textbf{Note:} It may be necessary to quote the URL when using the querystring method, depending on the shell being used to run the command.

\texttt{salt.modules.cp.cache_local_file(path)}

Cache a local file on the minion in the localfiles cache

CLI Example:

```
salt '*' cp.cache_local_file /etc/hosts
```

\texttt{salt.modules.cp.cache_master(saltenv='base', env=None)}

Retrieve all of the files on the master and cache them locally

CLI Example:

```
salt '*' cp.cache_master
```

\texttt{salt.modules.cp.get_dir(path, dest, saltenv='base', template=None, gzip=None, env=None, **kwargs)}

Used to recursively copy a directory from the salt master

CLI Example:

```
salt '*' cp.get_dir salt://path/to/dir/ /minion/dest
```

\texttt{get\_dir} supports the same template and gzip arguments as \texttt{get\_file}.

\texttt{salt.modules.cp.get_file(path, dest, saltenv='base', makedirs=False, template=None, gzip=None, env=None, **kwargs)}

Used to get a single file from the salt master

CLI Example:

```
salt '*' cp.get_file salt://path/to/file /minion/dest
```

Template rendering can be enabled on both the source and destination file names like so:

```
salt '*' cp.get_file "salt://{{grains.os}}/vimrc" /etc/vimrc template=jinja
```
This example would instruct all Salt minions to download the vimrc from a directory with the same name as
their os grain and copy it to /etc/vimrc

For larger files, the cp.get_file module also supports gzip compression. Because gzip is CPU-intensive, this
should only be used in scenarios where the compression ratio is very high (e.g. pretty-printed JSON or YAML
files).

Use the gzip named argument to enable it. Valid values are 1..9, where 1 is the lightest compression and 9 the
heaviest. 1 uses the least CPU on the master (and minion), 9 uses the most.

There are two ways of defining the fileserver environment (a.k.a. saltenv) from which to retrieve the file.
One is to use the saltenv parameter, and the other is to use a querystring syntax in the salt:// URL. The
below two examples are equivalent:

```sh
salt '*' cp.get_file salt://foo/bar.conf /etc/foo/bar.conf saltenv=config
salt '*' cp.get_file salt://foo/bar.conf?saltenv=config /etc/foo/bar.conf
```

**Note:** It may be necessary to quote the URL when using the querystring method, depending on the shell being
used to run the command.

```
salt.modules.cp.get_file_str(path, saltenv='base', env=None)
```
Download a file from a URL to the Minion cache directory and return the contents of that file

Returns False if Salt was unable to cache a file from a URL.

**CLI Example:**

```sh
salt '*' cp.get_file_str salt://my/file
```

```
salt.modules.cp.get_template(path, dest, template='jinja', saltenv='base', env=None, makedirs=False, **kwargs)
```
Render a file as a template before sending it down. Warning, order is not the same as in fileclient.cp for non
breaking old API.

**CLI Example:**

```sh
salt '*' cp.get_template salt://path/to/template /minion/dest
```

```
salt.modules.cp.get_url(path, dest=' ', saltenv='base', env=None)
```
Used to get a single file from a URL.

**path** A URL to download a file from. Supported URL schemes are: salt://, http://, https://, ftp://, s3://, swift:// and file:// (local filesystem). If no scheme was specified, this is
equivalent of using file://. If a file:// URL is given, the function just returns absolute path
to that file on a local filesystem. The function returns False if Salt was unable to fetch a file from a
salt:// URL.

**dest** The default behaviour is to write the fetched file to the given destination path. If this parameter is omitted
or set as empty string ("'"), the function places the remote file on the local filesystem inside the Minion
cache directory and returns the path to that file.

**Note:** To simply return the file contents instead, set destination to None. This works with salt://, http://, https:// and file:// URLs. The files fetched by http:// and https:// will not
be cached.

**saltenv** [base] Salt fileserver environment from which to retrieve the file. Ignored if path is not a salt://
URL.

**CLI Example:**
Salt Documentation, Release 2016.3.6

```shell
salt '*' cp.get_url salt://my/file /tmp/this_file_is_mine
salt '*' cp.get_url http://www.slashdot.org /tmp/index.html
```

salt.modules.cp.hash_file(path, saltenv='base', env=None)
Return the hash of a file, to get the hash of a file on the salt master file server prepend the path with salt://<file on server> otherwise, prepend the file with / for a local file.

CLI Example:
```
salt '*' cp.hash_file salt://path/to/file
```

salt.modules.cp.is_cached(path, saltenv='base', env=None)
Return a boolean if the given path on the master has been cached on the minion

CLI Example:
```
salt '*' cp.is_cached salt://path/to/file
```

salt.modules.cp.list_master(saltenv='base', prefix='\', env=None)
List all of the files stored on the master

CLI Example:
```
salt '*' cp.list_master
```

salt.modules.cp.list_master_dirs(saltenv='base', prefix='\', env=None)
List all of the directories stored on the master

CLI Example:
```
salt '*' cp.list_master_dirs
```

salt.modules.cp.list_master_symlinks(saltenv='base', prefix='\', env=None)
List all of the symlinks stored on the master

CLI Example:
```
salt '*' cp.list_master_symlinks
```

salt.modules.cp.list_minion(saltenv='base', env=None)
List all of the files cached on the minion

CLI Example:
```
salt '*' cp.list_minion
```

salt.modules.cp.list_states(saltenv='base', env=None)
List all of the available state modules in an environment

CLI Example:
```
salt '*' cp.list_states
```

salt.modules.cp.push(path, keep_symlinks=False, upload_path=None, remove_source=False)
Push a file from the minion up to the master, the file will be saved to the salt master in the master’s minion files cachedir (defaults to /var/cache/salt/master/minions/minion-id/files)

Since this feature allows a minion to push a file up to the master server it is disabled by default for security purposes. To enable, set file_recv to True in the master configuration file, and restart the master.

keep_symlinks Keep the path value without resolving its canonical form

13.6. execution modules 923
**upload_path**  Provide a different path inside the master's minion files cachedir

**remove_source**  Remove the source file on the minion

New in version 2016.3.0.

CLI Example:

```
salt '*' cp.push /etc/fstab
salt '*' cp.push /etc/system-release keep_symlinks=True
salt '*' cp.push /etc/fstab upload_path='/new/path/fstab'
salt '*' cp.push /etc/fstab upload_path='/new/path/fstab'
```

salt.modules.cp.push_dir(path, glob=None, upload_path=None)

Push a directory from the minion up to the master, the files will be saved to the salt master in the master's minion files cachedir (defaults to /var/cache/salt/master/minions/minion-id/files). It also has a glob for matching specific files using globbing.

New in version 2014.7.0.

Since this feature allows a minion to push files up to the master server it is disabled by default for security purposes. To enable, set file_recv to True in the master configuration file, and restart the master.

**upload_path**  Provide a different path and directory name inside the master's minion files cachedir

CLI Example:

```
salt '*' cp.push /usr/lib/mysql
salt '*' cp.push /usr/lib/mysql upload_path='/newmysql/path'
salt '*' cp.push_dir /etc/modprobe.d/ glob='*.conf'
```
salt 'salt '*' cpan.remove Old::Package

salt.modules.cpan.show(module)
    Show information about a specific Perl module
    CLI Example:
    salt 'salt '*' cpan.show Template::Alloy

salt.modules.cpan.show_config()
    Return a dict of CPAN configuration values
    CLI Example:
    salt 'salt '*' cpan.show_config

13.6.55 salt.modules.cron

Work with cron

Note: Salt does not escape cron metacharacters automatically. You should backslash-escape percent characters and any other metacharacters that might be interpreted incorrectly by the shell.

salt.modules.cron.list_tab(user)
    Return the contents of the specified user's crontab
    CLI Example:
    salt 'salt '*' cron.list_tab root

salt.modules.cron.ls(user)
    This function is an alias of list_tab.
    Return the contents of the specified user's crontab
    CLI Example:
    salt 'salt '*' cron.list_tab root

salt.modules.cron.raw_cron(user)
    Return the contents of the user's crontab
    CLI Example:
    salt 'salt '*' cron.raw_cron root

salt.modules.cron.rm(user, cmd, minute=None, hour=None, daymonth=None, month=None, day-week=None, identifier=None)
    This function is an alias of rm_job.
    Remove a cron job for a specified user. If any of the day/time params are specified, the job will only be removed if the specified params match.
    CLI Example:
    salt 'salt '*' cron.rm_job root /usr/local/weekly
    salt 'salt '*' cron.rm_job root /usr/bin/foo dayweek=1

13.6. execution modules
salt.modules.cron.rm_env(user, name)
    Remove cron environment variable for a specified user.
    CLI Example:
    ```
salt '*' cron.rm_env root MAILTO
    ```

salt.modules.cron.rm_job(user, cmd, minute=None, hour=None, daymonth=None, month=None, dayweek=None, identifier=None)
    Remove a cron job for a specified user. If any of the day/time params are specified, the job will only be removed if the specified params match.
    CLI Example:
    ```
salt '*' cron.rm_job root /usr/local/weekly
salt '*' cron.rm_job root /usr/bin/foo dayweek=1
    ```

salt.modules.cron.rm_special(user, special, cmd)
    Remove a special cron job for a specified user.
    CLI Example:
    ```
salt '*' cron.rm_job root @hourly /usr/bin/foo
    ```

salt.modules.cron.set_env(user, name, value=None)
    Set up an environment variable in the crontab.
    CLI Example:
    ```
salt '*' cron.set_env root MAILTO user@example.com
    ```

salt.modules.cron.set_job(user, minute, hour, daymonth, month, dayweek, cmd, commented=False, comment=None, identifier=None)
    Sets a cron job up for a specified user.
    CLI Example:
    ```
salt '*' cron.set_job root '*' '*' '*' '*' 1 /usr/local/weekly
    ```

salt.modules.cron.set_special(user, special, cmd)
    Set up a special command in the crontab.
    CLI Example:
    ```
salt '*' cron.set_special root @hourly 'echo foobar'
    ```

salt.modules.cron.write_cron_file(user, path)
    Writes the contents of a file to a user's crontab
    CLI Example:
    ```
salt '*' cron.write_cron_file root /tmp/new_cron
    ```
    Changed in version 2015.8.9.
    
    **Note:** Solaris and AIX require that *path* is readable by *user*

salt.modules.cron.write_cron_file_verbose(user, path)
    Writes the contents of a file to a user's crontab and return error message on error
CLI Example:
```
salt '*' cron.write_cron_file_verbose root /tmp/new_cron
```

Changed in version 2015.8.9.

Note: Solaris and AIX require that `path` is readable by `user`

### 13.6.56 `salt.modules.cyg`

Manage cygwin packages.

Module file to accompany the cyg state.

salt.modules.cyg.check_valid_package(`package`, `cyg_arch='x86_64'`, `mirrors=None`)  
Check if the package is valid on the given mirrors.

salt.modules.cyg.install(`packages=None`, `cyg_arch='x86_64'`, `mirrors=None`)  
Install one or several packages.

- `packages` [None] The packages to install
- `cyg_arch` [x86_64] Specify the architecture to install the package under

Current options are x86 and x86_64

CLI Example:
```
salt '*' cyg.install dos2unix
salt '*' cyg.install dos2unix mirrors=[{'http://mirror': 'http://url/to/public/ →key}]
```

salt.modules.cyg.list(`package='``, `cyg_arch='x86_64'`)  
List locally installed packages.

- `package` [`]` package name to check. else all
- `cyg_arch` : Cygwin architecture to use

Options are x86 and x86_64

CLI Example:
```
salt '*' cyg.list
```

salt.modules.cyg.uninstall(`packages`, `cyg_arch='x86_64'`, `mirrors=None`)  
Uninstall one or several packages.

- `packages` The packages to uninstall.
- `cyg_arch` [x86_64] Specify the architecture to remove the package from

Current options are x86 and x86_64

CLI Example:
```
salt '*' cyg.uninstall dos2unix
salt '*' cyg.uninstall dos2unix mirrors=[{'http://mirror': 'http://url/to/public/ →key}]
```

salt.modules.cyg.update(`cyg_arch='x86_64'`, `mirrors=None`)  
Update all packages.

- `cyg_arch` [x86_64] Specify the cygwin architecture update

Current options are x86 and x86_64

CLI Example:
```
salt '*' cyg.update
salt '*' cyg.update dos2unix mirrors=[{'http://mirror': 'http://url/to/public/key} →]`
13.6.57 salt.modules.daemontools

daemontools service module. This module will create daemontools type service watcher.

This module is compatible with the service states, so it can be used to maintain services using the provider argument:

```python
myservice:
    service.running:
      - provider: daemontools
```

salt.modules.daemontools.available(name)
Returns True if the specified service is available, otherwise returns False.

CLI Example:
```
salt '*' daemontools.available foo
```

salt.modules.daemontools.disabled(name)
Return True if the named service is enabled, false otherwise

New in version 2015.5.6.

CLI Example:
```
salt '*' daemontools.disabled <service name>
```

salt.modules.daemontools.enabled(name, **kwargs)
Return True if the named service is enabled, false otherwise A service is considered enabled if in your service directory: - an executable ./run file exist - a file named ``down`` does not exist

New in version 2015.5.7.

name  Service name

CLI Example:
```
salt '*' daemontools.enabled <service name>
```

salt.modules.daemontools.full_restart(name)
Calls daemontools.restart() function

CLI Example:
```
salt '*' daemontools.full_restart <service name>
```

salt.modules.daemontools.get_all()
Return a list of all available services

CLI Example:
```
salt '*' daemontools.get_all
```

salt.modules.daemontools.missing(name)
The inverse of daemontools.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:
```
salt '*' daemontools.missing foo
```
salt.modules.daemontools.reload(name)

Wrapper for term()

CLI Example:
salt '*' daemontools.reload <service name>

salt.modules.daemontools.restart(name)

Restart service via daemontools.  This will stop/start service

CLI Example:
salt '*' daemontools.restart <service name>

salt.modules.daemontools.start(name)

Starts service via daemontools

CLI Example:
salt '*' daemontools.start <service name>

salt.modules.daemontools.status(name, sig=\None)

Return the status for a service via daemontools, return pid if running

CLI Example:
salt '*' daemontools.status <service name>

salt.modules.daemontools.stop(name)

 Stops service via daemontools

CLI Example:
salt '*' daemontools.stop <service name>

salt.modules.daemontools.term(name)

Send a TERM to service via daemontools

CLI Example:
salt '*' daemontools.term <service name>

13.6.58 salt.modules.data

Manage a local persistent data structure that can hold any arbitrary data specific to the minion

salt.modules.data.cas(key, value, old_value)

Check and set a value in the minion datastore

CLI Example:
salt '*' data.cas <key> <value> <old_value>

salt.modules.data.clear()

Clear out all of the data in the minion datastore, this function is destructive!

CLI Example:
salt '*' data.clear

salt.modules.data.dump(new_data)

Replace the entire datastore with a passed data structure

CLI Example:

    salt '*' data.dump '{eggs': 'spam'}'

salt.modules.data.get(key, default=None)

Get a (list of) value(s) from the minion datastore

New in version 2015.8.0.

CLI Example:

    salt '*' data.get <key(s)>

salt.modules.data.getval(key)

Get a value from the minion datastore

Deprecated since version Carbon: Use get instead

CLI Example:

    salt '*' data.getval <key>

salt.modules.data.getvals(*keylist)

Get values from the minion datastore

Deprecated since version Carbon: Use get instead

CLI Example:

    salt '*' data.getvals <key> [<key> ...]

salt.modules.data.has_key(key)

Check if key is in the minion datastore

New in version 2015.8.0.

CLI Example:

    salt '*' data.has_key <mykey>

salt.modules.data.items()

Get items from the minion datastore

New in version 2015.8.0.

CLI Example:

    salt '*' data.items

salt.modules.data.keys()

Get all keys from the minion datastore

New in version 2015.8.0.

CLI Example:
salt ' '*' data.keys

salt.modules.data.load()
    Return all of the data in the minion datastore
    CLI Example:
    salt ' '*' data.load

salt.modules.data.pop(key, default=None)
    Pop (return & delete) a value from the minion datastore
    New in version 2015.5.2.
    CLI Example:
    salt ' '*' data.pop <key> "there was no val"

salt.modules.data.update(key, value)
    Update a key with a value in the minion datastore
    CLI Example:
    salt ' '*' data.update <key> <value>

salt.modules.data.values()
    Get values from the minion datastore
    New in version 2015.8.0.
    CLI Example:
    salt ' '*' data.values

13.6.59  salt.modules.ddns

Support for RFC 2136 dynamic DNS updates.

depends
    • dnspython Python module

configuration If you want to use TSIG authentication for the server, there are a couple of optional
configuration parameters made available to support this (the keyname is only needed if the keyring
contains more than one key):

keyfile: keyring file (default= None)
keyname: key name in file (default= None)
keyalgorithm: algorithm used to create the key
    (default='HMAC-MD5.SIG-ALG.REG.INT').
    Other possible values: hmac-sha1, hmac-sha224, hmac-sha256,
    hmac-sha384, hmac-sha512

The keyring file needs to be in json format and the key name needs to end with an extra period in
the file, similar to this:

{"keyname." : "keycontent"}
salt.modules.ddns.add_host(zone, name, ttl, ip, nameserver='127.0.0.1', replace=True, **kwargs)
Add, replace, or update the A and PTR (reverse) records for a host.

CLI Example:
```
salt ns1 ddns.add_host example.com host1 60 10.1.1.1
```

salt.modules.ddns.delete(zone, name, rdtype=None, data=None, nameserver='127.0.0.1', **kwargs)
Delete a DNS record.

CLI Example:
```
salt ns1 ddns.delete example.com host1 A
```

salt.modules.ddns.delete_host(zone, name, nameserver='127.0.0.1', **kwargs)
Delete the forward and reverse records for a host.

Returns true if any records are deleted.

CLI Example:
```
salt ns1 ddns.delete_host example.com host1
```

salt.modules.ddns.update(zone, name, ttl, rdtype, data, nameserver='127.0.0.1', replace=False, **kwargs)
Add, replace, or update a DNS record. nameserver must be an IP address and the minion running this module must have update privileges on that server. If replace is true, first deletes all records for this name and type.

CLI Example:
```
salt ns1 ddns.update example.com host1 60 A 10.0.0.1
```

13.6.60 salt.modules.deb_apache

Support for Apache

Please note: The functions in here are Debian-specific. Placing them in this separate file will allow them to load only on Debian-based systems, while still loading under the apache namespace.

salt.modules.deb_apache.a2disconf(conf)
New in version 2016.3.0.
Runs a2disconf for the given conf.

This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).

CLI Examples:
```
salt '*' apache.a2disconf security
```

salt.modules.deb_apache.a2dismod(mod)
Runs a2dismod for the given mod.

This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).

CLI Examples:
```
salt '*' apache.a2dismod vhost_alias
```
salt.modules.deb_apache.a2dissite(site)
  Runs a2dissite for the given site.
  This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).
  CLI Examples:
  ```
salt '*' apache.a2dissite example.com
  ```

salt.modules.deb_apache.a2enconf(conf)
  New in version 2016.3.0.
  Runs a2enconf for the given conf.
  This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).
  CLI Examples:
  ```
salt '*' apache.a2enconf security
  ```

salt.modules.deb_apache.a2enmod(mod)
  Runs a2enmod for the given mod.
  This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).
  CLI Examples:
  ```
salt '*' apache.a2enmod vhost_alias
  ```

salt.modules.deb_apache.a2ensite(site)
  Runs a2ensite for the given site.
  This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).
  CLI Examples:
  ```
salt '*' apache.a2ensite example.com
  ```

salt.modules.deb_apache.check_conf_enabled(conf)
  New in version 2016.3.0.
  Checks to see if the specific conf symlink is in /etc/apache2/conf-enabled.
  This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).
  CLI Examples:
  ```
salt '*' apache.check_conf_enabled security
  ```

salt.modules.deb_apache.check_mod_enabled(mod)
  Checks to see if the specific mod symlink is in /etc/apache2/mods-enabled.
  This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).
  CLI Examples:
  ```
salt '*' apache.check_mod_enabled status
  ```
salt.modules.deb_apache.check_site_enabled(site)
Checks to see if the specific site symlink is in /etc/apache2/sites-enabled.

This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).

CLI Examples:

```
salt '*' apache.check_site_enabled example.com
salt '*' apache.check_site_enabled example.com.conf
```

### 13.6.61 salt.modules.deb_postgres

Module to provide Postgres compatibility to salt for debian family specific tools.

salt.modules.deb_postgres.cluster_create(version, name='main', port=None, locale=None, encoding=None, datadir=None)

Adds a cluster to the Postgres server.

CLI Example:

```
salt '*' postgres.cluster_create '9.3'
salt '*' postgres.cluster_create '9.3' 'main'
salt '*' postgres.cluster_create '9.3' locale='fr_FR'
```

salt.modules.deb_postgres.cluster_exists(version, name='main')

Checks if a given version and name of a cluster exists.

CLI Example:

```
salt '*' postgres.cluster_exists '9.3'
salt '*' postgres.cluster_exists '9.3' 'main'
```

salt.modules.deb_postgres.cluster_list( verbose=False)

Return a list of cluster of Postgres server (tuples of version and name).

CLI Example:

```
salt '*' postgres.cluster_list
salt '*' postgres.cluster_list verbose=True
```

salt.modules.deb_postgres.cluster_remove(version, name='main', stop=False)

Remove a cluster on a Postgres server. By default it doesn't try to stop the cluster.

CLI Example:

```
salt '*' postgres.cluster_remove '9.3'
salt '*' postgres.cluster_remove '9.3' 'main'
salt '*' postgres.cluster_remove '9.3' 'main' stop=True
```

### 13.6.62 salt.modules.debbuild

Debian Package builder system
New in version 2015.8.0.

This system allows for all of the components to build debs safely in chrooted environments. This also provides a function to generate debian repositories.

This module implements the pkgbuild interface

```python
salt.modules.debbuild.build(runas, tgt, dest_dir, spec, sources, deps, env, template, saltenv='base',
                           log_dir='/var/log/salt/pkgbuild')
```

Given the package destination directory, the tarball containing debian files (e.g. control) and package sources, use pbuilder to safely build the platform package

CLI Example:

**Debian**

```
salt '!' pkgbuild.make_src_pkg deb-8-x86_64 /var/www/html https://raw.githubusercontent.com/saltstack/libnacl/master/pkg/deb/python-libnacl.control
```

This example command should build the libnacl package for Debian using pbuilder and place it in /var/www/html/ on the minion

```python
salt.modules.debbuild.make_repo(repodir, keyid=None, env=None, use_passphrase=False,
                                gnupghome='/etc/salt/gpgkeys', runas='root', timeout=15.0)
```

Make a package repository and optionally sign it and packages present

Given the repodir (directory to create repository in), create a Debian repository and optionally sign it and packages present. This state is best used with onchanges linked to your package building states.

**repodir** The directory to find packages that will be in the repository.

**keyid** Changed in version 2016.3.0.

Optional Key ID to use in signing packages and repository. Utilizes Public and Private keys associated with keyid which have been loaded into the minion's Pillar data. Leverages gpg-agent and gpg-pret-passphrase for caching keys, etc.

For example, contents from a Pillar data file with named Public and Private keys as follows:

```plaintext
gpg_pkg_priv_key: |
```

```
-----BEGIN PGP PRIVATE KEY BLOCK-----
Version: GnuPG v1

IQo+BFCiiIfQBCADACPtzx7I5Rl32escCMZsPzaEKWe7bIX1em4KCKkBoX47IG54bw82PCE8Y1jF/9Uk2m3RKVwp3YcIC7Ap3gj6VO4ysvVz28UbnhPxsIkOlfcq8qC
.
.
Ebe+8JQTwqSXPRTzXmy/b5WXDeM79CkLwv0GpXFor76D+ECMRPv/awukEcNpntnRS0mgHqyvDEn04pWbn8JzQ09XY/Us0SMHBvzLC8eIi5IopZalvX=JvW8
-----END PGP PRIVATE KEY BLOCK-----
```

```plaintext
gpg_pkg_priv_keyname: gpg_pkg_key.pem
```

```plaintext
gpg_pkg_pub_key: |
```

```
-----BEGIN PGP PUBLIC KEY BLOCK------
Version: GnuPG v1

mQENBFciIfQBCADACPtzx7I5Rl32escCMZsPzaEKWe7bIX1em4KCKkBoX47IG54bw82PCE8Y1jF/9Uk2m3RKVwp3YcIC7Ap3gj6VO4ysvVz28UbnhPxsIkOlfcq8qC
.
.
```

For more information on how to use these states, see [pkgbuild](https://docs.saltstack.com/en/latest/ref/chttpd.html).
env

A dictionary of environment variables to be utilized in creating the repository.

use_passphrase [False] New in version 2016.3.0.

Use a passphrase with the signing key presented in keyid. Passphrase is received from Pillar data which could be passed on the command line with pillar parameter. For example:

```python
pillar='{ "gpg_passphrase" : "my_passphrase" }'
```

gnupghome [/etc/salt/gpgkeys] New in version 2016.3.0.

Location where GPG related files are stored, used with keyid.

User to create the repository as, and optionally sign packages.

Note: Ensure the user has correct permissions to any files and directories which are to be utilized.

timeout [15.0] New in version 2016.3.4.

Timeout in seconds to wait for the prompt for inputting the passphrase. 

CLI Example:

```bash
salt '*' pkgbuild.make_repo /var/www/html
```

salt.modules.debbuild.make_src_pkg(dest_dir, spec, sources, env=None, template=None, saltenv='base')

Create a platform specific source package from the given platform spec/control file and sources

CLI Example:

Debian

```bash
```

This example command should build the libnacl SOURCE package and place it in /var/www/html/ on the minion

13.6.63 salt.modules.debconfmod

Support for Debconf

salt.modules.debconfmod.get_selections(fetchempty=True)

Answers to debconf questions for all packages in the following format:

```python
[{'package': [['question', 'type', 'value'], ...]]
```

CLI Example:
salt '*/' debconf.get_selections

salt.modules.debconfmod.set(package, question, type, value, *extra)
Set answers to debconf questions for a package.

CLI Example:

    salt '*/' debconf.set <package> <question> <type> <value> [<value> ...]

salt.modules.debconfmod.set_file(path, saltenv='base', **kwargs)
Set answers to debconf questions from a file.

CLI Example:

    salt '*/' debconf.set_file salt://pathto/pkg.selections

salt.modules.debconfmod.set_template(path, template, context, defaults, saltenv='base', **kwargs)
Set answers to debconf questions from a template.

    path  location of the file containing the package selections
    template  template format
    context  variables to add to the template environment
    default  default values for the template environment

CLI Example:

    salt '*/' debconf.set_template salt://pathto/pkg.selections.jinja jinja None None

salt.modules.debconfmod.show(name)
Answers to debconf questions for a package in the following format:

    

If debconf doesn't know about a package, we return None.

CLI Example:

    salt '*/' debconf.show <package name>

13.6.64 salt.modules.debian_ip

The networking module for Debian based distros

References:

salt.modules.debian_ip.apply_network_settings(**settings)
Apply global network configuration.

CLI Example:

    salt '*/' ip.apply_network_settings

salt.modules.debian_ip.build_bond(_iface, **settings)
Create a bond script in /etc/modprobe.d with the passed settings and load the bonding kernel module.

CLI Example:
salt '*' ip.build_bond bond0 mode=balance-alb

salt.modules.debian_ip.build_interface(iface, iface_type, enabled, **settings)
Build an interface script for a network interface.
CLI Example:
salt '*' ip.build_interface eth0 eth <settings>

salt.modules.debian_ip.build_network_settings(**settings)
Build the global network script.
CLI Example:
salt '*' ip.build_network_settings <settings>

salt.modules.debian_ip.build_routes(iface, **settings)
Add route scripts for a network interface using up commands.
CLI Example:
salt '*' ip.build_routes eth0 <settings>

salt.modules.debian_ip.down(iface, iface_type)
Shutdown a network interface
CLI Example:
salt '*' ip.down eth0 eth

salt.modules.debian_ip.get_bond(iface)
Return the content of a bond script
CLI Example:
salt '*' ip.get_bond bond0

salt.modules.debian_ip.get_interface(iface)
Return the contents of an interface script
CLI Example:
salt '*' ip.get_interface eth0

salt.modules.debian_ip.get_network_settings()
Return the contents of the global network script.
CLI Example:
salt '*' ip.get_network_settings

salt.modules.debian_ip.get_routes(iface)
Return the routes for the interface
CLI Example:
salt '*' ip.get_routes eth0
salt.modules.debian_ip.up(iface, iface_type)
Start up a network interface

CLI Example:
```
salt '*' ip.up eth0 eth
```

### 13.6.65 salt.modules.debian_service

Service support for Debian systems (uses update-rc.d and /sbin/service)

**Important:** If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `service.start' is not available), see [here](#).

salt.modules.debian_service.available(name)
Returns True if the specified service is available, otherwise returns False.

CLI Example:
```
salt '*' service.available sshd
```

salt.modules.debian_service.disable(name, **kwargs)
Disable the named service to start at boot

CLI Example:
```
salt '*' service.disable <service name>
```

salt.modules.debian_service.disabled(name)
Return True if the named service is enabled, false otherwise

CLI Example:
```
salt '*' service.disabled <service name>
```

salt.modules.debian_service.enable(name, **kwargs)
Enable the named service to start at boot

CLI Example:
```
salt '*' service.enable <service name>
```

salt.modules.debian_service.enabled(name, **kwargs)
Return True if the named service is enabled, false otherwise

CLI Example:
```
salt '*' service.enabled <service name>
```

salt.modules.debian_service.force_reload(name)
Force-reload the named service

CLI Example:
```
salt '*' service.force_reload <service name>
```
salt.modules.debian_service.get_all()  
Return all available boot services

CLI Example:
```
salt '*' service.get_all
```

salt.modules.debian_service.get_disabled()  
Return a set of services that are installed but disabled

CLI Example:
```
salt '*' service.get_disabled
```

salt.modules.debian_service.get_enabled()  
Return a list of service that are enabled on boot

CLI Example:
```
salt '*' service.get_enabled
```

salt.modules.debian_service.missing(name)  
The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:
```
salt '*' service.missing sshd
```

salt.modules.debian_service.reload(name)  
Reload the named service

CLI Example:
```
salt '*' service.reload <service name>
```

salt.modules.debian_service.restart(name)  
Restart the named service

CLI Example:
```
salt '*' service.restart <service name>
```

salt.modules.debian_service.start(name)  
Start the specified service

CLI Example:
```
salt '*' service.start <service name>
```

salt.modules.debian_service.status(name, sig=None)  
Return the status for a service, pass a signature to use to find the service via ps

CLI Example:
```
salt '*' service.status <service name>
```

salt.modules.debian_service.stop(name)  
Stop the specified service

CLI Example:
13.6.66 salt.modules.defaults

salt.modules.defaults.get(key, default=``)

defaults.get is used much like pillar.get except that it will read a default value for a pillar from defaults.json or defaults.yaml files that are stored in the root of a salt formula.

CLI Example:

    salt '*' defaults.get core:users:root

The defaults is computed from pillar key. The first entry is considered as the formula namespace.

For example, querying core:users:root will try to load salt:///core.defaults.yaml and salt:///core/defaults.json.

salt.modules.defaults.merge(dest, upd)

Allows deep merging of dicts in formulas.

CLI Example: .. code-block:: bash

    salt '*' default.merge a=b d=e

It is more typical to use this in a templating language in formulas, instead of directly on the command-line.

13.6.67 salt.modules.devmap

Device-Mapper module

salt.modules.devmap.multipath_flush(device)

Device-Mapper Multipath flush

CLI Example:

    salt '*' devmap.multipath_flush mpath1

salt.modules.devmap.multipath_list()

Device-Mapper Multipath list

CLI Example:

    salt '*' devmap.multipath_list

13.6.68 salt.modules.dig

Compendium of generic DNS utilities. The `dig` command line tool must be installed in order to use this module.

salt.modules.dig.A(host, nameserver=None)

Return the A record for host.

Always returns a list.

CLI Example:

    salt ns1 dig.A www.google.com

13.6. execution modules
salt.modules.dig.AAAA(host, nameserver=None)

Return the AAAA record for host.

Always returns a list.

CLI Example:
```
salt ns1 dig.AAAA www.google.com
```

salt.modules.dig.MX(domain, resolve=False, nameserver=None)

Return a list of lists for the MX of domain.

If the `resolve` argument is True, resolve IPs for the servers.

It’s limited to one IP, because although in practice it’s very rarely a round robin, it is an acceptable configuration and pulling just one IP lets the data be similar to the non-resolved version. If you think an MX has multiple IPs, don’t use the resolver here, resolve them in a separate step.

CLI Example:
```
salt ns1 dig.MX google.com
```

salt.modules.dig.NS(domain, resolve=True, nameserver=None)

Return a list of IPs of the nameservers for domain.

If `resolve` is False, don’t resolve names.

CLI Example:
```
salt ns1 dig.NS google.com
```

salt.modules.dig.SPF(domain, record='SPF', nameserver=None)

Return the allowed IPv4 ranges in the SPF record for domain.

If record is SPF and the SPF record is empty, the TXT record will be searched automatically. If you know the domain uses TXT and not SPF, specifying that will save a lookup.

CLI Example:
```
salt ns1 dig.SPF google.com
```

salt.modules.dig.TXT(host, nameserver=None)

Return the TXT record for host.

Always returns a list.

CLI Example:
```
salt ns1 dig.TXT google.com
```

salt.modules.dig.check_ip(addr)

Check if address is a valid IP. returns True if valid, otherwise False.

CLI Example:
```
salt ns1 dig.check_ip 127.0.0.1
```
13.6.69 salt.modules.disk

Module for managing disks and blockdevices

salt.modules.disk.blkid(device=None)

Return block device attributes: UUID, LABEL, etc. This function only works on systems where blkid is available.

CLI Example:

```
salt '*' disk.blkid
salt '*' disk.blkid /dev/sda
```

salt.modules.disk.dump(device, args=None)

Return all contents of dumpe2fs for a specified device

CLI Example:

```
salt '*' disk.dump /dev/sda1
```

salt.modules.disk.hdparms(disks, args=None)

Retrieve all info’s for all disks parse ‘em into a nice dict (which, considering hdparms output, is quite a hassle)

New in version 2016.3.0.

CLI Example:

```
salt '*' disk.hdparms /dev/sda
```

salt.modules.disk.hpa(disks, size=None)

Get/set Host Protected Area settings

T13 INCITS 346-2001 (1367D) defines the BEER (Boot Engineering Extension Record) and PARTIES (Protected Area Run Time Interface Extension Services), allowing for a Host Protected Area on a disk.

It’s often used by OEMS to hide parts of a disk, and for overprovisioning SSD’s

**Warning:** Setting the HPA might clobber your data, be very careful with this on active disks!

New in version 2016.3.0.

CLI Example:

```
salt '*' disk.hpa /dev/sda
salt '*' disk.hpa /dev/sda 5%
salt '*' disk.hpa /dev/sda 10543256
```

salt.modules.disk_inodeusage(args=None)

Return inode usage information for volumes mounted on this minion

CLI Example:

```
salt '*' disk.inodeusage
```

salt.modules.disk.iostat(interval=1, count=5, disks=None)

Gather and return (averaged) IO stats.

New in version 2016.3.0.

CLI Example:
salt '*' disk.iostat 1 5 disks=sd

salt.modules.disk.percent (args=None)

Return partition information for volumes mounted on this minion

CLI Example:

```bash
salt '*' disk.percent /var
```

salt.modules.disk.resize2fs (device)

Resizes the filesystem.

CLI Example:

```bash
salt '*' disk.resize2fs /dev/sda1
```

salt.modules.disk.smart_attributes (dev, attributes=None, values=None)

Fetch SMART attributes. Providing attributes will deliver only requested attributes. Providing values will deliver only requested values for attributes.

Default is the Backblaze recommended set (https://www.backblaze.com/blog/hard-drive-smart-stats/):

(5,187,188,197,198)

New in version 2016.3.0.

CLI Example:

```bash
salt '*' disk.smart_attributes /dev/sda
salt '*' disk.smart_attributes /dev/sda attributes=(5,187,188,197,198)
```

salt.modules.disk.tune (device, **kwargs)

Set attributes for the specified device

CLI Example:

```bash
salt '*' disk.tune /dev/sda1 read-ahead=1024 read-write=True
```

Valid options are: read-ahead, filesystem-read-ahead, read-only, read-write.

See the blockdev(8) manpage for a more complete description of these options.

salt.modules.disk.usage (args=None)

Return usage information for volumes mounted on this minion

CLI Example:

```bash
salt '*' disk.usage
```

salt.modules.disk.wipe (device)

Remove the filesystem information

CLI Example:

```bash
salt '*' disk.wipe /dev/sda1
```

13.6.70 salt.modules.djangomod

Manage Django sites
salt.modules.djangomod.collectstatic(**settings_module, bin_env=None, no_post_process=False, ignore=None, dry_run=False, clear=False, link=False, no_default_ignore=False, pythonpath=None, env=None)

Collect static files from each of your applications into a single location that can easily be served in production.

CLI Example:
```
salt '*' django.collectstatic <settings_module>
```

salt.modules.djangomod.command(**settings_module, command, bin_env=None, pythonpath=None, env=None, *args, **kwargs)

Run arbitrary django management command

CLI Example:
```
salt '*' django.command <settings_module> <command>
```

salt.modules.djangomod.createsuperuser(**settings_module, username, email, bin_env=None, database=None, pythonpath=None, env=None)

Create a super user for the database. This function defaults to use the `--noinput` flag which prevents the creation of a password for the superuser.

CLI Example:
```
salt '*' django.createsuperuser <settings_module> user user@example.com
```

salt.modules.djangomod.loaddata(**settings_module, fixtures, bin_env=None, database=None, pythonpath=None, env=None)

Load fixture data

Fixtures: comma separated list of fixtures to load

CLI Example:
```
salt '*' django.loaddata <settings_module> <comma delimited list of fixtures>
```

salt.modules.djangomod.syncdb(**settings_module, bin_env=None, migrate=False, database=None, pythonpath=None, env=None, noinput=True)

Run syncdb

Execute the Django-Admin syncdb command, if South is available on the minion the `migrate` option can be passed as True calling the migrations to run after the syncdb completes

CLI Example:
```
salt '*' django.syncdb <settings_module>
```

13.6.71 salt.modules.dnsmasq

Module for managing dnsmasq

salt.modules.dnsmasq.fullversion()

Shows installed version of dnsmasq and compile options.

CLI Example:
```
salt '*' dnsmasq.version
```

salt.modules.dnsmasq.get_config(config_file='/etc/dnsmasq.conf')

Dumps all options from the config file.
**config_file**  The location of the config file from which to obtain contents. Defaults to /etc/dnsmasq.conf.

CLI Examples:

```python
salt '*' dnsmasq.get_config
salt '*' dnsmasq.get_config config_file=/etc/dnsmasq.conf
```

salt.modules.dnsmasq.set_config(**config_file='*/etc/dnsmasq.conf', follow=True, **kwargs)"

Sets a value or a set of values in the specified file. By default, if conf-dir is configured in this file, salt will attempt to set the option in any file inside the conf-dir where it has already been enabled. If it does not find it inside any files, it will append it to the main config file. Setting follow to False will turn off this behavior.

If a config option currently appears multiple times (such as dhcp-host, which is specified at least once per host), the new option will be added to the end of the main config file (and not to any includes). If you need an option added to a specific include file, specify it as the config_file.

**Parameters**

- **config_file**(string) -- config file where settings should be updated / added.
- **follow**(bool) -- attempt to set the config option inside any file within the conf-dir where it has already been enabled.
- **kwargs** -- key value pairs that contain the configuration settings that you want set.

CLI Examples:

```python
salt '*' dnsmasq.set_config domain=mydomain.com
salt '*' dnsmasq.set_config follow=False domain=mydomain.com
salt '*' dnsmasq.set_config config_file=/etc/dnsmasq.conf domain=mydomain.com
```

salt.modules.dnsmasq.version()

Shows installed version of dnsmasq.

CLI Example:

```python
salt '*' dnsmasq.version
```

### 13.6.72 salt.modules.dnsutil

Compendium of generic DNS utilities

salt.modules.dnsutil.A(***host, nameserver=None)"

Return the A record(s) for host.

Always returns a list.

CLI Example:

```python
salt ns1 dnsutil.A www.google.com
```

salt.modules.dnsutil.AAAA(***host, nameserver=None)"

Return the AAAA record(s) for host.

Always returns a list.

New in version 2014.7.5.

CLI Example:

```python
salt ns1 dnsutil.AAAA www.google.com
```
salt.modules.dnsutil.MX(domain, resolve=False, nameserver=None)

Return a list of lists for the MX of domain.

If the `resolve' argument is True, resolve IPs for the servers.

It's limited to one IP, because although in practice it's very rarely a round robin, it is an acceptable configuration and pulling just one IP lets the data be similar to the non-resolved version. If you think an MX has multiple IPs, don't use the resolver here, resolve them in a separate step.

CLI Example:
salt ns1 dig.MX google.com

salt.modules.dnsutil.NS(domain, resolve=True, nameserver=None)

Return a list of IPs of the nameservers for domain.

If 'resolve' is False, don't resolve names.

CLI Example:
salt ns1 dig.NS google.com

salt.modules.dnsutil.SPF(domain, record='SPF', nameserver=None)

Return the allowed IPv4 ranges in the SPF record for domain.

If record is SPF and the SPF record is empty, the TXT record will be searched automatically. If you know the domain uses TXT and not SPF, specifying that will save a lookup.

CLI Example:
salt ns1 dig.SPF google.com

salt.modules.dnsutil.check_ip(ip_addr)

Check that string ip_addr is a valid IP.

CLI Example:
salt ns1 dig.check_ip 127.0.0.1

salt.modules.dnsutil.hosts_append(hostsfile='/etc/hosts', ip_addr=None, entries=None)

Append a single line to the /etc/hosts file.

CLI Example:
salt '*' dnsutil.hosts_append /etc/hosts 127.0.0.1 ad1.yuk.co,ad2.yuk.co

salt.modules.dnsutil.hosts_remove(hostsfile='/etc/hosts', entries=None)

Remove a host from the /etc/hosts file. If doing so will leave a line containing only an IP address, then the line will be deleted. This function will leave comments and blank lines intact.

CLI Examples:
salt '*' dnsutil.hosts_remove /etc/hosts ad1.yuk.co
salt '*' dnsutil.hosts_remove /etc/hosts ad2.yuk.co,ad1.yuk.co

salt.modules.dnsutil.parse_hosts(hostsfile='/etc/hosts', hosts=None)

Parse /etc/hosts file.

CLI Example:
**salt '***' dnsutil.parse_hosts**

**salt.modules.dnsutil.parse_zone(zonefile=None, zone=None)**

Parses a zone file. Can be passed raw zone data on the API level.

CLI Example:

```
salt ns1 dnsutil.parse_zone /var/lib/named/example.com.zone
```

**salt.modules.dnsutil.serial(zone='`, update=False)**

Return, store and update a dns serial for your zone files.

- **zone**: a keyword for a specific zone
- **update**: store an updated version of the serial in a grain

If `update` is False, the function will retrieve an existing serial or return the current date if no serial is stored. Nothing will be stored.

If `update` is True, the function will set the serial to the current date if none exist or if the existing serial is for a previous date. If a serial for greater than the current date is already stored, the function will increment it.

This module stores the serial in a grain, you can explicitly set the stored value as a grain named `dnsserial_<zone_name>`.

CLI Example:

```
salt ns1 dnsutil.serial example.com
```

### 13.6.73 salt.modules.dockercompose module

Module to import docker-compose via saltstack

New in version 2016.3.0.

- **maintainer** Jean Praloran <jeanpralo@gmail.com>
- **maturity** new
- **depends** docker-compose>=1.5
- **platform** all

**Introduction**

This module allows one to deal with docker-compose file in a directory.

This is a first version only, the following commands are missing at the moment but will be built later on if the community is interested in this module:

- `run`
- `logs`
- `port`
- `scale`
Installation Prerequisites

This execution module requires at least version 1.4.0 of both `docker-compose` and `Docker`. `docker-compose` can easily be installed using `pip install`:

```
salt myminion pip.install docker-compose>=1.5.0
```

How to use this module?

In order to use the module if you have no docker-compose file on the server you can issue the command `create`, it takes two arguments the path where the docker-compose.yml will be stored and the content of this latter:

```
# salt-call -l debug dockercompose.create /tmp/toto 'database:
    image: mongo:3.0
    command: mongod --smallfiles --quiet --logpath=/dev/null'
```

Then you can execute a list of method defined at the bottom with at least one argument (the path where the docker-compose.yml will be read) and an optional python list which corresponds to the services names:

```
# salt-call -l debug dockercompose.up /tmp/toto
# salt-call -l debug dockercompose.restart /tmp/toto '[database]'
# salt-call -l debug dockercompose.stop /tmp/toto
# salt-call -l debug dockercompose.rm /tmp/toto
```

Docker-compose method supported

- up
- restart
- stop
- start
- pause
- unpause
- kill
- rm
- ps
- pull
- build

Functions

- `docker-compose.yml` management
  - `dockercompose.create`
  - `dockercompose.get`
- Manage containers
- dockercompose.restart
- dockercompose.stop
- dockercompose.pause
- dockercompose.unpause
- dockercompose.start
- dockercompose.kill
- dockercompose.rm
- dockercompose.up

- Manage containers image:
  - dockercompose.pull
  - dockercompose.build

- Gather information about containers:
  - dockercompose.ps

**Detailed Function Documentation**

**salt.modules.dockercompose.build**(path, service_names=None)
Build image for containers in the docker-compose file, service_names is a python list, if omitted build images for all containers. Please note that at the moment the module does not allow you to upload your Dockerfile, nor any other file you could need with your docker-compose.yml, you will have to make sure the files you need are actually in the directory specified in the build keyword

- **path** Path where the docker-compose file is stored on the server
- **service_names** If specified will pull only the image for the specified services

CLI Example:

```
salt myminion dockercompose.build /path/where/docker-compose/stored
salt myminion dockercompose.build /path/where/docker-compose/stored '[janus]' 
```

**salt.modules.dockercompose.create**(path, docker_compose)
Create and validate a docker-compose file into a directory

- **path** Path where the docker-compose file will be stored on the server
- **docker_compose** docker_compose file

CLI Example:

```
salt myminion dockercompose.create /path/where/docker-compose/stored content
```

**salt.modules.dockercompose.get**(path)
Get the content of the docker-compose file into a directory

- **path** Path where the docker-compose file is stored on the server

CLI Example:

```
salt myminion dockercompose.get /path/where/docker-compose/stored
```

**salt.modules.dockercompose.kill**(path, service_names=None)
Kill containers in the docker-compose file, service_names is a python list, if omitted kill all containers

- **path** Path where the docker-compose file is stored on the server
- **service_names** If specified will kill only the specified services

CLI Example:
salt modules.dockercompose.pause(path, service_names=None)
Pause running containers in the docker-compose file, service_names is a python list, if omitted pause all containers
path Path where the docker-compose file is stored on the server
service_names If specified will pause only the specified services
CLI Example:
salt myminion dockercompose.pause /path/where/docker-compose/stored
salt myminion dockercompose.pause /path/where/docker-compose/stored '[janus]'

salt modules.dockercompose.ps(path)
List all running containers and report some information about them
path Path where the docker-compose file is stored on the server
CLI Example:
salt myminion dockercompose.ps /path/where/docker-compose/stored

salt modules.dockercompose.pull(path, service_names=None)
Pull image for containers in the docker-compose file, service_names is a python list, if omitted pull all images
path Path where the docker-compose file is stored on the server
service_names If specified will pull only the image for the specified services
CLI Example:
salt myminion dockercompose.pull /path/where/docker-compose/stored
salt myminion dockercompose.pull /path/where/docker-compose/stored '[janus]'

salt modules.dockercompose.restart(path, service_names=None)
Restart container(s) in the docker-compose file, service_names is a python list, if omitted restart all containers
path Path where the docker-compose file is stored on the server
service_names If specified will restart only the specified services
CLI Example:
salt myminion dockercompose.restart /path/where/docker-compose/stored
salt myminion dockercompose.restart /path/where/docker-compose/stored '[janus]'

salt modules.dockercompose.rm(path, service_names=None)
Remove stopped containers in the docker-compose file, service_names is a python list, if omitted remove all stopped containers
path Path where the docker-compose file is stored on the server
service_names If specified will remove only the specified stopped services
CLI Example:
salt myminion dockercompose.rm /path/where/docker-compose/stored
salt myminion dockercompose.rm /path/where/docker-compose/stored '[janus]'

salt modules.dockercompose.start(path, service_names=None)
Start containers in the docker-compose file, service_names is a python list, if omitted start all containers
path Path where the docker-compose file is stored on the server
service_names If specified will start only the specified services
CLI Example:
salt.myminion dockercompose.start /path/where/docker-compose/stored
salt.myminion dockercompose.start /path/where/docker-compose/stored '[janus]'

salt.modules.dockercompose.stop(path, service_names=None)
Stop running containers in the docker-compose file, service_names is a python list, if omitted stop all containers
path Path where the docker-compose file is stored on the server
service_names If specified will stop only the specified services
CLI Example:
salt.myminion dockercompose.stop /path/where/docker-compose/stored
salt.myminion dockercompose.stop /path/where/docker-compose/stored '[janus]'

salt.modules.dockercompose.unpause(path, service_names=None)
Un-Pause containers in the docker-compose file, service_names is a python list, if omitted un-pause all containers
path Path where the docker-compose file is stored on the server
service_names If specified will un-pause only the specified services
CLI Example:
salt.myminion dockercompose.pause /path/where/docker-compose/stored
salt.myminion dockercompose.pause /path/where/docker-compose/stored '[janus]'

salt.modules.dockercompose.up(path, service_names=None)
Create and start containers defined in the docker-compose.yml file located in path, service_names is a python list, if omitted create and start all containers
path Path where the docker-compose file is stored on the server
service_names If specified will create and start only the specified services
CLI Example:
salt.myminion dockercompose.up /path/where/docker-compose/stored
salt.myminion dockercompose.up /path/where/docker-compose/stored '[janus]'

13.6.74 salt.modules.dockerio

Management of Docker Containers

New in version 2014.1.0.

Deprecated since version 2015.8.0: Future feature development will be done only in dockerng. See the documentation for this module for information on the deprecation path.

Note: The DockerIO integration is still in beta; the API is subject to change

General Notes

As we use states, we don't want to be continuously popping dockers, so we will map each container id (or image) with a grain whenever it is relevant.

As a corollary, we will resolve a container id either directly by the id or try to find a container id matching something stocked in grain.
Installation Prerequisites

- You will need the `docker-py` python package in your python installation path that is running salt. Its version should support Docker Remote API v1.12.

  Currently, `docker-py 0.6.0` is known to support Docker Remote API v1.12

  ```
  pip install docker-py==0.6.0
  ```

Prerequisite Pillar Configuration for Authentication

- To push or pull you will need to be authenticated as the `docker-py` bindings require it

- For this to happen, you will need to configure a mapping in the pillar representing your per URL authentication bits:

```python
docker-registries:
  registry_url:
    email: foo@foo.com
    password: s3cr3t
    username: foo
```

- You need at least an entry to the default docker index:

```python
docker-registries:
  https://index.docker.io/v1/:
    email: foo@foo.com
    password: s3cr3t
    username: foo
```

- You can define multiple registry blocks for them to be aggregated. The only thing to keep in mind is that their ID must finish with `-docker-registries`:

```python
ac-docker-registries:
  https://index.bar.io/v1/:
    email: foo@foo.com
    password: s3cr3t
    username: foo

ab-docker-registries:
  https://index.foo.io/v1/:
    email: foo@foo.com
    password: s3cr3t
    username: foo
```

This could be also written as:

```python
docker-registries:
  https://index.bar.io/v1/:
    email: foo@foo.com
    password: s3cr3t
    username: foo
  https://index.foo.io/v1/:
    email: foo@foo.com
    password: s3cr3t
    username: foo
```
Methods

- Registry Dialog
  - login
  - push
  - pull

- Docker Management
  - version
  - info

- Image Management
  - search
  - inspect_image
  - get_images
  - remove_image
  - import_image
  - build
  - tag
  - save
  - load

- Container Management
  - start
  - stop
  - restart
  - kill
  - wait
  - get_containers
  - inspect_container
  - remove_container
  - is_running
  - top
  - port
  - logs
  - diff
  - commit
  - create_container
  - export
  - get_container_root
Runtime Execution within a specific, already existing/running container

Idea is to use lxc-attach to execute inside the container context. We do not want to use docker run but want to execute something inside a running container.

These are the available methods:

- `retcode`
- `run`
- `run_all`
- `run_stderr`
- `run_stdout`
- `script`
- `script_retcode`

```python
salt.modules.dockerio.build(path=None, tag=None, quiet=False, fileobj=None, nocache=False, rm=True, timeout=None)
```

Build a docker image from a dockerfile or an URL

- **path** – url/branch/docker_dir or path on the filesystem to the dockerfile
- **tag** – tag of the image
- **quiet** – quiet mode, Default is False
- **nocache** – do not use docker image cache, Default is False
- **rm** – remove intermediate commits, Default is True
- **timeout** – timeout value before aborting (in seconds)

CLI Example:

```
salt '*' docker.build vieux/apache
salt '*' docker.build github.com/creack/docker-firefox
```

```python
salt.modules.dockerio.commit(container, repository=None, tag=None, message=None, author=None, conf=None)
```

Commit a container (promotes it to an image)

- **container** – container id
- **repository** – repository/image to commit to
- **tag** – tag of the image (Optional)
- **message** – commit message (Optional)
- **author** – author name (Optional)
- **conf** – conf (Optional)

CLI Example:

```
salt '*' docker.commit <container id>
```

```python
salt.modules.dockerio.create_container(image, command=None, hostname=None, user=None, detach=True, stdin_open=False, tty=False, mem_limit=None, ports=None, environment=None, dns=None, volumes=None, volumes_from=None, name=None, cpu_shares=None, cpuset=None, binds=None)
```

Create a new container

- **image** – image to create the container from
- **command** – command to execute while starting
- **hostname** – hostname of the container
- **user** – user to run docker as
- **detach** – daemon mode, Default is True
**environment** environment variable mapping ({'foo': 'BAR'})

**ports** port redirections ({'222': {}})

**volumes** list of volume mappings in either local volume, bound volume, or read-only bound volume form:

```ini
[['/var/lib/mysql/', '/usr/local/etc:/etc/ssl', '/etc/passwd:/etc/passwd:ro']]
```

**binds** complete dictionary of bound volume mappings:

```ini
{
'/usr/local/etc/ssl/certs/internal.crt': {  
'bind': '/etc/ssl/certs/com.example.internal.crt',  
'ro': True
},
'/var/lib/mysql': {  
'bind': '/var/lib/mysql/',  
'ro': False
}
}
```

This dictionary is suitable for feeding directly into the Docker API, and all keys are required. (see http://docker-py.readthedocs.org/en/latest/volumes/)

**tty** attach ttys, Default is False

**stdin_open** let stdin open, Default is False

**name** name given to container

**cpu_shares** CPU shares (relative weight)

**cpuset** CPUs in which to allow execution ('0-3' or '0,1')

**CLI Example:**

```
salt '*' docker.create_container o/ubuntu volumes=["s","m:/f"]
```

**salt.modules.dockerio.diff** *(container)*

Get container diffs

**container** container id

**CLI Example:**

```
salt '*' docker.diff <container id>
```

**salt.modules.dockerio.exists** *(container)*

Check if a given container exists

**container** container id

**Returns** True if container exists otherwise returns False

**CLI Example:**

```
salt '*' docker.exists <container id>
```

**salt.modules.dockerio.export** *(container, path)*

Export a container to a file

**container** container id

**path** path to which file is to be exported

**CLI Example:**

```
salt '*' docker.export <container id>
```

**salt.modules.dockerio.get_container_root** *(container)*

Get the container rootfs path

**container** container id or grain
CLI Example:
```
salt '*' docker.get_container_root <container id>
```

`salt.modules.dockerio.get_containers(all=True, trunc=False, since=None, before=None, limit=-1, host=False, inspect=False)`

Get a list of mappings representing all containers
- `all` return all containers, Default is True
- `trunc` set it to True to have the short ID, Default is False
- `host` include the Docker host’s ipv4 and ipv6 address in return, Default is False
- `inspect` Get more granular information about each container by running a docker inspect

CLI Example:
```
salt '*' docker.get_containers
salt '*' docker.get_containers host=True
salt '*' docker.get_containers host=True inspect=True
```

`salt.modules.dockerio.get_images(name=None, quiet=False, all=True)`

List docker images
- `name` repository name
- `quiet` only show image id, Default is False
- `all` show all images, Default is True

CLI Example:
```
salt '*' docker.get_images <name> [quiet=True|False] [all=True|False]
```

`salt.modules.dockerio.import_image(src, repo, tag=None)`

Import content from a local tarball or a URL to a docker image
- `src` content to import (URL or absolute path to a tarball)
- `repo` repository to import to
- `tag` set tag of the image (Optional)

CLI Example:
```
salt '*' docker.import_image <src> <repo> [tag]
```

`salt.modules.dockerio.info()`

Get the version information about docker. This is similar to docker info command

CLI Example:
```
salt '*' docker.info
```

`salt.modules.dockerio.inspect_container(container)`

Get container information. This is similar to docker inspect command but only for containers
- `container` container id

CLI Example:
```
salt '*' docker.inspect_container <container id>
```

`salt.modules.dockerio.inspect_image(image)`

Inspect the status of an image and return relative data. This is similar to docker inspect command but only for images.
- `image` name of the image

CLI Example:
```
salt '*' docker.inspect_image <image>
```
salt.modules.dockerio.is_running(container)
Check if the specified container is running
container container id
Returns True if container is running otherwise returns False

CLI Example:
salt '*' docker.is_running <container id>

salt.modules.dockerio.kill(container, signal=None)
Kill a running container
container container id
signal signal to send

New in version 2015.8.0.
CLI Example:
salt '*' docker.kill <container id>

salt.modules.dockerio.load(imagepath)
Load the specified file at imagepath into docker that was generated from a docker save command e.g. docker load < imagepath
imagepath imagepath to docker tar file

CLI Example:
salt '*' docker.load /path/to/image

salt.modules.dockerio.login(url=None, username=None, password=None, email=None)
Wrapper to the docker.py login method (does not do much yet)
url registry url to authenticate to
username username to authenticate
password password to authenticate
email email to authenticate

CLI Example:
salt '*' docker.login <url> <username> <password> <email>

salt.modules.dockerio.logs(container)
Return logs for a specified container
container container id

CLI Example:
salt '*' docker.logs <container id>

salt.modules.dockerio.port(container, private_port)
Private port mapping allocation information. This method is broken on docker-py side. Just use the result of inspect to mangle port allocation
container container id
private_port private port on the container to query for

CLI Example:
salt '*' docker.port <container id> <private port>

salt.modules.dockerio.pull(repo, tag=None, insecure_registry=False)
Pulls an image from any registry. See documentation at top of this page to configure authenticated access
repo name of repository
tag specific tag to pull (Optional)
**insecure_registry** set as True to use insecure (non HTTPS) registry. Default is False (only available if using docker-py >= 0.5.0)

CLI Example:

```bash
salt '*' docker.pull <repository> [tag]
```

salt.modules.dockerio.push(**repo**, **tag**=None, **quiet**=False, **insecure_registry**=False)

Pushes an image to any registry. See documentation at top of this page to configure authenticated access

**repo** name of repository
**tag** specific tag to push (Optional)
**quiet** set as True to quiet output, Default is False
**insecure_registry** set as True to use insecure (non HTTPS) registry. Default is False (only available if using docker-py >= 0.5.0)

CLI Example:

```bash
salt '*' docker.push <repository> [tag] [quiet=True|False]
```

salt.modules.dockerio.remove_container(**container**, **force**=False, **v**=False)

Remove a container from a docker installation

**container** container id
**force** remove a running container, Default is False
**v** remove the volumes associated to the container, Default is False

CLI Example:

```bash
salt '*' docker.remove_container <container id> [force=True|False] [v=True|False]
```

salt.modules.dockerio.remove_image(**image**)

Remove an image from a system.

**image** name of image

CLI Example:

```bash
salt '*' docker.remove_image <image>
```

salt.modules.dockerio.restart(**container**, **timeout**=10)

Restart a running container

**container** container id
**timeout** timeout for container to exit gracefully before killing it, Default is 10 seconds

CLI Example:

```bash
salt '*' docker.restart <container id> [timeout=20]
```

salt.modules.dockerio.retcode(**container**, **cmd**)

Wrapper for cmdmod.retcode inside a container context

**container** container id (or grain)
**cmd** command to execute

**Note:** The return is True or False depending on the commands success.

**Warning:** Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!
```python
salt '*' docker.run <container id> 'ls -l /etc'
```

### `salt.modules.dockerio.run` (*container, cmd*)
Wrapper for `cmdmod.run` inside a container context
- **container**: container id (or grain)
- **cmd**: command to execute

**Note:** The return is a bit different as we use the docker struct. Output of the command is in `out` and result is always `True`.

**Warning:** Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

**CLI Example:**
```python
salt '*' docker.run <container id> 'ls -l /etc'
```

### `salt.modules.dockerio.run_all` (*container, cmd*)
Wrapper for `cmdmod.run_all` inside a container context
- **container**: container id (or grain)
- **cmd**: command to execute

**Note:** The return is a bit different as we use the docker struct. Output of the command is in `out` and result is `False` if command failed to execute.

**Warning:** Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

**CLI Example:**
```python
salt '*' docker.run_all <container id> 'ls -l /etc'
```

### `salt.modules.dockerio.run_stderr` (*container, cmd*)
Wrapper for `cmdmod.run_stderr` inside a container context
- **container**: container id (or grain)
- **cmd**: command to execute

**Note:** The return is a bit different as we use the docker struct. Output of the command is in `out` and result is always `True`.

**Warning:** Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

**CLI Example:**
```python
salt '*' docker.run_stderr <container id> 'ls -l /etc'
```
salt.modules.dockerio.run_stdout(container, cmd)
Wrapper for cmdmod.run_stdout inside a container context
container container id (or grain)
cmd command to execute

Note: The return is a bit different as we use the docker struct. Output of the command is in `out' and result is always True.

Warning: Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

CLI Example:
```
salt '*' docker.run_stdout <container id> 'ls -l /etc'
```

salt.modules.dockerio.save(image, filename)
New in version 2015.5.0.
Save the specified image to filename from docker e.g. docker save image > filename
image name of image
filename The filename of the saved docker image

CLI Example:
```
salt '*' docker.save arch_image /path/to/save/image
```

salt.modules.dockerio.script(container, source, args=None, cwd=None, stdin=None, runas=None, shell='/bin/sh', env=None, template='jinja', umask=None, timeout=None, reset_system_locale=True, no_clean=False, saltenv='base')
Wrapper for cmdmod.script inside a container context
container container id (or grain)
additional parameters See cmd.script

Warning: Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

Download a script from a remote location and execute the script in the container. The script can be located on the salt master file server or on an HTTP/FTP server.
The script will be executed directly, so it can be written in any available programming language.
The script can also be formatted as a template, the default is jinja. Arguments for the script can be specified as well.

CLI Example:
```
salt '*' docker.script <container id> salt://docker_script.py
salt '*' docker.script <container id> salt://scripts/runme.sh 'arg1 arg2 "arg 3"'
salt '*' docker.script <container id> salt://scripts/windows_task.ps1 args=' - --Input c:\tmp\infile.txt' shell='powershell'
```

A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input.

CLI Example:
Salt modules documentation:

**salt.modules.dockerio.script_retcode**

```python
salt.modules.dockerio.script_retcode(container, source, cwd=None, stdin=None, runas=None, shell='/bin/sh', env=None, template='jinja', umask=None, timeout=None, reset_system_locale=True, no_clean=False, saltenv='base')
```

Wrapper for `cmdmod.script_retcode` inside a container context

- **container**: container id (or grain)
- **additional parameters**: See `cmd.script_retcode`

**Warning**: Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

**CLI Example**:

```bash
salt '*' docker.script_retcode <container id> salt://scripts/runme.sh stdin='one\ntwo\nthree\nfour\nfive\n'
```

**salt.modules.dockerio.search**

Search for an image on the registry

```python
salt.modules.dockerio.search(term)
```

**CLI Example**:

```bash
salt '*' docker.search <term>
```

**salt.modules.dockerio.start**

Start the specified container

```python
salt.modules.dockerio.start(container, binds=None, port_bindings=None, lxc_conf=None, publish_all_ports=None, links=None, privileged=False, dns=None, volumes_from=None, network_mode=None, restart_policy=None, cap_add=None, cap_drop=None)
```

**CLI Example**:

```bash
salt '*' docker.start <container id>
```

**salt.modules.dockerio.top**

Run the docker top command on a specific container

```python
salt.modules.dockerio.top(container)
```

**salt.modules.dockerio.tag**

Tag an image into a repository

```python
salt.modules.dockerio.tag(image, repository, tag=None, force=False)
```

**CLI Example**:

```bash
salt '*' docker.tag <image> <repository> [tag] [force=True|False]
```

**Notes**

- `cmd.script_retcode` is the function inside a container context.
- Be careful with raw shell access.
- Additional parameters can be explored in `cmd.script_retcode`.
- [962 Chapter 13. Salt Module Reference]
container  container id
  CLI Example:

```
salt '*' docker.top <container id>
```

```
salt.modules.dockerio.version()
  Get docker version
  CLI Example:

```
salt '*' docker.version
```

```
salt.modules.dockerio.wait(containter)
  Wait for a container to exit gracefully
  container  container id
  CLI Example:

```
salt '*' docker.wait <container id>
```

### 13.6.75 salt.modules.dockerng

Management of Docker Containers

New in version 2015.8.0.

**Why Make a Second Docker Execution Module?**

We have received a lot of feedback on our Docker support. In the process of implementing recommended improvements, it became obvious that major changes needed to be made to the functions and return data. In the end, a complete rewrite was done.

The changes being too significant, it was decided that making a separate execution module and state module (called dockerng) would be the best option. This will give users a couple release cycles to modify their scripts, SLS files, etc. to use the new functionality, rather than forcing users to change everything immediately.

In the Nitrogen release of Salt (due in 2017), this execution module will take the place of the default Docker execution module, and backwards-compatible naming will be maintained for a couple releases after that to allow users time to replace references to dockerng with docker.

**Installation Prerequisites**

This execution module requires at least version 1.4.0 of both docker-py and Docker. docker-py can easily be installed using `pip.install`:

```
salt myminion pip.install docker-py>1.4.0
```

**Authentication**

If you have previously performed a docker login from the minion, then the credentials saved in `~/.docker/config.json` will be used for any actions which require authentication. If not, then credentials can be configured in Pillar data. The configuration schema is as follows:
docker-registries:
  <registry_url>:
    username: <username>
    password: <password>

For example:

docker-registries:
  hub:
    username: foo
    password: s3cr3t

Note: As of the 2016.3.7, 2016.11.4, and Nitrogen releases of Salt, credentials for the Docker Hub can be configured simply by specifying hub in place of the registry URL. In earlier releases, it is necessary to specify the actual registry URL for the Docker Hub (i.e. https://index.docker.io/v1/).

More than one registry can be configured. Salt will look for Docker credentials in the `docker-registries` Pillar key, as well as any key ending in `-docker-registries`. For example:

```yaml
docker-registries:
  'https://mydomain.tld/registry:5000':
    username: foo
    password: s3cr3t

foo-docker-registries:
  https://index.foo.io/v1/:
    username: foo
    password: s3cr3t

bar-docker-registries:
  https://index.bar.io/v1/:
    username: foo
    password: s3cr3t
```

To login to the configured registries, use the `dockerng.login` function. This only needs to be done once for a given registry, and it will store/update the credentials in `~/.docker/config.json`.

Note: For Salt releases before 2016.3.7 and 2016.11.4, `dockerng.login` is not available. Instead, Salt will try to authenticate using each of your configured registries for each push/pull, behavior which is not correct and has been resolved in newer releases.

### Configuration Options

The following configuration options can be set to fine-tune how Salt uses Docker:

- **docker.url**: URL to the docker service (default: local socket).
- **docker.version**: API version to use (should not need to be set manually in the vast majority of cases)
- **docker.exec_driver**: Execution driver to use, one of `nsenter`, `lxc-attach`, or `docker-exec`. See the [Executing Commands Within a Running Container](#) section for more details on how this config parameter is used.

These configuration options are retrieved using `config.get` (click the link for further information).
Executing Commands Within a Running Container

**Note:** With the release of Docker 1.13.1, the Execution Driver has been removed. Starting in versions 2016.3.6, 2016.11.4, and Nitrogen, Salt defaults to using `docker exec` to run commands in containers, however for older Salt releases it will be necessary to set the `docker.exec_driver` config option to either `docker-exec` or `nsenter` for Docker versions 1.13.1 and newer.

Multiple methods exist for executing commands within Docker containers:

- `lxc-attach`: Default for older versions of docker
- `nsenter`: Enters container namespace to run command
- `docker-exec`: Native support for executing commands in Docker containers (added in Docker 1.3)

Adding a configuration option (see `config.get`) called `docker.exec_driver` will tell Salt which execution driver to use:

```bash
docker.exec_driver: docker-exec
```

If this configuration option is not found, Salt will use the appropriate interface (either `nsenter` or `lxc-attach`) based on the `Execution Driver` value returned from `docker info`. `docker-exec` will not be used by default, as it is presently (as of version 1.6.2) only able to execute commands as the effective user of the container. Thus, if a USER directive was used to run as a non-privileged user, `docker-exec` would be unable to perform the action as root. Salt can still use `docker-exec` as an execution driver, but must be explicitly configured (as in the example above) to do so at this time.

If possible, try to manually specify the execution driver, as it will save Salt a little work.

This execution module provides functions that shadow those from the `cmd` module. They are as follows:

- `dockerng.retc ode`
- `dockerng.run`
- `dockerng.run_all`
- `dockerng.run_stderr`
- `dockerng.run_stdout`
- `dockerng.script`
- `dockerng.script_retcode`

Detailed Function Documentation

```python
class salt.modules.dockerng.DockerJSONDecoder( encoding=None, object_hook=None, parse_float=None, parse_int=None, parse_constant=None, strict=True, object_pairs_hook=None)

decode(s, **w=None)
```

```python
salt.modules.dockerng.build(path=None, image=None, cache=True, rm=True, api_response=False, fileobj=None)
```

Builds a docker image from a Dockerfile or a URL

**path** Path to directory on the Minion containing a Dockerfile
image  Image to be built, in repo:tag notation. If just the repository name is passed, a tag name of latest will be assumed. If building from a URL, this parameter can be omitted.
cache  [True] Set to False to force the build process not to use the Docker image cache, and pull all required intermediate image layers
rm  [True] Remove intermediate containers created during build
api_response  [False] If True: an API_Response key will be present in the return data, containing the raw output from the Docker API.
fileobj  Allows for a file-like object containing the contents of the Dockerfile to be passed in place of a file path argument. This argument should not be used from the CLI, only from other Salt code.

RETURN DATA

A dictionary containing one or more of the following keys:
• Id - ID of the newly-built image
• Time_Elapsed - Time in seconds taken to perform the build
• Intermediate_Containers - IDs of containers created during the course of the build process

(Only present if rm=False)

• Images - A dictionary containing one or more of the following keys:
  - Already_Pulled - Layers that were already present on the Minion
  - Pulled - Layers that were pulled

(Only present if the image specified by the `image` argument was not present on the Minion, or if cache=False)

• Status - A string containing a summary of the pull action (usually a message saying that an image was downloaded, or that it was up to date).

(Only present if the image specified by the `image` argument was not present on the Minion, or if cache=False)

CLI Example:

```
salt myminion dockerng.build /path/to/docker/build/dir image=myimage:dev
salt myminion dockerng.build https://github.com/myuser/myrepo.git image=myimage:~latest
```

salt.modules.dockerng.commit(name, image, message=None, author=None)
Commits a container, thereby promoting it to an image. Equivalent to running the docker commit Docker CLI command.

name  Container name or ID to commit
image  Image to be committed, in repo:tag notation. If just the repository name is passed, a tag name of latest will be assumed.
message  Commit message (Optional)
author  Author name (Optional)

RETURN DATA

A dictionary containing the following keys:
• Id - ID of the newly-created image
• Image - Name of the newly-created image
• Time_Elapsed - Time in seconds taken to perform the commit

CLI Example:

```
salt myminion dockerng.commit mycontainer myuser/myimage
salt myminion dockerng.commit mycontainer myuser/myimage:mytag
```

salt.modules.dockerng.connect_container_to_network(container, network_id)

Connect container to network.

container  Container name or ID
**network_id**  ID of network
CLI Example:

```
salt myminion dockerng.connect_container_from_network web-1
  8f9d2454d0872b68d9e8744c6e7a4c66b86f10a8acc21e14f7f014f729b2bc
```

**salt.modules.dockerng.copy_from**(name, *args, **kwargs)
Copy a file from inside a container to the Minion

- **name**  Container name
- **source**  Path of the file on the container's filesystem
- **dest**  Destination on the Minion. Must be an absolute path. If the destination is a directory, the file will be copied into that directory.
- **overwrite**  [False] Unless this option is set to True, then if a file exists at the location specified by the dest argument, an error will be raised.
- **makedirs**  [False] Create the parent directory on the container if it does not already exist.

**RETURN DATA**
A boolean (True if successful, otherwise False)

CLI Example:

```
salt myminion dockerng.copy_from mycontainer /var/log/nginx/access.log /home/
  --myuser
```

**salt.modules.dockerng.copy_to**(name, *args, **kwargs)
Copy a file from the host into a container

- **name**  Container name
- **source**  File to be copied to the container. Can be a local path on the Minion or a remote file from the Salt fileserver.
- **dest**  Destination on the container. Must be an absolute path. If the destination is a directory, the file will be copied into that directory.
- **exec_driver**  [None] If not passed, the execution driver will be detected as described above.
- **overwrite**  [False] Unless this option is set to True, then if a file exists at the location specified by the dest argument, an error will be raised.
- **makedirs**  [False] Create the parent directory on the container if it does not already exist.

**RETURN DATA**
A boolean (True if successful, otherwise False)

CLI Example:

```
salt myminion dockerng.copy_to mycontainer /tmp/foo /root/foo
```

**salt.modules.dockerng.create**( *args, **kwargs)
Create a new container

- **name**  Name for the new container. If not provided, Docker will randomly generate one for you.
- **image**  Image from which to create the container
- **command or cmd**  Command to run in the container

  Example: command=bash or cmd=bash

  Changed in version 2015.8.1: cmd is now also accepted
- **hostname**  Hostname of the container. If not provided, and if a name has been provided, the hostname will default to the name that was passed.

  Example: hostname=web1
Warning: If the container is started with network_mode=host, the hostname will be overridden by the hostname of the Minion.

**domainname** Domain name of the container

Example: `domainname=domain.tld`

**interactive** [False] Leave stdin open

Example: `interactive=True`

**tty** [False] Attach TTYs

Example: `tty=True`

**detach** [True] If True, run command in the background (daemon mode)

Example: `detach=False`

**user** User under which to run docker

Example: `user=foo`

**memory** [0] Memory limit. Can be specified in bytes or using single-letter units (i.e. 512M, 2G, etc.). A value of 0 (the default) means no memory limit.

Example: `memory=512M, memory=1073741824`

**memory_swap** [-1] Total memory limit (memory plus swap). Set to -1 to disable swap. A value of 0 means no swap limit.

Example: `memory_swap=1G, memory_swap=2147483648`

**mac_address** MAC address to use for the container. If not specified, a random MAC address will be used.

Example: `mac_address=01:23:45:67:89:0a`

**network_disabled** [False] If True, networking will be disabled within the container

Example: `network_disabled=True`

**working_dir** Working directory inside the container

Example: `working_dir=/var/log/nginx`

**entrypoint** Entrypoint for the container. Either a string (e.g. "mycmd --arg1 --arg2") or a Python list (e.g. "['mycmd', '--arg1', '--arg2']")

Example: `entrypoint='cat access.log'`

**environment** Either a dictionary of environment variable names and their values, or a Python list of strings in the format VARNAME=value.

Example: 

```
'{{'VAR1': 'value','VAR2': 'value'}}',
'[['VAR1=value','VAR2=value']"
```

**ports** A list of ports to expose on the container. Can be passed as comma-separated list or a Python list. If the protocol is omitted, the port will be assumed to be a TCP port.

Example: `1111,2222/udp, ['1111/tcp', '2222/udp']`

**volumes** [None] List of directories to expose as volumes. Can be passed as a comma-separated list or a Python list.

Example: `volumes=/mnt/vol1,/mnt/vol2.volumes=['[/mnt/vol1,/mnt/vol2]`

**cpu_shares** CPU shares (relative weight)

Example: `cpu_shares=0.5, cpu_shares=1`

**cpuset** CPUs on which which to allow execution, specified as a string containing a range (e.g. 0-3) or a comma-separated list of CPUs (e.g. 0,1).

Example: `cpuset="0-3", cpuset="0,1"`

**client_timeout** Timeout in seconds for the Docker client. This is not a timeout for this function, but for receiving a response from the API.
labels Add Metadata to the container. Can be a list of strings/dictionaries or a dictionary of strings (keys and values).

Example:  labels=LABEL1, LABEL2, labels={"LABEL1": 'value1', 'LABEL2': 'value2'}

validate_ip_addrs [True] For parameters which accept IP addresses as input, IP address validation will be performed. To disable, set this to False.

binds Files/directories to bind mount. Each bind mount should be passed in the format <host_path>:<container_path>:<read_only>, where <read_only> is one of rw (for read-write access) or ro (for read-only access). Optionally, the read-only information can be left off the end and the bind mount will be assumed to be read-write. Examples 2 and 3 below are equivalent.

Example 1: binds=/srv/www:/var/www:ro
Example 2: binds=/srv/www:/var/www:rw
Example 3: binds=/srv/www:/var/www

port_bindings Bind exposed ports which were exposed using the ports argument to dockerng.create. These should be passed in the same way as the --publish argument to the docker run CLI command:

- ip:hostPort:containerPort - Bind a specific IP and port on the host to a specific port within the container.
- ip::containerPort - Bind a specific IP and an ephemeral port to a specific port within the container.
- hostPort:containerPort - Bind a specific port on all of the host's interfaces to a specific port within the container.
- containerPort - Bind an ephemeral port on all of the host's interfaces to a specific port within the container.

Multiple bindings can be separated by commas, or passed as a Python list. The below two examples are equivalent:

Example 1: port_bindings="5000:5000,2123:2123/udp,8080"
Example 2: port_bindings="[5000:5000,2123:2123/udp,8080]"

Note: When configuring bindings for UDP ports, the protocol must be passed in the containerPort value, as seen in the examples above.

lxc_conf Additional LXC configuration parameters to set before starting the container.

Example: lxc_conf="{lxc.utsname: docker}"

Note: These LXC configuration parameters will only have the desired effect if the container is using the LXC execution driver, which has not been the default for some time.

publish_all_ports [False] Allocates a random host port for each port exposed using the ports argument to dockerng.create.

Example: publish_all_ports=True
- **links**: Link this container to another. Links should be specified in the format `<container_name_or_id>:<link_alias>`. Multiple links can be passed, either as a comma-separated list or a Python list.

  Example 1: `links=mycontainer:myalias,links=web1:link1,web2:link2`

  Example 2: `links="['mycontainer:myalias','web1:link1','web2:link2']"`

- **dns**: List of DNS nameservers. Can be passed as a comma-separated list or a Python list.

  Example: `dns=8.8.8.8,8.8.4.4 or dns="[8.8.8.8,8.8.4.4]"`

  **Note**: To skip IP address validation, use `validate_ip_addrs=False`

- **dns_search**: List of DNS search domains. Can be passed as a comma-separated list or a Python list.

  Example: `dns_search=foo1.domain.tld,foo2.domain.tld or dns_search="[foo1.domain.tld,foo2.domain.tld]"

- **volumes_from**: Container names or IDs from which the container will get volumes. Can be passed as a comma-separated list or a Python list.

  Example: `volumes_from=foo,volumes_from=foo,bar,volumes_from="[foo,bar]"

- **network_mode**: [bridge] One of the following:
  - `bridge`: Creates a new network stack for the container on the docker bridge
  - `null`: No networking (equivalent of the Docker CLI argument `--net=none`)
  - `container:<name_or_id>`: Reuses another container's network stack
  - `host`: Use the host's network stack inside the container

  **Warning**: Using `host` mode gives the container full access to the host's system's services (such as D-bus), and is therefore considered insecure.

  Example: `network_mode=null,network_mode=container:web1`

- **restart_policy**: Set a restart policy for the container. Must be passed as a string in the format `policy[:retry_count]` where policy is one of `always` or `on-failure`, and `retry_count` is an optional limit to the number of retries. The retry count is ignored when using the `always` restart policy.

  Example 1: `restart_policy=on-failure:5`

  Example 2: `restart_policy=always`

- **cap_add**: List of capabilities to add within the container. Can be passed as a comma-separated list or a Python list. Requires Docker 1.2.0 or newer.

  Example: `cap_add=SYS_ADMIN,MKNOD, cap_add="[SYS_ADMIN,MKNOD]"

- **cap_drop**: List of capabilities to drop within the container. Can be passed as a comma-separated string or a Python list. Requires Docker 1.2.0 or newer.

  Example: `cap_drop=SYS_ADMIN,MKNOD, cap_drop="[SYS_ADMIN,MKNOD]"

- **extra_hosts**: Additional hosts to add to the container's `/etc/hosts` file. Can be passed as a comma-separated list or a Python list. Requires Docker 1.3.0 or newer.

  Example: `extra_hosts=web1:10.9.8.7,web2:10.9.8.8`

  **Note**: To skip IP address validation, use `validate_ip_addrs=False`
**pid_mode**  Set to `host` to use the host container's PID namespace within the container. Requires Docker 1.5.0 or newer.

Example: `pid_mode=host`

**RETURN DATA**

A dictionary containing the following keys:
- **Id** - ID of the newly-created container
- **Name** - Name of the newly-created container

**CLI Example:**

```
# Create a data-only container
salt myminion dockerng.create myuser/mycontainer volumes="/mnt/vol1,/mnt/vol2"

# Create a CentOS 7 container that will stay running once started
salt myminion dockerng.create centos:7 name=mycent7 interactive=True tty=True
   command=bash
```

**salt.modules.dockerng.create_network**(name, driver=None)

Create a new network

- **network_id**  ID of network
- **driver**  Driver of the network

**CLI Example:**

```
salt myminion dockerng.create_network web_network driver=bridge
```

**salt.modules.dockerng.create_volume**(name, driver=None, driver_opts=None)

Create a new volume

New in version 2015.8.4.

- **name**  name of volume
- **driver**  Driver of the volume
- **driver_opts**  Options for the driver volume

**CLI Example:**

```
salt myminion dockerng.create_volume my_volume driver=local
```

**salt.modules.dockerng.dangling**(prune=False, force=False)

Return top-level images (those on which no other images depend) which do not have a tag assigned to them. These include:
- Images which were once tagged but were later untagged, such as those which were superseded by committing a new copy of an existing tagged image.
- Images which were loaded using `docker.load` (or the `docker load` Docker CLI command), but not tagged.

- **prune**  [False] Remove these images
- **force**  [False] If True, and if `prune=True`, then forcibly remove these images.

**RETURN DATA**

If `prune=False`, the return data will be a list of dangling image IDs.

If `prune=True`, the return data will be a dictionary with each key being the ID of the dangling image, and the following information for each image:
- **Comment** - Any error encountered when trying to prune a dangling image

(Only present if prune failed)
- **Removed** - A boolean (`True` if prune was successful, `False` if not)

**CLI Example:**
salt.myminion.dockerng.dangling
salt.myminion.dockerng.dangling prune=True

**salt.modules.dockerng.depends(name)**

Returns the containers and images, if any, which depend on the given image

- **name** Name or ID of image

**RETURN DATA**

A dictionary containing the following keys:

- **Containers** - A list of containers which depend on the specified image
- **Images** - A list of IDs of images which depend on the specified image

**CLI Example:**

```
salt myminion dockerng.depends myimage
salt myminion dockerng.depends 0123456789ab
```

**salt.modules.dockerng.diff(name, *args, **kwargs)**

Get information on changes made to container's filesystem since it was created. Equivalent to running the `docker diff` Docker CLI command.

- **name** Container name or ID

**RETURN DATA**

A dictionary containing any of the following keys:

- **Added** - A list of paths that were added.
- **Changed** - A list of paths that were changed.
- **Deleted** - A list of paths that were deleted.

These keys will only be present if there were changes, so if the container has no differences the return dict will be empty.

**CLI Example:**

```
salt myminion dockerng.diff mycontainer
```

**salt.modules.dockerng.disconnect_container_from_network(container, network_id)**

Disconnect container from network.

- **container** Container name or ID
- **network_id** ID of network

**CLI Example:**

```
salt myminion dockerng.disconnect_container_from_network web-1
```

**salt.modules.dockerng.exists(name)**

Check if a given container exists

- **name** Container name or ID

**RETURN DATA**

A boolean (True if the container exists, otherwise False)

**CLI Example:**

```
salt myminion dockerng.exists mycontainer
```

**salt.modules.dockerng.export(name, *args, **kwargs)**

Exports a container to a tar archive. It can also optionally compress that tar archive, and push it up to the Master.

- **name** Container name or ID
**path**  Absolute path on the Minion where the container will be exported

**overwrite**  [False] Unless this option is set to True, then if a file exists at the location specified by the path argument, an error will be raised.

**makedirs**  [False] If True, then if the parent directory of the file specified by the path argument does not exist, Salt will attempt to create it.

**compression**  [None] Can be set to any of the following:

- gzip or gz for gzip compression
- bzip2 or bz2 for bzip2 compression
- xz or lzma for XZ compression (requires xz-utils, as well as the lzma module from Python 3.3, available in Python 2 and Python 3.0-3.2 as backports.lzma)

This parameter can be omitted and Salt will attempt to determine the compression type by examining the filename passed in the path parameter.

**push**  [False] If True, the container will be pushed to the master using cp.push.

*Note:* This requires file_recv to be set to True on the Master.

**RETURN DATA**

A dictionary will containing the following keys:

- **Path** - Path of the file that was exported
- **Push** - Reports whether or not the file was successfully pushed to the Master

*(Only present if push=True)*

- **Size** - Size of the file, in bytes
- **Size_Human** - Size of the file, in human-readable units
- **Time_Elapsed** - Time in seconds taken to perform the export

**CLI Examples:**

```plaintext
salt myminion dockerng.export mycontainer /tmp/mycontainer.tar
salt myminion dockerng.export mycontainer /tmp/mycontainer.tar.xz push=True
```

salt.modules.dockerng.get_client_args()  
New in version 2016.3.6,2016.11.4,Nitrogen.

Returns the args for docker-py's low-level API, organized by container config, host config, and networking config.

**CLI Example:**

```plaintext
salt myminion docker.get_client_args
```

salt.modules.dockerng.history(name, quiet=False)  
Return the history for an image. Equivalent to running the docker history Docker CLI command.

**name**  Container name or ID

**quiet**  [False] If True, the return data will simply be a list of the commands run to build the container.

```plaintext
$ salt myminion dockerng.history nginx:latest quiet=True
myminion:
- FROM scratch
- ADD file: ef063ed9ae9579362871b9f23d2bc9781ef7c4de6ac822052cf6c9c5a12b1e2 in /
- CMD [/bin/bash]
- MAINTAINER NGINX Docker Maintainers "docker-maint@nginx.com"
- apt-key adv --keyserver pgp.mit.edu --recv-keys  
- 573BF6D6B3DBFBC641079A6ABABF5BD827BD9BF62
```

**13.6. execution modules**  973
- echo "deb http://nginx.org/packages/mainline/debian/ wheezy nginx" >> /etc/apt/sources.list
- ENV NGINX_VERSION=1.7.10-1~wheezy
- apt-get update && apt-get install -y ca-certificates nginx=${NGINX_VERSION} &&
  rm -rf /var/lib/apt/lists/*
- ln -sf /dev/stdout /var/log/nginx/access.log
- ln -sf /dev/stderr /var/log/nginx/error.log
- VOLUME ["/var/cache/nginx"]
- EXPOSE map[80/tcp:{}] 443/tcp:[]
- CMD [nginx -g daemon off;]

https://github.com/saltstack/salt/pull/22421

RETURN DATA

If quiet=False, the return value will be a list of dictionaries containing information about each step taken to build the image. The keys in each step include the following:

- **Command** - The command executed in this build step
- **Id** - Layer ID
- **Size** - Cumulative image size, in bytes
- **Size_Human** - Cumulative image size, in human-readable units
- **Tags** - Tag(s) assigned to this layer
- **Time_Created_Epoch** - Time this build step was completed (Epoch time)
- **Time_Created_Local** - Time this build step was completed (Minion's local timezone)

CLI Example:

```
salt myminion dockerng.exists mycontainer
```

salt.modules.dockerng.images( **kwargs)

Returns information about the Docker images on the Minion. Equivalent to running the `docker images` Docker CLI command.

- **all** [False] If True, untagged images will also be returned
- **verbose** [False] If True, a `docker inspect` will be run on each image returned.

RETURN DATA

A dictionary with each key being an image ID, and each value some general info about that image (time created, size, tags associated with the image, etc.)

CLI Example:

```
salt myminion dockerng.images
```

salt.modules.dockerng.import( source, image, api_response=False )

Imports content from a local tarball or a URL as a new docker image

- **source** Content to import (URL or absolute path to a tarball). URL can be a file on the Salt fileserver (i.e. `salt://path/to/rootfs/tarball.tar.xz`). To import a file from a saltenv other than base (e.g. `dev`), pass it at the end of the URL (ex. `salt://path/to/rootfs.tarball.tar.xz?saltenv=dev`).
- **image** Image to be created by the import, in repo:tag notation. If just the repository name is passed, a tag name of latest will be assumed.
- **api_response** [False] If True an api_response key will be present in the return data, containing the raw output from the Docker API.

RETURN DATA

A dictionary containing the following keys:

- **Id** - ID of the newly-created image
- **Image** - Name of the newly-created image
Time_elapsed - Time in seconds taken to perform the commit

CLI Example:
```
salt myminion dockerng.import /tmp/cent7-minimal.tar.xz myuser/centos
salt myminion dockerng.import /tmp/cent7-minimal.tar.xz myuser/centos:7
salt myminion dockerng.import salt://dockerimages/cent7-minimal.tar.xz myuser/centos:7
```

salt.modules.dockerng.info()
Returns a dictionary of system-wide information. Equivalent to running the docker info Docker CLI command.

CLI Example:
```
salt myminion dockerng.info
```

salt.modules.dockerng.inspect(name)
This is a generic container/image inspecton function. It will first attempt to get container information for the passed name/ID using docker.inspect_container, and then will try to get image information for the passed name/ID using docker.inspect_image. If it is already known that the name/ID is an image, it is slightly more efficient to use docker.inspect_image.

name Container/image name or ID

RETURN DATA
A dictionary of container/image information

CLI Example:
```
salt myminion dockerng.inspect mycontainer
salt myminion dockerng.inspect busybox
```

salt.modules.dockerng.inspect_container(name, *args, **kwargs)
Retrieves container information. Equivalent to running the docker inspect Docker CLI command, but will only look for container information.

name Container name or ID

RETURN DATA
A dictionary of container information

CLI Example:
```
salt myminion dockerng.inspect_container mycontainer
salt myminion dockerng.inspect_container 0123456789ab
```

salt.modules.dockerng.inspect_image(name)
Retrieves image information. Equivalent to running the docker inspect Docker CLI command, but will only look for image information.

Note: To inspect an image, it must have been pulled from a registry or built locally. Images on a Docker registry which have not been pulled cannot be inspected.

name Image name or ID

RETURN DATA
A dictionary of image information

CLI Examples:
salt myminion dockerng.inspect_image busybox
salt myminion dockerng.inspect_image centos:6
salt myminion dockerng.inspect_image 0123456789ab

```python
salt.modules.dockernginspect_network(network_id)
```

Inspect Network

network_id ID of network

CLI Example:

```bash
salt myminion dockerng.inspect_network
```

---

```bash
!1f9d2454d0872b68dd9e8744c6e7a4c66b86f10abaccc21e14f7f014f729b2bc
```

salt.modules.dockerng.inspect_volume(name)

Inspect Volume

New in version 2015.8.4.

name Name of volume

CLI Example:

```bash
salt myminion dockerng.inspect_volume my_volume
```

---

```python
salt.modules.dockerng.kill(*args, **kwargs)
```

Kill all processes in a running container instead of performing a graceful shutdown

name Container name or ID

RETURN DATA

A dictionary will be returned, containing the following keys:

- status - A dictionary showing the prior state of the container as well as the new state
- result - A boolean noting whether or not the action was successful
- comment - Only present if the container cannot be killed

CLI Example:

```bash
salt myminion dockerng.kill mycontainer
```

---

```python
salt.modules.dockerng.layers(name)
```

Returns a list of the IDs of layers belonging to the specified image, with the top-most layer (the one corresponding to the passed name) appearing last.

name Image name or ID

CLI Example:

```bash
salt myminion dockerng.layers centos:7
```

---

```python
salt.modules.dockerng.list_containers(**kwargs)
```

Returns a list of containers by name. This is different from `dockerng.ps` in that `dockerng.ps` returns its results organized by container ID.

all [False] If True, stopped containers will be included in return data

CLI Example:

```bash
salt myminion dockerng.inspect_image <image>
```

---

```python
salt.modules.dockerng.list_tags()
```

Returns a list of tagged images

CLI Example:

```bash
salt myminion dockerng.list_tags
```
salt.modules.dockerng.load(path, image=None)

Load a tar archive that was created using `dockerng.save` (or via the Docker CLI using `docker save`).

- **path**: Path to docker tar archive. Path can be a file on the Minion, or the URL of a file on the Salt fileserver (i.e. `salt://path/to/docker/saved/image.tar`). To load a file from a saltenv other than `base` (e.g. `dev`), pass it at the end of the URL (ex. `salt://path/to/rootfs/tarball.tar.xz?saltenv=dev`).

- **image**: [None] If specified, the topmost layer of the newly-loaded image will be tagged with the specified repo and tag using `dockerng.tag`. The image name should be specified in `repo:tag` notation. If just the repository name is passed, a tag name of `latest` will be assumed.

**RETURN DATA**

A dictionary will be returned, containing the following keys:

- **Path**: Path of the file that was saved
- **Layers**: A list containing the IDs of the layers which were loaded. Any layers in the file that was loaded, which were already present on the Minion, will not be included.
- **Image**: Name of tag applied to topmost layer

(Only present if tag was specified and tagging was successful)

- **Time_Elapsed**: Time in seconds taken to load the file
- **Warning**: Message describing any problems encountered in attempt to tag the topmost layer

(Only present if tag was specified and tagging failed)

**CLI Example:**

```python
salt myminion dockerng.load /path/to/image.tar
salt myminion dockerng.load salt://path/to/docker/saved/image.tar image=myuser/myimage:mytag
```

salt.modules.dockerng.login(registries)

New in version 2016.3.7, 2016.11.4, Nitrogen.

Performs a `docker login` to authenticate to one or more configured repositories. See the documentation at the top of this page to configure authentication credentials.

Multiple registry URLs (matching those configured in Pillar) can be passed, and Salt will attempt to login to just those registries. If no registry URLs are provided, Salt will attempt to login to all configured registries.

**RETURN DATA**

A dictionary containing the following keys:

- **Results**: A dictionary mapping registry URLs to the authentication result. `True` means a successful login, `False` means a failed login.
- **Errors**: A list of errors encountered during the course of this function.

**CLI Example:**

```python
salt myminion dockerng.login
salt myminion dockerng.login hub
salt myminion dockerng.login hub https://mydomain.tld/registry/
```

salt.modules.dockerng.logs(name)

Returns the logs for the container. Equivalent to running the `docker logs` Docker CLI command.

- **name**: Container name or ID

**CLI Example:**

```python
salt myminion dockerng.logs mycontainer
```

salt.modules.dockerng.networks(names=None, ids=None)

List existing networks

- **names**: Filter by name

**13.6. execution modules**
ids  Filter by id
CLI Example:

```
salt myminion dockerng.networks names=["network-web"]
salt myminion dockerng.networks ids=['1f9d2454d0872b68dd9e8744c6e7a4c66b86f10abaccc21e14f7f014f729b2bc']
```

salt.modules.dockerng.pause(*args, **kwargs)
Pauses a container
name  Container name or ID

RETURN DATA
A dictionary will be returned, containing the following keys:
- status - A dictionary showing the prior state of the container as well as the new state
- result - A boolean noting whether or not the action was successful
- comment - Only present if the container cannot be paused

CLI Example:
```
salt myminion dockerng.pause mycontainer
```

salt.modules.dockerng.pid(name, *args, **kwargs)
Returns the PID of a container
name  Container name or ID

CLI Example:
```
salt myminion dockerng.pid mycontainer
salt myminion dockerng.pid 0123456789ab
```

salt.modules.dockerng.port(name, *args, **kwargs)
Returns port mapping information for a given container. Equivalent to running the docker port Docker CLI command.
name  Container name or ID
private_port  [None] If specified, get information for that specific port. Can be specified either as a port number (i.e. 5000), or as a port number plus the protocol (i.e. 5000/udp).

If this argument is omitted, all port mappings will be returned.

RETURN DATA
A dictionary of port mappings, with the keys being the port and the values being the mapping(s) for that port.

CLI Examples:
```
salt myminion dockerng.port mycontainer
salt myminion dockerng.port mycontainer 5000
salt myminion dockerng.port mycontainer 5000/udp
```

salt.modules.dockerng.ps(filters=None, **kwargs)
Returns information about the Docker containers on the Minion. Equivalent to running the docker ps Docker CLI command.
all  [False] If True, stopped containers will also be returned
host  [False] If True, local host's network topology will be included
verbose  [False] If True, a docker inspect will be run on each container returned.
filters  None  A dictionary of filters to be processed on the container list. Available filters:
- exited (int): Only containers with specified exit code
- status (str): One of restarting, running, paused, exited
- label (str): format either ``key`` or ``key=value``
RETURN DATA

A dictionary with each key being an container ID, and each value some general info about that container (time created, name, command, etc.)

CLI Example:

```
salt myminion dockerng.ps
salt myminion dockerng.ps all=True
salt myminion dockerng.ps filters="{'label': 'role=web'}"
```

`salt.modules.dockerng.pull(image, insecure_registry=False, api_response=False, client_timeout=60)`

Pulls an image from a Docker registry

- **image** Image to be pulled, in `repo:tag` notation. If just the repository name is passed, a tag name of `latest` will be assumed.
- **insecure_registry** [False] If True, the Docker client will permit the use of insecure (non-HTTPS) registries.
- **api_response** [False] If True, an API_Response key will be present in the return data, containing the raw output from the Docker API.

**Note:** This may result in a lot of additional return data, especially for larger images.

**client_timeout** Timeout in seconds for the Docker client. This is not a timeout for this function, but for receiving a response from the API.

RETURN DATA

A dictionary will be returned, containing the following keys:

- **Layers** - A dictionary containing one or more of the following keys:
  - **Already_Pulled** - Layers that that were already present on the Minion
  - **Pulled** - Layers that that were pulled
- **Status** - A string containing a summary of the pull action (usually a message saying that an image was downloaded, or that it was up to date).
- **TimeElapsed** - Time in seconds taken to perform the pull

CLI Example:

```
salt myminion dockerng.pull centos
salt myminion dockerng.pull centos:6
```

`salt.modules.dockerng.push(image, insecure_registry=False, api_response=False, client_timeout=60)`

Changed in version 2015.8.4: The Id and Image keys are no longer present in the return data. This is due to changes in the Docker Remote API.

Pushes an image to a Docker registry. See the documentation at top of this page to configure authentication credentials.

- **image** Image to be pushed, in `repo:tag` notation.

  Changed in version 2015.8.4: If just the repository name is passed, then all tagged images for the specified repo will be pushed. In prior releases, a tag of `latest` was assumed if the tag was omitted.

- **insecure_registry** [False] If True, the Docker client will permit the use of insecure (non-HTTPS) registries.
- **api_response** [False] If True, an API_Response key will be present in the return data, containing the raw output from the Docker API.

**client_timeout** Timeout in seconds for the Docker client. This is not a timeout for this function, but for receiving a response from the API.

RETURN DATA

A dictionary will be returned, containing the following keys:

- **Layers** - A dictionary containing one or more of the following keys:
- Already_Pushed - Layers that that were already present on the Minion
- Pushed - Layers that were pushed
- Time_Elapsed - Time in seconds taken to perform the push

CLI Example:

```
salt myminion dockerng.push myuser/mycontainer
salt myminion dockerng.push myuser/mycontainer:mytag
```

salt.modules.dockerng.remove_network(network_id)
Remove a network

```
salt myminion dockerng.remove_network
1f9d2454d0872b68dd9e8744c6e7a4c66b86f10abaccc21e14f7f014f729b2bc
```

salt.modules.dockerng.remove_volume(name)
Remove a volume

```
salt myminion dockerng.remove_volume my_volume
```

salt.modules.dockerng.restart(name, *args, **kwargs)
Restarts a container

```
salt myminion dockerng.restart mycontainer
salt myminion dockerng.restart mycontainer timeout=20
```

salt.modules.dockerng.retcode(name, cmd, exec_driver=None, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)
Run cmd.retcode within a container

```
Run cmd.retcode within a container
name Container name or ID in which to run the command
cmd Command to run
eexec_driver [None] If not passed, the execution driver will be detected as described above.
stdin [None] Standard input to be used for the command
output_loglevel [debug] Level at which to log the output from the command. Set to quiet to suppress logging.
use_vt [False] Use SaltStack's utils.vt to stream output to console.
keep_env [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.
```
**CLI Example:**
```
salt myminion dockerng.retcode mycontainer 'ls -l /etc'
```

```python
salt.modules.dockerng.rm(*args, **kwargs)
```
Removes a container

- **name** Container name or ID
- **force** (False] If True, the container will be killed first before removal, as the Docker API will not permit a running container to be removed. This option is set to False by default to prevent accidental removal of a running container.
- **volumes** (False] Also remove volumes associated with container

**RETURN DATA**
A list of the IDs of containers which were removed

**CLI Example:**
```
salt myminion dockerng.rm mycontainer
salt myminion dockerng.rm mycontainer force=True
```

```python
salt.modules.dockerng.rmi(*names, **kwargs)
```
Removes an image

- **name** Name (in repo:tag notation) or ID of image.
- **force** (False] If True, the image will be removed even if the Minion has containers created from that image
- **prune** [True] If True, untagged parent image layers will be removed as well, set this to False to keep them.

**RETURN DATA**
A dictionary will be returned, containing the following two keys:
- **Layers** - A list of the IDs of image layers that were removed
- **Tags** - A list of the tags that were removed
- **Errors** - A list of any errors that were encountered

**CLI Examples:**
```
salt myminion dockerng.rmi busybox
salt myminion dockerng.rmi busybox force=True
salt myminion dockerng.rmi foo bar baz
```

```python
salt.modules.dockerng.run(name, cmd, exec_driver=None, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)
```
Run `cmd.run` within a container

- **name** Container name or ID in which to run the command
- **cmd** Command to run
- **exec_driver** [None] If not passed, the execution driver will be detected as described above.
- **stdin** [None] Standard input to be used for the command
- **output_loglevel** [debug] Level at which to log the output from the command. Set to quiet to suppress logging.
- **use_vt** [False] Use SaltStack's utils.vt to stream output to console.
- **keep_env** [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

**CLI Example:**
```
salt myminion dockerng.run mycontainer 'ls -l /etc'
```
salt.modules.dockerng.run_all(name, cmd, exec_driver=None, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)

Run `cmd.run_all` within a container

**Note:** While the command is run within the container, it is initiated from the host. Therefore, the PID in the return dict is from the host, not from the container.

- **name** Container name or ID in which to run the command
- **cmd** Command to run
- **exec_driver** [None] If not passed, the execution driver will be detected as described above.
- **stdin** [None] Standard input to be used for the command
- **output_loglevel** [debug] Level at which to log the output from the command. Set to `quiet` to suppress logging.
- **use_vt** [False] Use SaltStack’s `utils.vt` to stream output to console.
- **keep_env** [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container’s host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:

```
salt myminion dockerng.run_all mycontainer 'ls -l /etc'
```

salt.modules.dockerng.run_stderr(name, cmd, exec_driver=None, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)

Run `cmd.run_stderr` within a container

- **name** Container name or ID in which to run the command
- **cmd** Command to run
- **exec_driver** [None] If not passed, the execution driver will be detected as described above.
- **stdin** [None] Standard input to be used for the command
- **output_loglevel** [debug] Level at which to log the output from the command. Set to `quiet` to suppress logging.
- **use_vt** [False] Use SaltStack’s `utils.vt` to stream output to console.
- **keep_env** [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container’s host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:

```
salt myminion dockerng.run_stderr mycontainer 'ls -l /etc'
```

salt.modules.dockerng.run_stdout(name, cmd, exec_driver=None, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)

Run `cmd.run_stdout` within a container

- **name** Container name or ID in which to run the command
- **cmd** Command to run
- **exec_driver** [None] If not passed, the execution driver will be detected as described above.
- **stdin** [None] Standard input to be used for the command
- **output_loglevel** [debug] Level at which to log the output from the command. Set to `quiet` to suppress logging.
- **use_vt** [False] Use SaltStack’s `utils.vt` to stream output to console.
**keep_env** [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:

```bash
salt myminion dockerng.run_stdout mycontainer 'ls -l /etc'
```

salt.modules.dockerng.save*(name, path, overwrite=False, makedirs=False, compression=None, **kwargs)*

Saves an image and to a file on the minion. Equivalent to running the docker save Docker CLI command, but unlike docker save this will also work on named images instead of just images IDs.

- **name** Name or ID of image. Specify a specific tag by using the repo:tag notation.
- **path** Absolute path on the Minion where the image will be exported
- **overwrite** [False] Unless this option is set to True, then if the destination file exists an error will be raised.
- **makedirs** [False] If True, then if the parent directory of the file specified by the path argument does not exist, Salt will attempt to create it.
- **compression** [None] Can be set to any of the following:
  - gzip or gz for gzip compression
  - bzip2 or bz2 for bzip2 compression
  - xz or lzma for XZ compression (requires xz-utils, as well as the lzma module from Python 3.3, available in Python 2 and Python 3.0-3.2 as backports.lzma)

This parameter can be omitted and Salt will attempt to determine the compression type by examining the filename passed in the path parameter.

**Note:** Since the Docker API does not support docker save, compression will be a bit slower with this function than with docker.export since the image(s) will first be saved and then the compression done afterwards.

- **push** [False] If True, the container will be pushed to the master using cp.push.

  **Note:** This requires file_recv to be set to True on the Master.

**RETURN DATA**

A dictionary will be returned, containing the following keys:
- **Path** - Path of the file that was saved
- **Push** - Reports whether or not the file was successfully pushed to the Master

  *(Only present if push=True)*
- **Size** - Size of the file, in bytes
- **Size_Human** - Size of the file, in human-readable units
- **Time_Elapsed** - Time in seconds taken to perform the save

CLI Examples:

```bash
salt myminion dockerng.save centos:7 /tmp/cent7.tar
salt myminion dockerng.save 0123456789ab cdef01234567 /tmp/saved.tar
```

salt.modules.dockerng.script*(name, source, saltenv='base', args=None, template=None, exec_driver=None, stdin=None, python_shell=True, output_loglevel='debug', ignore_retcode=False, use_vt=False, keep_env=None)*

Run cmd.script within a container
Note: While the command is run within the container, it is initiated from the host. Therefore, the PID in the return dict is from the host, not from the container.

**name**  Container name or ID  
**source**  Path to the script. Can be a local path on the Minion or a remote file from the Salt fileserver.  
**args**  A string containing additional command-line options to pass to the script.  
**template**  [None] Templating engine to use on the script before running.  
**exec_driver**  [None] If not passed, the execution driver will be detected as described above.  
**stdin**  [None] Standard input to be used for the script  
**output_loglevel**  [debug] Level at which to log the output from the script. Set to quiet to suppress logging.  
**use_vt**  [False] Use SaltStack's utils.vt to stream output to console.  
**keep_env**  [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.  

**CLI Example:**

```bash
salt myminion dockerng.script mycontainer salt://docker_script.py
salt myminion dockerng.script mycontainer salt://scripts/runme.sh 'arg1 arg2 "arg 3"
salt myminion dockerng.script mycontainer salt://scripts/runme.sh stdin=
	'one\ntwo\nthree\nfour\nfive' output_loglevel=quiet
```

**salt.modules.dockerng.script_retcode**  
Run `cmd.script_retcode` within a container  
**name**  Container name or ID  
**source**  Path to the script. Can be a local path on the Minion or a remote file from the Salt fileserver.  
**args**  A string containing additional command-line options to pass to the script.  
**template**  [None] Templating engine to use on the script before running.  
**exec_driver**  [None] If not passed, the execution driver will be detected as described above.  
**stdin**  [None] Standard input to be used for the script  
**output_loglevel**  [debug] Level at which to log the output from the script. Set to quiet to suppress logging.  
**use_vt**  [False] Use SaltStack's utils.vt to stream output to console.  
**keep_env**  [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.  

**CLI Example:**

```bash
salt myminion dockerng.script_retcode mycontainer salt://docker_script.py
salt myminion dockerng.script_retcode mycontainer salt://scripts/runme.sh 'arg1 arg2 "arg 3"
salt myminion dockerng.script_retcode mycontainer salt://scripts/runme.sh stdin=
	'one\ntwo\nthree\nfour\nfive' output_loglevel=quiet
```

**salt.modules.dockerng.search**  
Searches the registry for an image  
**name**  Search keyword  
**official**  [False] Limit results to official builds  
**trusted**  [False] Limit results to trusted builds
RETURN DATA

A dictionary with each key being the name of an image, and the following information for each image:
- Description - Image description
- Official - A boolean (True if an official build, False if not)
- Stars - Number of stars the image has on the registry
- Trusted - A boolean (True if a trusted build, False if not)

CLI Example:
salt myminion dockerng.search centos
salt myminion dockerng.search centos official=True

salt.modules.dockerng.signal(*args, **kwargs)
Send a signal to a container. Signals can be either strings or numbers, and are defined in the Standard Signals section of the signal(7) manual page. Run man 7 signal on a Linux host to browse this manual page.
- name Container name or ID
- signal Signal to send to container

RETURN DATA

If the signal was successfully sent, True will be returned. Otherwise, an error will be raised.

CLI Example:
salt myminion dockerng.signal mycontainer SIGHUP

salt.modules.dockerng.start(*args, **kwargs)
Start a container
- name Container name or ID

RETURN DATA

A dictionary will be returned, containing the following keys:
- status - A dictionary showing the prior state of the container as well as the new state
- result - A boolean noting whether or not the action was successful
- comment - Only present if the container cannot be started

CLI Example:
salt myminion dockerng.start mycontainer

salt.modules.dockerng.state(name, *args, **kwargs)
Returns the state of the container
- name Container name or ID

RETURN DATA

A string representing the current state of the container (either running, paused, or stopped)

CLI Example:
salt myminion dockerng.state mycontainer

salt.modules.dockerng.stop(*args, **kwargs)
Stops a running container
- name Container name or ID
- unpause [False] If True and the container is paused, it will be unpaused before attempting to stop the container.
- timeout [10] Timeout in seconds after which the container will be killed (if it has not yet gracefully shut down)

RETURN DATA

A dictionary will be returned, containing the following keys:
• **status** - A dictionary showing the prior state of the container as well as the new state
• **result** - A boolean noting whether or not the action was successful
• **comment** - Only present if the container can not be stopped

**CLI Examples:**
```
salt myminion dockerng.stop mycontainer
salt myminion dockerng.stop mycontainer unpause=True
salt myminion dockerng.stop mycontainer timeout=20
```

```python
salt.modules.dockerng.tag(name, image, force=False)
```
Tag an image into a repository and return True. If the tag was unsuccessful, an error will be raised.

- **name** ID of image
- **image** Tag to apply to the image, in repo:tag notation. If just the repository name is passed, a tag name of latest will be assumed.
- **force** [False] Force apply tag

**CLI Example:**
```
salt myminion dockerng.tag 0123456789ab myrepo/mycontainer
salt myminion dockerng.tag 0123456789ab myrepo/mycontainer:mytag
```

```python
salt.modules.dockerng.top(name, *args, **kwargs)
```
Runs the docker top command on a specific container

- **name** Container name or ID

**RETURN DATA**
A list of dictionaries containing information about each process

```
salt myminion dockerng.top mycontainer
salt myminion dockerng.top 0123456789ab
```

```python
salt.modules.dockerng.unpause(*args, **kwargs)
```
Unpauses a container

- **name** Container name or ID

**RETURN DATA**
A dictionary will be returned, containing the following keys:

- **status** - A dictionary showing the prior state of the container as well as the new state
- **result** - A boolean noting whether or not the action was successful
- **comment** - Only present if the container can not be unpaused

**CLI Example:**
```
salt myminion dockerng.unpause mycontainer
```

```python
salt.modules.dockerng.version()
```
Returns a dictionary of Docker version information. Equivalent to running the docker version Docker CLI command.

**CLI Example:**
```
salt myminion dockerng.version
```

```python
salt.modules.dockerng.volumes(filters=None)
```
List existing volumes

New in version 2015.8.4.

- **filters** There is one available filter: dangling=true
CLI Example:
```
salt myminion dockerng.volumes filters="{"dangling": True}"
```

```python
salt.modules.dockerng.wait(name, ignore_already_stopped=False, fail_on_exit_status=False)
```
Wait for the container to exit gracefully, and return its exit code

**Note:** This function will block until the container is stopped.

- **name**  Container name or ID
- **ignore_already_stopped**  Boolean flag that prevent execution to fail, if a container is already stopped.
- **fail_on_exit_status**  Boolean flag to report execution as failure if **exit_status** is different than 0.

**RETURN DATA**
A dictionary will be returned, containing the following keys:

- **status**  - A dictionary showing the prior state of the container as well as the new state
- **result**  - A boolean noting whether or not the action was successful
- **exit_status**  - Exit status for the container
- **comment**  - Only present if the container is already stopped

CLI Example:
```
salt myminion dockerng.wait mycontainer
```

### 13.6.76 salt.modules.dpkg

Support for DEB packages

```python
salt.modules.dpkg.bin_pkg_info(path, saltenv='base')
```
New in version 2015.8.0.

Parses RPM metadata and returns a dictionary of information about the package (name, version, etc.).

- **path**  Path to the file. Can either be an absolute path to a file on the minion, or a salt fileserver URL (e.g. `salt://path/to/file.rpm`). If a salt fileserver URL is passed, the file will be cached to the minion so that it can be examined.
- **saltenv**  [base] Salt fileserver environment from which to retrieve the package. Ignored if **path** is a local file path on the minion.

CLI Example:
```
salt '*' lowpkg.bin_pkg_info /root/foo-1.2.3-1ubuntu1_all.deb
salt '*' lowpkg.bin_pkg_info salt://foo-1.2.3-1ubuntu1_all.deb
```

```python
salt.modules.dpkg.file_list('packages')
```
List the files that belong to a package, grouped by package. Not specifying any packages will return a list of _every_ file on the system's package database (not generally recommended).

CLI Examples:
```
salt '*' lowpkg.file_list httpd
salt '*' lowpkg.file_list httpd postfix
salt '*' lowpkg.file_list
```

```python
salt.modules.dpkg.file_list('packages')
```
List the files that belong to a package. Not specifying any packages will return a list of _every_ file on the system's package database (not generally recommended).
CLI Examples:

```makefile
salt '*' lowpkg.file_list httpd
salt '*' lowpkg.file_list httpd postfix
salt '*' lowpkg.file_list
```

`salt.modules.dpkg.info(*packages)`

Returns a detailed summary of package information for provided package names. If no packages are specified, all packages will be returned.

- `packages` The names of the packages for which to return information.

CLI example:

```makefile
salt '*' lowpkg.info
salt '*' lowpkg.info apache2 bash
```

`salt.modules.dpkg.list_pkgs(*packages)`

List the packages currently installed in a dict:

```makefile
{'<package_name>': '<version>'}
```

External dependencies:

Virtual package resolution requires aptitude. Because this function uses dpkg, virtual packages will be reported as not installed.

CLI Example:

```makefile
salt '*' lowpkg.list_pkgs
salt '*' lowpkg.list_pkgs httpd
```

`salt.modules.dpkg.unpurge(*packages)`

Change package selection for each package specified to `install`

CLI Example:

```makefile
salt '*' lowpkg.unpurge curl
```

13.6.77 salt.modules.drac

Manage Dell DRAC

`salt.modules.drac.change_password(username, password, uid=None)`

Change users password

CLI Example:

```bash
salt dell drac.change_password [USERNAME] [PASSWORD] [UID - optional]
salt dell drac.change_password diana secret
```

`salt.modules.drac.create_user(username, password, permissions, users=None)`

Create user accounts

CLI Example:

```bash
salt dell drac.create_user [USERNAME] [PASSWORD] [PRIVILEGES]
salt dell drac.create_user diana secret login,test_alerts,clear_logs
```
DRAC Privileges

- login: Login to iDRAC
- drac: Configure iDRAC
- user_management: Configure Users
- clear_logs: Clear Logs
- server_control_commands: Execute Server Control Commands
- console_redirection: Access Console Redirection
- virtual_media: Access Virtual Media
- test_alerts: Test Alerts
- debug_commands: Execute Debug Commands

```
salt.modules.drac.delete_user(username, uid=None)
```
Delete a user

CLI Example:
```
salt dell drac.delete_user [USERNAME] [UID - optional]
salt dell drac.delete_user diana 4
```

```
salt.modules.drac.email_alerts(action)
```
Enable/Disable email alerts

CLI Example:
```
salt dell drac.email_alerts True
salt dell drac.email_alerts False
```

```
salt.modules.drac.list_users()
```
List all DRAC users

CLI Example:
```
salt dell drac.list_users
```

```
salt.modules.drac.nameservers(*ns)
```
Configure the nameservers on the DRAC

CLI Example:
```
salt dell drac.nameservers [NAMESERVERS]
salt dell drac.nameservers ns1.example.com ns2.example.com
```

```
salt.modules.drac.network_info()
```
Return Network Configuration

CLI Example:
```
salt dell drac.network_info
```

```
salt.modules.drac.server_hardreset()
```
Performs a reset (reboot) operation on the managed server.

CLI Example:
salt dell drac.server_hardreset

salt.modules.drac.server_poweroff()
  Powers down the managed server.
  CLI Example:
  
  salt dell drac.server_poweroff

salt.modules.drac.server_poweron()
  Powers up the managed server.
  CLI Example:
  
  salt dell drac.server_poweron

salt.modules.drac.server_pxe()
  Configure server to PXE perform a one off PXE boot
  CLI Example:
  
  salt dell drac.server_pxe

salt.modules.drac.server_reboot()
  Issues a power-cycle operation on the managed server. This action is similar to pressing the power button on the system's front panel to power down and then power up the system.
  CLI Example:
  
  salt dell drac.server_reboot

salt.modules.drac.set_network(ip, netmask, gateway)
  Configure Network
  CLI Example:
  
  salt dell drac.set_network 192.168.0.2 255.255.255.0 192.168.0.1

salt.modules.drac.set_permissions(username, permissions, uid=None)
  Configure users permissions
  CLI Example:
  
  salt dell drac.set_permissions diana login,test_alerts,clear_logs 4

**DRAC Privileges**

- login: Login to iDRAC
- drac: Configure iDRAC
- user_management: Configure Users
- clear_logs: Clear Logs
- server_control_commands: Execute Server Control Commands
- console_redirection: Access Console Redirection
- virtual_media: Access Virtual Media
• test_alerts : Test Alerts
• debug_commands : Execute Debug Commands

salt.modules.drac.set_snmp(community)
Configure SNMP community string
CLI Example:
```
salt dell drac.set_snmp [COMMUNITY]
salt dell drac.set_snmp public
```

salt.modules.drac.syslog(server, enable=True)
Configure syslog remote logging, by default syslog will automatically be enabled if a server is specified. However, if you want to disable syslog you will need to specify a server followed by False
CLI Example:
```
salt dell drac.syslog [SYSLOG IP] [ENABLE/DISABLE]
salt dell drac.syslog 0.0.0.0 False
```

salt.modules.drac.system_info()
Return System information
CLI Example:
```
salt dell drac.system_info
```

13.6.78 salt.modules.dracr
Manage Dell DRAC.
New in version 2015.8.2.

salt.modules.dracr.bare_rac_cmd(cmd, host=None, admin_username=None, admin_password=None)

salt.modules.dracr.change_password(username, password, uid=None, host=None, admin_username=None, admin_password=None, module=None)
Change user's password
CLI Example:
```
salt dell dracr.change_password [USERNAME] [PASSWORD] uid=[OPTIONAL] host=<remote DRAC> admin_username=<DRAC user> admin_password=<DRAC PW>
salt dell dracr.change_password diana secret
```

Note that if only a username is specified then this module will look up details for all 16 possible DRAC users. This is time consuming, but might be necessary if one is not sure which user slot contains the one you want. Many late-model Dell chassis have ‘root’ as UID 1, so if you can depend on that then setting the password is much quicker. Raises an error if the supplied password is greater than 20 chars.

salt.modules.dracr.create_user(username, password, permissions, users=None, host=None, admin_username=None, admin_password=None)
Create user accounts
CLI Example:
salt dell dracr.create_user [USERNAME] [PASSWORD] [PRIVILEGES]
salt dell dracr.create_user diana secret login,test_alerts,clear_logs

DRAC Privileges

- **login**: Login to iDRAC
- **drac**: Configure iDRAC
- **user_management**: Configure Users
- **clear_logs**: Clear Logs
- **server_control_commands**: Execute Server Control Commands
- **console_redirection**: Access Console Redirection
- **virtual_media**: Access Virtual Media
- **test_alerts**: Test Alerts
- **debug_commands**: Execute Debug Commands

salt.modules.dracr.delete_user(username, uid=None, host=None, admin_username=None, admin_password=None)

Delete a user

CLI Example:

```
salt dell dracr.delete_user [USERNAME] [UID - optional]
salt dell dracr.delete_user diana 4
```

salt.modules.dracr.deploy_password(username, password, host=None, admin_username=None, admin_password=None, module=None)

Change the QuickDeploy password, used for switches as well

CLI Example:

```
salt dell dracr.deploy_password [USERNAME] [PASSWORD]
    host=<remote DRAC> admin_username=<DRAC user>
    admin_password=<DRAC PW>
salt dell dracr.change_password diana secret
```

Note that if only a username is specified then this module will look up details for all 16 possible DRAC users. This is time consuming, but might be necessary if one is not sure which user slot contains the one you want. Many late-model Dell chassis have 'root' as UID 1, so if you can depend on that then setting the password is much quicker.

salt.modules.dracr.deploy_snmp(snmp, host=None, admin_username=None, admin_password=None, module=None)

Change the QuickDeploy SNMP community string, used for switches as well

CLI Example:

```
salt dell dracr.deploy_snmp SNMP_STRING
    host=<remote DRAC or CMC> admin_username=<DRAC user>
    admin_password=<DRAC PW>
salt dell dracr.deploy_password diana secret
```

salt.modules.dracr.email_alerts(action, host=None, admin_username=None, admin_password=None)

Enable/Disable email alerts
CLI Example:
```
salt dell dracr.email_alerts True
salt dell dracr.email_alerts False
```

```
salt.modules.dracr.get_chassis_datacenter(host=None, admin_username=None, admin_password=None)
```

Get the datacenter of the chassis.
- **host** The chassis host.
- **admin_username** The username used to access the chassis.
- **admin_password** The password used to access the chassis.

CLI Example:
```
salt '*' dracr.set_chassis_location host=111.222.333.444
   admin_username=root admin_password=secret
```

```
salt.modules.dracr.get_chassis_location(host=None, admin_username=None, admin_password=None)
```

Get the location of the chassis.
- **host** The chassis host.
- **admin_username** The username used to access the chassis.
- **admin_password** The password used to access the chassis.

CLI Example:
```
salt '*' dracr.set_chassis_location host=111.222.333.444
   admin_username=root admin_password=secret
```

```
salt.modules.dracr.get_chassis_name(host=None, admin_username=None, admin_password=None)
```

Get the name of a chassis.
- **host** The chassis host.
- **admin_username** The username used to access the chassis.
- **admin_password** The password used to access the chassis.

CLI Example:
```
salt '*' dracr.get_chassis_name host=111.222.333.444
   admin_username=root admin_password=secret
```

```
salt.modules.dracr.get_dns_dracname(host=None, admin_username=None, admin_password=None)
```

```
salt.modules.dracr.get_general(cfg_sec, cfg_var, host=None, admin_username=None, admin_password=None)
```

```
salt.modules.dracr.get_slotname(slot, host=None, admin_username=None, admin_password=None)
```

Get the name of a slot number in the chassis.
- **slot** The number of the slot for which to obtain the name.
- **host** The chassis host.
- **admin_username** The username used to access the chassis.
- **admin_password** The password used to access the chassis.

CLI Example:
```
salt-call --local dracr.get_slotname 0 host=111.222.333.444
   admin_username=root admin_password=secret
```

```
salt.modules.dracr.idrac_general(blade_name, command, idrac_password=None, host=None, admin_username=None, admin_password=None)
```

13.6. execution modules
Run a generic racadm command against a particular blade in a chassis. Blades are usually named things like `server-1', `server-2', etc. If the iDRAC has a different password than the CMC, then you can pass it with the idrac_password kwarg.

**Parameters**

- **blade_name** -- Name of the blade to run the command on
- **command** -- Command like to pass to racadm
- **idrac_password** -- Password for the iDRAC if different from the CMC
- **host** -- Chassis hostname
- **admin_username** -- CMC username
- **admin_password** -- CMC password

**Returns**

stdout if the retcode is 0, otherwise a standard cmd.run_all dictionary

CLI Example:

```
salt fx2 chassis.cmd idrac_general server-1 'get BIOS.SysProfileSettings'
```

salt.modules.dracr.inventory(host=None, admin_username=None, admin_password=None)

List the names of all slots in the chassis.

- **host** The chassis host.
- **admin_username** The username used to access the chassis.
- **admin_password** The password used to access the chassis.

CLI Example:

```
salt-call --local dracr.list_slotnames host=111.222.333.444
  admin_username=root admin_password=secret
```

salt.modules.dracr.list_users(host=None, admin_username=None, admin_password=None, module=None)

List all DRAC users

CLI Example:

```
salt dell dracr.list_users
```

salt.modules.dracr.nameservers(ns, host=None, admin_username=None, admin_password=None, module=None)

Configure the nameservers on the DRAC

CLI Example:

```
salt dell dracr.nameservers [NAMESERVERS]
salt dell dracr.nameservers ns1.example.com ns2.example.com
  admin_username=root admin_password=calvin module=server-1
  host=192.168.1.1
```

salt.modules.dracr.network_info(host=None, admin_username=None, admin_password=None, module=None)

Return Network Configuration

CLI Example:

```
salt dell dracr.network_info
```
salt.modules.dracr.server_hardreset(host=None, admin_username=None, admin_password=None, module=None)

Performs a reset (reboot) operation on the managed server.
- **host** The chassis host.
- **admin_username** The username used to access the chassis.
- **admin_password** The password used to access the chassis.
- **module** The element to hard reset on the chassis such as a blade. If not provided, the chassis will be reset.

CLI Example:
```
salt dell dracr.server_hardreset
salt dell dracr.server_hardreset module=server-1
```

salt.modules.dracr.server_power(status, host=None, admin_username=None, admin_password=None, module=None)

- **status** One of `powerup`, `powerdown`, `powercycle`, `hardreset`, `graceshutdown`
- **host** The chassis host.
- **admin_username** The username used to access the chassis.
- **admin_password** The password used to access the chassis.
- **module** The element to reboot on the chassis such as a blade. If not provided, the chassis will be rebooted.

CLI Example:
```
salt dell dracr.server_reboot
salt dell dracr.server_reboot module=server-1
```

salt.modules.dracr.server_poweroff(host=None, admin_username=None, admin_password=None, module=None)

Powers down the managed server.
- **host** The chassis host.
- **admin_username** The username used to access the chassis.
- **admin_password** The password used to access the chassis.
- **module** The element to power off on the chassis such as a blade. If not provided, the chassis will be powered off.

CLI Example:
```
salt dell dracr.server_poweroff
salt dell dracr.server_poweroff module=server-1
```

salt.modules.dracr.server_poweron(host=None, admin_username=None, admin_password=None, module=None)

Powers up the managed server.
- **host** The chassis host.
- **admin_username** The username used to access the chassis.
- **admin_password** The password used to access the chassis.
- **module** The element to power on located on the chassis such as a blade. If not provided, the chassis will be powered on.

CLI Example:
```
salt dell dracr.server_poweron
salt dell dracr.server_poweron module=server-1
```

salt.modules.dracr.server_powerstatus(host=None, admin_username=None, admin_password=None, module=None)

Return the power status for the passed module

CLI Example:
salt.modules.dracr.server_powerstatus

Configure server to PXE perform a one off PXE boot

CLI Example:
salt dell dracr.server_powerstatus

salt.modules.dracr.server_pxe(host=None, admin_username=None, admin_password=None)

CLI Example:
salt dell dracr.server_pxe

salt.modules.dracr.server_reboot(host=None, admin_username=None, admin_password=None, module=None)

Issues a power-cycle operation on the managed server. This action is similar to pressing the power button on the system's front panel to power down and then power up the system.

host The chassis host.
admin_username The username used to access the chassis.
admin_password The password used to access the chassis.
module The element to reboot on the chassis such as a blade. If not provided, the chassis will be rebooted.

CLI Example:
salt dell dracr.server_reboot
salt dell dracr.server_reboot module=server-1

salt.modules.dracr.set_chassis_datacenter(location, host=None, admin_username=None, admin_password=None)

Set the location of the chassis.

location The name of the datacenter to be set on the chassis.
host The chassis host.
admin_username The username used to access the chassis.
admin_password The password used to access the chassis.

CLI Example:
salt '*' dracr.set_chassis_datacenter datacenter-name host=111.222.333.444 admin_username=root admin_password=secret

salt.modules.dracr.set_chassis_location(location, host=None, admin_username=None, admin_password=None)

Set the location of the chassis.

location The name of the location to be set on the chassis.
host The chassis host.
admin_username The username used to access the chassis.
admin_password The password used to access the chassis.

CLI Example:
salt '*' dracr.set_chassis_location location-name host=111.222.333.444 admin_username=root admin_password=secret

salt.modules.dracr.set_chassis_name(name, host=None, admin_username=None, admin_password=None)

Set the name of the chassis.

name The name to be set on the chassis.
host The chassis host.
admin_username The username used to access the chassis.
admin_password The password used to access the chassis.

CLI Example:
salt 'dracr.set_chassis_name my-chassis host=111.222.333.444
    admin_username=root admin_password=secret

salt.modules.dracr.set_dns_dracname(name, host=None, admin_username=None, admin_password=None)

salt.modules.dracr.set_general(cfg_sec, cfg_var, val, host=None, admin_username=None, admin_password=None)

salt.modules.dracr.set_network(ip, netmask, gateway, host=None, admin_username=None, admin_password=None)

    Configure Network on the CMC or individual iDRAC. Use set_niccfg for blade and switch addresses.

    CLI Example:
    salt dell dracr.set_network 192.168.0.2 255.255.255.0 192.168.0.1
    
    admin_username=root admin_password=calvin host=192.168.1.1

salt.modules.dracr.set_niccfg(ip=None, netmask=None, gateway=None, dhcp=False, host=None, admin_username=None, admin_password=None, module=None)

salt.modules.dracr.set_nicvlan(vlan=None, host=None, admin_username=None, admin_password=None, module=None)

salt.modules.dracr.set_permissions(username, permissions, uid=None, host=None, admin_username=None, admin_password=None)

    Configure users permissions

    CLI Example:
    salt dell dracr.set_permissions username permissions [uid] [host] [admin_username] [admin_password]

    salt dell dracr.set_permissions diana login,test_alerts,clear_logs 4

    DRAC Privileges

    login: Login to iDRAC
    drac: Configure iDRAC
    user_management: Configure Users
    clear_logs: Clear Logs
    server_control_commands: Execute Server Control Commands
    console_redirection: Access Console Redirection
    virtual_media: Access Virtual Media
    test_alerts: Test Alerts
    debug_commands: Execute Debug Commands

salt.modules.dracr.set_slotname(slot, name, host=None, admin_username=None, admin_password=None)

    Set the name of a slot in a chassis.
    slot: The slot number to change.
    name: The name to set. Can only be 15 characters long.
    host: The chassis host.
    admin_username: The username used to access the chassis.
    admin_password: The password used to access the chassis.
CLI Example:

```
salt '*' dracr.set_slotname 2 my-slotname host=111.222.333.444
    admin_username=root admin_password=secret
```

```
salt.modules.dracr.set_snmp(community, host=None, admin_username=None, admin_password=None)
```

Configure CMC or individual iDRAC SNMP community string. Use deploy_snmp for configuring chassis switch SNMP.

CLI Example:

```
salt dell dracr.set_snmp [COMMUNITY]
salt dell dracr.set_snmp public
```

```
salt.modules.dracr.syslog(server, enable=True, host=None, admin_username=None, admin_password=None, module=None)
```

Configure syslog remote logging. by default syslog will automatically be enabled if a server is specified. However, if you want to disable syslog you will need to specify a server followed by False

CLI Example:

```
salt dell dracr.syslog [SYSLOG IP] [ENABLE/DISABLE]
salt dell dracr.syslog 0.0.0.0 False
```

```
salt.modules.dracr.system_info(host=None, admin_username=None, admin_password=None, module=None)
```

Return System information

CLI Example:

```
salt dell dracr.system_info
```

```
salt.modules.dracr.update_firmware(filename, host=None, admin_username=None, admin_password=None)
```

Updates firmware using local firmware file

```
salt dell dracr.update_firmware firmware.exe
```

This executes the following command on your FX2 (using username and password stored in the pillar data)

```
racadm update -f firmware.exe -u user –p pass
```

```
salt.modules.dracr.update_firmware_nfs_or_cifs(filename, share, host=None, admin_username=None, admin_password=None)
```

Executes the following for CIFS (using username and password stored in the pillar data)

```
racadm update -f <updatefile> -u user –p pass -l //IP-Address/share
```

Or for NFS (using username and password stored in the pillar data)

```
racadm update -f <updatefile> -u user –p pass -l IP-address:/share
```

Salt command for CIFS:

```
salt dell dracr.update_firmware_nfs_or_cifs firmware.exe //IP-Address/!
```
Salt command for NFS:

```
salt dell dracr.update_firmware_nfs_or_cifs firmware.exe IP-address:/share
```

### 13.6.79 salt.modules.drbd

DRBD administration module

`salt.modules.drbd.overview()`  
Show status of the DRBD devices

CLI Example:

```
salt '*' drbd.overview
```

### 13.6.80 salt.modules.ebuild

Support for Portage

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install' is not available), see [here](#).

**optdepends**

- portage Python adapter

For now all package names **MUST** include the package category, i.e. `vim` will not work, `app-editors/vim` will.

`salt.modules.ebuild.check_db(*names, **kwargs)`  
New in version 0.17.0.

Returns a dict containing the following information for each specified package:

1. A key `found`, which will be a boolean value denoting if a match was found in the package database.
2. If `found` is `False`, then a second key called `suggestions` will be present, which will contain a list of possible matches. This list will be empty if the package name was specified in `category/pkgname` format, since the suggestions are only intended to disambiguate ambiguous package names (ones submitted without a category).

CLI Examples:

```
salt '*' pkg.check_db <package1> <package2> <package3>
```

`salt.modules.ebuild.check_extra_requirements(pkgname, pkgver)`  
Check if the installed package already has the given requirements.

CLI Example:

```
salt '*' pkg.check_extra_requirements 'sys-devel/gcc' '~>4.1.2:4.1::gentoo[nls,fortran]'
```

`salt.modules.ebuild.depclean(name=None, slot=None, fromrepo=None, pkgs=None)`  
Portage has a function to remove unused dependencies. If a package is provided, it will only removed the package if no other package depends on it.

- **name** The name of the package to be cleaned.
- **slot** Restrict the remove to a specific slot. Ignored if `name` is None.
fromrepo  Restrict the remove to a specific slot. Ignored if name is None.

pkgs  Clean multiple packages. slot and fromrepo arguments are ignored if this argument is present. Must be passed as a python list.

Return a list containing the removed packages:

CLI Example:

```
salt '*' pkg.depclean <package name>
```

**salt.modules.ebuild.ex_mod_init**(*low*)

If the config option ebuild.enforce_nice_config is set to True, this module will enforce a nice tree structure for /etc/portage/package.* configuration files.

New in version 0.17.0: Initial automatic enforcement added when pkg is used on a Gentoo system.

Changed in version 2014.1.0-Hydrogen: Configure option added to make this behaviour optional, defaulting to off.

See also:

```
EBUILD.EX_MOD_INIT is called automatically when a state invokes a pkg state on a Gentoo system.
```

```
salt.states.pkg.mod_init()
```

```
ebuild.ex_mod_init uses portage_config.enforce_nice_config to do the lifting.
```

```
salt.modules.portage_config.enforce_nice_config()
```

CLI Example:

```
salt '*' pkg.ex_mod_init
```

**salt.modules.ebuild.install**(*name=None, refresh=False, pkgs=None, sources=None, slot=None, fromrepo=None, uses=None, binhost=None, **kwargs*)

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, systemd-run(1) is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any emerge commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Install the passed package(s), add refresh=True to sync the portage tree before package is installed.

name  The name of the package to be installed. Note that this parameter is ignored if either ``pkgs`` or ``sources`` is passed. Additionally, please note that this option can only be used to emerge a package from the portage tree. To install a tbz2 package manually, use the ``sources`` option described below.

CLI Example:

```
salt '*' pkg.install <package name>
```

refresh  Whether or not to sync the portage tree before installing.

version  Install a specific version of the package, e.g. 1.0.9-r1. Ignored if ``pkgs`` or ``sources`` is passed.

slot  Similar to version, but specifies a valid slot to be installed. It will install the latest available version in the specified slot. Ignored if ``pkgs`` or ``sources`` or ``version`` is passed.

CLI Example:

```
salt '*' pkg.install sys-devel/gcc slot='4.4'
```

fromrepo  Similar to slot, but specifies the repository from the package will be installed. It will install the latest available version in the specified repository. Ignored if ``pkgs`` or ``sources`` or ``version`` is passed.

CLI Example:
uses Similar to slot, but specifies a list of use flag. Ignored if `"pkgs"` or `"sources"` or `"version"` is passed.

CLI Example:
```
salt '*' pkg.install sys-devel/gcc uses='["nptl", "-nossp"]'
```

Multiple Package Installation Options:

**pkgs** A list of packages to install from the portage tree. Must be passed as a python list.

CLI Example:
```
salt '*' pkg.install pkgs='["foo", "bar", "-category/package:slot:: repository[use]"]'
```

**sources** A list of tbz2 packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

CLI Example:
```
salt '*' pkg.install sources='[{"foo": "salt://foo.tbz2"}, {"bar": "salt://bar.tbz2"}]'
```

**binhost** has two options try and force. try - tells emerge to try and install the package from a configured binhost. force - forces emerge to install the package from a binhost otherwise it fails out.

Returns a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>', 'new': '<new-version>'}}
```

**salt.modules.ebuild.latest_version**(*names, **kwargs*)

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:
```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

**salt.modules.ebuild.list_pkgs**(*versions_as_list=False, **kwargs*)

List the packages currently installed in a dict:

```
{'<package_name>': '<version>'}
```

CLI Example:
```
salt '*' pkg.list_pkgs
```

**salt.modules.ebuild.list_upgrades**(*refresh=True, backtrack=3, **kwargs*)

List all available package upgrades.

- **refresh** Whether or not to sync the portage tree before checking for upgrades.
- **backtrack** Specifies an integer number of times to backtrack if dependency calculation fails due to a conflict or an unsatisfied dependency (default: 3).

CLI Example:
```
salt '*' pkg.list_upgrades
```

**salt.modules.ebuild.porttree_matches**(*name*)

Returns a list containing the matches for a given package name from the portage tree. Note that the specific
version of the package will not be provided for packages that have several versions in the portage tree, but rather the name of the package (i.e. ‘dev-python/paramiko’).

**salt.modules.ebuild.purge** *(name=None, slot=None, fromrepo=None, pkgs=None, **kwargs)*

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any emerge commands spawned by Salt when the salt-minion service is restarted. (see [KillMode](systemd.kill(5)) manpage for more information). If desired, usage of `systemd-run(1)` can be suppressed by setting a [config option](systemd.scope) called systemd.scope, with a value of `False` (no quotes).

Portage does not have a purge, this function calls remove followed by depclean to emulate a purge process

- **name** The name of the package to be deleted.
- **slot** Restrict the remove to a specific slot. Ignored if name is None.
- **fromrepo** Restrict the remove to a specific slot. Ignored if name is None.

Multiple Package Options:
- **pkgs** Uninstall multiple packages. slot and fromrepo arguments are ignored if this argument is present. Must be passed as a python list.

New in version 0.16.0.

Returns a dict containing the changes.

**CLI Example:**

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package name> slot=4.4
salt '*' pkg.purge <package name>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'
```

**salt.modules.ebuild.refresh_db** *

Updates the portage tree (emerge --sync). Uses eix-sync if available.

**CLI Example:**

```
salt '*' pkg.refresh_db
```

**salt.modules.ebuild.remove** *(name=None, slot=None, fromrepo=None, pkgs=None, **kwargs)*

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any emerge commands spawned by Salt when the salt-minion service is restarted. (see [KillMode](systemd.kill(5)) manpage for more information). If desired, usage of `systemd-run(1)` can be suppressed by setting a [config option](systemd.scope) called systemd.scope, with a value of `False` (no quotes).

Remove packages via emerge --unmerge.

- **name** The name of the package to be deleted.
- **slot** Restrict the remove to a specific slot. Ignored if name is None.
- **fromrepo** Restrict the remove to a specific slot. Ignored if name is None.

Multiple Package Options:
- **pkgs** Uninstall multiple packages. slot and fromrepo arguments are ignored if this argument is present. Must be passed as a python list.

New in version 0.16.0.

Returns a dict containing the changes.

**CLI Example:**

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package name> slot=4.4 fromrepo=gentoo
```
salt modules.ebuild.update(pkg, slat=None, fromrepo=None, refresh=False, binhost=None)

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, systemd-run(1) is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any emerge commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Updates the passed package (emerge --update package)
slot Restrict the update to a particular slot. It will update to the latest version within the slot.
fromrepo Restrict the update to a particular repository. It will update to the latest version within the repository.
binhost has two options try and force. try - tells emerge to try and install the package from a configured binhost. force - forces emerge to install the package from a binhost otherwise it fails out.

Return a dict containing the new package names and versions:

```json
{'<package>': {'old': '<old-version>',
              'new': '<new-version>'}}
```

CLI Example:

```
salt '*' pkg.update <package name>
```

salt modules.ebuild.upgrade(refresh=True, binhost=None, backtrack=3)

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, systemd-run(1) is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any emerge commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Run a full system upgrade (emerge -uDN @world)
binhost has two options try and force. try - tells emerge to try and install the package from a configured binhost. force - forces emerge to install the package from a binhost otherwise it fails out.
backtrack Specifies an integer number of times to backtrack if dependency calculation fails due to a conflict or an unsatisfied dependency (default: 3').

Return a dict containing the new package names and versions:

```json
{'<package>': {'old': '<old-version>',
              'new': '<new-version>'}}
```

CLI Example:

```
salt '*' pkg.upgrade
```

salt modules.ebuild.upgrade_available(name)

Check whether or not an upgrade is available for a given package

CLI Example:

```
salt '*' pkg.upgrade_available <package name>
```

salt modules.ebuild.version(*names, **kwargs)

Returns a string representing the package version or an empty string if not installed. If more than one package
name is specified, a dict of name/version pairs is returned.

CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

```
salt.modules.ebuild.version_clean(version)
Clean the version string removing extra data.
```

CLI Example:

```
salt '*' pkg.version_clean <version_string>
```

```
salt.modules.ebuild.version_cmp(pkg1, pkg2, **kwargs)
Do a cmp-style comparison on two packages. Return -1 if pkg1 < pkg2, 0 if pkg1 == pkg2, and 1 if pkg1 > pkg2. Return None if there was a problem making the comparison.
```

CLI Example:

```
salt '*' pkg.version_cmp '0.2.4-0' '0.2.4.1-0'
```

13.6.81 salt.modules.eix

Support for Eix

```
salt.modules.eix.sync()
Sync portage/overlay trees and update the eix database
```

CLI Example:

```
salt '*' eix.sync
```

```
salt.modules.eix.update()
Update the eix database
```

CLI Example:

```
salt '*' eix.update
```

13.6.82 salt.modules.elasticsearch

Elasticsearch - A distributed RESTful search and analytics server

Module to provide Elasticsearch compatibility to Salt (compatible with Elasticsearch version 1.5.2+)

New in version 2015.8.0.

```
depends elasticsearch-py
```

```
configuration This module accepts connection configuration details either as parameters or as configuration settings in /etc/salt/minion on the relevant minions:
```

```
elasticsearch:
  host: '10.10.10.100:9200'
elasticsearch:
  hosts:
```

1004 Chapter 13. Salt Module Reference
elasticsearch:
  hosts:
    - '10.10.10.100:9200'
    - '10.10.10.101:9200'
    - '10.10.10.102:9200'
  number_of_shards: 1
  number_of_replicas: 0
  functions_blacklist:
    - 'saltutil.find_job'
    - 'pillar.items'
    - 'grains.items'

This data can also be passed into pillar. Options passed into opts will overwrite options passed into pillar.

```
salt.modules.elasticsearch.alias_create(indices, alias, hosts=None, body=None, profile=None)
```
Create an alias for a specific index/indices

CLI example:
```
salt myminion elasticsearch.alias_create testindex_v1 testindex
```

```
salt.modules.elasticsearch.alias_delete(indices, aliases, hosts=None, body=None, profile=None)
```
Delete an alias of an index

CLI example:
```
salt myminion elasticsearch.alias_delete testindex_v1 testindex
```

```
salt.modules.elasticsearch.alias_exists(aliases, indices=None, hosts=None, profile=None)
```
Return a boolean indicating whether given alias exists

CLI example:
```
salt myminion elasticsearch.alias_exists testindex
```

```
salt.modules.elasticsearch.alias_get(indices=None, aliases=None, hosts=None, profile=None)
```
Check for the existence of an alias and if it exists, return it

CLI example:
```
salt myminion elasticsearch.alias_get testindex
```

```
salt.modules.elasticsearch.document_create(index, doc_type, body=None, id=None, hosts=None, profile=None)
```
Create a document in a specified index

CLI example:
```
salt myminion elasticsearch.document_create testindex doctype1 '{}'
```

```
salt.modules.elasticsearch.document_delete(index, doc_type, id, hosts=None, profile=None)
```
Delete a document from an index

CLI example:
salt.myminion.elasticsearch.document_delete(testindex, doctype1=AUX-384m0Bug__8U80wQZ)

salt.modules.elasticsearch.document_exists(index, id, doc_type=’_all’, hosts=None, profile=None)

Return a boolean indicating whether given document exists

CLI example:
salt myminion elasticsearch.document_exists testindex AUX-384m0Bug_8U80wQZ

salt.modules.elasticsearch.document_get(index, id, doc_type=’_all’, hosts=None, profile=None)

Check for the existence of a document and if it exists, return it

CLI example:
salt myminion elasticsearch.document_get testindex AUX-384m0Bug_8U80wQZ

salt.modules.elasticsearch.index_create(index, body=None, hosts=None, profile=None)

Create an index

CLI example:
salt myminion elasticsearch.index_create testindex

salt.modules.elasticsearch.index_delete(index, hosts=None, profile=None)

Delete an index

CLI example:
salt myminion elasticsearch.index_delete testindex

salt.modules.elasticsearch.index_exists(index, hosts=None, profile=None)

Return a boolean indicating whether given index exists

CLI example:
salt myminion elasticsearch.index_exists testindex

salt.modules.elasticsearch.index_get(index, hosts=None, profile=None)

Check for the existence of an index and if it exists, return it

CLI example:
salt myminion elasticsearch.index_get testindex

salt.modules.elasticsearch.index_template_create(name, body, hosts=None, profile=None)

Create an index template

CLI example:
salt myminion elasticsearch.index_template_create testindex_templ '{ "template": "logstash-*", "order": 1, "settings": { "number_of_shards": 1 } }'

salt.modules.elasticsearch.index_template_delete(name, hosts=None, profile=None)

Delete an index template (type) along with its data

CLI example:
salt.modules.elasticsearch.index_template_delete(name, hosts=None, profile=None)

Delete a mapping (type) along with its data

CLI example:
```
salt myminion elasticsearch.index_template_delete testindex_temp user
```

salt.modules.elasticsearch.index_template_get(name, hosts=None, profile=None)

Retrieve mapping definition of index or index/type

CLI example:
```
salt myminion elasticsearch.index_template_get testindex_temp user
```

salt.modules.elasticsearch.mapping_create(index, doc_type, body, hosts=None, profile=None)

Create a mapping in a given index

CLI example:
```
salt myminion elasticsearch.mapping_create testindex user '{ "user" : { "properties" : { "message" : { "type" : "string", "store" : true } } } }
```

salt.modules.elasticsearch.mapping_delete(index, doc_type, hosts=None, profile=None)

Delete a mapping (type) along with its data

CLI example:
```
salt myminion elasticsearch.mapping_delete testindex user
```

salt.modules.elasticsearch.mapping_get(index, doc_type, hosts=None, profile=None)

Retrieve mapping definition of index or index/type

CLI example:
```
salt myminion elasticsearch.mapping_get testindex user
```

13.6.83 salt.modules.environ

Support for getting and setting the environment variables of the current salt process.

salt.modules.environ.get(key, default=``)

Get a single salt process environment variable.

key String used as the key for environment lookup.

default If the key is not found in the environment, return this value. Default: ```

CLI Example:
```
salt '*' environ.get foo
salt '*' environ.get baz default=False
```

salt.modules.environ.has_value(key, value=None)

Determine whether the key exists in the current salt process environment dictionary. Optionally compare the current value of the environment against the supplied value string.

key Must be a string. Used as key for environment lookup.
value: Optional. If key exists in the environment, compare the current value with this value. Return True if they are equal.

CLI Example:

```
salt '*' environ.has_value foo
```

salt.modules.environ.item(keys, default=``)

Get one or more salt process environment variables. Returns a dict.

**keys** Either a string or a list of strings that will be used as the keys for environment lookup.

**default** If the key is not found in the environment, return this value. Default: ``

CLI Example:

```
salt '*' environ.item foo
salt '*' environ.item ['foo', 'baz'] default=None
```

salt.modules.environ.items()

Return a dict of the entire environment set for the salt process

CLI Example:

```
salt '*' environ.items
```

salt.modules.environ.setenv(environ, false_unsets=False, clear_all=False, update_minion=False, permanent=False)

Set multiple salt process environment variables from a dict. Returns a dict.

**environ** Must be a dict. The top-level keys of the dict are the names of the environment variables to set. Each key's value must be a string or False. Refer to the `false_unsets` parameter for behavior when a value set to False.

**false_unsets** If a key's value is False and false_unsets is True, then the key will be removed from the salt processes environment dict entirely. If a key's value is False and false_unsets is not True, then the key's value will be set to an empty string. Default: False

**clear_all** USE WITH CAUTION! This option can unset environment variables needed for salt to function properly. If clear_all is True, then any environment variables not defined in the environ dict will be deleted. Default: False

**update_minion** If True, apply these environ changes to the main salt-minion process. If False, the environ changes will only affect the current salt subprocess. Default: False

**permanent** On Windows minions this will set the environment variable in the registry so that it is always added as a environment variable when applications open. If you want to set the variable to HKLM instead of HKCU just pass in `"HKLM"` for this parameter. On all other minion types this will be ignored. Note: This will only take affect on applications opened after this has been set.

CLI Example:

```
salt '*' environ.setenv {'"foo": "bar", "baz": "quux"'}
salt '*' environ.setenv {'"a": "b", "c": False'} false_unsets=True
```

salt.modules.environ.setval(key, val, false_unsets=False, permanent=False)

Set a single salt process environment variable. Returns True on success.

**key** The environment key to set. Must be a string.

**val** The value to set. Must be a string or False. Refer to the `false_unsets` parameter for behavior when set to False.

**false_unsets** If val is False and false_unsets is True, then the key will be removed from the salt processes environment dict entirely. If val is False and false_unsets is not True, then the key's value will be set to an empty string. Default: False

**permanent** On Windows minions this will set the environment variable in the registry so that it is always added as a environment variable when applications open. If you want to set the variable to HKLM instead
of HKCU just pass in `HKLM` for this parameter. On all other minion types this will be ignored. Note: This will only take affect on applications opened after this has been set.

CLI Example:

```
salt '*' environ.setval foo bar
salt '*' environ.setval baz val=False false_unsets=True
salt '*' environ.setval baz bar permanent=True
salt '*' environ.setval baz bar permanent=HKLM
```

### 13.6.84 `salt.moduleseselect`

Support for `eselect`, Gentoo’s configuration and management tool.

```
salt.moduleseselect.exec_action(module, action, module_parameter=None, action_parameter=None, state_only=False)
```

Execute an arbitrary action on a module.

- **module**: name of the module to be executed
- **action**: name of the module’s action to be run
- **module_parameter**: additional params passed to the defined module
- **action_parameter**: additional params passed to the defined action
- **state_only**: don’t return any output but only the success/failure of the operation

CLI Example (updating the php implementation used for apache2):

```
salt '*' eselect.exec_action php update action_parameter='apache2'
```

```
salt.moduleseselect.get_current_target(module, module_parameter=None, action_parameter=None)
```

Get the currently selected target for the given module.

- **module**: name of the module to be queried for its current target
- **module_parameter**: additional params passed to the defined module
- **action_parameter**: additional params passed to the ‘show’ action

CLI Example (current target of system-wide java-vm):

```
salt '*' eselect.get_current_target java-vm action_parameter='system'
```

CLI Example (current target of kernel symlink):

```
salt '*' eselect.get_current_target kernel
```

```
salt.moduleseselect.get_modules()
```

List available `eselect` modules.

CLI Example:

```
salt '*' eselect.get_modules
```

```
salt.moduleseselect.get_target_list(module)
```

List available targets for the given module.

- **module**: name of the module to be queried for its targets

CLI Example:

```
salt '*' eselect.get_target_list kernel
```

```
salt.moduleseselect.set_target(module, target, module_parameter=None, action_parameter=None)
```

Set the target for the given module. Target can be specified by index or name.
module name of the module for which a target should be set
target name of the target to be set for this module
module_parameter additional params passed to the defined module
action_parameter additional params passed to the defined action

CLI Example (setting target of system-wide java-vm):
salt '*' eselect.set_target java-vm icedtea-bin-7  
  action_parameter='system'

CLI Example (setting target of kernel symlink):
salt '*' eselect.set_target kernel linux-3.17.5-gentoo

13.6.85 salt.modules.esxi

Glues the VMware vSphere Execution Module to the VMware ESXi Proxy Minions to the esxi proxymodule.

New in version 2015.8.4.

Depends: vSphere Remote Execution Module (salt.modules.vsphere)

For documentation on commands that you can direct to an ESXi host via proxy, look in the documentation for salt.modules.vsphere.

This execution module calls through to a function in the ESXi proxy module called ch_config, which looks up the function passed in the command parameter in salt.modules.vsphere and calls it.

To execute commands with an ESXi Proxy Minion using the vSphere Execution Module, use the esxi.cmd <vsphere-function-name> syntax. Both args and kwargs needed for various vsphere execution module functions must be passed through in a kwarg-type manner.

salt 'esxi-proxy' esxi.cmd system_info
salt 'esxi-proxy' esxi.cmd get_service_policy service_name='ssh'

salt.modules.esxi.cmd(command, *args, **kwargs)

13.6.86 salt.modules.etcd_mod

Execution module to work with etcd

depends
  - python-etcd

Configuration

To work with an etcd server you must configure an etcd profile. The etcd config can be set in either the Salt Minion configuration file or in pillar:

```yaml
my_etd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001
```

It is technically possible to configure etcd without using a profile, but this is not considered to be a best practice, especially when multiple etcd servers or clusters are available.
etcd.host: 127.0.0.1
etcd.port: 4001

Note: The etcd configuration can also be set in the Salt Master config file, but in order to use any etcd configurations defined in the Salt Master config, the `pillar_opts` must be set to `True`.

Be aware that setting `pillar_opts` to `True` has security implications as this makes all master configuration settings available in all minion's pillars.

```python
salt.modules.etcd_mod.get(key, recurse=False, profile=None)
```
New in version 2014.7.0.

Get a value from etcd, by direct path. Returns None on failure.

CLI Examples:

```
salt myminion etcd.get /path/to/key
salt myminion etcd.get /path/to/key profile=my_etcd_config
salt myminion etcd.get /path/to/key recurse=True profile=my_etcd_config
```

```python
salt.modules.etcd_mod.ls(path='/', profile=None)
```
New in version 2014.7.0.

Return all keys and dirs inside a specific path. Returns an empty dict on failure.

CLI Example:

```
salt myminion etcd.ls /path/to/dir/
```

```python
salt.modules.etcd_mod.rm(key, recurse=False, profile=None)
```
New in version 2014.7.0.

Delete a key from etcd. Returns True if the key was deleted, False if it wasn't and None if there was a failure.

CLI Example:

```
salt myminion etcd.rm /path/to/key
salt myminion etcd.rm /path/to/key profile=my_etcd_config
salt myminion etcd.rm /path/to/key recurse=True profile=my_etcd_config
```

```python
salt.modules.etcd_mod.set(key, value, profile=None, ttl=None, directory=False)
```
New in version 2014.7.0.

Set a key in etcd by direct path. Optionally, create a directory or set a TTL on the key. Returns None on failure.

CLI Example:

```
salt myminion etcd.set /path/to/key value
salt myminion etcd.set /path/to/key value profile=my_etcd_config
salt myminion etcd.set /path/to/dir '' directory=True
salt myminion etcd.set /path/to/key value ttl=5
```

```python
salt.modules.etcd_mod.tree(path='/', profile=None)
```
New in version 2014.7.0.

Recurse through etcd and return all values. Returns None on failure.

CLI Example:
salt.modules.etcd_mod.update(fields, path='', profile=None)

New in version 2016.3.0.

Sets a dictionary of values in one call. Useful for large updates in syndic environments. The dictionary can contain a mix of formats such as:

```python
{
    '/some/example/key': 'bar',
    '/another/example/key': 'baz'
}
```

Or it may be a straight dictionary, which will be flattened to look like the above format:

```python
{
    'some': {
        'example': {
            'key': 'bar'
        }
    },
    'another': {
        'example': {
            'key': 'baz'
        }
    }
}
```

You can even mix the two formats and it will be flattened to the first format. Leading and trailing `'/` will be removed.

Empty directories can be created by setting the value of the key to an empty dictionary.

The `path` parameter will optionally set the root of the path to use.

CLI Example:

```bash
salt myminion etcd.update "{'/path/to/key': 'baz', '/another/key': 'bar'}"
salt myminion etcd.update "{'/path/to/key': 'baz', '/another/key': 'bar'}" profile=my_etcd_config
salt myminion etcd.update "{'/path/to/key': 'baz', '/another/key': 'bar'}" path='/' some/root'
```

salt.modules.etcd_mod.watch(key, recurse=False, profile=None, timeout=0, index=None)

New in version 2016.3.0.

Makes a best effort to watch for a key or tree change in etcd. Returns a dict containing the new key value (or None if the key was deleted), the modifiedIndex of the key, whether the key changed or not, the path to the key that changed and whether it is a directory or not.

If something catastrophic happens, returns {}.

CLI Example:

```bash
salt myminion etcd.watch /path/to/key
salt myminion etcd.watch /path/to/key timeout=10
salt myminion etcd.watch /patch/to/key profile=my_etcd_config index=10
```
13.6.87 salt.modules.ethtool module

Module for running ethtool command

New in version 2016.3.0.

codeauthor Krzysztof Pawlowski <msciciel@msciciel.eu>
maturity new
depends python-ethtool
platform linux

salt.modules.ethtool.set_coalesce(devname, **kwargs)
Changes the coalescing settings of the specified network device

CLI Example:

```
salt '*' ethtool.set_coalesce <devname> [adaptive_rx=on|off] [adaptive_tx=on|off]
[rx_usecs=N] [rx_frames=N]
[rx_usecs_irq=N] [rx_frames_irq=N] [tx_usecs=N] [tx_frames=N] [tx_usecs_irq=N] [tx_frames_irq=N]
[stats_block_usecs=N] [pkt_rate_low=N] [rx_usecs_low=N] [rx_frames_low=N] [tx_usecs_low=N] [tx_frames_low=N]
[pkt_rate_high=N] [rx_usecs_high=N] [rx_frames_high=N] [tx_usecs_high=N] [tx_frames_high=N]
[sample_interval=N]
```

salt.modules.ethtool.set_offload(devname, **kwargs)
Changes the offload parameters and other features of the specified network device

CLI Example:

```
salt '*' ethtool.show_offload <devname>
```

salt.modules.ethtool.set_ring(devname, **kwargs)
Changes the rx/tx ring parameters of the specified network device

CLI Example:

```
salt '*' ethtool.set_ring <devname> [ring=N] [rx_mini=N] [rx_jumbo=N] [tx=N]
```

salt.modules.ethtool.show_coalesce(devname)
Queries the specified network device for coalescing information

CLI Example:

```
salt '*' ethtool.show_coalesce <devname>
```

salt.modules.ethtool.show_driver(devname)
Queries the specified network device for associated driver information

CLI Example:

```
salt '*' ethtool.show_driver <devname>
```

salt.modules.ethtool.show_offload(devname)
Queries the specified network device for the state of protocol offload and other features

CLI Example:
salt ' '*' ethtool.show_offload <devname>

salt.modules.ethtool.show_ring(devname)
Queries the specified network device for rx/tx ring parameter information

CLI Example:
salt ' '*' ethtool.show_ring <devname>

13.6.88  salt.modules.event

Use the Salt Event System to fire events from the master to the minion and vice-versa.

salt.modules.event.fire(data, tag)
Fire an event on the local minion event bus. Data must be formed as a dict.

CLI Example:
salt ' '*' event.fire '{"data":"my event data"}' 'tag'

salt.modules.event.fire_master(data, tag, preload=None)
Fire an event off up to the master server

CLI Example:
salt ' '*' event.fire_master '{"data":"my event data"}' 'tag'

salt.modules.event.send(tag, data=None, preload=None, with_env=False, with_grains=False, with_pillar=False, **kwargs)
Send an event to the Salt Master

New in version 2014.7.0.

Parameters

- **tag** -- A tag to give the event. Use slashes to create a namespace for related events. E.g., myco/build/buildserver1/start, myco/build/buildserver1/success, myco/build/buildserver1/failure.

- **data** -- A dictionary of data to send in the event. This is free-form. Send any data points that are needed for whoever is consuming the event. Arguments on the CLI are interpreted as YAML so complex data structures are possible.

- **with_env** (Specify True to include all environment variables, or specify a list of strings of variable names to include.) -- Include environment variables from the current shell environment in the event data as environ. This is a short-hand for working with systems that seed the environment with relevant data such as Jenkins.

- **with_grains** (Specify True to include all grains, or specify a list of strings of grain names to include.) -- Include grains from the current minion in the event data as grains.

- **with_pillar** (Specify True to include all Pillar values, or specify a list of strings of Pillar keys to include. It is a best-practice to only specify a relevant subset of Pillar data.) -- Include Pillar values from the current minion in the event data as pillar. Remember Pillar data is often sensitive data so be careful. This is useful for passing ephemeral Pillar values through an event. Such as passing the pillar={} kwarg in state.sls from the Master, through an event on the Minion, then back to the Master.
• **kwargs** -- Any additional keyword arguments passed to this function will be interpreted as key-value pairs and included in the event data. This provides a convenient alternative to YAML for simple values.

CLI Example:

```bash
salt-call event.send myco/mytag foo=Foo bar=Bar
salt-call event.send myco/mytag '{foo: Foo, bar: Bar}'
```

A convenient way to allow Jenkins to execute `salt-call` is via sudo. The following rule in sudoers will allow the `jenkins` user to run only the following command.

/etc/sudoers (allow preserving the environment):

```
jenkins ALL=(ALL) NOPASSWD:SETENV: /usr/bin/salt-call event.send*
```

Call Jenkins via sudo (preserve the environment):

```
sudo -E salt-call event.send myco/jenkins/build/success with_env=[BUILD_ID, BUILD_URL, GIT_BRANCH, GIT_COMMIT]
```

### 13.6.89 `salt.modules.extfs`

Module for managing ext2/3/4 file systems

**Function List**

- `salt.modules.extfs.attributes(device, args=None)`
  - Return attributes from dumpe2fs for a specified device
  - CLI Example:
    ```bash
    salt '*' extfs.attributes /dev/sda1
    ```

- `salt.modules.extfs.blocks(device, args=None)`
  - Return block and inode info from dumpe2fs for a specified device
  - CLI Example:
    ```bash
    salt '*' extfs.blocks /dev/sda1
    ```

- `salt.modules.extfs.dump(device, args=None)`
  - Return all contents of dumpe2fs for a specified device
  - CLI Example:
    ```bash
    salt '*' extfs.dump /dev/sda1
    ```

- `salt.modules.extfs.mkfs(device, fs_type, **kwargs)`
  - Create a file system on the specified device
  - CLI Example:
    ```bash
    salt '*' extfs.mkfs /dev/sda1 fs_type=ext4 opts='acl,noexec'
    ```

Valid options are:

- `block_size`: 1024, 2048 or 4096
- `check`: check for bad blocks
- `direct`: use direct IO
- `ext_opts`: extended file system options (comma-separated)
- `fragment_size`: size of fragments
• **force**: setting force to True will cause mke2fs to specify the -F option twice (it is already set once); this is truly dangerous
• **blocks_per_group**: number of blocks in a block group
• **number_of_groups**: ext4 option for a virtual block group
• **bytes_per_inode**: set the bytes/inode ratio
    • **inode_size**: size of the inode
• **journal**: set to True to create a journal (default on ext3/4)
• **journal_opts**: options for the fs journal (comma separated)
• **blocks_file**: read bad blocks from file
• **label**: label to apply to the file system
• **reserved**: percentage of blocks reserved for super-user
• **last_dir**: last mounted directory
• **test**: set to True to not actually create the file system (mke2fs -n)
• **number_of_inodes**: override default number of inodes
• **creator_os**: override “creator operating system” field
• **opts**: mount options (comma separated)
• **revision**: set the filesystem revision (default 1)
• **super**: write superblock and group descriptors only
• **fs_type**: set the filesystem type (REQUIRED)
• **usage_type**: how the filesystem is going to be used
• **uuid**: set the UUID for the file system

See the mke2fs(8) manpage for a more complete description of these options.

salt.modules.extfs.tune(
    device, **kwargs)

Set attributes for the specified device (using tune2fs)

CLI Example:

```
salt '*' extfs.tune /dev/sda1 force=True label=wildstallyns opts='acl,noexec'
```

Valid options are:
• **max**: max mount count
• **count**: mount count
• **error**: error behavior
• **extended_opts**: extended options (comma separated)
• **force**: force, even if there are errors (set to True)
• **group**: group name or gid that can use the reserved blocks
• **interval**: interval between checks
• **journal**: set to True to create a journal (default on ext3/4)
• **journal_opts**: options for the fs journal (comma separated)
• **label**: label to apply to the file system
• **reserved**: percentage of blocks reserved for super-user
• **last_dir**: last mounted directory
• **opts**: mount options (comma separated)
• **feature**: set or clear a feature (comma separated)
• **mmp_check**: mmp check interval
• **reserved**: reserved blocks count
• **quota_opts**: quota options (comma separated)
• **time**: time last checked
• **user**: user or uid who can use the reserved blocks
• **uuid**: set the UUID for the file system

See the mke2fs(8) manpage for a more complete description of these options.
13.6.90 salt.modules.file

Manage information about regular files, directories, and special files on the minion, set/read user, group, mode, and data

salt.modules.file.access(path, mode)
  New in version 2014.1.0.
  Test whether the Salt process has the specified access to the file. One of the following modes must be specified:
  CLI Example:

<table>
<thead>
<tr>
<th>CLI Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt '*' file.access /path/to/file f</td>
</tr>
<tr>
<td>salt '*' file.access /path/to/file x</td>
</tr>
</tbody>
</table>

salt.modules.file.append(path, *args, **kwargs)
  New in version 0.9.5.
  Append text to the end of a file
  path  path to file
  *args  strings to append to file
  CLI Example:

<table>
<thead>
<tr>
<th>CLI Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt '*' file.append /etc/motd</td>
</tr>
</tbody>
</table>

**Attention**

If you need to pass a string to append and that string contains an equal sign, you must include the argument name, args. For example:

<table>
<thead>
<tr>
<th>CLI Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt '*' file.append /etc/motd args='cheese=spam'</td>
</tr>
<tr>
<td>salt '*' file.append /etc/motd args=&quot;[cheese=spam','spam=cheese']&quot;</td>
</tr>
</tbody>
</table>

salt.modules.file.apply_template_on_contents(contents, template, context, defaults, saltenv)
  Return the contents after applying the templating engine
  contents  template string
  template  template format
  context  Overrides default context variables passed to the template.
  defaults  Default context passed to the template.
  CLI Example:

<table>
<thead>
<tr>
<th>CLI Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt '*' file.apply_template_on_contents</td>
</tr>
</tbody>
</table>

salt.modules.file.basename(path)
  Returns the final component of a pathname
  New in version 2015.5.0.
  This can be useful at the CLI but is frequently useful when scripting.
salt.modules.file.blockreplace\n\n`salt.modules.file.blockreplace(path, marker_start='#-- start managed zone --', marker_end='#-- end managed zone --', content='', append_if_not_found=False, prepend_if_not_found=False, backup='.bak', dry_run=False, show_changes=True, append_newline=False)`

New in version 2014.1.0.

Replace content of a text block in a file, delimited by line markers

A block of content delimited by comments can help you manage several lines entries without worrying about old entries removal.

Note: This function will store two copies of the file in-memory (the original version and the edited version) in order to detect changes and only edit the targeted file if necessary.

**path**  Files system path to the file to be edited

**marker_start**  The line content identifying a line as the start of the content block. Note that the whole line containing this marker will be considered, so whitespace or extra content before or after the marker is included in final output

**marker_end**  The line content identifying a line as the end of the content block. Note that the whole line containing this marker will be considered, so whitespace or extra content before or after the marker is included in final output

**content**  The content to be used between the two lines identified by marker_start and marker_stop.

**append_if_not_found**  [False] If markers are not found and set to `True` then, the markers and content will be appended to the file.

**prepend_if_not_found**  [False] If markers are not found and set to `True` then, the markers and content will be prepended to the file.

**backup**  The file extension to use for a backup of the file if any edit is made. Set to `False` to skip making a backup.

**dry_run**  Don't make any edits to the file.

**show_changes**  Output a unified diff of the old file and the new file. If `False`, return a boolean if any changes were made.

**append_newline**  Append a newline to the content block. For more information see: [https://github.com/saltstack/salt/issues/33686](https://github.com/saltstack/salt/issues/33686)

New in version 2016.3.4.

CLI Example:

```
salt '*' file.blockreplace /etc/hosts '#-- start managed zone foobar : DO NOT EDIT --'
'#-- end managed zone foobar --' $'10.0.1.1 foo.foobar\n10.0.1.2 bar.foobar' True
```

salt.modules.file.check_file_meta\n
`salt.modules.file.check_file_meta(name, sfn, source, source_sum, user, group, mode, saltenv, contents=None)`

Check for the changes in the file metadata.

CLI Example:

```
salt '*' file.check_file_meta /etc/httpd/conf.d/httpd.conf salt://http/httpd.conf
'${hash_type: 'md5', 'hsum': <md5sum>}' root, root, '755' base
```
**Note:** Supported hash types include sha512, sha384, sha256, sha224, sha1, and md5.

- **name** Path to file destination
- **sfn** Template-processed source file contents
- **source** URL to file source
- **source_sum** File checksum information as a dictionary
  ```python
  {hash_type: 'md5', hsum: '<md5sum>'}
  ```
- **user** Destination file user owner
- **group** Destination file group owner
- **mode** Destination file permissions mode
- **saltenv** Salt environment used to resolve source files
- **contents** File contents

**salt.modules.file.check_hash(path, file_hash)**

Check if a file matches the given hash string

Returns true if the hash matched, otherwise false. Raises ValueError if the hash was not formatted correctly.

- **path** A file path
- **hash** A string in the form `<hash_type>:<hash_value>`. For example: `md5:e138491e9d5b97023cea823fe17bac22`

**CLI Example:**

```bash
salt '*' file.check_hash /etc/fstab md5:<md5sum>
```

**salt.modules.file.check_managed(name, source, source_hash, source_hash_name, user, group, mode, template, context, defaults, saltenv, contents=None, skip_verify=False, **kwargs)**

Check to see what changes need to be made for a file

**CLI Example:**

```bash
salt '*' file.check_managed /etc/httpd/conf.d/httpd.conf salt://http/httpd.conf '!' '{hash_type: 'md5', 'hsum': <md5sum>}' root, root, '755' jinja True None None base
```

**salt.modules.file.check_managed_changes(name, source, source_hash, source_hash_name, user, group, mode, template, context, defaults, saltenv, contents=None, skip_verify=False, **kwargs)**

Return a dictionary of what changes need to be made for a file

**CLI Example:**

```bash
salt '*' file.check_managed_changes /etc/httpd/conf.d/httpd.conf salt://http/httpd.conf '!' '{hash_type: 'md5', 'hsum': <md5sum>}' root, root, '755' jinja True None None base
```

**salt.modules.file.check_perms(name, ret, user, group, mode, follow_symlinks=False)**

Check the permissions on files and chown if needed

**CLI Example:**

```bash
salt '*' file.check_perms /etc/sudoers '{}' root root 400
```

Changed in version 2014.1.3: follow_symlinks option added

**salt.modules.file.chgrp(path, group)**

Change the group of a file

---

13.6. execution modules

1019
path  path to the file or directory

group  group owner

CLI Example:

```bash
salt '*' file.chgrp /etc/passwd root
```

salt.modules.file.chown(path, user, group)
Chown a file, pass the file the desired user and group
path  path to the file or directory
user  user owner

CLI Example:

```bash
salt '*' file.chown /etc/passwd root root
```

salt.modules.file.comment(path, regex, char='#', backup='.bak')
Deprecated since version 0.17.0: Use replace() instead.
Comment out specified lines in a file
path  The full path to the file to be edited
regex  A regular expression used to find the lines that are to be commented; this pattern will be wrapped in parenthesis and will move any preceding/trailing ^ or $ characters outside the parenthesis (e.g., the pattern ^foo$ will be rewritten as ^(foo)$)
char  [#] The character to be inserted at the beginning of a line in order to comment it out
backup  [.bak] The file will be backed up before edit with this file extension

**Warning:** This backup will be overwritten each time sed / comment / uncomment is called. Meaning the backup will only be useful after the first invocation.

CLI Example:

```bash
salt '*' file.comment /etc/modules pcspkr
```

salt.modules.file.comment_line(path, regex, char='#', cmnt=True, backup='.bak')
Comment or Un_comment a line in a file.
Parameters

- **path** -- string The full path to the text file.
- **regex** -- string A regex expression that begins with ^ that will find the line you wish to comment. Can be as simple as ^color =
- **char** -- string The character used to comment a line in the type of file you’re referencing. Default is #
- **cmnt** -- boolean True to comment the line. False to uncomment the line. Default is True.
- **backup** -- string The file extension to give the backup file. Default is .bak Set to False/None to not keep a backup.

Returns  boolean Returns True if successful, False if not

CLI Example:

The following example will comment out the pcspkr line in the /etc/modules file using the default # character and create a backup file named modules.bak
salt 'salt' file.comment_line '/etc/modules' '^pcspkr'

CLI Example:
The following example will uncomment the log_level setting in minion config file if it is set to either warning, info, or debug using the # character and create a backup file named minion.bk

salt 'salt' file.comment_line 'C:\salt\conf\minion' '^log_level: (warning|info|debug)
˓→ ' # False '.bk'

salt.modules.file.contains(path, text)
Deprecation since version 0.17.0: Use search() instead.
Return True if the file at path contains text

CLI Example:
salt '*' file.contains /etc/crontab 'mymaintenance.sh'

salt.modules.file.contains_glob(path, glob_expr)
Deprecation since version 0.17.0: Use search() instead.
Return True if the given glob matches a string in the named file

CLI Example:
salt '*' file.contains_glob /etc/foobar '*cheese*'

salt.modules.file.contains_regex(path, regex, lchar='')
Deprecation since version 0.17.0: Use search() instead.
Return True if the given regular expression matches on any line in the text of a given file.
If the lchar argument (leading char) is specified, it will strip lchar from the left side of each line before trying to match

CLI Example:
salt '*' file.contains_regex /etc/crontab

salt.modules.file.contains_regex_multiline(path, regex)
Deprecation since version 0.17.0: Use search() instead.
Return True if the given regular expression matches anything in the text of a given file
Traverses multiple lines at a time, via the salt BufferedReader (reads in chunks)

CLI Example:
salt '*' file.contains_regex_multiline /etc/crontab '^maint'

salt.modules.file.copy(src, dst, recurse=False, remove_existing=False)
Copy a file or directory from source to dst
In order to copy a directory, the recurse flag is required, and will by default overwrite files in the destination with the same path, and retain all other existing files. (similar to cp -r on unix)
remove_existing will remove all files in the target directory, and then copy files from the source.
Note: The copy function accepts paths that are local to the Salt minion. This function does not support salt://, http://, or the other additional file paths that are supported by states.file.managed and states.file.recurse.

CLI Example:

```
salt '*' file.copy /path/to/src /path/to/dst
salt '*' file.copy /path/to/src_dir /path/to/dst_dir recurse=True
salt '*' file.copy /path/to/src_dir /path/to/dst_dir recurse=True remove_=True
```

salt.modules.file.delete_backup(path, backup_id)

New in version 0.17.0.

Delete a previous version of a file that was backed up using Salt's file state backup system.

- **path** The path on the minion to check for backups
- **backup_id** The numeric id for the backup you wish to delete, as found using file.list_backups

CLI Example:

```
salt '*' file.delete_backup /var/cache/salt/minion/file_backup/home/foo/bar/baz.\-txt 0
```

salt.modules.file.directory_exists(path)

Tests to see if path is a valid directory. Returns True/False.

CLI Example:

```
salt '*' file.directory_exists /etc
```

salt.modules.file.dirname(path)

Returns the directory component of a pathname

New in version 2015.5.0.

This can be useful at the CLI but is frequently useful when scripting.

```
{%- from salt['file.dirname'](tpldir) + '/vars.jinja' import parent_vars %}
```

CLI Example:

```
salt '*' file.dirname 'test/path/filename.config'
```

salt.modules.file.diskusage(path)

Recursively calculate disk usage of path and return it in bytes

CLI Example:

```
salt '*' file.diskusage /path/to/check
```

salt.modules.file.extract_hash(hash_fn, hash_type='sha256', file_name=''', source=''';
source_hash_name=None)

Changed in version 2016.3.5: Prior to this version, only the file_name argument was considered for filename matches in the hash file. This would be problematic for cases in which the user was relying on a remote checksum file that they do not control, and they wished to use a different name for that file on the minion from the filename on the remote server (and in the checksum file). For example, managing /tmp/myfile.tar.gz when the remote file was at https://mydomain.tld/different_name.tar.gz. The file.managed state now also passes
this function the source URI as well as the source_hash_name (if specified). In cases where source_hash_name is specified, it takes precedence over both the file_name and source. When it is not specified, file_name takes precedence over source. This allows for better capability for matching hashes.

This routine is called from the file.managed state to pull a hash from a remote file. Regular expressions are used line by line on the source_hash file, to find a potential candidate of the indicated hash type. This avoids many problems of arbitrary file lay out rules. It specifically permits pulling hash codes from debian *.dsc files.

For example:

```
openerp_7.0-latest-1.tar.gz:
  file.managed:
    - name: /tmp/openerp_7.0-20121227-075624-1_all.deb
    - source: http://nightly.openerp.com/7.0/nightly/deb/openerp_7.0-20121227-
      075624-1.tar.gz
    - source_hash: http://nightly.openerp.com/7.0/nightly/deb/openerp_7.0-
      20121227-075624-1.dsc
```

CLI Example:

```
salt '*' file.extract_hash /path/to/hash/file sha512 /etc/foo
```

salt.modules.file.file_exists(path)
Tests to see if path is a valid file. Returns True/False.

CLI Example:

```
salt '*' file.file_exists /etc/passwd
```

salt.modules.file.find(path, *args, **kwargs)
Approximate the Unix find(1) command and return a list of paths that meet the specified criteria.

The options include match criteria:

```
name = path-glob # case sensitive
iname = path-glob # case insensitive
regex = path-regex # case sensitive
iregex = path-regex # case insensitive
type = file-types # match any listed type
user = users # match any listed user
group = groups # match any listed group
size = [+][-]number[size-unit] # default unit = byte
mtime = interval # modified since date
grep = regex # search file contents
```

and/or actions:

```
delete [= file-types] # default type = 'f'
exec = command [arg ...] # where {} is replaced by pathname
print [= print-opts]
```

and/or depth criteria:

```
maxdepth = maximum depth to transverse in path
mindepth = minimum depth to transverse before checking files or directories
```

The default action is print=path
path-glob:

* = match zero or more chars
? = match any char
[abc] = match a, b, or c
[!abc] or [^abc] = match anything except a, b, and c
[x-y] = match chars x through y
[!x-y] or [^x-y] = match anything except chars x through y
{a,b,c} = match a or b or c

path-regex: a Python Regex (regular expression) pattern to match pathnames

file-types: a string of one or more of the following:

a: all file types
b: block device
c: character device
d: directory
p: FIFO (named pipe)
f: plain file
l: symlink
s: socket

users: a space and/or comma separated list of user names and/or uids

groups: a space and/or comma separated list of group names and/or gids

size-unit:

b: bytes
k: kilobytes
m: megabytes
g: gigabytes
t: terabytes

interval:

[<num>W] [<num>D] [<num>H] [<num>M] [<num>S]

where:
    w: week
d: day
h: hour
m: minute
s: second

print-opts: a comma and/or space separated list of one or more of the following:

- group: group name
- md5: MD5 digest of file contents
- mode: file permissions (as integer)
- mtime: last modification time (as time_t)
- name: file basename
- path: file absolute path
- size: file size in bytes
- type: file type
- user: user name

CLI Examples:
```
salt '*' file.find / type=f name=\*.bak size=+10m
salt '*' file.find /var mtime=+30d size=+10m print=path,size,mtime
salt '*' file.find /var/log name=\*[0-9] mtime=+30d size=+10m delete
```

salt.modules.file.get_devmm(name)
Get major/minor info from a device

**CLI Example:**
```
salt '*' file.get_devmm /dev/chr
```

salt.modules.file.get_diff(minionfile, masterfile, env=None, saltenv='base')
Return unified diff of file compared to file on master

**CLI Example:**
```
salt '*' file.get_diff /home/fred/.vimrc salt://users/fred/.vimrc
```

salt.modules.file.get_gid(path, follow_symlinks=True)
Return the id of the group that owns a given file
path file or directory of which to get the gid
follow_symlinks indicated if symlinks should be followed

**CLI Example:**
```
salt '*' file.get_gid /etc/passwd
```

Changed in version 0.16.4: follow_symlinks option added

salt.modules.file.get_group(path, follow_symlinks=True)
Return the group that owns a given file
path file or directory of which to get the group
follow_symlinks indicated if symlinks should be followed

**CLI Example:**
```
salt '*' file.get_group /etc/passwd
```

Changed in version 0.16.4: follow_symlinks option added

salt.modules.file.get_hash(path, form='sha256', chunk_size=65536)
Get the hash sum of a file
This is better than get_sum for the following reasons:
- It does not read the entire file into memory.
- It does not return a string on error. The returned value of get_sum cannot really be trusted since it is vulnerable to collisions: get_sum(...,'xyz') == 'Hash xyz not supported'

path path to the file or directory
form desired sum format
chunk_size amount to sum at once

**CLI Example:**
```
salt '*' file.get_hash /etc/shadow
```

salt.modules.file.get_managed(name, template, source, source_hash, source_hash_name, user, group, mode, saltenv, context, defaults, skip_verify=False, **kwargs)
Return the managed file data for file.managed
name  location where the file lives on the server

template  template format

source  managed source file

source_hash  hash of the source file

source_hash_name  When source_hash refers to a remote file, this specifies the filename to look for in that file.

   New in version 2016.3.5.

user  Owner of file

group  Group owner of file

mode  Permissions of file

context  Variables to add to the template context

defaults  Default values of for context_dict

skip_verify  If True, hash verification of remote file sources (http://, https://, ftp://) will be skipped, and the source_hash argument will be ignored.

   New in version 2016.3.0.

CLI Example:

```
<conf '
   {hash_type: 'md5', 'hsum': <md5sum>}
   ' None root root '755' base None None
```

salt.modules.file.get_mode(path, follow_symlinks=True)

Return the mode of a file

path  file or directory of which to get the mode

follow_symlinks  indicated if symlinks should be followed

CLI Example:

```
salt '*' file.get_mode /etc/passwd
```

Changed in version 2014.1.0: follow_symlinks option added

salt.modules.file.get_selinux_context(path)

Get an SELinux context from a given path

CLI Example:

```
salt '*' file.get_selinux_context /etc/hosts
```

salt.modules.file.get_sum(path, form='sha256')

Return the checksum for the given file. The following checksum algorithms are supported:

- md5
- sha1
- sha224
- sha256 (default)
- sha384
- sha512

path  path to the file or directory

form  desired sum format

CLI Example:

```
salt '*' file.get_sum /etc/passwd sha512
```

salt.modules.file.get_uid(path, follow_symlinks=True)

Return the id of the user that owns a given file

path  file or directory of which to get the uid

CLI Example:
**follow_symlinks** indicated if symlinks should be followed

CLI Example:

```
salt '*' file.get_uid /etc/passwd
```

Changed in version 0.16.4: `follow_symlinks` option added

salt.modules.file.get_user(path, follow_symlinks=True)

Return the user that owns a given file

- **path** file or directory of which to get the user
- **follow_symlinks** indicated if symlinks should be followed

CLI Example:

```
salt '*' file.get_user /etc/passwd
```

Changed in version 0.16.4: `follow_symlinks` option added

salt.modules.file.gid_to_group(gid)

Convert the group id to the group name on this system

- **gid** gid to convert to a group name

CLI Example:

```
salt '*' file.gid_to_group 0
```

salt.modules.file.grep(path, pattern, *opts)

Grep for a string in the specified file

**Note:** This function’s return value is slated for refinement in future versions of Salt

- **path** Path to the file to be searched
  
  **Note:** Globbing is supported (i.e. `/var/log/foo/*.log`), but if globbing is being used then the path should be quoted to keep the shell from attempting to expand the glob expression.

- **pattern** Pattern to match. For example: `test`, or `a[0-5]`

- **opts** Additional command-line flags to pass to the grep command. For example: `-v`, or `-i -B2`

  **Note:** The options should come after a double-dash (as shown in the examples below) to keep Salt’s own argument parser from interpreting them.

CLI Example:

```
salt '*' file.grep /etc/passwd nobody
salt '*' file.grep /etc/sysconfig/network-scripts/ifcfg-eth0 ipaddr -- -i
salt '*' file.grep /etc/sysconfig/network-scripts/ifcfg-eth0 ipaddr -- -i -B2
salt '*' file.grep "/etc/sysconfig/network-scripts/*" ipaddr -- -i -l
```

salt.modules.file.group_to_gid(group)

Convert the group to the gid on this system

- **group** group to convert to its gid

CLI Example:

```
salt '*' file.group_to_gid root
```

13.6. execution modules
salt.modules.file.is_blkdev(name)
Check if a file exists and is a block device.

CLI Example:
```
salt '*' file.is_blkdev /dev/blk
```

salt.modules.file.is_chrdev(name)
Check if a file exists and is a character device.

CLI Example:
```
salt '*' file.is_chrdev /dev/chr
```

salt.modules.file.is_fifo(name)
Check if a file exists and is a FIFO.

CLI Example:
```
salt '*' file.is_fifo /dev/fifo
```

salt.modules.file.is_link(path)
Check if the path is a symbolic link

CLI Example:
```
salt '*' file.is_link /path/to/link
```

salt.modules.file.join(*args)
Return a normalized file system path for the underlying OS
New in version 2014.7.0.

This can be useful at the CLI but is frequently useful when scripting combining path variables:

```
{% set www_root = '/var' %}
{% set app_dir = 'myapp' %}

myapp_config:
  file:
    - managed
    - name: {{ salt['file.join'](www_root, app_dir, 'config.yaml') }}
```

CLI Example:
```
salt '*' file.join '/usr' 'local' 'bin'
```

salt.modules.file.lchown(path, user, group)
Chown a file, pass the file the desired user and group without following symlinks.

path path to the file or directory
user user owner
group group owner

CLI Example:
```
salt '*' file.chown /etc/passwd root root
```

salt.modules.file.line(path, content, match=None, mode=None, location=None, before=None, after=None, show_changes=True, backup=False, quiet=False, indent=True)
New in version 2015.8.0.
Edit a line in the configuration file. The `path` and `content` arguments are required, as well as passing in one of the `mode` options.

- **path**: Filesystem path to the file to be edited.
- **content**: Content of the line.
- **match**: Match the target line for an action by a fragment of a string or regular expression.

If neither `before` nor `after` are provided, and `match` is also `None`, match becomes the `content` value.

- **mode**: Defines how to edit a line. One of the following options is required:
  - `ensure`: If line does not exist, it will be added. This is based on the `content` argument.
  - `replace`: If line already exists, it will be replaced.
  - `delete`: Delete the line, once found.
  - `insert`: Insert a line.

**Note**: If `mode=insert` is used, at least one of the following options must also be defined: `location`, `before`, or `after`. If `location` is used, it takes precedence over the other two options.

- **location**: Defines where to place content in the line. Note this option is only used when `mode=insert` is specified. If a location is passed in, it takes precedence over both the `before` and `after` kwargs. Valid locations are:
  - `start`: Place the content at the beginning of the file.
  - `end`: Place the content at the end of the file.

- **before**: Regular expression or an exact case-sensitive fragment of the string. This option is only used when either the `ensure` or `insert` mode is defined.

- **after**: Regular expression or an exact case-sensitive fragment of the string. This option is only used when either the `ensure` or `insert` mode is defined.

- **show_changes**: Output a unified diff of the old file and the new file. If `False` return a boolean if any changes were made. Default is `True`.

**Note**: Using this option will store two copies of the file in-memory (the original version and the edited version) in order to generate the diff.

- **backup**: Create a backup of the original file with the extension: `Year-Month-Day-Hour-Minutes-Seconds`.

- **quiet**: Do not raise any exceptions. E.g. ignore the fact that the file that is tried to be edited does not exist and nothing really happened.

- **indent**: Keep indentation with the previous line. This option is not considered when the `delete` mode is specified.

**CLI Example:**

```
salt '*' file.line /etc/nsswitch.conf "networks:   files dns" after="hosts:.*?"
```

**Note**: If an equal sign (`=`) appears in an argument to a Salt command, it is interpreted as a keyword argument in the format of `key=val`. That processing can be bypassed in order to pass an equal sign through to the remote shell command by manually specifying the kwarg:

```
salt '*' file.line /path/to/file content="CREATEMAIL_SPOOL=no" match="CREATE_MAIL_
SPOOL=yes" mode="replace"
```
salt.modules.file.link(src, path)
New in version 2014.1.0.
Create a hard link to a file
CLI Example:
```
salt '*' file.link /path/to/file /path/to/link
```

salt.modules.file.list_backups(path, limit=None)
New in version 0.17.0.
Lists the previous versions of a file backed up using Salt's file state backup system.
path The path on the minion to check for backups
limit Limit the number of results to the most recent N backups
CLI Example:
```
salt '*' file.list_backups /foo/bar/baz.txt
```

salt.modules.file.list_backups_dir(path, limit=None)
Lists the previous versions of a directory backed up using Salt's file state backup system.
path The directory on the minion to check for backups
limit Limit the number of results to the most recent N backups
CLI Example:
```
salt '*' file.list_backups_dir /foo/bar/baz/
```

salt.modules.file.lstat(path)
New in version 2014.1.0.
Returns the lstat attributes for the given file or dir. Does not support symbolic links.
CLI Example:
```
salt '*' file.lstat /path/to/file
```

salt.modules.file.makedirs(path, user=None, group=None, mode=None)
Ensure that the directory containing this path is available.

Note: The path must end with a trailing slash otherwise the directory/directories will be created up to the parent directory. For example if path is /opt/code, then it would be treated as /opt/ but if the path ends with a trailing slash like /opt/code/, then it would be treated as /opt/code/.

CLI Example:
```
salt '*' file.makedirs /opt/code/
```

salt.modules.file.makedirs_perms(name, user=None, group=None, mode=`0755`)  
Taken and modified from os.makedirs to set user, group and mode for each directory created.

CLI Example:
```
salt '*' file.makedirs_perms /opt/code
```

salt.modules.file.manage_file(name, sfn, ret, source, source_sum, user, group, mode, saltenv, backup, makedirs=False, template=None, show_diff=True, contents=None, dir_mode=None, follow_symlinks=True, skip_verify=False)
Checks the destination against what was retrieved with get_managed and makes the appropriate modifications (if necessary).

- **name** location to place the file
- **sfn** location of cached file on the minion

This is the path to the file stored on the minion. This file is placed on the minion using cp.cache_file. If the hash sum of that file matches the source_sum, we do not transfer the file to the minion again.

This file is then grabbed and if it has template set, it renders the file to be placed into the correct place on the system using salt.files.utils.copyfile()

- **ret** The initial state return data structure. Pass in None to use the default structure.
- **source** file reference on the master
- **source_hash** sum hash for source
- **user** user owner
- **group** group owner
- **backup** backup_mode
- **makedirs** make directories if they do not exist
- **template** format of templating
- **show_diff** Include diff in state return
- **contents**: contents to be placed in the file
- **dir_mode** mode for directories created with makedirs
- **skip_verify** [False] If True, hash verification of remote file sources (http://, https://, ftp://) will be skipped, and the source_hash argument will be ignored.

New in version 2016.3.0.

CLI Example:

```
```

Changed in version 2014.7.0: follow_symlinks option added

**salt.modules.file.mkdir** *(dir_path, user=None, group=None, mode=None)*

Ensure that a directory is available.

CLI Example:

```
salt '*' file.mkdir /opt/jetty/context
```

**salt.modules.file.mknod** *(name, ntype, major=0, minor=0, user=None, group=None, mode=`0600' )*

Create a block device, character device, or fifo pipe. Identical to the gnu mknod.

CLI Examples:

```
salt '*' file.mknod /dev/chr c 180 31
salt '*' file.mknod /dev/blk b 8 999
salt '*' file.mknod /dev/fifo p
```

**salt.modules.file.mknod_blkdev** *(name, major, minor, user=None, group=None, mode=`0660' )*

Create a block device.

CLI Example:

```
salt '*' file.mknod_blkdev /dev/blk 8 999
```
salt.modules.file.mknod_chrdev(name, major, minor, user=None, group=None, mode=`0660`)  
New in version 0.17.0.  
Create a character device.  
CLI Example:
```
salt '*' file.mknod_chrdev /dev/chr 180 31
```

salt.modules.file.mknod_fifo(name, user=None, group=None, mode=`0660`)  
New in version 0.17.0.  
Create a FIFO pipe.  
CLI Example:
```
salt '*' file.mknod_fifo /dev/fifo
```

salt.modules.file.move(src, dst)  
Move a file or directory  
CLI Example:
```
salt '*' file.move /path/to/src /path/to/dst
```

salt.modules.file.normpath(path)  
Returns Normalize path, eliminating double slashes, etc.  
New in version 2015.5.0.  
This can be useful at the CLI but is frequently useful when scripting.  
```
{% from salt['file.normpath'](tpldir + '/../vars.jinja') import parent_vars %}
```
CLI Example:
```
salt '*' file.normpath 'a/b/c/..
```

salt.modules.file.open_files(by_pid=False)  
Return a list of all physical open files on the system.  
CLI Examples:
```
salt '*' file.open_files
salt '*' file.open_files by_pid=True
```

salt.modules.file.pardir()  
Return the relative parent directory path symbol for underlying OS  
New in version 2014.7.0.  
This can be useful when constructing Salt Formulas.  
```
{% set pardir = salt['file.pardir']() %}
{% set final_path = salt['file.join']('subdir', pardir, 'confdir') %}
```
CLI Example:
```
salt '*' file.pardir
salt.modules.file.patch

New in version 0.10.4.

Apply a patch to a file or directory.

Equivalent to:

```
patch <options> -i <patchfile> <originalfile>
```

Or, when a directory is patched:

```
patch <options> -i <patchfile> -d <originalfile> -p0
```

- `originalfile`: The full path to the file or directory to be patched
- `patchfile`: A patch file to apply to `originalfile`
- `options`: Options to pass to `patch`

CLI Example:

```
salt '*' file.patch /opt/file.txt /tmp/file.txt.patch
```

salt.modules.file.path_exists_glob

Tests to see if path after expansion is a valid path (file or directory). Expansion allows usage of `?`, `*` and character ranges `[ ]`. Tilde expansion is not supported. Returns True/False.

New in version Hellium.

CLI Example:

```
salt '*' file.path_exists_glob /etc/pam*/pass*
```

salt.modules.file.prepend

New in version 2014.7.0.

Prepend text to the beginning of a file

- `path`: path to file
- `*args`: strings to prepend to the file

CLI Example:

```
salt '*' file.prepend /etc/motd
  "With all thine offerings thou shalt offer salt."
  "Salt is what makes things taste bad when it isn't in them."
```

Attention

If you need to pass a string to append and that string contains an equal sign, you must include the argument name, args. For example:

```
salt '*' file.prepend /etc/motd args='cheese=spam'
salt '*' file.prepend /etc/motd args="['cheese=spam','spam=cheese']"
```

salt.modules.file.psed

Deprecated since version 0.17.0: Use replace() instead.

Make a simple edit to a file (pure Python version)

Equivalent to:
sed <backup> <options> "/<limit>/ s/<before>/<after>/<flags> <file>"

**path**  The full path to the file to be edited
**before** A pattern to find in order to replace with **after**
**limit** ["'] An initial pattern to search for before searching for **before**
**backup** [.bak] The file will be backed up before edit with this file extension; **WARNING:** each time
**sed/comment/uncomment** is called will overwrite this backup
**flags** [gMS]

Flags to modify the search. Valid values are:

- **g**: Replace all occurrences of the pattern, not just the first.
- **I**: Ignore case.
- **L**: Make \w, \W, \b, \B, \s and \S dependent on the locale.
- **M**: Treat multiple lines as a single line.
- **S**: Make . match all characters, including newlines.
- **U**: Make \w, \W, \b, \B, \d, \D, \s and \S dependent on Unicode.
- **X**: Verbose (whitespace is ignored).

**multi**: False If True, treat the entire file as a single line

Forward slashes and single quotes will be escaped automatically in the **before** and **after** patterns.

CLI Example:
salt '!' file.sed /etc/httpd/httpd.conf 'LogLevel warn' 'LogLevel info'

salt.modules.file.readdir(path)
New in version 2014.1.0.
Return a list containing the contents of a directory

CLI Example:
salt '!' file.readdir /path/to/dir/

salt.modules.file.readlink(path, canonicalize=False)
New in version 2014.1.0.
Return the path that a symlink points to If canonicalize is set to True, then it return the final target

CLI Example:
salt '!' file.readlink /path/to/link

salt.modules.file.remove(path)
Remove the named file. If a directory is supplied, it will be recursively deleted.

CLI Example:
salt '!' file.remove /tmp/foo

salt.modules.file.rename(src, dst)
Rename a file or directory

CLI Example:
Replace occurrences of a pattern in a file. If `show_changes` is `True`, then a diff of what changed will be returned, otherwise a `True` will be returned when changes are made, and `False` when no changes are made.

This is a pure Python implementation that wraps Python’s `sub()` method.

**path**  
Filesystem path to the file to be edited

**pattern**  
A regular expression, to be matched using Python’s `search()` method.

**repl**  
The replacement text

**count**  
Maximum number of pattern occurrences to be replaced. If count is a positive integer n, only n occurrences will be replaced, otherwise all occurrences will be replaced.

**flags**  
A list of flags defined in the `re` module documentation. Each list item should be a string that will correlate to the human-friendly flag name. E.g., `['IGNORECASE', 'MULTILINE']`. Optionally, flags may be an int, with a value corresponding to the XOR (`|`) of all the desired flags. Defaults to 8 (which supports `MULTILINE`).

**buFSIZE**  
How much of the file to buffer into memory at once. The default value 1 processes one line at a time. The special value `file` may be specified which will read the entire file into memory before processing.

**append_if_not_found**  
If set to `True`, and pattern is not found, then the content will be appended to the file.

**prepend_if_not_found**  
If set to `True` and pattern is not found, then the content will be prepended to the file.

**not_found_content**  
Content to use for append/prepend if not found. If None (default), uses `repl`. Useful when `repl` uses references to group in pattern.

**backup**  
The file extension to use for a backup of the file before editing. Set to `False` to skip making a backup.

**dry_run**  
If set to `True`, no changes will be made to the file, the function will just return the changes that would have been made (or a `True/False` value if `show_changes` is set to `False`).

**search_only**  
If set to `True`, this no changes will be performed on the file, and this function will simply return `True` if the pattern was matched, and `False` if not.

**show_changes**  
If `True`, return a diff of changes made. Otherwise, return `True` if changes were made, and `False` if not.

**ignore_if_missing**  
If set to `True`, this function will simply return `False` if the file doesn’t exist. Otherwise, an error will be thrown.

**preserve_inode**  
Preserve the inode of the file, so that any hard links continue to share the inode with the original file-name. This works by copying the file, reading from the copy, and writing to the file at the original inode.

Note: Using this option will store two copies of the file in memory (the original version and the edited version) in order to generate the diff. This may not normally be a concern, but could impact performance if used with large files.
If False, the file will be moved rather than copied, and a new file will be written to a new inode, but using the original filename. Hard links will then share an inode with the backup, instead (if using backup to create a backup copy).

If an equal sign (=) appears in an argument to a Salt command it is interpreted as a keyword argument in the format key=val. That processing can be bypassed in order to pass an equal sign through to the remote shell command by manually specifying the kwarg:

```
salt '*' file.replace /path/to/file pattern='=' repl=':'
salt '*' file.replace /path/to/file pattern="bind-address\s*=" repl='bind-address: '
```

CLI Examples:

```
salt '*' file.replace /etc/httpd/httpd.conf pattern='LogLevel warn' repl=
    '\n  ->' 'LogLevel info'
salt '*' file.replace /some/file pattern='before' repl='after' flags='[MULTILINE,\n    ->IGNORECASE]' 
```

salt.modules.file.restore_backup(path, backup_id)

New in version 0.17.0.

Restore a previous version of a file that was backed up using Salt’s file state backup system.

- `path` The path on the minion to check for backups
- `backup_id` The numeric id for the backup you wish to restore, as found using `file.list_backups`

CLI Example:

```
salt '*' file.restore_backup /foo/bar/baz.txt 0
```

salt.modules.file.restorecon(path, recursive=False)

Reset the SELinux context on a given path

CLI Example:

```
salt '*' file.restorecon /home/user/.ssh/authorized_keys
```

salt.modules.file.rmdir(path)

New in version 2014.1.0.

Remove the specified directory. Fails if a directory is not empty.

CLI Example:

```
salt '*' file.rmdir /tmp/foo/
```

salt.modules.file.search(path, pattern, flags=8, bufsize=1, ignore_if_missing=False, multiline=False)

New in version 0.17.0.

Search for occurrences of a pattern in a file

Except for multiline, params are identical to `replace()`.

- `multiline` If true, inserts `MULTILINE` into `flags` and sets `bufsize` to `file`.

New in version 2015.8.0.

CLI Example:

```
salt '*' file.search /etc/crontab 'mymaintenance.sh'
```
salt.modules.file.sed(path, before, after, limit='', backup='.bak', options='-r -e', flags='g', escape_all=False, negate_match=False)

Deprecated since version 0.17.0: Use replace() instead.

Make a simple edit to a file

Equivalent to:

```
sed <backup> <options> "/<limit>/ s/<before>/<after>/<flags> <file>
```

- **path**  The full path to the file to be edited
- **before**  A pattern to find in order to replace with **after**
- **after**  Text that will replace **before**
- **limit**  [''] An initial pattern to search for before searching for **before**
- **backup** [.bak]  The file will be backed up before edit with this file extension; WARNING: each time sed/comment/uncomment is called will overwrite this backup
- **options**  [-r -e] Options to pass to sed
- **flags**  [g] Flags to modify the sed search; e.g., i for case-insensitive pattern matching
- **negate_match**  [False] Negate the search command (!)

New in version 0.17.0.

Forward slashes and single quotes will be escaped automatically in the **before** and **after** patterns.

CLI Example:

```
salt '*' file.sed /etc/httpd/httpd.conf 'LogLevel warn' 'LogLevel info'
```

salt.modules.file.sed_contains(path, text, limit='', flags='g')

Deprecated since version 0.17.0: Use search() instead.

Return True if the file at **path** contains **text**. Utilizes sed to perform the search (line-wise search).

Note: the p flag will be added to any flags you pass in.

CLI Example:

```
salt '*' file.contains /etc/crontab 'mymaintenance.sh'
```

salt.modules.file.seek_read(path, size, offset)

New in version 2014.1.0.

Seek to a position on a file and read it

- **path**  path to file
- **size**  amount to read at once
- **offset**  position in file to start reading

CLI Example:

```
salt '*' file.seek_read /path/to/file 4096 0
```

salt.modules.file.seek_write(path, data, offset)

New in version 2014.1.0.

Seek to a position on a file and write to it

- **path**  path to file
- **data**  data to write to file
- **offset**  position in file to start writing

CLI Example:
salt '!' file.seek_write /path/to/file 'some data' 4096

salt.modules.file.set_mode(path, mode)
Set the mode of a file
path file or directory of which to set the mode
mode mode to set the path to
CLI Example:
salt '!' file.set_mode /etc/passwd 0644

salt.modules.file.set_selinux_context(path, user=None, role=None, type=None, range=None)
Set a specific SELinux label on a given path
CLI Example:
salt '!' file.set_selinux_context path <role> <type> <range>

salt.modules.file.source_list(source, source_hash, saltenv)
Check the source list and return the source to use
CLI Example:
salt '!' file.source_list salt://http/httpd.conf '{hash_type: 'md5', 'hsum': ...

salt.modules.file.stats(path, hash_type=None, follow_symlinks=True)
Return a dict containing the stats for a given file
CLI Example:
salt '!' file.stats /etc/passwd

salt.modules.file.statvfs(path)
New in version 2014.1.0.
Perform a statvfs call against the filesystem that the file resides on
CLI Example:
salt '!' file.statvfs /path/to/file

salt.modules.file.symlink(src, path)
Create a symbolic link (symlink, so link) to a file
CLI Example:
salt '!' file.symlink /path/to/file /path/to/link

salt.modules.file.touch(name, atime=None, mtime=None)
New in version 0.9.5.
Just like the touch command, create a file if it doesn't exist or simply update the atime and mtime if it already does.
atime: Access time in Unix epoch time
mtime: Last modification in Unix epoch time
CLI Example:
salt '!' file.touch /var/log/emptyfile
**salt.modules.file.truncate** (*path, length*)

New in version 2014.1.0.

Seek to a position on a file and delete everything after that point.

- **path** path to file
- **length** offset into file to truncate

CLI Example:

```
salt '*' file.truncate /path/to/file 512
```

**salt.modules.file.uid_to_user** (*uid*)

Convert a uid to a user name.

- **uid** uid to convert to a username

CLI Example:

```
salt '*' file.uid_to_user 0
```

**salt.modules.file.uncomment** (*path, regex='^', char='#', backup='.bak')

Deprecated since version 0.17.0: Use `replace()` instead.

Uncomment specified commented lines in a file.

- **path** The full path to the file to be edited
- **regex** A regular expression used to find the lines that are to be uncommented. This regex should not include the comment character. A leading ^ character will be stripped for convenience (for easily switching between `comment()` and `uncomment()`).
- **char** [#] The character to remove in order to uncomment a line
- **backup** [.bak] The file will be backed up before edit with this file extension; **WARNING**: each time `sed/comment/uncomment` is called will overwrite this backup

CLI Example:

```
salt '*' file.uncomment /etc/hosts.deny 'ALL: PARANOID'
```

**salt.modules.file.user_to_uid** (*user*)

Convert user name to a uid.

- **user** user name to convert to its uid

CLI Example:

```
salt '*' file.user_to_uid root
```

**salt.modules.file.write** (*path, *args, **kwargs*)

New in version 2014.7.0.

Write text to a file, overwriting any existing contents.

- **path** path to file
- ***args** strings to write to the file

CLI Example:

```
salt '*' file.write /etc/motd "With all thine offerings thou shalt offer salt."
```

**Attention**

If you need to pass a string to append and that string contains an equal sign, you **must** include the argument name, `args`. For example:
13.6.91 salt.modules.firewalld

Support for firewalld.

New in version 2015.2.0.

salt.modules.firewalld.add_interface(zone, interface)

Bind an interface to a zone

New in version 2016.3.0.

CLI Example:

```bash
salt '*' firewalld.add_interface zone eth0
```

salt.modules.firewalld.add_masquerade(zone)

Enable masquerade on a zone.

New in version 2015.8.0.

CLI Example:

```bash
salt '*' firewalld.add_masquerade
```

salt.modules.firewalld.add_port(zone, port, permanent=True)

Allow specific ports in a zone.

New in version 2015.8.0.

CLI Example:

```bash
salt '*' firewalld.add_port internal 443/tcp
```

salt.modules.firewalld.add_port_fwd(zone, src, dest, proto='tcp', dstaddr='')

Add port forwarding.

New in version 2015.8.0.

CLI Example:

```bash
salt '*' firewalld.add_port_fwd public 80 443 tcp
```

salt.modules.firewalld.add_service(name, zone=None, permanent=True)

Add a service for zone. If zone is omitted, default zone will be used.

CLI Example:

```bash
salt '*' firewalld.add_service ssh
```

To assign a service to a specific zone:

```bash
salt '*' firewalld.add_service ssh my_zone
```
salt.modules.firewalld.add_source(zone, source)
Bind a source to a zone
New in version 2016.3.0.
CLI Example:

```
salt '*' firewalld.add_source zone 192.168.1.0/24
```

salt.modules.firewalld.allow_icmp(zone, icmp)
Allow a specific ICMP type on a zone
New in version 2015.8.0.
CLI Example:

```
salt '*' firewalld.allow_icmp zone echo-reply
```

salt.modules.firewalld.block_icmp(zone, icmp)
Block a specific ICMP type on a zone
New in version 2015.8.0.
CLI Example:

```
salt '*' firewalld.block_icmp zone echo-reply
```

salt.modules.firewalld.default_zone()
Print default zone for connections and interfaces
CLI Example:

```
salt '*' firewalld.default_zone
```

salt.modules.firewalld.delete_service(name, restart=True)
Delete an existing service
CLI Example:

```
salt '*' firewalld.delete_service my_service
```

By default firewalld will be reloaded. However, to avoid reloading you need to specify the restart as False

```
salt '*' firewalld.delete_service my_service False
```

salt.modules.firewalld.delete_zone(zone, restart=True)
Delete an existing zone
CLI Example:

```
salt '*' firewalld.delete_zone my_zone
```

By default firewalld will be reloaded. However, to avoid reloading you need to specify the restart as False

```
salt '*' firewalld.delete_zone my_zone False
```

salt.modules.firewalld.get_icmp_types()
Print predefined icmptypes
CLI Example:
salt '*' firewalld.get_icmp_types

salt.modules.firewalld.get_interfaces(zone)
List interfaces bound to a zone
New in version 2016.3.0.
CLI Example:
salt '*' firewalld.get_interfaces zone

salt.modules.firewalld.get_masquerade(zone)
Show if masquerading is enabled on a zone
CLI Example:
salt '*' firewalld.get_masquerade zone

salt.modules.firewalld.get_services()
Print predefined services
CLI Example:
salt '*' firewalld.get_services

salt.modules.firewalld.get_sources(zone)
List sources bound to a zone
New in version 2016.3.0.
CLI Example:
salt '*' firewalld.get_sources zone

salt.modules.firewalld.get_zones()
Print predefined zones
CLI Example:
salt '*' firewalld.get_zones

salt.modules.firewalld.list_all(zone=None)
List everything added for or enabled in a zone
CLI Example:
salt '*' firewalld.list_all

List a specific zone
salt '*' firewalld.list_all my_zone

salt.modules.firewalld.list_icmp_block(zone)
List ICMP blocks on a zone
New in version 2015.8.0.
CLI Example:
salt '*' firewalld.list_icmp_block zone
salt.modules.firewalld.list_port_fwd(zone)
List port forwarding
New in version 2015.8.0.
CLI Example:
salt '* firewalld.list_port_fwd public

salt.modules.firewalld.list_ports(zone)
List all ports in a zone.
New in version 2015.8.0.
CLI Example:
salt '* firewalld.list_ports

salt.modules.firewalld.list_services(zone=None)
List services added for zone as a space separated list. If zone is omitted, default zone will be used.
CLI Example:
salt '* firewalld.list_services

List a specific zone
salt '* firewalld.list_services my_zone

salt.modules.firewalld.list_zones()
List everything added for or enabled in all zones
CLI Example:
salt '* firewalld.list_zones

salt.modules.firewalld.make_permanent()
Make current runtime configuration permanent.
New in version 2016.3.0.
CLI Example:
salt '* firewalld.make_permanent

salt.modules.firewalld.new_service(name, restart=True)
Add a new service
CLI Example:
salt '* firewalld.new_service my_service

By default firewalld will be reloaded. However, to avoid reloading you need to specify the restart as False
salt '* firewalld.new_service my_service False

salt.modules.firewalld.new_zone(zone, restart=True)
Add a new zone
CLI Example:
By default firewalld will be reloaded. However, to avoid reloading you need to specify the restart as False.

```text
salt '*' firewalld.new_zone my_zone False
```

salt.modules.firewalld.remove_interface(zone, interface)
Remove an interface bound to a zone
New in version 2016.3.0.
CLI Example:

```text
salt '*' firewalld.remove_interface zone eth0
```

salt.modules.firewalld.remove_masquerade(zone)
Remove masquerade on a zone.
New in version 2015.8.0.
CLI Example:

```text
salt '*' firewalld.remove_masquerade
```

salt.modules.firewalld.remove_port(zone, port, permanent=True)
Remove a specific port from a zone.
New in version 2015.8.0.
CLI Example:

```text
salt '*' firewalld.remove_port internal 443/tcp
```

salt.modules.firewalld.remove_port_fwd(zone, src, dest, proto='tcp')
Remove Port Forwarding.
New in version 2015.8.0.
CLI Example:

```text
salt '*' firewalld.remove_port_fwd public 80 443 tcp
```

salt.modules.firewalld.remove_service(name, zone=None, permanent=True)
Remove a service from zone. This option can be specified multiple times. If zone is omitted, default zone will be used.
CLI Example:

```text
salt '*' firewalld.remove_service ssh
```

To remove a service from a specific zone

```text
salt '*' firewalld.remove_service ssh dmz
```

salt.modules.firewalld.remove_source(zone, source)
Remove a source bound to a zone
New in version 2016.3.0.
CLI Example:
salt ' '*' firewalld.remove_source zone 192.168.1.0/24

salt.modules.firewalld.set_default_zone(zone)
Set default zone

    CLI Example:

        salt ' '*' firewalld.set_default_zone damian

salt.modules.firewalld.version()
Return version from firewall-cmd

    CLI Example:

        salt ' '*' firewalld.version

### 13.6.92 salt.modules.freebsd_sysctl

Module for viewing and modifying sysctl parameters

salt.modules.freebsd_sysctl.assign(name, value)
Assign a single sysctl parameter for this minion

    CLI Example:

        salt ' '*' sysctl.assign net.inet.icmp.icmplim 50

salt.modules.freebsd_sysctl.get(name)
Return a single sysctl parameter for this minion

    CLI Example:

        salt ' '*' sysctl.get hw.physmem

salt.modules.freebsd_sysctl.persist(name, value, config='/etc/sysctl.conf')
Assign and persist a simple sysctl parameter for this minion

    CLI Example:

        salt ' '*' sysctl.persist net.inet.icmp.icmplim 50
        salt ' '*' sysctl.persist coretemp_load NO config=/boot/loader.conf

salt.modules.freebsd_sysctl.show(config_file=False)
Return a list of sysctl parameters for this minion

    CLI Example:

        salt ' '*' sysctl.show

### 13.6.93 salt.modules.freebsdjail

The jail module for FreeBSD

salt.modules.freebsdjail fstab(jail)
Display contents of a fstab(5) file defined in specified jail's configuration. If no file is defined, return False.

    CLI Example:
salt 'jail.fstab <jail name>

salt.modules.freebsdjail.get_enabled()
Return which jails are set to be run

CLI Example:
salt '*' jail.get_enabled

salt.modules.freebsdjail.is_enabled()
See if jail service is actually enabled on boot

CLI Example:
salt '*' jail.is_enabled <jail name>

salt.modules.freebsdjail.restart(jail='')
Restart the specified jail or all, if none specified

CLI Example:
salt '*' jail.restart [jail name]

salt.modules.freebsdjail.show_config(jail)
Display specified jail's configuration

CLI Example:
salt '*' jail.show_config <jail name>

salt.modules.freebsdjail.start(jail='')
Start the specified jail or all, if none specified

CLI Example:
salt '*' jail.start [jail name]

salt.modules.freebsdjail.status(jail)
See if specified jail is currently running

CLI Example:
salt '*' jail.status <jail name>

salt.modules.freebsdjail.stop(jail='')
Stop the specified jail or all, if none specified

CLI Example:
salt '*' jail.stop [jail name]

salt.modules.freebsdjail.sysctl()
Dump all jail related kernel states (sysctl)

CLI Example:
salt '*' jail.sysctl
13.6.94 salt.modules.freebsdkmod

Module to manage FreeBSD kernel modules

salt.modules.freebsdkmod.available()
    Return a list of all available kernel modules
    
    CLI Example:
    
    salt '*' kmod.available

salt.modules.freebsdkmod.check_available(mod)
    Check to see if the specified kernel module is available
    
    CLI Example:
    
    salt '*' kmod.check_available vmm

salt.modules.freebsdkmod.is_loaded(mod)
    Check to see if the specified kernel module is loaded
    
    CLI Example:
    
    salt '*' kmod.is_loaded vmm

salt.modules.freebsdkmod.load(mod, persist=False)
    Load the specified kernel module
    mod Name of the module to add
    persist Write the module to sysrc kld_modules to make it load on system reboot
    
    CLI Example:
    
    salt '*' kmod.load bhyve

salt.modules.freebsdkmod.lsmod()
    Return a dict containing information about currently loaded modules
    
    CLI Example:
    
    salt '*' kmod.lsm

salt.modules.freebsdkmod.mod_list(only_persist=False)
    Return a list of the loaded module names
    
    CLI Example:
    
    salt '*' kmod.mod_list

salt.modules.freebsdkmod.remove(mod, persist=False)
    Remove the specified kernel module
    
    CLI Example:
    
    salt '*' kmod.remove vmm

13.6.95 salt.modules.freebsdpkg

Remote package support using pkg_add(1)
**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install' is not available), see here.

**Warning:** This module has been completely rewritten. Up to and including version 0.17.0, it supported `pkg.add(1)`, but checked for the existence of a pkgng local database and, if found, would provide some of pkgng's functionality. The rewrite of this module has removed all pkgng support, and moved it to the pkgng execution module. For versions <= 0.17.0, the documentation here should not be considered accurate. If your Minion is running one of these versions, then the documentation for this module can be viewed using the `sys.doc` function:

```
salt bsdminion sys.doc pkg
```

This module acts as the default package provider for FreeBSD 9 and older. If you need to use pkgng on a FreeBSD 9 system, you will need to override the `pkg` provider by setting the `providers` parameter in your Minion config file, in order to use pkgng.

```yaml
providers:
    pkg: pkgng
```

More information on pkgng support can be found in the documentation for the `pkgng` module.

This module will respect the `PACKAGEROOT` and `PACKAGESITE` environment variables, if set, but these values can also be overridden in several ways:

1. **Salt configuration parameters.** The configuration parameters `freebsdpkg.PACKAGEROOT` and `freebsdpkg.PACKAGESITE` are recognized. These config parameters are looked up using `config.get` and can thus be specified in the Master config file, Grains, Pillar, or in the Minion config file. Example:

   ```
   ```

2. **CLI arguments.** Both the packageroot (used interchangeably with `fromrepo` for API compatibility) and packagesite CLI arguments are recognized, and override their config counterparts from section 1 above.

   ```
   salt -G 'os:FreeBSD' pkg.install zsh fromrepo=ftp://ftp2.freebsd.org/
   salt -G 'os:FreeBSD' pkg.install zsh packageroot=ftp://ftp2.freebsd.org/
   salt -G 'os:FreeBSD' pkg.install zsh packagesite=ftp://ftp2.freebsd.org/pub/
   ~FreeBSD/ports/ia64/packages-9-stable/Latest/
   ```

   ```
   .. note::
   These arguments can also be passed through in states:

   .. code-block:: yaml

   zsh:
       pkg.installed:
   ```

   ```
   salt.modules.freebsdpkg.file_dict('packages')
   List the files that belong to a package, grouped by package. Not specifying any packages will return a list of _every_ file on the system's package database (not generally recommended).

   CLI Examples:
   ```
salt.modules.freebsdpkg.file_list("packages")
List the files that belong to a package. Not specifying any packages will return a list of _every_ file on the
system's package database (not generally recommended).

CLI Examples:

```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

salt.modules.freebsdpkg.install(name=None, refresh=False, fromrepo=None, pkgs=None,
sources=None, **kwargs)
Install package(s) using pkg_add(1)

name                The name of the package to be installed.
refresh             Whether or not to refresh the package database before installing.
fromrepo or packageroot Specify a package repository from which to install. Overrides the system default,
as well as the PACKAGEROOT environment variable.
packagesite         Specify the exact directory from which to install the remote package. Overrides the PACKAGESITE
environment variable, if present.
Multiple Package Installation Options:

pkgs                A list of packages to install from a software repository. Must be passed as a python list.

CLI Example:
```
salt '*' pkg.install pkgs='["foo", "bar"]'
```

sources            A list of packages to install. Must be passed as a list of dicts, with the keys being package names, and
the values being the source URI or local path to the package.

CLI Example:
```
salt '*' pkg.install sources='[{"foo": "salt://foo.deb"}, {"bar": "salt://bar.deb"}]'
```

Return a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
              'new': '<new-version>'}}
```

CLI Example:
```
salt '*' pkg.install <package name>
```

salt.modules.freebsdpkg.latest_version("names", **kwargs)
pkg_add(1) is not capable of querying for remote packages, so this function will always return results as if
there is no package available for install or upgrade.

CLI Example:
```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...'
```

salt.modules.freebsdpkg.list_pkgs(versions_as_list=False, with_origin=False, **kwargs)
List the packages currently installed as a dict:
with_origin [False] Return a nested dictionary containing both the origin name and version for each installed package.

New in version 2014.1.0.

CLI Example:
```
salt '*' pkg.list_pkgs
```

salt.modules.freebsdpkg.refresh_db()

`pkg_add(1)` does not use a local database of available packages, so this function simply returns `True`. It exists merely for API compatibility.

CLI Example:
```
salt '*' pkg.refresh_db
```

salt.modules.freebsdpkg.remove(name=None, pkgs=None, **kwargs)

Remove packages using `pkg_delete(1)`

*name* The name of the package to be deleted.

Multiple Package Options:

*pkgs* A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:
```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

salt.modules.freebsdpkg.upgrade()

Upgrades are not supported with `pkg_add(1)`. This function is included for API compatibility only and always returns an empty dict.

CLI Example:
```
salt '*' pkg.upgrade
```

salt.modules.freebsdpkg.version(*names, **kwargs)

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

with_origin [False] Return a nested dictionary containing both the origin name and version for each specified package.

New in version 2014.1.0.

CLI Example:
```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

**13.6.96 salt.modules.freebsdports**

Install software from the FreeBSD ports(7) system
New in version 2014.1.0.

This module allows you to install ports using `BATCH=yes` to bypass configuration prompts. It is recommended to use the `ports state` to install ports, but it is also possible to use this module exclusively from the command line.

```bash
salt minion-id ports.config security/nmap IPV6=off
salt minion-id ports.install security/nmap
```

```python
salt.modules.freebsdports.config(name, reset=False, **kwargs)
    Modify configuration options for a given port. Multiple options can be specified. To see the available options for a port, use `ports.showconfig`.
    name  The port name, in `category/name` format
    reset [False] If True, runs a make `rmconfig` for the port, clearing its configuration before setting the desired options
```

CLI Examples:

```bash
salt '*' ports.config security/nmap IPV6=off
```

```python
salt.modules.freebsdports.deinstall(name)
    De-install a port.
```

CLI Example:

```bash
salt '*' ports.deinstall security/nmap
```

```python
salt.modules.freebsdports.install(name, clean=True)
    Install a port from the ports tree. Installs using `BATCH=yes` for non-interactive building. To set config options for a given port, use `ports.config`.
    clean  [True] If True, cleans after installation. Equivalent to running make `install clean BATCH=yes`.
```

Note: It may be helpful to run this function using the `-t` option to set a higher timeout, since compiling a port may cause the Salt command to exceed the default timeout.

CLI Example:

```bash
salt -t 1200 '*' ports.install security/nmap
```

```python
salt.modules.freebsdports.list_all()
    Lists all ports available.
```

CLI Example:

```bash
salt '*' ports.list_all
```

**Warning:** Takes a while to run, and returns a LOT of output

```python
salt.modules.freebsdports.rmconfig(name)
    Clear the cached options for the specified port; run a make `rmconfig`
    name  The name of the port to clear
```

CLI Example:

```bash
salt '*' ports.rmconfig security/nmap
```

```python
salt.modules.freebsdports.search(name)
    Search for matches in the ports tree. Globs are supported, and the category is optional
```

13.6. execution modules
CLI Examples:

```
salt '*' ports.search 'security/*'
salt '*' ports.search 'security/n*' nslookup
```

**Warning**: Takes a while to run

```python
salt.modules.freebsdports.showconfig(name, default=False, dict_return=False)
```

Show the configuration options for a given port.

- **default** [False] Show the default options for a port (not necessarily the same as the current configuration)
- **dict_return** [False] Instead of returning the output of `make showconfig`, return the data in an dictionary

CLI Example:

```
salt '*' ports.showconfig security/nmap
```

```python
salt.modules.freebsdports.update(extract=False)
```

Update the ports tree

- **extract** [False] If True, runs a `portsnap extract` after fetching, should be used for first-time installation of the ports tree.

CLI Example:

```
salt '*' ports.update
```

### 13.6.97 salt.modules.freebsdservice

The service module for FreeBSD

**Important**: If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `service.start' is not available), see [here](#).

```python
salt.modules.freebsdservice.available(name)
```

Check that the given service is available.

CLI Example:

```
salt '*' service.available sshd
```

```python
salt.modules.freebsdservice.disable(name, **kwargs)
```

Disable the named service to start at boot

Arguments the same as for enable()

CLI Example:

```
salt '*' service.disable <service name>
```

```python
salt.modules.freebsdservice.disabled(name)
```

Return True if the named service is enabled, false otherwise

CLI Example:
salt '*' service.disabled <service name>

```python
salt.modules.freebsdservice.enable(name, **kwargs)
```
Enable the named service to start at boot

- **name** service name
- **config** [/etc/rc.conf] Config file for managing service. If config value is empty string, then
  /etc/rc.conf.d/<service> used. See man rc.conf(5) for details.
  Also service.config variable can be used to change default.

CLI Example:
```
salt '*' service.enable <service name>
```

```python
salt.modules.freebsdservice.enabled(name, **kwargs)
```
Return True if the named service is enabled, false otherwise

- **name** Service name

CLI Example:
```
salt '*' service.enabled <service name>
```

```python
salt.modules.freebsdservice.get_all()
```
Return a list of all available services

CLI Example:
```
salt '*' service.get_all
```

```python
salt.modules.freebsdservice.get_disabled()
```
Return what services are available but not enabled to start at boot

CLI Example:
```
salt '*' service.get_disabled
```

```python
salt.modules.freebsdservice.get_enabled()
```
Return what services are set to run on boot

CLI Example:
```
salt '*' service.get_enabled
```

```python
salt.modules.freebsdservice.missing(name)
```
The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:
```
salt '*' service.missing sshd
```

```python
salt.modules.freebsdservice.reload(name)
```
Restart the named service

CLI Example:
```
salt '*' service.reload <service name>
```

```python
salt.modules.freebsdservice.restart(name)
```
Restart the named service
## 13.6.98 salt.modules.gem

Manage ruby gems.

salt.modules.gem.install\(\text{gems}, \text{ruby}=\text{None}, \text{gem_bin}=\text{None}, \text{runas}=\text{None}, \text{version}=\text{None}, \text{rdoc}=\text{False}, \text{ri}=\text{False}, \text{pre_releases}=\text{False}, \text{proxy}=\text{None}, \text{source}=\text{None}\)

Installs one or several gems.

**Parameters**

- **gems** -- string The gems to install
- **gem_bin** -- string : None Full path to gem binary to use.
- **ruby** -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
- **runas** -- string : None The user to run gem as.
- **version** -- string : None Specify the version to install for the gem. Doesn't play nice with multiple gems at once
- **rdoc** -- boolean : False Generate RDoc documentation for the gem(s).
- **ri** -- boolean : False Generate RI documentation for the gem(s).
- **pre_releases** -- boolean : False Include pre-releases in the available versions
- **proxy** -- string : None Use the specified HTTP proxy server for all outgoing traffic. Format: http://hostname[:port]
- **source** [None] Use the specified HTTP gem source server to download gem. Format: http://hostname[:port]

CLI Example:
salt '*' gem.install vagrant
salt '*' gem.install redphone gem_bin=/opt/sensu/embedded/bin/gem

salt.modules.gem.list(prefix='*', ruby=None, runas=None, gem_bin=None)
List locally installed gems.

Parameters

- **prefix** -- string : Only list gems when the name matches this prefix.
- **gem_bin** -- string : None Full path to gem binary to use.
- **ruby** -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
- **runas** -- string : None The user to run gem as.

CLI Example:
salt '*' gem.list

salt.modules.gem.list_upgrades(ruby=None, runas=None, gem_bin=None)
New in version 2015.8.0.
Check if an upgrade is available for installed gems

gem_bin [None] Full path to gem binary to use.
ruby [None] If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
runas [None] The user to run gem as.

CLI Example:
salt '*' gem.list_upgrades

salt.modules.gem.sources_add(source_uri, ruby=None, runas=None, gem_bin=None)
Add a gem source.

Parameters

- **source_uri** -- string The source URI to add.
- **gem_bin** -- string : None Full path to gem binary to use.
- **ruby** -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
- **runas** -- string : None The user to run gem as.

CLI Example:
salt '*' gem.sources_add http://rubygems.org/

salt.modules.gem.sources_list(ruby=None, runas=None, gem_bin=None)
List the configured gem sources.

Parameters

- **gem_bin** -- string : None Full path to gem binary to use.
- **ruby** -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
- **runas** -- string : None The user to run gem as.

CLI Example:
salt '*' gem.sources_list

gem.sources_remove(source_uri, ruby=None, runas=None, gem_bin=None)
    Remove a gem source.
    Parameters
    • source_uri -- string The source URI to remove.
    • gem_bin -- string : None Full path to gem binary to use.
    • ruby -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
    • runas -- string : None The user to run gem as.
    CLI Example:
    salt '*' gem.sources_remove http://rubygems.org/

gem.uninstall(gems, ruby=None, runas=None, gem_bin=None)
    Uninstall one or several gems.
    Parameters
    • gems -- string The gems to uninstall.
    • gem_bin -- string : None Full path to gem binary to use.
    • ruby -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
    • runas -- string : None The user to run gem as.
    CLI Example:
    salt '*' gem.uninstall vagrant

gem.update(gems, ruby=None, runas=None, gem_bin=None)
    Update one or several gems.
    Parameters
    • gems -- string The gems to update.
    • gem_bin -- string : None Full path to gem binary to use.
    • ruby -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
    • runas -- string : None The user to run gem as.
    CLI Example:
    salt '*' gem.update vagrant

gem.update_system(version='*', ruby=None, runas=None, gem_bin=None)
    Update rubygems.
    Parameters
    • version -- string : (newest) The version of rubygems to install.
    • gem_bin -- string : None Full path to gem binary to use.
    • ruby -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
    • runas -- string : None The user to run gem as.
CLI Example:
```
salt '*' gem.update_system
```

13.6.99 salt.modules.genesis

Module for managing container and VM images

New in version 2014.7.0.

salt.modules.genesis.avail_platforms()
Return which platforms are available

CLI Example:
```
salt myminion genesis.avail_platforms
```

salt.modules.genesis.bootstrap(platform, root, img_format='dir', fs_format='ext2',
fs_opts=None, arch=None, flavor=None, repo_url=None,
static_qemu=None, img_size=None, mount_dir=None,
pkg_cache=None, pkgs=None, exclude_pkgs=None,
epel_url='http://download.fedoraproject.org/pub/epel/6/i386/epel-release-6-8.noarch.rpm')

Create an image for a specific platform.

Please note that this function MUST be run as root, as images that are created make files belonging to root.

**platform** Which platform to use to create the image. Currently supported platforms are rpm, deb and pacman.

**root** Local path to create the root of the image filesystem.

**img_format** Which format to create the image in. By default, just copies files into a directory on the local filesystem (dir). Future support will exist for sparse.

**fs_format** When using a non-dir img_format, which filesystem to format the image to. By default, ext2.

**fs_opts** When using a non-dir img_format, a dict of opts may be specified.

**arch** Architecture to install packages for, if supported by the underlying bootstrap tool. Currently only used for deb.

**flavor** Which flavor of operating system to install. This correlates to a specific directory on the distribution repositories. For instance, wheezy on Debian.

**repo_url** Mainly important for Debian-based repos. Base URL for the mirror to install from. (e.x.: http://ftp.debian.org/debian/)

**static_qemu** Local path to the static qemu binary required for this arch. (e.x.: /usr/bin/qemu-amd64-static)

**pkg_confs** The location of the conf files to copy into the image, to point the installer to the right repos and configuration.

**img_size** If img_format is not dir, then the size of the image must be specified.

**mount_dir** If img_format is not dir, then the image must be mounted somewhere. If the mount_dir is not specified, then it will be created at /opt/salt-genesis.<random_uuid>. This directory will be unmounted and removed when the process is finished.

**pkg_cache** This points to a directory containing a cache of package files to be copied to the image. It does not need to be specified.

**pkgs** A list of packages to be installed on this image. For RedHat, this will include yum, centos-release and iputils by default.

**exclude_pkgs** A list of packages to be excluded. If you do not want to install the defaults, you need to include them in this list.

**epel_url** The URL to download the EPEL release package from.

CLI Examples:
**Salt Documentation, Release 2016.3.6**

```
salt myminion genesis.bootstrap pacman /root/arch
salt myminion genesis.bootstrap rpm /root/redhat
salt myminion genesis.bootstrap deb /root/wheezy arch=amd64
   --flavor=wheezy static_qemu=/usr/bin/qemu-x86_64-static
```

**salt.modules.genesis.ldd_deps(filename, ret=None)**

Recurse through a set of dependencies reported by `ldd`, to find associated dependencies.

Please note that this does not necessarily resolve all (non-package) dependencies for a file; but it does help.

CLI Example:
```
salt myminion genesis.ldd_deps bash salt myminion genesis.ldd_deps /bin/bash
```

**salt.modules.genesis.mksls(fmt, src, dst=None)**

Convert an installation file/script to an SLS file. Currently supports kickstart, preseed, and autoyast.

CLI Examples:
```
salt <minion> genesis.mksls kickstart /path/to/kickstart.cfg salt <minion> genesis.mksls kickstart /path/to/kickstart.cfg /path/to/dest.sls
```

New in version Beryllium.

**salt.modules.genesis.pack(name, root, path=None, pack_format='tar', compress='bzip2')**

Pack up a directory structure, into a specific format

CLI Examples:
```
salt myminion genesis.pack centos /root/centos
salt myminion genesis.pack centos /root/centos pack_format='tar'
```

**salt.modules.genesis.unpack(name, dest=None, path=None, pack_format='tar', compress='bz2')**

Unpack an image into a directory structure

CLI Example:
```
salt myminion genesis.unpack centos /root/centos
```

### 13.6.100 salt.modules.gentoo_service

Top level package command wrapper, used to translate the os detected by grains to the correct service manager

**Important:** If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `service.start` is not available), see [here](#).

**salt.modules.gentoo_service.available(name)**

Returns `True` if the specified service is available, otherwise returns `False`.

CLI Example:
```
salt '*' service.available sshd
```

**salt.modules.gentoo_service.disable(name, **kwargs)**

Disable the named service to start at boot

CLI Example:
```
salt '*' service.disable <service name>
```
salt.modules.gentoo_service.disabled(name)
Return True if the named service is enabled, false otherwise

CLI Example:
salt '*' service.disabled <service name>

salt.modules.gentoo_service.enable(name, **kwargs)
Enable the named service to start at boot

CLI Example:
salt '*' service.enable <service name>

salt.modules.gentoo_service.enabled(name, **kwargs)
Return True if the named service is enabled, false otherwise

CLI Example:
salt '*' service.enabled <service name>

salt.modules.gentoo_service.get_all()
Return all available boot services

CLI Example:
salt '*' service.get_all

salt.modules.gentoo_service.get_disabled()
Return a set of services that are installed but disabled

CLI Example:
salt '*' service.get_disabled

salt.modules.gentoo_service.get_enabled()
Return a list of service that are enabled on boot

CLI Example:
salt '*' service.get_enabled

salt.modules.gentoo_service.missing(name)
The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:
salt '*' service.missing sshd

salt.modules.gentoo_service.restart(name)
Restart the named service

CLI Example:
salt '*' service.restart <service name>

salt.modules.gentoo_service.start(name)
Start the specified service

CLI Example:
salt 'salt '*' service.start <service name>

salt.modules.gentoo_service.status(name, sig=None)
Return the status for a service, returns the PID or an empty string if the service is running or not, pass a signature to use to find the service via ps

CLI Example:
salt 'salt '*' service.status <service name> [service signature]

salt.modules.gentoo_service.stop(name)
Stop the specified service

CLI Example:
salt 'salt '*' service.stop <service name>

13.6.101 salt.modules.gentoolkitmod
Support for Gentoolkit

salt.modules.gentoolkitmod.eclean_dist(destructive=False, package_names=False, size_limit=0, time_limit=0, fetch_restricted=False, exclude_file='/etc/eclean/distfiles.exclude')
Clean obsolete portage sources

destructive Only keep minimum for reinstalltion
package_names Protect all versions of installed packages. Only meaningful if used with destructive=True
size_limit <size> Don't delete distfiles bigger than <size>. <size> is a size specification: ''10M'' is ''ten megabytes'', ''200K'' is ''two hundreds kilobytes'', etc. Units are: G, M, K and B.
time_limit <time> Don't delete distfiles files modified since <time> <time> is an amount of time: ''1y'' is ''one year'', ''2w'' is ''two weeks'', etc. Units are: y (years), m (months), w (weeks), d (days) and h (hours).
fetch_restricted Protect fetch-restricted files. Only meaningful if used with destructive=True
exclude_file Path to exclusion file. Default is /etc/eclean/distfiles.exclude This is the same default eclean-dist uses. Use None if this file exists and you want to ignore.

Returns a dict containing the cleaned, saved, and deprecated dists:

```python
{'cleaned': {<dist file>: <size>},
'deprecated': {<package>: <dist file>},
'saved': {<package>: <dist file>},
'total_cleaned': <size>
}
```

CLI Example:
salt 'salt '*' gentoolkit.eclean_dist destructive=True

salt.modules.gentoolkitmod.eclean_pkg(destructive=False, package_names=False, time_limit=0, exclude_file='/etc/eclean/packages.exclude')
Clean obsolete binary packages

destructive Only keep minimum for reinstalltion
package_names Protect all versions of installed packages. Only meaningful if used with destructive=True
time_limit <time> Don't delete distfiles files modified since <time> <time> is an amount of time: ''1y'' is ''one year'', ''2w'' is ''two weeks'', etc. Units are: y (years), m (months), w (weeks), d (days) and h (hours).
**exclude_file**  Path to exclusion file. Default is /etc/eelean/packages.exclude This is the same default eelean-pkg uses. Use None if this file exists and you want to ignore.

Returns a dict containing the cleaned binary packages:

```python
{'cleaned': {...}, 'total_cleaned': size}
```

CLI Example:

```
salt '*' gentoolkit.elean_pkg destructive=True
```

**salt.modules.gentoolkitmod.glsa_check_list**

List the status of Gentoo Linux Security Advisories

**glsa_list** can contain an arbitrary number of GLSA ids, filenames containing GLSAs or the special identifiers 'all' and 'affected'

Returns a dict containing glsa ids with a description, status, and CVEs:

```python
{'glsa_id': {"description": glsa_description, 'status': glsa_status, 'CVEs': [list of CVEs]}}
```

CLI Example:

```
salt '*' gentoolkit.glsa_check_list 'affected'
```

**salt.modules.gentoolkitmod.revdep_rebuild**

Fix up broken reverse dependencies

**lib** Search for reverse dependencies for a particular library rather than every library on the system. It can be a full path to a library or basic regular expression.

CLI Example:

```
salt '*' gentoolkit.revdep_rebuild
```

### 13.6.102 **salt.modules.git**

Support for the Git SCM

**salt.modules.git.add**

Changed in version 2015.8.0: The `--verbose` command line argument is now implied

Interface to `git-add(1)`

**cwd** The path to the git checkout

**filename** The location of the file/directory to add, relative to **cwd**

**opts** Any additional options to add to the command line, in a single string

**Note:** On the Salt CLI, if the **opts** are preceded with a dash, it is necessary to precede them with **opts=** (as in the CLI examples below) to avoid causing errors with Salt’s own argument parsing.

**user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

**password** Windows only. Required when specifying **user**. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.
ignore_retcode [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```
salt myminion git.add /path/to/repo foo/bar.py
salt myminion git.add /path/to/repo foo/bar.py opts='--dry-run'
```

salt.modules.git.archive(cwd, output, rev='HEAD', fmt=None, prefix=None, user=None, password=None, ignore_retcode=False, **kwargs)

Changed in version 2015.8.0: Returns True if successful, raises an error if not.

Interface to `git-archive(1)`, exports a tarball/zip file of the repository

cwd The path to be archived

Note: `git archive` permits a partial archive to be created. Thus, this path does not need to be the root of the git repository. Only the files within the directory specified by `cwd` (and its subdirectories) will be in the resulting archive. For example, if there is a git checkout at `/tmp/foo`, then passing `/tmp/foo/bar` as the `cwd` will result in just the files underneath `/tmp/foo/bar` to be exported as an archive.

output The path of the archive to be created

overwrite [False] Unless set to True, Salt will over overwrite an existing archive at the path specified by the `output` argument.

New in version 2015.8.0.

rev [HEAD] The revision from which to create the archive

format Manually specify the file format of the resulting archive. This argument can be omitted, and `git archive` will attempt to guess the archive type (and compression) from the filename. `zip`, `tar`, `tar.gz`, and `tgz` are extensions that are recognized automatically, and git can be configured to support other archive types with the addition of git configuration keys.

See the `git-archive(1)` manpage explanation of the `--format` argument (as well as the `CONFIGURATION` section of the manpage) for further information.

New in version 2015.8.0.

fmt Replaced by `format` in version 2015.8.0

Deprecated since version 2015.8.0.

prefix Prepend `<prefix>` to every filename in the archive. If unspecified, the name of the directory at the top level of the repository will be used as the prefix (e.g. if `cwd` is set to `/foo/bar/baz`, the prefix will be `baz`, and the resulting archive will contain a top-level directory by that name).

Note: The default behavior if the `--prefix` option for `git archive` is not specified is to not prepend a prefix, so Salt's behavior differs slightly from `git archive` in this respect. Use `prefix=' '` to create an archive with no prefix.

Changed in version 2015.8.0: The behavior of this argument has been changed slightly. As of this version, it is necessary to include the trailing slash when specifying a prefix, if the prefix is intended to create a top-level directory.

user User under which to run the git command. By default, the command is run by the user under which the minion is running.

password
Windows only. Required when specifying user. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

ignore_recode [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Example:

```bash
salt myminion git.archive /path/to/repo /path/to/archive.tar
```

**salt.modules.git.branch** (cwd, name=None, opts='`, user=None, password=None, ignore_recode=False)

Interface to `git-branch(1)`

- **cwd** The path to the git checkout
- **name** Name of the branch on which to operate. If not specified, the current branch will be assumed.
- **opts** Any additional options to add to the command line, in a single string

**Note:** To create a branch based on something other than HEAD, pass the name of the revision as `opts`. If the revision is in the format remotename/branch, then this will also set the remote tracking branch.

Additionally, on the Salt CLI, if the `opts` are preceded with a dash, it is necessary to precede them with `opts=` (as in the CLI examples below) to avoid causing errors with Salt's own argument parsing.

- **user** User under which to run the git command. By default, the command is run by the user under which the minion is running.
- **password**

Windows only. Required when specifying user. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

ignore_recode [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```bash
# Set remote tracking branch
salt myminion git.branch /path/to/repo mybranch opts='--set-upstream-to origin/\n⇒mybranch'

# Create new branch
salt myminion git.branch /path/to/repo mybranch upstream/somebranch

# Delete branch
salt myminion git.branch /path/to/repo mybranch opts='--d'

# Rename branch (2015.8.0 and later)
salt myminion git.branch /path/to/repo newbranch opts='--m oldbranch'
```

**salt.modules.git.checkout** (cwd, rev=None, force=False, opts='`, user=None, password=None, ignore_recode=False)

Interface to `git-checkout(1)`

- **cwd** The path to the git checkout
- **opts** Any additional options to add to the command line, in a single string

**Note:** On the Salt CLI, if the `opts` are preceded with a dash, it is necessary to precede them with `opts=`.
(as in the CLI examples below) to avoid causing errors with Salt’s own argument parsing.

**rev**  The remote branch or revision to checkout.

- Changed in version 2015.8.0: Optional when using `-b` or `-B` in opts.

**force**  [False] Force a checkout even if there might be overwritten changes

**user**  User under which to run the git command. By default, the command is run by the user under which the minion is running.

**password**

- Windows only. Required when specifying user. This parameter will be ignored on non-Windows platforms.

- New in version 2016.3.4.

**ignore_retcode**  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

- New in version 2015.8.0.

**CLI Examples:**

```
# Checking out local local revisions
salt myminion git.checkout /path/to/repo somebranch user=jeff
salt myminion git.checkout /path/to/repo opts='testbranch -- conf/file1 file2'
salt myminion git.checkout /path/to/repo rev=origin/mybranch opts='--track'

# Checking out remote revision into new branch
salt myminion git.checkout /path/to/repo upstream/master opts='--b newbranch'

# Checking out current revision into new branch (2015.8.0 and later)
