```

New in version 2017.7.0.
salt.modules.statuspage.create(endpoint='incidents', api_url=None, page_id=None, api_key=None, api_version=None, **kwargs)

Insert a new entry under a specific endpoint.

**Parameters:**
- **endpoint:** incidents
  - Insert under this specific endpoint.
- **page_id:** Page ID. Can also be specified in the config file.
- **api_key:** API key. Can also be specified in the config file.
- **api_version:** 1
  - API version. Can also be specified in the config file.
- **api_url:** Custom API URL in case the user has a StatusPage service running in a custom environment.

**CLI Example:**
salt 'minion' statuspage.create endpoint='components' name='my component' group_<id>='993vgplshj12'

**Example output:**

```
minion:  
    comment:  
      out:  
      created_at:  
      2017-01-05T19:35:27.135Z  
      description:  
      None  
      group_id:  
      993vgplshj12  
      id:  
      mjkmtt5lhdgc  
      name:  
      my component  
      page_id:  
      ksdhgfyiuhaa  
      position:  
      7  
      status:  
      operational  
      updated_at:  
      2017-01-05T19:35:27.135Z  
      result:  
      True
```

salt.modules.statuspage.delete(endpoint='incidents', id=None, api_url=None, page_id=None, api_key=None, api_version=None)

Remove an entry from an endpoint.

**Parameters:**
- **endpoint:** incidents
  - Request a specific endpoint.
- **page_id:** Page ID. Can also be specified in the config file.
- **api_key:** API key. Can also be specified in the config file.
- **api_version:** 1
  - API version. Can also be specified in the config file.
- **api_url:** Custom API URL in case the user has a StatusPage service running in a custom environment.

**CLI Example:**
salt 'minion' statuspage.delete endpoint='components' id='ftgks51sfs2d'

**Example output:**

```
minion:  
```
Retrieve a specific endpoint from the Statuspage API.

- **endpoint**: incidents  Request a specific endpoint.
- **page_id**: Page ID. Can also be specified in the config file.
- **api_key**: API key. Can also be specified in the config file.
- **api_version**: 1  API version. Can also be specified in the config file.
- **api_url**: Custom API URL in case the user has a StatusPage service running in a custom environment.

### CLI Example

```bash
salt 'minion' statuspage.retrieve components
```

### Example output:

```yaml
minion:  # ---
  comment:  # -----
  out:
    |_  # ---
      backfilled: False
      created_at: 2015-01-26T20:25:02.702Z
      id: kh2qwjbheqdc36
      impact: major
      impact_override: None
      incident_updates:
        |_  # ---
          affected_components:
            None
          body:
            We are currently investigating this issue.
          created_at: 2015-01-26T20:25:02.849Z
          display_at: 2015-01-26T20:25:02.849Z
          id: zvx7xz2z5skr
          incident_id: kh2qwjbheqdc36
          status: investigating
          twitter_updated_at: None
          updated_at: 2015-01-26T20:25:02.849Z
```
salt.modules.statuspage.update(endpoint='incidents', id=None, api_url=None, page_id=None, api_key=None, api_version=None, **kwargs)

Update attribute(s) of a specific endpoint.

id The unique ID of the endpoint entry.
endpoint: incidents Endpoint name.
page_id Page ID. Can also be specified in the config file.
api_key API key. Can also be specified in the config file.
api_version: 1 API version. Can also be specified in the config file.
api_url Custom API URL in case the user has a StatusPage service running in a custom environment.

CLI Example:

```
salt 'minion' statuspage.update id=dz959yz2nd4l status=resolved
```

Example output:
19.9.374 **salt.modules.stormpath**

Support for Stormpath

New in version 2015.8.0.

```python
salt.modules.stormpath.create_account(directory_id, email, password, givenName, surname, **kwargs)
```

Create an account

CLI Examples:

```
salt myminion stormpath.create_account <directory_id> shemp@example.com letmein Shemp Howard
```

```python
salt.modules.stormpath.delete_account(account_id)
```

Delete an account.

CLI Examples:
```
salt myminion stormpath.delete_account <account_id>
```

```python
salt.modules.stormpath.list_accounts()
```

Show all accounts.

CLI Example:
```
salt myminion stormpath.list_accounts
```

```python
salt.modules.stormpath.list_directories()
```

Show all directories.

CLI Example:
```
salt myminion stormpath.list_directories
```
salt.modules.stormpath.show_account(account_id=None, email=None, directory_id=None, application_id=None, group_id=None, **kwargs)

Show a specific account.

CLI Example:
    salt myminion stormpath.show_account <account_id>

salt.modules.stormpath.show_tenant()

Get the tenant for the login being used.

salt.modules.stormpath.update_account(account_id, key=None, value=None, items=None)

Update one or more items for this account. Specifying an empty value will clear it for that account.

CLI Examples:
    salt myminion stormpath.update_account <account_id> givenName shemp
    salt myminion stormpath.update_account <account_id> middleName `' salt myminion stormpath.update_account <account_id> items='{``givenName'': `Shemp''} salt myminion stormpath.update_account <account_id> items='{``middlename'': ``''}

19.9.375 salt.modules.supervisord

Provide the service module for system supervisord or supervisord in a virtualenv

salt.modules.supervisord.add(name, user=None, conf_file=None, bin_env=None)

Activates any updates in config for process/group.

    user user to run supervisorctl as
    conf_file path to supervisord config file
    bin_env path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:
    salt '*' supervisord.add <name>

salt.modules.supervisord.custom(command, user=None, conf_file=None, bin_env=None)

Run any custom supervisord command

    user user to run supervisorctl as
    conf_file path to supervisorctl config file
    bin_env path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:
    salt '*' supervisord.custom "mstop '*gunicorn*'"

salt.modules.supervisord.options(name, conf_file=None)

New in version 2014.1.0.

Read the config file and return the config options for a given process

    name Name of the configured process
    conf_file path to supervisorctl config file

CLI Example:
    salt '*' supervisord.options foo

salt.modules.supervisord.remove(name, user=None, conf_file=None, bin_env=None)

Removes process/group from active config

    user user to run supervisorctl as
    conf_file path to supervisorctl config file
    bin_env path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:
salt '*' supervisord.remove <name>  

salt.modules.supervisord.reread(user=None, conf_file=None, bin_env=None)  
Reload the daemon's configuration files  
user user to run supervisorctl as  
conf_file path to supervisord config file  
bin_env path to supervisorctl bin or path to virtualenv with supervisor installed  
CLI Example:  
salt '*' supervisord.reread  

salt.modules.supervisord.restart(name='all', user=None, conf_file=None, bin_env=None)  
Restart the named service. Process group names should not include a trailing asterisk.  
user user to run supervisorctl as  
conf_file path to supervisord config file  
bin_env path to supervisorctl bin or path to virtualenv with supervisor installed  
CLI Example:  
salt '*' supervisord.restart <service>  
salt '*' supervisord.restart <group>:  

salt.modules.supervisord.start(name='all', user=None, conf_file=None, bin_env=None)  
Start the named service. Process group names should not include a trailing asterisk.  
user user to run supervisorctl as  
conf_file path to supervisord config file  
bin_env path to supervisorctl bin or path to virtualenv with supervisor installed  
CLI Example:  
salt '*' supervisord.start <service>  
salt '*' supervisord.start <group>:  

salt.modules.supervisord.status(name=None, user=None, conf_file=None, bin_env=None)  
List programs and its state  
user user to run supervisorctl as  
conf_file path to supervisord config file  
bin_env path to supervisorctl bin or path to virtualenv with supervisor installed  
CLI Example:  
salt '*' supervisord.status  

salt.modules.supervisord.status_raw(name=None, user=None, conf_file=None, bin_env=None)  
Display the raw output of status  
user user to run supervisorctl as  
conf_file path to supervisord config file  
bin_env path to supervisorctl bin or path to virtualenv with supervisor installed  
CLI Example:  
salt '*' supervisord.status_raw  

salt.modules.supervisord.stop(name='all', user=None, conf_file=None, bin_env=None)  
Stop the named service. Process group names should not include a trailing asterisk.  
user user to run supervisorctl as  
conf_file path to supervisord config file  
bin_env path to supervisorctl bin or path to virtualenv with supervisor installed  
CLI Example:
salt '...' supervisord.stop <service>
salt '...' supervisord.stop <group>:

```
salt.modules.supervisord.update(
    user=None,
    conf_file=None,
    bin_env=None,
    name=None
)
```

Reload config and add/remove/update as necessary

**user** user to run supervisorctl as
**conf_file** path to supervisord config file
**bin_env** path to supervisorctl bin or path to virtualenv with supervisor installed
**name** name of the process group to update. if none then update any process group that has changes

CLI Example:
```
salt '...' supervisord.update
```

## 19.9.376 salt.modules.suse_apache

Support for Apache

Please note: The functions in here are SUSE-specific. Placing them in this separate file will allow them to load only on SUSE systems, while still loading under the apache namespace.

```
salt.modules.suse_apache.a2dismod(mod)
```

Runs a2dismod for the given mod.

CLI Example:
```
salt '...' apache.a2dismod vhost_alias
```

```
salt.modules.suse_apache.a2enmod(mod)
```

Runs a2enmod for the given mod.

CLI Example:
```
salt '...' apache.a2enmod vhost_alias
```

```
salt.modules.suse_apache.check_mod_enabled(mod)
```

Checks to see if the specific apache mod is enabled.

This will only be functional on operating systems that support `a2enmod -l` to list the enabled mods.

CLI Example:
```
salt '...' apache.check_mod_enabled status
```

## 19.9.377 salt.modules.svn

Subversion SCM

```
salt.modules.svn.add(cwd, targets, user=None, username=None, password=None, *opts)
```

Add files to be tracked by the Subversion working-copy checkout

**cwd** The path to the Subversion repository
**targets** [None] files and directories to pass to the command as arguments
**user** [None] Run svn as a user other than what the minion runs as
**username** [None] Connect to the Subversion server as another user
**password** [None] Connect to the Subversion server with this password

New in version 0.17.0.
CLI Example:
```
salt '*' svn.add /path/to/repo /path/to/new/file
```

salt.modules.svn.checkout(cwd, remote='None', target='None', user='None', username='None', password='None', *opts)

Download a working copy of the remote Subversion repository directory or file

- **cwd**: The path to the Subversion repository
- **remote**: [None] URL to checkout
- **target**: [None] The name to give the file or directory working copy Default: svn uses the remote basename
- **user**: [None] Run svn as a user other than what the minion runs as
- **username**: [None] Connect to the Subversion server as another user
- **password**: [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:
```
salt '*' svn.checkout /path/to/repo svn://remote/repo
```

salt.modules.svn.commit(cwd, targets='None', msg='None', user='None', username='None', password='None', *opts)

Commit the current directory, files, or directories to the remote Subversion repository

- **cwd**: The path to the Subversion repository
- **targets**: [None] files and directories to pass to the command as arguments Default: svn uses `.`
- **msg**: [None] Message to attach to the commit log
- **user**: [None] Run svn as a user other than what the minion runs as
- **username**: [None] Connect to the Subversion server as another user
- **password**: [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:
```
salt '*' svn.commit /path/to/repo
```

salt.modules.svn.diff(cwd, targets='None', user='None', username='None', password='None', *opts)

Return the diff of the current directory, files, or directories from the remote Subversion repository

- **cwd**: The path to the Subversion repository
- **targets**: [None] files and directories to pass to the command as arguments Default: svn uses `.`
- **user**: [None] Run svn as a user other than what the minion runs as
- **username**: [None] Connect to the Subversion server as another user
- **password**: [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:
```
salt '*' svn.diff /path/to/repo
```

salt.modules.svn.export(cwd, remote='None', target='None', user='None', username='None', password='None', revision='HEAD', *opts)

Create an unversioned copy of a tree.

- **cwd**: The path to the Subversion repository
- **remote**: [None] URL and path to file or directory checkout
- **target**: [None] The name to give the file or directory working copy Default: svn uses the remote basename
- **user**: [None] Run svn as a user other than what the minion runs as
- **username**: [None] Connect to the Subversion server as another user
- **password**: [None] Connect to the Subversion server with this password

New in version 0.17.0.
CLI Example:

```bash
salt '*' svn.export /path/to/repo svn://remote/repo
```

```bash
salt.modules.svn.info(cwd, targets=None, user=None, username=None, password=None, fmt='str')
```

Display the Subversion information from the checkout.

- **cwd** The path to the Subversion repository
- **targets** [None] files, directories, and URLs to pass to the command as arguments svn uses `.` by default
- **user** [None] Run svn as a user other than what the minion runs as
- **username** [None] Connect to the Subversion server as another user
- **password** [None] Connect to the Subversion server with this password

New in version 0.17.0.

```bash
salt '*' svn.info /path/to/svn/repo
```

```bash
salt.modules.svn.remove(cwd, targets, msg=None, user=None, username=None, password=None, *opts)
```

Remove files and directories from the Subversion repository

- **cwd** The path to the Subversion repository
- **targets** [None] files, directories, and URLs to pass to the command as arguments
- **msg** [None] Message to attach to the commit log
- **user** [None] Run svn as a user other than what the minion runs as
- **username** [None] Connect to the Subversion server as another user
- **password** [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:

```bash
salt '*' svn.remove /path/to/repo /path/to/repo/remove
```

```bash
salt.modules.svn.status(cwd, targets=None, user=None, username=None, password=None, *opts)
```

Display the status of the current directory, files, or directories in the Subversion repository

- **cwd** The path to the Subversion repository
- **targets** [None] files, directories, and URLs to pass to the command as arguments Default: svn uses `.
- **user** [None] Run svn as a user other than what the minion runs as
- **username** [None] Connect to the Subversion server as another user
- **password** [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:

```bash
salt '*' svn.status /path/to/repo
```

```bash
salt.modules.svn.switch(cwd, remote, target=None, user=None, username=None, password=None, *opts)
```

New in version 2014.1.0.

Switch a working copy of a remote Subversion repository directory

- **cwd** The path to the Subversion repository
- **remote** [None] URL to switch
- **target** [None] The name to give the file or directory working copy Default: svn uses the remote basename
- **user** [None] Run svn as a user other than what the minion runs as
- **username** [None] Connect to the Subversion server as another user
- **password** [None] Connect to the Subversion server with this password

19.9. execution modules 2141
CLI Example:

```
salt '*' svn.switch /path/to/repo svn://remote/repo
```

```
salt.modules.svn.update(cwd, targets=None, user=None, username=None, password=None, *opts)
```

- **cwd** The path to the Subversion repository
- **targets** [None] files and directories to pass to the command as arguments Default: svn uses `.`
- **user** [None] Run svn as a user other than what the minion runs as
- **password** [None] Connect to the Subversion server with this password

New in version 0.17.0.
- **username** [None] Connect to the Subversion server as another user

CLI Example:

```
salt '*' svn.update /path/to/repo
```

### 19.9.378 salt.modules.swift

Module for handling OpenStack Swift calls

**Author:** Anthony Stanton <anthony.stanton@gmail.com>

**Inspired by:** the S3 and Nova modules

**depends**

- swiftclient Python module

**configuration** This module is not usable until the user, tenant, auth URL, and password or auth_key are specified either in a pillar or in the minion's config file. For example:

```
keystone.user: admin
keystone.tenant: admin
keystone.auth_url: 'http://127.0.0.1:5000/v2.0/
keystone.password: verybadpass
# or
keystone.auth_key: 203802934809284k2j34lkj2l3kj43k
```

If configuration for multiple OpenStack accounts is required, they can be set up as different configuration profiles: For example:

```
openstack1:
keystone.user: admin
keystone.tenant: admin
keystone.auth_url: 'http://127.0.0.1:5000/v2.0/
keystone.password: verybadpass
# or
keystone.auth_key: 203802934809284k2j34lkj2l3kj43k
```

```
openstack2:
keystone.user: admin
keystone.tenant: admin
keystone.auth_url: 'http://127.0.0.2:5000/v2.0/
keystone.password: verybadpass
# or
keystone.auth_key: 303802934809284k2j34lkj2l3kj43k
```

With this configuration in place, any of the swift functions can make use of a configuration profile by declaring it explicitly. For example:
salt Documentation, Release 2017.7.8

```bash
salt '*' swift.get mycontainer myfile /tmp/file profile=openstack1
```

NOTE: For Rackspace cloud files setting keystone.auth_version = 1 is recommended.

**salt.modules.swift.delete** *(cont, path=``None``*, profile=``None``*)
Delete a container, or delete an object from a container.

CLI Example to delete a container:

```bash
salt myminion swift.delete mycontainer
```

CLI Example to delete an object from a container:

```bash
salt myminion swift.delete mycontainer remoteobject
```

**salt.modules.swift.get** *(cont=``None``*, path=``None``*, local_file=``None``*, return_bin=``False``*, profile=``None``*)
List the contents of a container, or return an object from a container. Set return_bin to True in order to retrieve an object wholesale. Otherwise, Salt will attempt to parse an XML response.

CLI Example to list containers:

```bash
salt myminion swift.get
```

CLI Example to list the contents of a container:

```bash
salt myminion swift.get mycontainer
```

CLI Example to return the binary contents of an object:

```bash
salt myminion swift.get mycontainer myfile.png return_bin=True
```

CLI Example to save the binary contents of an object to a local file:

```bash
salt myminion swift.get mycontainer myfile.png local_file=/tmp/myfile.png
```

**salt.modules.swift.head()**

**salt.modules.swift.put** *(cont, path=``None``*, local_file=``None``*, profile=``None``*)
Create a new container, or upload an object to a container.

CLI Example to create a container:

```bash
salt myminion swift.put mycontainer
```

CLI Example to upload an object to a container:

```bash
salt myminion swift.put mycontainer remotepath local_file=/path/to/file
```

### 19.9.379 salt.modules.sysbench

The `sysbench` module is used to analyze the performance of the minions, right from the master! It measures various system parameters such as CPU, Memory, File I/O, Threads and Mutex.

**salt.modules.sysbench.cpu()**
Tests for the CPU performance of minions.

CLI Examples:
salt 'sysbench.cpu'

salt.modules.sysbench.fileio()

This tests for the file read and write operations. Various modes of operations are
- sequential write
- sequential rewrite
- sequential read
- random read
- random write
- random read and write

The test works with 32 files with each file being 1Gb in size. The test consumes a lot of time. Be patient!

CLI Examples:
salt '*' sysbench.fileio

salt.modules.sysbench.memory()

This tests the memory for read and write operations.

CLI Examples:
salt '*' sysbench.memory

salt.modules.sysbench.mutex()

Tests the implementation of mutex

CLI Examples:
salt '*' sysbench.mutex

salt.modules.sysbench.ping()

salt.modules.sysbench.threads()

This tests the performance of the processor’s scheduler

CLI Example:
salt '*' sysbench.threads

19.9.380 salt.modules.sysfs module

Module for interfacing with SysFS

See also:
https://www.kernel.org/doc/Documentation/filesystems/sysfs.txt

New in version 2016.3.0.

salt.modules.sysfs.attr(key, value=None)

Access/write a SysFS attribute. If the attribute is a symlink, it’s destination is returned

Returns: value or bool

CLI example:
salt '*' sysfs.attr block/sda/queue/logical_block_size

salt.modules.sysfs.interfaces(root)

Generate a dictionary with all available interfaces relative to root. Symlinks are not followed.
CLI example:

```
salt '*' sysfs.interfaces block/bcache0/bcache
```

Output example:

```
{
    "r": [
        "state",
        "partial_stripes_expensive",
        "writeback_rate_debug",
        "stripe_size",
        "dirty_data",
        "stats_total/cache_hits",
        "stats_total/cache_bypass_misses",
        "stats_total/bypassed",
        "stats_total/cache_readahead",
        "stats_total/cache_hit_ratio",
        "stats_total/cache_miss_collisions",
        "stats_total/cache_misses",
        "stats_total/cache_bypass_hits",
    ],
    "rw": [
        "writeback_rate",
        "writeback_rate_update_seconds",
        "cache_mode",
        "writeback_delay",
        "label",
        "writeback_running",
        "writeback_metadata",
        "running",
        "writeback_rate_p_term_inverse",
        "sequential_cutoff",
        "writeback_percent",
        "writeback_rate_d_term",
        "readahead"
    ],
    "w": [
        "stop",
        "clear_stats",
        "attach",
        "detach"
    ]
}
```

Note:
- `r` interfaces are read-only
- `w` interfaces are write-only (e.g. actions)
- `rw` are interfaces that can both be read or written

```
salt.modules.sysfs.read(key, root=``)
```

Read from SysFS

Parameters key -- file or path in SysFS; if key is a list then root will be prefixed on each key

Returns the full (tree of) SysFS attributes under key

CLI example:
salt '*' sysfs.read class/net/em1/statistics

salt.modules.sysfs.target(key, full=True)
    Return the basename of a SysFS key path

Parameters

* key -- the location to resolve within SysFS
* full -- full path instead of basename

Returns fullpath or basename of path

CLI example:

salt '*' sysfs.read class/ttyS0

salt.modules.sysfs.write(key, value)
    Write a SysFS attribute/action

CLI example:

salt '*' sysfs.write devices/system/cpu/cpu0/cpufreq/scaling_governor
    performance

19.9.381 salt.modules.syslog_ng

Module for getting information about syslog-ng

* maintainer  Tibor Benke <btibi@sch.bme.hu>
* maturity new
* depends cmd
* platform all

This module is capable of managing syslog-ng instances which were installed via a package manager or from source. Users can use a directory as a parameter in the case of most functions, which contains the syslog-ng and syslog-ng-ctl binaries.

Syslog-ng can be installed via a package manager or from source. In the latter case, the syslog-ng and syslog-ng-ctl binaries are not available from the PATH, so users should set location of the sbin directory with "syslog_ng.set_binary_path".

Similarly, users can specify the location of the configuration file with "syslog_ng.set_config_file", then the module will use it. If it is not set, syslog-ng uses the default configuration file.

class salt.modules.syslog_ng.Argument(value='`)
    A TypedParameterValue has one or more Arguments. For example this can be the value of key_file.

    Does not need examples.

    build()

class salt.modules.syslog_ng.Buildable(iterable, join_body_on='`, append_extra_newline=True)
    Base class of most classes, which have a build method.

    It contains a common build function.

    Does not need examples.

    build()

    Builds the textual representation of the whole configuration object with it's children.
Salt Documentation, Release 2017.7.8

build_body()
Builds the body of a syslog-ng configuration object.

build_header()
Builds the header of a syslog-ng configuration object.

build_tail()
Builds the tail of a syslog-ng configuration object.

class salt.modules.syslog_ng.GivenStatement(value, add_newline=True)
This statement returns a string without modification. It can be used to use existing configuration snippets. Does not need examples.

build()

class salt.modules.syslog_ng.NamedStatement(type=' ', id=' ', options=None)
It represents a configuration statement, which has a name, e.g. a source.

Does not need examples.

class salt.modules.syslog_ng.Option(type=' ', params=None)
A Statement class contains Option instances.

An instance of Option can represent a file(), tcp(), udp(), etc. option.

Does not need examples.

add_parameter(param)

build()

class salt.modules.syslog_ng.Parameter(iterable=None, join_body_on='')
An Option has one or more Parameter instances.

Does not need examples.

class salt.modules.syslog_ng.SimpleParameterValue(iterable=None, join_body_on='')
A TypedParameter can have one or more values.

Does not need examples.

class salt.modules.syslog_ng.SimpleParameter(value=' ')
A Parameter is a SimpleParameter, if it's just a simple type, like a string.

For example:

destination d_file {
    file('/var/log/messages');
}

/ var/log/messages is a SimpleParameter.

Does not need examples.

build()

class salt.modules.syslog_ng.SimpleParameterValue(value=' ')
A ParameterValue which holds a simple type, like a string or a number.

For example in ip(127.0.0.1) 127.0.0.1 is a SimpleParameterValue.

Does not need examples.
class salt.modules.syslog_ng.Statement(type='none', id='none', options=None, has_name=True)
   It represents a syslog-ng configuration statement, e.g. source, destination, filter.

   Does not need examples.

   add_child(option)
   build_header()
   build_tail()

exception salt.modules.syslog_ng.SyslogNgError

class salt.modules.syslog_ng.TypedParameter(type='none', values=None)
   A Parameter, which has a type:

   destination d_tcp {
      tcp(
         ip(127.0.0.1)
      );
   }

   ip(127.0.0.1) is a TypedParameter.

   Does not need examples.

   add_value(value)
   build()

class salt.modules.syslog_ng.TypedParameterValue(type='none', arguments=None)
   We have to go deeper...

   A TypedParameter can have a `parameter', which also have a type. For example key_file and cert_file:

   source demo_tls_source {
      tcp(
         ip(0.0.0.0)
         port(1999)
         tls(
            key_file('/opt/syslog-ng/etc/syslog-ng/key.d/syslog-ng.key')
            cert_file('/opt/syslog-ng/etc/syslog-ng/cert.d/syslog-ng.cert')
         )
      );
   }

   Does not need examples.

   add_argument(arg)
   build()

class salt.modules.syslog_ng.UnnamedStatement(type, options=None)
   It represents a configuration statement, which doesn't have a name, e.g. a log path.

   Does not need examples.

salt.modules.syslog_ng.config(name, config, write=True)
   Builds syslog-ng configuration. This function is intended to be used from the state module, users should not use it directly!

   name : the id of the Salt document or it is the format of <statement name>.id
   config : the parsed YAML code
   write : if True, it writes the config into the configuration file, otherwise just returns it

CLI Example:
salt.modules.syslog_ng.config(name='s_local', config='[[tcp:[{'ip':'127.0.0.1'},
              {'port':1233}]]]

salt.modules.syslog_ng.config_test(syslog_ng_sbin_dir=None, cfgfile=None)
Runs syntax check against cfgfile. If syslog_ng_sbin_dir is specified, it is added to the PATH during the test.

CLI Example:
salt '*' syslog_ng.config_test
salt '*' syslog_ng.config_test /home/user/install/syslog-ng/sbin
salt '*' syslog_ng.config_test /home/user/install/syslog-ng/sbin /etc/syslog-ng/
  syslog-ng.conf

salt.modules.syslog_ng.get_config_file()
Returns the configuration directory, which contains syslog-ng.conf.

CLI Example:
salt '*' syslog_ng.get_config_file

salt.modules.syslog_ng.modules(syslog_ng_sbin_dir=None)
Returns the available modules. If syslog_ng_sbin_dir is specified, it is added to the PATH during the execution of the command syslog-ng.

CLI Example:
salt '*' syslog_ng.modules
salt '*' syslog_ng.modules /home/user/install/syslog-ng/sbin

salt.modules.syslog_ng.reload_(name)
Reloads syslog-ng. This function is intended to be used from states.

If syslog_ng.set_config_file, is called before, this function will use the set binary path.

CLI Example:
salt '*' syslog_ng.reload

salt.modules.syslog_ng.set_binary_path(name)
Sets the path, where the syslog-ng binary can be found. This function is intended to be used from states.

If syslog-ng is installed via a package manager, users don't need to use this function.

CLI Example:
salt '*' syslog_ng.set_binary_path name=/usr/sbin

salt.modules.syslog_ng.set_config_file(name)
Sets the configuration's name. This function is intended to be used from states.

CLI Example:
salt '*' syslog_ng.set_config_file name=/etc/syslog-ng

salt.modules.syslog_ng.set_parameters(version=None, binary_path=None, config_file=None, *args, **kwargs)
Sets variables.

CLI Example:
salt '...' syslog_ng.set_parameters version='3.6'
salt '...' syslog_ng.set_parameters binary_path=/home/user/install/syslog-ng/sbin
        --config_file=/home/user/install/syslog-ng/etc/syslog-ng.conf

salt.modules.syslog_ng.start(name=None, user=None, group=None, chroot=None, caps=None,
                                     no_caps=False, pidfile=None, enable_core=False, fd_limit=None,
                                     verbose=False, debug=False, trace=False, yydebug=False, persist_file=None, control=None, worker_threads=None)

Ensures, that syslog-ng is started via the given parameters. This function is intended to be used from the state module.

Users shouldn't use this function, if the service module is available on their system. If syslog_ng.set_config_file is called before, this function will use the set binary path.

CLI Example:
salt '...' syslog_ng.start

salt.modules.syslog_ng.stats(syslog_ng_sbin_dir=None)

Returns statistics from the running syslog-ng instance. If syslog_ng_sbin_dir is specified, it is added to the PATH during the execution of the command syslog-ng-ctl.

CLI Example:
salt '...' syslog_ng.stats
salt '...' syslog_ng.stats /home/user/install/syslog-ng/sbin

salt.modules.syslog_ng.stop(name=None)

Kills syslog-ng. This function is intended to be used from the state module.

Users shouldn't use this function, if the service module is available on their system. If syslog_ng.set_config_file is called before, this function will use the set binary path.

CLI Example:
salt '...' syslog_ng.stop

salt.modules.syslog_ng.version(syslog_ng_sbin_dir=None)

Returns the version of the installed syslog-ng. If syslog_ng_sbin_dir is specified, it is added to the PATH during the execution of the command syslog-ng.

CLI Example:
salt '...' syslog_ng.version
salt '...' syslog_ng.version /home/user/install/syslog-ng/sbin

salt.modules.syslog_ng.write_config(config, newlines=2)

Writes the given parameter config into the config file. This function is intended to be used from states.

If syslog_ng.set_config_file is called before, this function will use the set config file.

CLI Example:
salt '...' syslog_ng.write_config config='# comment'

salt.modules.syslog_ng.write_version(name)

Removes the previous configuration file, then creates a new one and writes the name line. This function is intended to be used from states.

If syslog_ng.set_config_file is called before, this function will use the set config file.
CLI Example:

```bash
salt '*' syslog_ng.write_version name="3.6"
```

### 19.9.382 salt.modules.sysmod

The `sys` module provides information about the available functions on the minion.

**salt.modules.sysmod.argspec(module='')**

Return the argument specification of functions in Salt execution modules.

CLI Example:

```bash
salt '*' sys.argspec pkg.install
salt '*' sys.argspec sys
salt '*' sys.argspec
```

Module names can be specified as globs.

New in version 2015.5.0.

```bash
salt '*' sys.argspec 'pkg.*'
```

**salt.modules.sysmod.doc(args)**

Return the docstrings for all modules. Optionally, specify a module or a function to narrow the selection.

The strings are aggregated into a single document on the master for easy reading.

Multiple modules/functions can be specified.

CLI Example:

```bash
salt '*' sys.doc
salt '*' sys.doc sys
salt '*' sys.doc sys.doc
salt '*' sys.doc network.traceroute user.info
```

Modules can be specified as globs.

New in version 2015.5.0.

```bash
salt '*' sys.doc 'sys.*'
salt '*' sys.doc 'sys.list_*'
```

**salt.modules.sysmod.list_functions(*args, **kwargs)**

List the functions for all modules. Optionally, specify a module or modules from which to list.

CLI Example:

```bash
salt '*' sys.list_functions
salt '*' sys.list_functions sys
salt '*' sys.list_functions sys user
```

Function names can be specified as globs.

New in version 2015.5.0.

```bash
salt '*' sys.list_functions 'sys.list_*'
```

New in version ?.
**salt.modules.sysmod.list_modules(\*args)**

List the modules loaded on the minion

New in version 2015.5.0.

CLI Example:

```
salt '*' sys.list_modules
```

Module names can be specified as globs.

```
salt '*' sys.list_modules 's*'
```

**salt.modules.sysmod.list_renderers(\*args)**

List the renderers loaded on the minion

New in version 2015.5.0.

CLI Example:

```
salt '*' sys.list_renderers
```

Render names can be specified as globs.

```
salt '*' sys.list_renderers 'yaml*'
```

**salt.modules.sysmod.list_returner_functions(\*args, **kwargs)**

List the functions for all returner modules. Optionally, specify a returner module or modules from which to list.

New in version 2014.7.0.

CLI Example:

```
salt '*' sys.list_returner_functions
salt '*' sys.list_returner_functions mysql
salt '*' sys.list_returner_functions mysql etcd
```

Returner names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.list_returner_functions 'sqlite3.get_*'
```

**salt.modules.sysmod.list_returners(\*args)**

List the returners loaded on the minion

New in version 2014.7.0.

CLI Example:

```
salt '*' sys.list_returners
```

Returner names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.list_returners 's*'
```
salt.modules.sysmod.list_runner_functions(*args, **kwargs)
List the functions for all runner modules. Optionally, specify a runner module or modules from which to list.

New in version 2014.7.0.

CLI Example:
```
salt '*' sys.list_runner_functions
salt '*' sys.list_runner_functions state
salt '*' sys.list_runner_functions state virt
```
Runner function names can be specified as globs.

New in version 2015.5.0.
```
salt '*' sys.list_runner_functions 'state.*' 'virt.*'
```

salt.modules.sysmod.list_runners(*args)
List the runners loaded on the minion

New in version 2014.7.0.

CLI Example:
```
salt '*' sys.list_runners
```
Runner names can be specified as globs.

New in version 2015.5.0.
```
salt '*' sys.list_runners 'm*'
```

salt.modules.sysmod.list_state_functions(*args, **kwargs)
List the functions for all state modules. Optionally, specify a state module or modules from which to list.

New in version 2014.7.0.

CLI Example:
```
salt '*' sys.list_state_functions
salt '*' sys.list_state_functions file
salt '*' sys.list_state_functions pkg user
```
State function names can be specified as globs.

New in version 2015.5.0.
```
salt '*' sys.list_state_functions 'file.*'
salt '*' sys.list_state_functions 'file.s*'
```
New in version ?.
```
salt '*' sys.list_state_functions 'module.specific_function'
```

salt.modules.sysmod.list_state_modules(*args)
List the modules loaded on the minion

New in version 2014.7.0.

CLI Example:
salt '*' sys.list_state_modules

State module names can be specified as globs.
New in version 2015.5.0.

salt '*' sys.list_state_modules 'mysql_*'

salt.modules.sysmod.reload_modules()
Tell the minion to reload the execution modules

CLI Example:
salt '*' sys.reload_modules

tsalt.modules.sysmod.renderer_doc('args')
Return the docstrings for all renderers. Optionally, specify a renderer or a function to narrow the selection.
The strings are aggregated into a single document on the master for easy reading.
Multiple renderers can be specified.
New in version 2015.5.0.

CLI Example:
salt '*' sys.renderer_doc
salt '*' sys.renderer_doc cheetah
salt '*' sys.renderer_doc jinja json

Renderer names can be specified as globs.
salt '*' sys.renderer_doc 'c*' 'j*'

tsalt.modules.sysmod.returner_argspec(module='')
Return the argument specification of functions in Salt returner modules.
New in version 2015.5.0.

CLI Example:
salt '*' sys.returner_argspec xmpp
salt '*' sys.returner_argspec xmpp smtp
salt '*' sys.returner_argspec

Returner names can be specified as globs.
salt '*' sys.returner_argspec 'sqlite3.*'

tsalt.modules.sysmod.returner_doc('args')
Return the docstrings for all returners. Optionally, specify a returner or a function to narrow the selection.
The strings are aggregated into a single document on the master for easy reading.
Multiple returners/functions can be specified.
New in version 2014.7.0.

CLI Example:
Returner names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.returner_doc 'sqlite3.get_*'
```

```
salt.modules.sysmod.runner_argspec(module='')
Return the argument specification of functions in Salt runner modules.

New in version 2015.5.0.

CLI Example:

```
salt '*' sys.runner_argspec state
salt '*' sys.runner_argspec http
salt '*' sys.runner_argspec
```

Runner names can be specified as globs.

```
salt '*' sys.runner_argspec 'winrepo.*'
```

```
salt.modules.sysmod.runner_doc(*args)
Return the docstrings for all runners. Optionally, specify a runner or a function to narrow the selection.

The strings are aggregated into a single document on the master for easy reading.

Multiple runners/functions can be specified.

New in version 2014.7.0.

CLI Example:

```
salt '*' sys.runner_doc
salt '*' sys.runner_doc cache
salt '*' sys.runner_doc cache.grains
salt '*' sys.runner_doc cache.grains mine.get
```

Runner names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.runner_doc 'cache.clear_*'
```

```
salt.modules.sysmod.state_argspec(module='')
Return the argument specification of functions in Salt state modules.

New in version 2015.5.0.

CLI Example:

```
salt '*' sys.state_argspec pkg.installed
salt '*' sys.state_argspec file
salt '*' sys.state_argspec
```

State names can be specified as globs.
```
salt 'sysstate' state_argspec 'pkg.*'
```

```
salt.modules.sysmod.state_doc(*args)

Return the docstrings for all states. Optionally, specify a state or a function to narrow the selection.

The strings are aggregated into a single document on the master for easy reading.

Multiple states/functions can be specified.

New in version 2014.7.0.

CLI Example:
```
salt 'sysstate' state_doc
salt 'sysstate' state_doc service
salt 'sysstate' state_doc service.running
salt 'sysstate' state_doc service.running ipables.append
```

State names can be specified as globs.

New in version 2015.5.0.

```
salt 'sysstate' state_doc 'service.*' 'iptables.*'
```

```
salt.modules.sysmod.state_schema(module='')

Return a JSON Schema for the given state function(s)

New in version 2016.3.0.

CLI Example:
```
salt 'sysstate' state_schema
salt 'sysstate' state_schema pkg.installed
```

---

19.9.383 salt.modules.sysrc

sysrc module for FreeBSD

```
salt.modules.sysrc.get(**kwargs)

Return system rc configuration variables

CLI Example:
```
salt 'sysrc' get includeDefaults=True
```

```
salt.modules.sysrc.remove(name, **kwargs)

Remove system rc configuration variables

CLI Example:
```
salt 'sysrc' remove name=sshd_enable
```

```
salt.modules.sysrc.set_(name, value, **kwargs)

Set system rc configuration variables

CLI Example:
```
salt 'sysrc' set name=sshd_flags value="-p 2222"
```
19.9.384 salt.modules.system

Support for reboot, shutdown, etc

salt.modules.system.get_computer_desc()
Get PRETTY_HOSTNAME value stored in /etc/machine-info If this file doesn't exist or the variable doesn't exist return False.

Returns Value of PRETTY_HOSTNAME if this does not exist False.
Return type str
CLI Example:

```
salt '*' system.get_computer_desc
```

salt.modules.system.get_computer_name()
Get hostname.

CLI Example:

```
salt '*' network.get_hostname
```

salt.modules.system.get_system_date(utc_offset=None)
Get the system date

Parameters utc_offset (str) -- The utc offset in 4 digit (+0600) format with an optional sign (+/-). Will default to None which will use the local timezone. To set the time based off of UTC use `'+0000'`. Note: if being passed through the command line will need to be quoted twice to allow negative offsets.

Returns Returns the system date.
Return type str
CLI Example:

```
salt '*' system.get_system_date
```

salt.modules.system.get_system_date_time(utc_offset=None)
Get the system date/time.

Parameters utc_offset (str) -- The utc offset in 4 digit (+0600) format with an optional sign (+/-). Will default to None which will use the local timezone. To set the time based off of UTC use `'+0000'`. Note: if being passed through the command line will need to be quoted twice to allow negative offsets.

Returns Returns the system time in YYYY-MM-DD hh:mm:ss format.
Return type str
CLI Example:

```
salt '*' system.get_system_date_time '+-0500'
```

salt.modules.system.get_system_time(utc_offset=None)
Get the system time.

Parameters utc_offset (str) -- The utc offset in 4 digit (+0600) format with an optional sign (+/-). Will default to None which will use the local timezone. To set the time based off of UTC use `'+0000'`. Note: if being passed through the command line will need to be quoted twice to allow negative offsets.

Returns Returns the system time in HH:MM:SS AM/PM format.
Return type str
CLI Example:

```
salt '*' system.get_system_time
```
salt.modules.system.halt()
    Halt a running system
    CLI Example:
    salt '*' system.halt

salt.modules.system.has_settable_hwclock()
    Returns True if the system has a hardware clock capable of being set from software.
    CLI Example:
    salt '*' system.has_settable_hwclock

salt.modules.system.init(runlevel)
    Change the system runlevel on sysV compatible systems
    CLI Example:
    salt '*' system.init 3

salt.modules.system.poweroff()
    Poweroff a running system
    CLI Example:
    salt '*' system.poweroff

salt.modules.system.reboot(at_time=None)
    Reboot the system
    at_time  The wait time in minutes before the system will be rebooted.
    CLI Example:
    salt '*' system.reboot

salt.modules.system.set_computer_desc(desc)
    Set PRETTY_HOSTNAME value stored in /etc/machine-info This will create the file if it does not exist. If it is unable to create or modify this file returns False.
    Parameters desc (str) -- The computer description
    Returns False on failure. True if successful.
    CLI Example:
    salt '*' system.set_computer_desc "Michael's laptop"

salt.modules.system.set_computer_name(hostname)
    Modify hostname.
    CLI Example:
    salt '*' system.set_computer_name master.saltstack.com

salt.modules.system.set_system_date(newdate, utc_offset=None)
    Set the Windows system date. Use <mm-dd-yy> format for the date.
    Parameters newdate (str) -- The date to set. Can be any of the following formats:
        • YYYY-MM-DD
        • MM-DD-YYYY
        • MM/DD/YY
        • MM/DD/YYY
        • MM/DD/YY

2158 Chapter 19. Salt Module Reference
---

**CLI Example:**

```
salt '*' system.set_system_date '03-28-13'
```

```python
salt.modules.system.set_system_date_time(years=None, months=None, days=None, hours=None, minutes=None, seconds=None, utc_offset=None)
```

Set the system date and time. Each argument is an element of the date, but not required. If an element is not passed, the current system value for that element will be used. For example, if you don’t pass the year, the current system year will be used. (Used by set_system_date and set_system_time)

Updates hardware clock, if present, in addition to software (kernel) clock.

**Parameters**

- `years (int) -- Years digit, ie: 2015`
- `months (int) -- Months digit: 1-12`
- `days (int) -- Days digit: 1-31`
- `hours (int) -- Hours digit: 0-23`
- `minutes (int) -- Minutes digit: 0-59`
- `seconds (int) -- Seconds digit: 0-59`
- `utc_offset (str) -- The utc offset in 4 digit (+0600) format with an optional sign (+/-). Will default to None which will use the local timezone. To set the time based off of UTC use `'+0000'`. Note: if being passed through the command line will need to be quoted twice to allow negative offsets.`

**Returns** True if successful. Otherwise False.

**Return type** bool

**CLI Example:**

```
salt '*' system.set_system_date_time 2015 5 12 11 37 53 '-0500'
```

```python
class setup.eventbus:
    def _init_(self, eventbus):
        self.eventbus = eventbus
```

**Parameters**

- `eventbus (EventBus) -- The EventBus to use for event handling`

**Return type** None

**CLI Example:**

```
salt '*' system.shutdown 5
```

---

19.9. execution modules

---

**CLI Example:**

```
salt '*' system.shutdown 5
```

---

**CLI Example:**

```
salt '*' system.shutdown 5
```

---

**CLI Example:**

```
salt '*' system.shutdown 5
```

---

**CLI Example:**

```
salt '*' system.shutdown 5
```

---

**CLI Example:**

```
salt '*' system.shutdown 5
```
19.9.385 salt.modules.system_profiler

System Profiler Module

Interface with macOS's command-line System Profiler utility to get information about package receipts and installed applications.

New in version 2015.5.0.

```python
salt.modules.system_profiler.applications()
```

Return the results of a call to `system_profiler -xml -detail full SPApplicationsDataType` as a dictionary. Top-level keys of the dictionary are the names of each set of install receipts, since there can be multiple receipts with the same name. Contents of each key are a list of dictionaries.

Note that this can take a long time depending on how many applications are installed on the target Mac.

CLI Example:
```
salt '*' systemprofiler.applications
```

```python
salt.modules.system_profiler.receipts()
```

Return the results of a call to `system_profiler -xml -detail full SPInstallHistoryDataType` as a dictionary. Top-level keys of the dictionary are the names of each set of install receipts, since there can be multiple receipts with the same name. Contents of each key are a list of dictionaries.

CLI Example:
```
salt '*' systemprofiler.receipts
```

19.9.386 salt.modules.systemd

Provides the service module for systemd

New in version 0.10.0.

**Important:** If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `service.start' is not available), see [here](#).

```python
salt.modules.systemd.available(name)
```

New in version 0.10.4.

Check that the given service is available taking into account template units.

CLI Example:
```
salt '*' service.available sshd
```

```python
salt.modules.systemd.disable(name, no_block=False, **kwargs)
```

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands run by this function from the salt-minion daemon's control group. This is done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of `systemd-run(1)` can be suppressed by setting a config option called `systemd.scope`, with a value of `False` (no quotes).

Disable the named service to not start when the system boots

**no_block** [False] Set to True to start the service using `--no-block`.

New in version 2017.7.0.
CLI Example:

    salt '*' service.disable <service name>

salt.modules.systemd.disabled(name)
Return if the named service is disabled from starting on boot

CLI Example:

    salt '*' service.disabled <service name>

salt.modules.systemd.enable(name, no_block=False, unmask=False, unmask_runtime=False, **kwargs)
Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, systemd-run(1) is now used to isolate commands run by this function from the salt-minion daemon's control group. This is done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).
Enable the named service to start when the system boots

    no_block [False] Set to True to start the service using --no-block.
    New in version 2017.7.0.
    unmask [False] Set to True to remove an indefinite mask before attempting to enable the service.
    New in version 2017.7.0: In previous releases, Salt would simply unmask a service before enabling. This behavior is no longer the default.
    unmask_runtime [False] Set to True to remove a runtime mask before attempting to enable the service.
    New in version 2017.7.0: In previous releases, Salt would simply unmask a service before enabling. This behavior is no longer the default.

CLI Example:

    salt '*' service.enable <service name>

salt.modules.systemd.enabled(name, **kwargs)
Return if the named service is enabled to start on boot

CLI Example:

    salt '*' service.enabled <service name>

salt.modules.systemd.execs()
New in version 2014.7.0.
Return a list of all files specified as ExecStart for all services.

CLI Example:

    salt '*' service.execs

salt.modules.systemd.force_reload(name, no_block=True, unmask=False, unmask_runtime=False)
Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, systemd-run(1) is now used to isolate commands run by this function from the salt-minion daemon's control group. This is done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).
New in version 0.12.0.
Force-reload the specified service with systemd
no_block  [False] Set to True to start the service using --no-block.

New in version 2017.7.0.

unmask  [False] Set to True to remove an indefinite mask before attempting to force-reload the service.

New in version 2017.7.0: In previous releases, Salt would simply unmask a service before force-reloading. This behavior is no longer the default.

unmask_runtime  [False] Set to True to remove a runtime mask before attempting to force-reload the service.

New in version 2017.7.0: In previous releases, Salt would simply unmask a service before force-reloading. This behavior is no longer the default.

CLI Example:

```
salt '*' service.force_reload <service name>
```

salt.modules.systemd.get_all()

Return a list of all available services

CLI Example:

```
salt '*' service.get_all
```

salt.modules.systemd.get_disabled()

Return a list of all disabled services

CLI Example:

```
salt '*' service.get_disabled
```

salt.modules.systemd.get_enabled()

Return a list of all enabled services

CLI Example:

```
salt '*' service.get_enabled
```

salt.modules.systemd.get_running()

Return a list of all running services, so far as systemd is concerned

CLI Example:

```
salt '*' service.get_running
```

salt.modules.systemd.get_static()

New in version 2015.8.5.

Return a list of all static services

CLI Example:

```
salt '*' service.get_static
```

salt.modules.systemd.mask(name, runtime=False)

New in version 2015.5.0.

Changed in version 2015.8.12,2016.3.3,2016.11.0: On minions running systemd>=205, systemd-run(1) is now used to isolate commands run by this function from the salt-minion daemon's control group. This is done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of systemd-run() can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).
Mask the specified service with systemd

**runtime** [False] Set to True to mask this service only until the next reboot

New in version 2015.8.5.

CLI Example:

```bash
salt '*' service.mask foo
salt '*' service.mask foo runtime=True
```

`salt.modules.systemd.masked(name, runtime=False)`

New in version 2015.8.0.

Changed in version 2015.8.5: The return data for this function has changed. If the service is masked, the return value will now be the output of the `systemctl is-enabled` command (so that a persistent mask can be distinguished from a runtime mask). If the service is not masked, then False will be returned.

Changed in version 2017.7.0: This function now returns a boolean telling the user whether a mask specified by the new runtime argument is set. If runtime is False, this function will return True if an indefinite mask is set for the named service (otherwise False will be returned). If runtime is False, this function will return True if a runtime mask is set, otherwise False.

Check whether or not a service is masked

**runtime** [False] Set to True to check for a runtime mask

New in version 2017.7.0: In previous versions, this function would simply return the output of `systemctl is-enabled` when the service was found to be masked. However, since it is possible to both have both indefinite and runtime masks on a service simultaneously, this function now only checks for runtime masks if this argument is set to True. Otherwise, it will check for an indefinite mask.

CLI Examples:

```bash
salt '*' service.masked foo
salt '*' service.masked foo runtime=True
```

`salt.modules.systemd.missing(name)`

New in version 2014.1.0.

The inverse of `service.available`. Returns True if the specified service is not available, otherwise returns False.

CLI Example:

```bash
salt '*' service.missing sshd
```

`salt.modules.systemd.reload_(name, no_block=False, unmask=False, unmask_runtime=False)`

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands run by this function from the salt-minion daemon's control group. This is done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of `systemd-run(1)` can be suppressed by setting a `config option` called `systemd.scope`, with a value of False (no quotes).

Reload the specified service with systemd

**no_block** [False] Set to True to reload the service using --no-block.

New in version 2017.7.0.

**unmask** [False] Set to True to remove an indefinite mask before attempting to reload the service.

New in version 2017.7.0: In previous releases, Salt would simply unmask a service before reloading. This behavior is no longer the default.

**unmask_runtime** [False] Set to True to remove a runtime mask before attempting to reload the service.
New in version 2017.7.0: In previous releases, Salt would simply unmask a service before reloading. This behavior is no longer the default.

CLI Example:

```bash
salt '*' service.reload <service name>
```

**salt.modules.systemd.restart** *(name, no_block=False, unmask=False, unmask_runtime=False)*

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands run by this function from the salt-minion daemon's control group. This is done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of `systemd-run(1)` can be suppressed by setting a `config option` called `systemd.scope`, with a value of `False` (no quotes).

Restart the specified service with systemd

**no_block** [False] Set to True to start the service using `--no-block`.

New in version 2017.7.0.

**unmask** [False] Set to True to remove an indefinite mask before attempting to restart the service.

New in version 2017.7.0: In previous releases, Salt would simply unmask a service before attempting to restart. This behavior is no longer the default.

**unmask_runtime** [False] Set to True to remove a runtime mask before attempting to restart the service.

New in version 2017.7.0: In previous releases, Salt would simply unmask a service before attempting to restart. This behavior is no longer the default.

CLI Example:

```bash
salt '*' service.restart <service name>
```

**salt.modules.systemd.show** *(name)*

New in version 2014.7.0.

Show properties of one or more units/jobs or the manager

CLI Example:

```bash
salt '*' service.show <service name>
```

**salt.modules.systemd.start** *(name, no_block=False, unmask=False, unmask_runtime=False)*

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands run by this function from the salt-minion daemon's control group. This is done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of `systemd-run(1)` can be suppressed by setting a `config option` called `systemd.scope`, with a value of `False` (no quotes).

Start the specified service with systemd

**no_block** [False] Set to True to start the service using `--no-block`.

New in version 2017.7.0.

**unmask** [False] Set to True to remove an indefinite mask before attempting to start the service.

New in version 2017.7.0: In previous releases, Salt would simply unmask a service before starting. This behavior is no longer the default.

**unmask_runtime** [False] Set to True to remove a runtime mask before attempting to start the service.

New in version 2017.7.0: In previous releases, Salt would simply unmask a service before starting. This behavior is no longer the default.

CLI Example:

```bash
salt '*' service.start <service name>
```
salt.modules.systemd.status(name, sig=None)

Return the status for a service via systemd, returns True if the service is running and False if it is not.

CLI Example:

```
salt '*' service.status <service name>
```

salt.modules.systemd.stop(name, no_block=False)

Changed in version 2015.8.12,2016.3.3,2016.11.0: On minions running systemd>=205, systemctl-run(1) is now used to isolate commands run by this function from the salt-minion daemon's control group. This is done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of systemctl-run(1) can be suppressed by setting a config option called systemctl.scope, with a value of False (no quotes).

Stop the specified service with systemd

no_block [False] Set to True to start the service using --no-block.

New in version 2017.7.0.

CLI Example:

```
salt '*' service.stop <service name>
```

salt.modules.systemd.systemctl_reload()

New in version 0.15.0.

Reloads systemctl, an action needed whenever unit files are updated.

CLI Example:

```
salt '*' service.systemctl_reload
```

salt.modules.systemd.unmask_(name, runtime=False)

New in version 2015.5.0.

Changed in version 2015.8.12,2016.3.3,2016.11.0: On minions running systemd>=205, systemctl-run(1) is now used to isolate commands run by this function from the salt-minion daemon's control group. This is done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of systemctl-run(1) can be suppressed by setting a config option called systemctl.scope, with a value of False (no quotes).

Unmask the specified service with systemd

runtime [False] Set to True to unmask this service only until the next reboot

New in version 2017.7.0: In previous versions, this function would remove whichever mask was identified by running systemctl is-enabled on the service. However, since it is possible to both have both indefinite and runtime masks on a service simultaneously, this function now removes a runtime mask only when this argument is set to True, and otherwise removes an indefinite mask.

CLI Example:

```
salt '*' service.unmask foo
salt '*' service.unmask foo runtime=True
```

19.9.387 salt.modules.telemetry

Connection module for Telemetry

New in version 2016.3.0.

https://github.com/mongolab/mongolab-telemetry-api-docs/blob/master/alerts.md
configuration

This module accepts explicit telemetry credentials or can also read api key credentials from a pillar. More Information available here.

In the minion’s config file:

```yaml
telemetry.telemetry_api_keys:
  - abc123  # Key 1
  - efg321  # Backup Key 1

# Key 1
# Backup Key 1
```

```
telemetry_api_base_url: https://telemetry-api.mongolab.com/v0
```

depends requests

salt.modules.telemetry.create_alarm(deployment_id, metric_name, data, api_key=None, profile='telemetry')

create a telemetry alarm.

data a dict of alert configuration data.

Returns (bool success, str message) tuple.

CLI Example:

  salt myminion telemetry.create_alarm rs-ds033197 {} profile=telemetry

salt.modules.telemetry.delete_alarms(deployment_id, alert_id=None, metric_name=None, api_key=None, profile='telemetry')

delete an alert specified by alert_id or if not specified blows away all the alerts in the current deployment.

Returns (bool success, str message) tuple.

CLI Example:

  salt myminion telemetry.delete_alarms rs-ds033197 profile=telemetry

salt.modules.telemetry.get_alarms(deployment_id, profile='telemetry')

get all the alarms set up against the current deployment

Returns dictionary of alarm information

CLI Example:

  salt myminion telemetry.get_alarms rs-ds033197 profile=telemetry

salt.modules.telemetry.get_alert_config(deployment_id, metric_name=None, api_key=None, profile='telemetry')

Get all alert definitions associated with a given deployment or if metric_name is specified, obtain the specific alert config.

Returns dictionary or list of dictionaries.

CLI Example:

  salt myminion telemetry.get_alert_config rs-ds033197 currentConnections profile=telemetry

salt.modules.telemetry.get_notification_channel_id(notify_channel, profile='telemetry')

Given an email address, creates a notification-channel if one is not found and also returns the corresponding notification channel id.

notify_channel Email escalation policy

profile A dict of telemetry config information.

CLI Example:

  salt myminion telemetry.get_notification_channel_id userx@company.com profile=telemetry

salt.modules.telemetry.update_alarm(deployment_id, metric_name, data, api_key=None, profile='telemetry')

update a telemetry alarm.

data a dict of alert configuration data.
Returns (bool success, str message) tuple.

CLI Example:
salt myminion telemetry.update_alarm rs-ds033197 {'profile': 'telemetry'}

19.9.388 salt.modules.temp

Simple module for creating temporary directories and files

This is a thin wrapper around Python's tempfile module

New in version 2015.8.0.

salt.modules.temp.dir(suffix='', prefix='tmp', parent=None)
Create a temporary directory

CLI Example:
salt '*' temp.dir
salt '*' temp.dir prefix='mytemp-' parent='/var/run/

salt.modules.temp.file(suffix='', prefix='tmp', parent=None)
Create a temporary file

CLI Example:
salt '*' temp.file
salt '*' temp.file prefix='mytemp-' parent='/var/run/

19.9.389 salt.modules.test

Module for running arbitrary tests

salt.modules.test.arg(*args, **kwargs)
Print out the data passed into the function *args and **kwargs, this is used to both test the publication data and cli argument passing, but also to display the information available within the publication data. Returns {'args': args, 'kwargs': kwargs}.

CLI Example:
salt '*' test.arg 1 "two" 3.1 txt="hello" wow='{a: 1, b: "hello"}'}

salt.modules.test.arg_clean(*args, **kwargs)
Like test.arg but cleans kwargs of the __pub* items CLI Example:
salt '*' test.arg_clean 1 "two" 3.1 txt="hello" wow='{a: 1, b: "hello"}'}

salt.modules.test.arg_repr(*args, **kwargs)
Print out the data passed into the function *args and **kwargs, this is used to both test the publication data and cli argument passing, but also to display the information available within the publication data. Returns {'args': repr(args), 'kwargs': repr(kwargs)}.

CLI Example:
salt '*' test.arg_repr 1 "two" 3.1 txt="hello" wow='{a: 1, b: "hello"}'}
salt.modules.test.arg_type(*args, **kwargs)
Print out the types of the args and kwargs. This is used to test the types of the args and kwargs passed down
to the minion

CLI Example:
```
salt '*' test.arg_type 1 'int'
```

salt.modules.test.assertion(assertion)
Assert the given argument

CLI Example:
```
salt '*' test.assertion False
```

salt.modules.test.attr_call()
Call grains.items via the attribute

CLI Example:
```
salt '*' test.attr_call
```

salt.modules.test.collatz(start)
Execute the collatz conjecture from the passed starting number, returns the sequence and the time it took to
calculate. Used for performance tests.

CLI Example:
```
salt '*' test.collatz 3
```

salt.modules.test.conf_test()
Return the value for test.foo in the minion configuration file, or return the default value

CLI Example:
```
salt '*' test.conf_test
```

salt.modules.test.cross_test(func, args=None)
Execute a minion function via the __salt__ object in the test module, used to verify that the minion functions
can be called via the __salt__ module.

CLI Example:
```
salt '*' test.cross_test file.gid_to_group 0
```

salt.modules.test.echo(text)
Return a string - used for testing the connection

CLI Example:
```
salt '*' test.echo 'foo bar baz quo qux'
```

salt.modules.test.exception(message='Test Exception')
Raise an exception

Optionally provide an error message or output the full stack.

CLI Example:
salt '*' test.exception 'Oh noes!'

salt.modules.test.false_()
Always return False

CLI Example:
salt '*' test.false

salt.modules.test.fib(num)
Return the num-th Fibonacci number, and the time it took to compute in seconds. Used for performance tests.
This function is designed to have terrible performance.

CLI Example:
salt '*' test.fib 3

salt.modules.test.get_opts()
Return the configuration options passed to this minion

CLI Example:
salt '*' test.get_opts

salt.modules.test.kwarg(**kwargs)
Print out the data passed into the function **kwargs, this is used to both test the publication data and cli kwarg passing, but also to display the information available within the publication data.

CLI Example:
salt '*' test.kwarg num=1 txt="two" env='{a: 1, b: "hello"}"

salt.modules.test.missing_func()
salt.modules.test.module_report()
Return a dict containing all of the execution modules with a report on the overall availability via different references

CLI Example:
salt '*' test.module_report

salt.modules.test.not_loaded()
List the modules that were not loaded by the salt loader system

CLI Example:
salt '*' test.not_loaded

salt.modules.test.opts_pkg()
Return an opts package with the grains and opts for this minion. This is primarily used to create the options used for master side state compiling routines

CLI Example:
salt '*' test.opts_pkg
salt.modules.test.outputter(data)
    Test the outputter, pass in data to return

    CLI Example:
    ```
salt '*' test.outputter foobar
    ```

salt.modules.test.ping()
    Used to make sure the minion is up and responding. Not an ICMP ping.
    Returns True.

    CLI Example:
    ```
salt '*' test.ping
    ```

salt.modules.test.provider(module)
    Pass in a function name to discover what provider is being used

    CLI Example:
    ```
salt '*' test.provider service
    ```

salt.modules.test.providers()
    Return a dict of the provider names and the files that provided them

    CLI Example:
    ```
salt '*' test.providers
    ```

salt.modules.test.rand_sleep(max=60)
    Sleep for a random number of seconds, used to test long-running commands and minions returning at differing intervals

    CLI Example:
    ```
salt '*' test.rand_sleep 60
    ```

salt.modules.test.rand_str(size=999999999, hash_type=None)
    Return a random string

    CLI Example:
    ```
salt '*' test.rand_str
    ```

salt.modules.test.retcod(code=42)
    Test that the returncode system is functioning correctly

    CLI Example:
    ```
salt '*' test.retcod 42
    ```

salt.modules.test.sleep(length)
    Instruct the minion to initiate a process that will sleep for a given period of time.

    CLI Example:
salt '*' test.sleep 20

salt.modules.test.stack()
Return the current stack trace

   CLI Example:
   salt '*' test.stack

salt.modules.test.true_()
Always return True

   CLI Example:
   salt '*' test.true

salt.modules.test.try_(module, return_try_exception=False, **kwargs)
Try to run a module command. On an exception return None. If return_try_exception is set True return the exception. This can be helpful in templates where running a module might fail as expected.

   CLI Example:
   ```
   {% for i in range(0,230) %}
   {{ salt['test.try'](module='ipmi.get_users', bmc_host='172.2.2.\'+i)|yaml(False) }}
   {% endfor %}
   ```

salt.modules.test.tty(*args, **kwargs)
Deprecated! Moved to cmdmod.

   CLI Example:
   salt '*' test.tty tty0 'This is a test'
salt '*' test.tty pts3 'This is a test'

salt.modules.test.version()
Return the version of salt on the minion

   CLI Example:
   salt '*' test.version

salt.modules.test.versions()
This function is an alias of versions_report.
Returns versions of components used by salt

   CLI Example:
   salt '*' test.versions_report

salt.modules.test.versions_information()
Report the versions of dependent and system software

   CLI Example:
   salt '*' test.versions_information
salt.modules.test.versions_report()

Returns versions of components used by salt

CLI Example:

```
salt '*' test.versions_report
```

19.9.390 salt.modules.testinframod module

This module exposes the functionality of the TestInfra library for use with SaltStack in order to verify the state of your minions. In order to allow for the addition of new resource types in TestInfra this module dynamically generates wrappers for the various resources by iterating over the values in the `__all__` variable exposed by the testinfra.modules namespace.

19.9.391 salt.modules.test_virtual

Module for running arbitrary tests with a `__virtual__` function

salt.modules.test_virtual.ping()

19.9.392 salt.modules.timezone

Module for managing timezone on POSIX-like systems.

salt.modules.timezone.get_hwclock()

Get current hardware clock setting (UTC or localtime)

CL  CLI Example:

```
salt '*' timezone.get_hwclock
```

salt.modules.timezone.get_offset()

Get current numeric timezone offset from UCT (i.e. -0700)

CLI Example:

```
salt '*' timezone.get_offset
```

salt.modules.timezone.get_zone()

Get current timezone (i.e. America/Denver)

Changed in version 2016.11.4.

**Note:** On AIX operating systems, Posix values can also be returned `CST6CDT,M3.2.0/2:00:00,M11.1.0/2:00:00`

CLI Example:

```
salt '*' timezone.get_zone
```

salt.modules.timezone.get_zonecode()

Get current timezone (i.e. PST, MDT, etc)

CLI Example:
salt 'salt' timezone.get_zonecode

salt.modules.timezone.set_hwclock(clock)
Sets the hardware clock to be either UTC or localtime

CLI Example:
salt 'salt' timezone.set_hwclock UTC

salt.modules.timezone.set_zone(timezone)
Unlinks, then symlinks /etc/localtime to the set timezone.

The timezone is crucial to several system processes, each of which SHOULD be restarted (for instance, whatever you system uses as its cron and syslog daemons). This will not be automagically done and must be done manually!

CLI Example:
salt 'salt' timezone.set_zone 'America/Denver'

Changed in version 2016.11.4.

Note: On AIX operating systems, Posix values are also allowed, see below

salt 'salt' timezone.set_zone 'CST6CDT,M3.2.0/2:00:00,M11.1.0/2:00:00'

salt.modules.timezone.zone_compare(timezone)
Compares the given timezone name with the system timezone name. Checks the hash sum between the given timezone, and the one set in /etc/localtime. Returns True if names and hash sums match, and False if not. Mostly useful for running state checks.

Changed in version 2016.3.0.

Note: On Solaris-link operating systems only a string comparison is done.

Changed in version 2016.11.4.

Note: On AIX operating systems only a string comparison is done.

CLI Example:
salt 'salt' timezone.zone_compare 'America/Denver'

19.9.393 salt.modules.tls

A salt module for SSL/TLS. Can create a Certificate Authority (CA) or use Self-Signed certificates.

depends PyOpenSSL Python module (0.10 or later, 0.14 or later for X509 extension support)

configuration Add the following values in /etc/salt/minion for the CA module to function properly:

ca.cert_base_path: '/etc/pki'
CLI Example #1: Creating a CA, a server request and its signed certificate:

```bash
# salt-call tls.create_ca my_little \
  days=5 \
  CN='My Little CA' \
  C=US \n  ST=Utah \n  L=Salt Lake City \
  O=Saltstack \
  emailAddress=pleasedontemail@example.com

Created Private Key: "/etc/pki/my_little/my_little_ca_cert.key"
Created CA "my_little_ca": "/etc/pki/my_little/my_little_ca_cert.crt"

# salt-call tls.create_csr my_little CN=www.example.com

Created Private Key: "/etc/pki/my_little/certs/www.example.com.key"
Created CSR for "www.example.com": "/etc/pki/my_little/certs/www.example.com.csr"

# salt-call tls.create_ca_signed_cert my_little CN=www.example.com

Created Certificate for "www.example.com": "/etc/pki/my_little/certs/www.example.com.crt"
```

CLI Example #2: Creating a client request and its signed certificate

```bash
# salt-call tls.create_csr my_little CN=DBReplica_No.1 cert_type=client

Created Private Key: "/etc/pki/my_little/certs/DBReplica_No.1.key."
Created CSR for "DBReplica_No.1": "/etc/pki/my_little/certs/DBReplica_No.1.csr."

# salt-call tls.create_ca_signed_cert my_little CN=DBReplica_No.1

Created Certificate for "DBReplica_No.1": "/etc/pki/my_little/certs/DBReplica_No.1.crt"
```

CLI Example #3: Creating both a server and client req + cert for the same CN

```bash
# salt-call tls.create_csr my_little CN=MasterDBReplica_No.2 \n  cert_type=client

Created Private Key: "/etc/pki/my_little/certs/MasterDBReplica_No.2.key."
Created CSR for "MasterDBReplica_No.1": "/etc/pki/my_little/certs/MasterDBReplica_No.2.csr."

# salt-call tls.create_ca_signed_cert my_little CN=MasterDBReplica_No.2

Created Certificate for "MasterDBReplica_No.1": "/etc/pki/my_little/certs/MasterDBReplica_No.1.crt"

# salt-call tls.create_csr my_little CN=MasterDBReplica_No.2 \n  cert_type=server

Certificate "MasterDBReplica_No.2" already exists (doh!)

# salt-call tls.create_csr my_little CN=MasterDBReplica_No.2 \n  cert_type=server type_ext=True

Created Private Key: "/etc/pki/my_little/certs/DBReplica_No.1_client.key."
Created CSR for "DBReplica_No.1": "/etc/pki/my_little/certs/DBReplica_No.1_client.csr."

# salt-call tls.create_ca_signed_cert my_little CN=MasterDBReplica_No.2

Certificate "MasterDBReplica_No.2" already exists (DOH!)

# salt-call tls.create_ca_signed_cert my_little CN=MasterDBReplica_No.2 \n  cert_type=server type_ext=True
```
CLI Example #4: Create a server req + cert with non-CN filename for the cert

```
# salt-call tls.create_csr my_little CN=www.anothersometh.ing \
   cert_type=server type_ext=True
Created Private Key: "/etc/pki/my_little/certs/www.anothersometh.ing_server.key."
Created CSR for "DBReplica_No.1": "/etc/pki/my_little/certs/www.anothersometh.ing_\n   →server.csr."

# salt-call tls_create_ca_signed_cert my_little CN=www.anothersometh.ing \
   cert_type=server cert_filename="something_completely_different"
Created Certificate for "www.anothersometh.ing": /etc/pki/my_little/certs/something_\n   →completely_different.crt
```

salt.modules.tls.ca_exists(ca_name, cacert_path=None, ca_filename=None)
Verify whether a Certificate Authority (CA) already exists
ca_name name of the CA
 cacert_path absolute path to ca certificates root directory
 ca_filename alternative filename for the CA

New in version 2015.5.3.

CLI Example:
```
salt '*' tls.ca_exists test_ca /etc/certs
```

salt.modules.tls.cert_base_path(cacert_path=None)
Return the base path for certs from CLI or from options
 cacert_path absolute path to ca certificates root directory

CLI Example:
```
salt '*' tls.cert_base_path
```

salt.modules.tls.cert_info(cert_path, digest='sha256')
Return information for a particular certificate
cert_path path to the cert file
digest what digest to use for fingerprinting

CLI Example:
```
salt '*' tls.cert_info /dir/for/certs/cert.pem
```

salt.modules.tls.create_ca(ca_name, bits=2048, days=365, CN='localhost', C='US', ST='Utah', L='Salt Lake City', O='SaltStack', OU=None, emailAddress='xyz@pdq.net', fixmode=False, cacert_path=None, ca_filename=None, digest='sha256', onlyif=None, unless=None, replace=False)
Create a Certificate Authority (CA)
ca_name name of the CA
 bits number of RSA key bits, default is 2048
days number of days the CA will be valid, default is 365
 CN common name in the request, default is "localhost"
 C country, default is "US"
 ST state, default is "Utah"
 L locality, default is "Centerville", the city where SaltStack originated
 O organization, default is "SaltStack"
OU  organizational unit, default is None
emailAddress  email address for the CA owner, default is `xyz@pdq.net`
cacert_path  absolute path to ca certificates root directory
ca_filename  alternative filename for the CA

    New in version 2015.5.3.
digest  The message digest algorithm. Must be a string describing a digest algorithm supported by OpenSSL (by EVP_get_digestbyname, specifically). For example, `"md5"` or `"sha1"`. Default: `sha256`
replace  Replace this certificate even if it exists

    New in version 2015.5.1.
Writes out a CA certificate based upon defined config values. If the file already exists, the function just returns assuming the CA certificate already exists.

If the following values were set:

```
c.a.cert_base_path="/etc/pki"
c.a.name="koji"
```

the resulting CA, and corresponding key, would be written in the following location:

```
/etc/pki/koji/koji_ca_cert.crt
/etc/pki/koji/koji_ca_cert.key
```

CLI Example:

```
salt '*' tls.create_ca test_ca
```
salt.modules.tls.create_ca_signed_cert(ca_name, CN, days=365, cacert_path=None, ca_filename=None, cert_path=None, cert_filename=None, digest='sha256', cert_type=None, type_ext=False, replace=False)

Create a Certificate (CERT) signed by a named Certificate Authority (CA)

If the certificate file already exists, the function just returns assuming the CERT already exists.

The CN must match an existing CSR generated by create_csr. If it does not, this method does nothing.
ca_name  name of the CA
CN  common name matching the certificate signing request
days  number of days certificate is valid, default is 365 (1 year)
cacert_path  absolute path to ca certificates root directory
ca_filename  alternative filename for the CA

cert_path  full path to the certificates directory
cert_filename  alternative filename for the certificate, useful when using special characters in the CN. If this option is set it will override the certificate filename output effects of cert_type. type_ext will be completely overridden.

cert_file_confidence  New in version 2015.5.3.
digest  The message digest algorithm. Must be a string describing a digest algorithm supported by OpenSSL (by EVP_get_digestbyname, specifically). For example, `"md5"` or `"sha1"`. Default: `sha256`
replace  Replace this certificate even if it exists

cert_type  string. Either `server` or `client` (see create_csr() for details).

    If create_csr(type_ext=True) this function must be called with the same cert_type so it can find the CSR file.
Note: `create_csr()` defaults to `cert_type='server'`; therefore, if it was also called with `type_ext`, `cert_type` becomes a required argument for `create_ca_signed_cert()`

type_ext bool. If set True, use `cert_type` as an extension to the CN when formatting the filename.

  e.g.: some_subject_CN_server.crt or some_subject_CN_client.crt

  This facilitates the context where both types are required for the same subject

  If `cert_filename` is not `None`, setting `type_ext` has no effect

If the following values were set:

```python
c.a.cert_base_path='/etc/pki'
c.a_name='koji'
CN='test.egavas.org'
```

the resulting signed certificate would be written in the following location:

```
/etc/pki/koji/certs/test.egavas.org.crt
```

CLI Example:

```
salt '*' tls.create_ca_signed_cert test localhost
global.salt.modules.tls.create_csr(ca_name, bits=2048, CN='localhost', C='US', ST='Utah', L='Salt Lake City', O='SaltStack', OU=None, emailAddress='xyz@pdq.net', subjectAltName=None, cacert_path=None, ca_filename=None, csr_path=None, csr_filename=None, digest='sha256', type_ext=False, cert_type='server', replace=False)
```

Create a Certificate Signing Request (CSR) for a particular Certificate Authority (CA)

```
c.a_name name of the CA
bits number of RSA key bits, default is 2048
CN common name in the request, default is `localhost`
C country, default is `US`
ST state, default is `Utah`
L locality, default is `Centerville`, the city where SaltStack originated
O organization, default is `SaltStack` NOTE: Must the same as CA certificate or an error will be raised
OU organizational unit, default is None
eEmail address email address for the request, default is `xyz@pdq.net`
s.subjectAltName valid subjectAltNames in full form, e.g. to add DNS entry you would call this function with this value:
examples: `[DNS:somednsname.com`, `DNS:1.2.3.4`, `IP:1.2.3.4`, `IP:2001:4801:7821:77:be76:4eff:fe11:e51`, `email:me@i.like.pie.com`]
```

Note: some libraries do not properly query IP: prefixes, instead looking for the given req. source with a DNS: prefix. To be thorough, you may want to include both DNS: and IP: entries if you are using subjectAltNames for destinations for your TLS connections. e.g.: requests to https://1.2.3.4 will fail from python's requests library w/out the second entry in the above list

New in version 2015.8.0.

cert_type Specify the general certificate type. Can be either `server` or `client`. Indicates the set of common extensions added to the CSR.
server: {
    'basicConstraints': 'CA:FALSE',
    'extendedKeyUsage': 'serverAuth',
    'keyUsage': 'digitalSignature, keyEncipherment'
}

client: {
    'basicConstraints': 'CA:FALSE',
    'extendedKeyUsage': 'clientAuth',
    'keyUsage': 'nonRepudiation, digitalSignature, keyEncipherment'
}

type_ext boolean. Whether or not to extend the filename with CN_[cert_type] This can be useful if a server and client certificate are needed for the same CN. Defaults to False to avoid introducing an unexpected file naming pattern.

The files normally named some_subject_CN.csr and some_subject_CN.key will then be saved

```
replace Replace this signing request even if it exists
```

New in version 2015.5.1.

Writs out a Certificate Signing Request (CSR) If the file already exists, the function just returns assuming the CSR already exists.

If the following values were set:

```
ca.cert_base_path='/etc/pki'
ca_name='koji'
CN='test.egavas.org'
```

the resulting CSR, and corresponding key, would be written in the following location:

```
/etc/pki/koji/certs/test.egavas.org.csr
/etc/pki/koji/certs/test.egavas.org.key
```

CLI Example:

```
salt '*' tls.create_csr test
```

salt.modules.tls.create_empty_crl(ca_name, cacert_path=None, ca_filename=None, crl_file=None)

Create an empty Certificate Revocation List.

New in version 2015.8.0.
ca_name name of the CA
cacert_path absolute path to ca certificates root directory
cafilename alternative filename for the CA

New in version 2015.5.3.
crl_file full path to the CRL file

CLI Example:

```
salt '*' tls.create_empty_crl ca_name='koji' --
    ca_filename='ca'
    crl_file='/etc/openvpn/team1/crl.pem'
```

salt.modules.tls.create_pkcs12(ca_name, CN, passphrase='', cacert_path=None, replace=False)

Create a PKCS#12 browser certificate for a particular Certificate (CN)
ca_name name of the CA
CN common name matching the certificate signing request
passphrase used to unlock the PKCS#12 certificate when loaded into the browser
**cacert_path** absolute path to ca certificates root directory

**replace** Replace this certificate even if it exists

New in version 2015.5.1.

If the following values were set:

```
cacert_path="/etc/pki"
ca_name="koji"
CN="test.egavas.org"
```

the resulting signed certificate would be written in the following location:

```
/etc/pki/koji/certs/test.egavas.org.p12
```

CLI Example:

```
salt '*' tls.create_pkcs12 test localhost
```

```python
salt.modules.tls.create_self_signed_cert(tls_dir='tls', bits=2048, days=365, CN='localhost', C='US', ST='Utah', L='Salt Lake City', O='SaltStack', OU=None, emailAddress='xyz@pdq.net', cacert_path=None, cert_filename=None, digest='sha256', replace=False)
```

Create a Self-Signed Certificate (CERT)

tls_dir location appended to the ca.cert_base_path, default is `tls`

bits number of RSA key bits, default is 2048

CN common name in the request, default is ``localhost``

C country, default is ``US``

ST state, default is ``Utah``

L locality, default is ``Centerville``, the city where SaltStack originated

O organization, default is ``SaltStack`` NOTE: Must the same as CA certificate or an error will be raised

OU organizational unit, default is None

emailAddress email address for the request, default is `xyz@pdq.net`

**cacert_path** absolute path to ca certificates root directory

**digest** The message digest algorithm. Must be a string describing a digest algorithm supported by OpenSSL (by EVP_get_digestbyname, specifically). For example, ``md5`` or ``sha1``. Default: `sha256`

**replace** Replace this certificate even if it exists

New in version 2015.5.1.

Writes out a Self-Signed Certificate (CERT). If the file already exists, the function just returns.

If the following values were set:

```
cacert_path="/etc/pki"
tls_dir=koji"
CN="test.egavas.org"
```

the resulting CERT, and corresponding key, would be written in the following location:

```
/etc/pki/koji/certs/test.egavas.org.crt
/etc/pki/koji/certs/test.egavas.org.key
```

CLI Example:

```
salt '*' tls.create_self_signed_cert
```

Passing options from the command line:
salt 'minion' tls.create_self_signed_cert CN='test.mysite.org'

salt.modules.tls.get_ca(ca_name, as_text=False, cacert_path=None)

    Get the certificate path or content
    ca_name  name of the CA
    as_text  if true, return the certificate content instead of the path
    cacert_path  absolute path to ca certificates root directory

CLI Example:
salt '*' tls.get_ca test_ca as_text=False cacert_path=/etc/certs

salt.modules.tls.get_ca_signed_cert(ca_name, CN='localhost', as_text=False, cacert_path=None, cert_filename=None)

    Get the certificate path or content
    ca_name  name of the CA
    CN  common name of the certificate
    as_text  if true, return the certificate content instead of the path
    cacert_path  absolute path to certificates root directory
    cert_filename  alternative filename for the certificate, useful when using special characters in the CN

    New in version 2015.5.3.

CLI Example:
salt '*' tls.get_ca_signed_cert test_ca CN=localhost as_text=False cacert_path=/

salt.modules.tls.get_ca_signed_key(ca_name, CN='localhost', as_text=False, cacert_path=None, key_filename=None)

    Get the certificate path or content
    ca_name  name of the CA
    CN  common name of the certificate
    as_text  if true, return the certificate content instead of the path
    cacert_path  absolute path to certificates root directory
    key_filename  alternative filename for the key, useful when using special characters

    New in version 2015.5.3.

CLI Example:
salt '*' tls.get_ca_signed_key test_ca CN=localhost as_text=False cacert_path=/

salt.modules.tls.get_extensions(cert_type)

    Fetch X509 and CSR extension definitions from tls:extensions: (common|server|client) or set them to standard defaults.

    New in version 2015.8.0.

cert_type:  The type of certificate such as server or client.

CLI Example:
salt '*' tls.get_extensions client

salt.modules.tls.maybe_fix_ssl_version(ca_name, cacert_path=None, ca_filename=None)

    Check that the X509 version is correct (was incorrectly set in previous salt versions). This will fix the version
    if needed.

    ca_name  ca authority name
**cachet_path** absolute path to ca certificates root directory
**ca_filename** alternative filename for the CA

New in version 2015.5.3.

CLI Example:

```
salt '*' tls.maybe_fix_ssl_version test_ca /etc/certs
```

salt.modules.tls.revoke_cert(**ca_name**, **CN**, **cacert_path**=None, **ca_filename**=None,
**cert_path**=None, **cert_filename**=None, **crl_file**=None)

Revoke a certificate.

New in version 2015.8.0.

**ca_name** Name of the CA.
**CN** Common name matching the certificate signing request.
**cacert_path** Absolute path to ca certificates root directory.
**ca_filename** Alternative filename for the CA.
**cert_path** Path to the cert file.
**cert_filename** Alternative filename for the certificate, useful when using special characters in the CN.
**crl_file** Full path to the CRL file.

CLI Example:

```
salt '*' tls.revoke_cert ca_name='koji' ca_filename='ca'
crl_file='/etc/openvpn/team1/crl.pem'
```

salt.modules.tls.set_ca_path(**cacert_path**)

If wanted, store the aforementioned cacert_path in context to be used as the basepath for further operations

CLI Example:

```
salt '*' tls.set_ca_path /etc/certs
```

19.9.394 salt.modules.tomcat

Support for Tomcat

This module uses the manager webapp to manage Apache tomcat webapps. If the manager webapp is not configured some of the functions won't work.

**configuration**

- Java bin path should be in default path
- If ipv6 is enabled make sure you permit manager access to ipv6 interface `::0:0:0:0:0:1`
- If you are using tomcat.tar.gz it has to be installed or symlinked under `/opt`, preferably using name tomcat
- ``tomcat.signal start/stop'' works but it does not use the startup scripts

The following grains/pillar should be set:

```
tomcat-manager:
  user: <username>
  passwd: <password>
```

or the old format:
tomcat-manager.user: <username>
tomcat-manager.passwd: <password>

Also configure a user in the conf/tomcat-users.xml file:

```xml
<?xml version='1.0' encoding='utf-8'?>
<tomcat-users>
    <role rolename="manager-script"/>
    <user username="tomcat" password="tomcat" roles="manager-script"/>
</tomcat-users>
```

Note:

- If you use only this module for deployments you might want to strict access to the manager only from local-host for more info: http://tomcat.apache.org/tomcat-7.0-doc/manager-howto.html#Configuring_Manager_Application_Access
- Tested on:
  JVM Vendor: Sun Microsystems Inc.
  JVM Version: 1.6.0_43-b01
  OS Architecture: amd64
  OS Name: Linux
  OS Version: 2.6.32-358.el6.x86_64
  Tomcat Version: Apache Tomcat/7.0.37

salt.modules.tomcat.deploy_war(war, context, force='no', url='http://localhost:8080/manager', saltenv='base', timeout=180, temp_war_location=None, version=True)

Deploy a WAR file

- war absolute path to WAR file (should be accessible by the user running tomcat) or a path supported by the salt.modules.cp.get_file function
- context the context path to deploy
- force [False] set True to deploy the webapp even one is deployed in the context
- url [http://localhost:8080/manager] the URL of the server manager webapp
- saltenv [base] the environment for WAR file in used by salt.modules.cp.get_url function
- timeout [180] timeout for HTTP request
- temp_war_location [None] use another location to temporarily copy to war file by default the system’s temp directory is used
- version [''] Specify the war version. If this argument is provided, it overrides the version encoded in the war file name, if one is present.

Examples:

```
salt '*' tomcat.deploy_war salt://salt-2015.8.6.war version=2015.08.r6
```

CLI Examples:

cp module
salt '*' tomcat.deploy_war salt://application.war /api
salt '*' tomcat.deploy_war salt://application.war /api no
salt '*' tomcat.deploy_war salt://application.war /api yes http://localhost:8080/

minion local file system

salt '*' tomcat.deploy_war /tmp/application.war /api
salt '*' tomcat.deploy_war /tmp/application.war /api no
salt '*' tomcat.deploy_war /tmp/application.war /api yes http://localhost:8080/

**salt.modules.tomcat.extract_war_version**(war)
Extract the version from the war file name. There does not seem to be a standard for encoding the version into the war file name

Examples:

/path/salt-2015.8.6.war -> 2015.8.6
/path/V6R2013xD5.war -> None

**salt.modules.tomcat.fullversion**()
Return all server information from catalina.sh version

CLI Example:

salt '*' tomcat.fullversion

**salt.modules.tomcat.leaks**(url='http://localhost:8080/manager', timeout=180)
Find memory leaks in tomcat
url [http://localhost:8080/manager] the URL of the server manager webapp
timeout [180] timeout for HTTP request

CLI Examples:

salt '*' tomcat.leaks

**salt.modules.tomcat.ls**(url='http://localhost:8080/manager', timeout=180)
list all the deployed webapps
url [http://localhost:8080/manager] the URL of the server manager webapp
timeout [180] timeout for HTTP request

CLI Examples:

salt '*' tomcat.ls
salt '*' tomcat.ls http://localhost:8080/manager

**salt.modules.tomcat.passwd**(passwd, user='`, alg='sha1', realm=None)
This function replaces the $CATALINA_HOME/bin/digest.sh script convert a clear-text password to the $CATALINA_BASE/conf/tomcat-users.xml format

CLI Examples:

salt '*' tomcat.passwd secret
salt '*' tomcat.passwd secret tomcat shal
salt '*' tomcat.passwd secret tomcat shal 'Protected Realm'

**salt.modules.tomcat.reload_**(app, url='http://localhost:8080/manager', timeout=180)
Reload the webapp
app the webapp context path

19.9. execution modules
url [http://localhost:8080/manager] the URL of the server manager webapp

timeout [180] timeout for HTTP request

CLI Examples:

```bash
salt '*' tomcat.reload /jenkins
dsalt '*' tomcat.reload /jenkins http://localhost:8080/manager
```

salt.modules.tomcat.serverinfo(url='http://localhost:8080/manager', timeout=180)
return details about the server

url [http://localhost:8080/manager] the URL of the server manager webapp

timeout [180] timeout for HTTP request

CLI Examples:

```bash
dsalt '*' tomcat.serverinfo
dsalt '*' tomcat.serverinfo http://localhost:8080/manager
```

salt.modules.tomcat.sessions(app, url='http://localhost:8080/manager', timeout=180)
return the status of the webapp sessions

app the webapp context path

url [http://localhost:8080/manager] the URL of the server manager webapp

timeout [180] timeout for HTTP request

CLI Examples:

```bash
dsalt '*' tomcat.sessions /jenkins
dsalt '*' tomcat.sessions /jenkins http://localhost:8080/manager
```

salt.modules.tomcat.signal(signal=None)
Signals catalina to start, stop, securestart, forcestop.

CLI Example:

```bash
dsalt '*' tomcat.signal start
```

salt.modules.tomcat.start(app, url='http://localhost:8080/manager', timeout=180)
Start the webapp

app the webapp context path

url [http://localhost:8080/manager] the URL of the server manager webapp

timeout timeout for HTTP request

CLI Examples:

```bash
dsalt '*' tomcat.start /jenkins
dsalt '*' tomcat.start /jenkins http://localhost:8080/manager
```

salt.modules.tomcat.status(url='http://localhost:8080/manager', timeout=180)
Used to test if the tomcat manager is up

url [http://localhost:8080/manager] the URL of the server manager webapp

timeout [180] timeout for HTTP request

CLI Examples:

```bash
dsalt '*' tomcat.status
dsalt '*' tomcat.status http://localhost:8080/manager
```

salt.modules.tomcat.status_webapp(app, url='http://localhost:8080/manager', timeout=180)
return the status of the webapp (stopped | running | missing)

app the webapp context path

url [http://localhost:8080/manager] the URL of the server manager webapp

timeout [180] timeout for HTTP request
CLI Examples:

```
salt '*' tomcat.status_webapp /jenkins
salt '*' tomcat.status_webapp /jenkins http://localhost:8080/manager
```

```
salt '*' tomcat.stop /jenkins
salt '*' tomcat.stop /jenkins http://localhost:8080/manager
```

```
salt '*' tomcat.undeploy /jenkins
salt '*' tomcat.undeploy /jenkins http://localhost:8080/manager
```

```
salt '*' tomcat.version
```

19.9.395 salt.modules.trafficserver

Apache Traffic Server execution module.

New in version 2015.8.0.

traffic_ctl is used to execute individual Traffic Server commands and to script multiple commands in a shell.

salt.modules.trafficserver.alarms()

List all alarm events that have not been acknowledged (cleared).

```
salt '*' trafficserver.alarms
```

salt.modules.trafficserver.bounce_cluster()

```
salt '*' trafficserver.bounce_cluster
```

salt.modules.trafficserver.bounce_local(drain=False)

```
drain This option modifies the restart behavior such that traffic_server is not shut down until the number of active client connections drops to the number given by the proxy.config.restart.active_client_threshold configuration variable.
```
### salt modules.trafficserver.clear_alarms(alarm)
Clear (acknowledge) an alarm event. The arguments are “all” for all current alarms, a specific alarm number (e.g. “1”), or an alarm string identifier (e.g. “MGMT_ALARM_PROXY_CONFIG_ERROR”).

#### Examples
```bash
salt '*' trafficserver.clear_alarms [all | #event | name]
```

### salt modules.trafficserver.clear_cluster()
Clears accumulated statistics on all nodes in the cluster.

#### Example
```bash
salt '*' trafficserver.clear_cluster
```

### salt modules.trafficserver.clear_node()
Clears accumulated statistics on the local node.

#### Example
```bash
salt '*' trafficserver.clear_node
```

### salt modules.trafficserver.match_config(regex)
Display the current values of all configuration variables whose names match the given regular expression.

New in version 2016.11.0.

#### Example
```bash
salt '*' trafficserver.match_config regex
```

### salt modules.trafficserver.match_metric(regex)
Display the current values of all metrics whose names match the given regular expression.

New in version 2016.11.0.

#### Example
```bash
salt '*' trafficserver.match_metric regex
```

### salt modules.trafficserver.match_var(regex)
Display the current values of all performance statistics or configuration variables whose names match the given regular expression.

Deprecated since version Fluorine: Use match_metric or match_config instead.

#### Example
```bash
salt '*' trafficserver.match_var regex
```

### salt modules.trafficserver.offline(path)
Mark a cache storage device as offline. The storage is identified by a path which must match exactly a path specified in storage.config. This removes the storage from the cache and redirects requests that would have used this storage to other storage. This has exactly the same effect as a disk failure for that storage. This does not persist across restarts of the traffic_server process.

#### Example
```bash
salt '*' trafficserver.offline /path/to/cache
```

### salt modules.trafficserver.read_config(“args)
Read Traffic Server configuration variable definitions.

New in version 2016.11.0.

#### Example
```bash
salt '*' trafficserver.read_config proxy.config.http.keep_alive_post_out
```

### salt modules.trafficserver.read_metric(“args)
Read Traffic Server one or more metrics.
New in version 2016.11.0.

```typescript
salt '*' trafficserver.read_metric proxy.process.http.tcp_hit_count_stat
```

`salt.modules.trafficserver.read_var('args')`
Read variable definitions from the traffic_line command.

Depreciated since version Fluorine: Use `read_metric` or `read_config` instead. Note that this function does not work for Traffic Server versions >= 7.0.

```typescript
salt '*' trafficserver.read_var proxy.process.http.tcp_hit_count_stat
```

`salt.modules.trafficserver.refresh()`
Initiate a Traffic Server configuration file reread. Use this command to update the running configuration after any configuration file modification.

The timestamp of the last reconfiguration event (in seconds since epoch) is published in the `proxy.node.config.reconfigure_time` metric.

```typescript
salt '*' trafficserver.refresh
```

`salt.modules.trafficserver.restart_cluster()`
Restart the traffic_manager process and the traffic_server process on all the nodes in a cluster.

```typescript
salt '*' trafficserver.restart_cluster
```

`salt.modules.trafficserver.restart_local(drain=False)`
Restart the traffic_manager and traffic_server processes on the local node.

drain This option modifies the restart behavior such that traffic_server is not shut down until the number of active client connections drops to the number given by the `proxy.config.restart.active_client_threshold` configuration variable.

```typescript
salt '*' trafficserver.restart_local
salt '*' trafficserver.restart_local drain=True
```

`salt.modules.trafficserver.set_config(variable, value)`
Set the value of a Traffic Server configuration variable.

```typescript
salt '*' trafficserver.set_config proxy.config.http.keep_alive_post_out 0
```

Depreciated since version Fluorine: Use `set_config` instead. Note that this function does not work for Traffic Server versions >= 7.0.

```typescript
salt '*' trafficserver.set_var proxy.config.http_server_ports
```

`salt.modules.trafficserver.shutdown()`
Shut down Traffic Server on the local node.

```typescript
salt '*' trafficserver.shutdown
```
salt.modules.trafficserver.startup()
    Start Traffic Server on the local node.

    salt '*' trafficserver.start

salt.modules.trafficserver.status()
    Show the current proxy server status, indicating if we’re running or not.

    salt '*' trafficserver.status

salt.modules.trafficserver.zero_cluster()
    Reset performance statistics to zero across the cluster.

    salt '*' trafficserver.zero_cluster

salt.modules.trafficserver.zero_node()
    Reset performance statistics to zero on the local node.

    salt '*' trafficserver.zero_cluster

19.9.396  salt.modules.travisci

Commands for working with travisci.

    depends pyOpenSSL >= 16.0.0

salt.modules.travisci.verify_webhook(signature, body)
    Verify the webhook signature from travisci
    signature  The signature header from the webhook header
    body      The full payload body from the webhook post

    Note:  The body needs to be the urlencoded version of the body.

    CLI Example:

    salt '*' travisci.verify_webhook 'M6NucCX5722bx1sQs7e...' 'payload=%7B%22id%22
    --%3A183791261%2C%22repository...'

19.9.397  salt.modules.tuned

Interface to Red Hat tuned-adm module

    maintainer  Syed Ali <alicsyed@gmail.com>
    maturity    new
    depends     tuned-adm
    platform    Linux

salt.modules.tuned.active()
    Return current active profile

    CLI Example:
salt '::*' tuned.active

salt.modules.tuned.list()  
List the profiles available  
CLI Example:  
salt '::*' tuned.list

salt.modules.tuned.off()  
Turn off all profiles  
CLI Example:  
salt '::*' tuned.off

salt.modules.tuned.profile(profile_name)  
Activate specified profile  
CLI Example:  
salt '::*' tuned.profile virtual-guest

19.9.398 salt.modules.twilio_notify

Module for notifications via Twilio  
New in version 2014.7.0.

depends

- twilio python module

configuration Configure this module by specifying the name of a configuration profile in the minion config, minion pillar, or master config.

For example:

my-twilio-account:  
twilio.account_sid: AC32a3c83990934481addd5ce1659f04d2  
twilio.auth_token: mytoken

salt.modules.twilio_notify.send_sms(profile, body, to, from_)  
Send an sms  
CLI Example:  
twilio.send_sms twilio-account `Test sms` `+18019999999` `+18011111111`

19.9.399 salt.modules.udev

Manage and query udev info  
New in version 2015.8.0.

salt.modules.udev.env(dev)  
Return all environment variables udev has for dev  
CLI Example:
**19.9.400 salt.modules.upstart**

Module for the management of upstart systems. The Upstart system only supports service starting, stopping and restarting.

**Important:** If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `service.start` is not available), see [here](#).

Currently (as of Ubuntu 12.04) there is no tool available to disable Upstart services (like update-rc.d). This[1] is the recommended way to disable an Upstart service. So we assume that all Upstart services that have not been disabled in this manner are enabled.

But this is broken because we do not check to see that the dependent services are enabled. Otherwise we would have to do something like parse the output of `initctl show-config` to determine if all service dependencies are enabled.

---

```python
salt '*' udev.env /dev/sda
salt '*' udev.env /sys/class/net/eth0

salt.modules.udev.exportdb()
    Return all the udev database

    CLI Example:
    salt '*' udev.exportdb

salt.modules.udev.info(dev)
    Extract all info delivered by udevadm

    CLI Example:
    salt '*' udev.info /dev/sda
    salt '*' udev.info /sys/class/net/eth0

salt.modules.udev.links(dev)
    Return all udev-created device symlinks

    CLI Example:
    salt '*' udev.links /dev/sda
    salt '*' udev.links /sys/class/net/eth0

salt.modules.udev.name(dev)
    Return the actual dev name(s?) according to udev for dev

    CLI Example:
    salt '*' udev.dev /dev/sda
    salt '*' udev.dev /sys/class/net/eth0

salt.modules.udev.path(dev)
    Return the physical device path(s?) according to udev for dev

    CLI Example:
    salt '*' udev.path /dev/sda
    salt '*' udev.path /sys/class/net/eth0
```
to start on boot. For example, see the "start on" condition for the lightdm service below[2]. And this would be too hard. So we wait until the upstart developers have solved this problem. :) This is to say that an Upstart service that is enabled may not really be enabled.

Also, when an Upstart service is enabled, should the dependent services be enabled too? Probably not. But there should be a notice about this, at least.

[2] example upstart configuration file:

```
lighdm
emits login-session-start
emits desktop-session-start
emits desktop-shutdown
start on ((((filesystem and runlevel ![06]) and started dbus) and (drm-device-added ! card0 PRIMARY_DEVICE_FOR_DISPLAY=1 or stopped udev-fallback-graphics)) or runlevel ! PREVLEVEL=S)
stop on runlevel [016]
```

**Warning:** This module should not be used on Red Hat systems. For these, the rh_service module should be used, as it supports the hybrid upstart/sysvinit system used in RHEL/CentOS 6.

salt.modules.upstart.available(name)

Returns True if the specified service is available, otherwise returns False.

CLI Example:
```
salt '*' service.available sshd
```

salt.modules.upstart.disable(name, **kwargs)

Disable the named service from starting on boot

CLI Example:
```
salt '*' service.disable <service name>
```

salt.modules.upstart.disabled(name)

Check to see if the named service is disabled to start on boot

CLI Example:
```
salt '*' service.disabled <service name>
```

salt.modules.upstart.enable(name, **kwargs)

Enable the named service to start at boot

CLI Example:
```
salt '*' service.enable <service name>
```

salt.modules.upstart.enabled(name, **kwargs)

Check to see if the named service is enabled to start on boot

CLI Example:
```
salt '*' service.enabled <service name>
```
salt.modules.upstart\texttt{.force\_reload}(\texttt{name})\n
Force-reload the named service

CLI Example:
```
salt `*` service.force_reload <service name>
```

salt.modules.upstart\texttt{.full\_restart}(\texttt{name})

Do a full restart (stop/start) of the named service

CLI Example:
```
salt `*` service.full_restart <service name>
```

salt.modules.upstart\texttt{.get\_all}()

Return all installed services

CLI Example:
```
salt `*` service.get_all
```

salt.modules.upstart\texttt{.get\_disabled}()

Return the disabled services

CLI Example:
```
salt `*` service.get_disabled
```

salt.modules.upstart\texttt{.get\_enabled}()

Return the enabled services

CLI Example:
```
salt `*` service.get_enabled
```

salt.modules.upstart\texttt{.missing}(\texttt{name})

The inverse of service\texttt{.available}. Returns True if the specified service is not available, otherwise returns False.

CLI Example:
```
salt `*` service.missing sshd
```

salt.modules.upstart\texttt{.reload\_}(\texttt{name})

Reload the named service

CLI Example:
```
salt `*` service.reload <service name>
```

salt.modules.upstart\texttt{.restart}(\texttt{name})

Restart the named service

CLI Example:
```
salt `*` service.restart <service name>
```

salt.modules.upstart\texttt{.start}(\texttt{name})

Start the specified service

CLI Example:
salt 'salt '*' service.start <service name>

salt.modules.upstart.status(name, sig=None)

Return the status for a service, returns a bool whether the service is running.

CLI Example:
salt 'salt '*' service.status <service name>

salt.modules.upstart.stop(name)

Stop the specified service

CLI Example:
salt 'salt '*' service.stop <service name>

19.9.401 salt.modules.uptime

Wrapper around uptime API

salt.modules.uptime.check_exists(name)

Check if a given URL is in being monitored by uptime

CLI Example:
salt 'salt '*' uptime.check_exists http://example.org

salt.modules.uptime.checks_list()

List URL checked by uptime

CLI Example:
salt 'salt '*' uptime.checks_list

salt.modules.uptime.create(name, **params)

Create a check on a given URL.

Additional parameters can be used and are passed to API (for example interval, maxTime, etc). See the documentation https://github.com/fzaninotto/uptime for a full list of the parameters.

CLI Example:
salt 'salt '*' uptime.create http://example.org

salt.modules.uptime.delete(name)

Delete a check on a given URL

CLI Example:
salt 'salt '*' uptime.delete http://example.org

19.9.402 salt.modules.useradd

Manage users with the useradd command
Important: If you feel that Salt should be using this module to manage users on a minion, and it is using a different module (or gives an error similar to 'user.info' is not available), see here.

salt.modules.useradd.add(name, uid=None, gid=None, groups=None, home=None, shell=None, unique=True, system=False, fullname='', roomnumber='', workphone='', homephone='', createhome=True, loginclass=None, root=None, nologinit=False)

Add a user to the minion

CLI Example:

```
salt '*' user.add name <uid> <gid> <groups> <home> <shell>
```

salt.modules.useradd.chfullname(name, fullname)

Change the user's Full Name

CLI Example:

```
salt '*' user.chfullname foo "Foo Bar"
```

salt.modules.useradd.chgid(name, gid, root=None)

Change the default group of the user

CLI Example:

```
salt '*' user.chgid foo 4376
```

salt.modules.useradd.chgroups(name, groups, append=False, root=None)

Change the groups to which this user belongs

name User to modify
groups Groups to set for the user
append [False] If True, append the specified group(s). Otherwise, this function will replace the user's groups with the specified group(s).

CLI Examples:

```
salt '*' user.chgroups foo wheel,root
salt '*' user.chgroups foo wheel,root append=True
```

salt.modules.useradd.chhome(name, home, persist=False, root=None)

Change the home directory of the user, pass True for persist to move files to the new home directory if the old home directory exist.

CLI Example:

```
salt '*' user.chhome foo /home/users/foo True
```

salt.modules.useradd.chhomephone(name, homephone)

Change the user's Home Phone

CLI Example:

```
salt '*' user.chhomephone foo 7735551234
```

salt.modules.useradd.chloginclass(name, loginclass, root=None)

Change the default login class of the user
### Note: This function only applies to OpenBSD systems.

**salt.modules.useradd.chloginclass**

**name, roomnumber**

Change the user's Room Number

**CLI Example:**

```
salt '*' user.chloginclass foo staff
```

**salt.modules.useradd.chroomnumber**

**name, roomnumber**

Change the user's Room Number

**CLI Example:**

```
salt '*' user.chroomnumber foo 123
```

**salt.modules.useradd.chshell**

**name, shell, root=None**

Change the default shell of the user

**CLI Example:**

```
salt '*' user.chshell foo /bin/zsh
```

**salt.modules.useradd.chuid**

**name, uid**

Change the uid for a named user

**CLI Example:**

```
salt '*' user.chuid foo 4376
```

**salt.modules.useradd.chworkphone**

**name, workphone**

Change the user's Work Phone

**CLI Example:**

```
salt '*' user.chworkphone foo 7735550123
```

**salt.modules.useradd.delete**

**name, remove=False, force=False, root=None**

Remove a user from the minion

**CLI Example:**

```
salt '*' user.delete name remove=True force=True
```

**salt.modules.useradd.get_loginclass**

**name**

Get the login class of the user

**Note: This function only applies to OpenBSD systems.**

**CLI Example:**

```
salt '*' user.get_loginclass foo
```

**salt.modules.useradd.getent**

**refresh=False**

Return the list of all info for all users

**CLI Example:**

```
```
salt '*/' user.getent

salt.modules.useradd.info(name)
Return user information
CLI Example:
salt '*/' user.info root

salt.modules.useradd.list_groups(name)
Return a list of groups the named user belongs to
CLI Example:
salt '*/' user.list_groups foo

salt.modules.useradd.list_users()
Return a list of all users
CLI Example:
salt '*/' user.list_users

salt.modules.useradd.primary_group(name)
Return the primary group of the named user
New in version 2016.3.0.
CLI Example:
salt '*/' user.primary_group saltadmin

salt.modules.useradd.rename(name, new_name, root=None)
Change the username for a named user
CLI Example:
salt '*/' user.rename name new_name

19.9.403 salt.modules.uwsgi

Maintainer Peter Baumgartner <pete@lincolnloop.com>
Maturity new
Platform all

salt.modules.uwsgi.stats(socket)
Return the data from uwsgi --connect-and-read as a dictionary.
socket The socket the uWSGI stats server is listening on
CLI Example:
salt '*/' uwsgi.stats /var/run/mystatsserver.sock
salt '*/' uwsgi.stats 127.0.0.1:5050

2196 Chapter 19. Salt Module Reference
19.9.404 salt.modules.varnish

Support for Varnish

New in version 2014.7.0.

**Note:** These functions are designed to work with all implementations of Varnish from 3.x onwards

```
salt.modules.varnish.ban(ban_expression)
    Add ban to the varnish cache
    CLI Example:
    salt '*' varnish.ban ban_expression
```

```
salt.modules.varnish.ban_list()
    List varnish cache current bans
    CLI Example:
    salt '*' varnish.ban_list
```

```
salt.modules.varnish.param_set(param, value)
    Set a param in varnish cache
    CLI Example:
    salt '*' varnish.param_set param value
```

```
salt.modules.varnish.param_show(param=None)
    Show params of varnish cache
    CLI Example:
    salt '*' varnish.param_show param
```

```
salt.modules.varnish.purge()
    Purge the varnish cache
    CLI Example:
    salt '*' varnish.purge
```

```
salt.modules.varnish.version()
    Return server version from varnishd -V
    CLI Example:
    salt '*' varnish.version
```

19.9.405 salt.modules.vault module

maintainer SaltStack
maturity new
platform all
Functions to interact with Hashicorp Vault.

**configuration** The salt-master must be configured to allow peer-runner configuration, as well as configuration for the module.

Add this segment to the master configuration file, or `/etc/salt/master.d/vault.conf`:

```yaml
vault:
  url: https://vault.service.domain:8200
  auth:
    method: token
    token: 11111111-2222-3333-4444-555555555555
  policies:
    - saltstack/minions
    - saltstack/minion/{minion}
    .. more policies
```

- **url** Url to your Vault installation. Required.
- **auth** Currently only token auth is supported. The token must be able to create tokens with the policies that should be assigned to minions. Required.
- **policies** Policies that are assigned to minions when requesting a token. These can either be static, eg saltstack/minions, or templated, eg saltstack/minion/{minion}. {minion} is shorthand for grains[id]. Grains are also available, for example like this: my-policies/[grains[os]]

  If a template contains a grain which evaluates to a list, it will be expanded into multiple policies. For example, given the template saltstack/by-role/{grains[roles]}, and a minion having these grains:

  The minion will have the policies saltstack/by-role/web and saltstack/by-role/database. Note however that list members which do not have simple string representations, such as dictionaries or objects, do not work and will throw an exception. Strings and numbers are examples of types which work well.

  Optional. If policies is not configured, saltstack/minions and saltstack/{minion} are used as defaults.

Add this segment to the master configuration file, or `/etc/salt/master.d/peer_run.conf`:

```yaml
peer_run:
  .*:
    - vault.generate_token
```

salt.modules.vault.delete_secret(path)

Delete secret at the path in vault. The vault policy used must allow this.

CLI Example:

```
salt '*' vault.delete_secret "secret/my/secret"
```

salt.modules.vault.list_secrets(path)

List secret keys at the path in vault. The vault policy used must allow this. The path should end with a trailing slash.

CLI Example:

```
salt '*' vault.list_secrets "secret/my/"
```
salt.modules.vault.read_secret(path, key=None)
Return the value of key at path in vault, or entire secret

Jinja Example:

```
my-secret: {{ salt['vault'].read_secret('secret/my/secret', 'some-key') }}
```

```
{% set supersecret = salt['vault'].read_secret('secret/my/secret') %}
secrets:
  first: {{ supersecret.first }}
  second: {{ supersecret.second }}
```

salt.modules.vault.write_secret(path, **kwargs)
Set secret at the path in vault. The vault policy used must allow this.

CLI Example:

```
salt '*' vault.write_secret "secret/my/secret" user="foo" password="bar"
```

19.9.406  salt.modules.vbox_guest

VirtualBox Guest Additions installer

salt.modules.vbox_guest.additions_install(*args, **kwargs)
Install VirtualBox Guest Additions. Uses the CD, connected by VirtualBox.

To connect VirtualBox Guest Additions via VirtualBox graphical interface press `Host+D` (`Host` is usually `Right Ctrl`).

See [https://www.virtualbox.org/manual/ch04.html#idp52733088](https://www.virtualbox.org/manual/ch04.html#idp52733088) for more details.

CLI Example:

```
salt '*' vbox_guest.additions_install
salt '*' vbox_guest.additions_install reboot=True
salt '*' vbox_guest.additions_install upgrade_os=True
```

Parameters

- reboot (bool) -- reboot computer to complete installation
- upgrade_os (bool) -- upgrade OS (to ensure the latests version of kernel and developer tools are installed)

Returns version of VirtualBox Guest Additions or string with error

salt.modules.vbox_guest.additions_mount()
Mount VirtualBox Guest Additions CD to the temp directory.

To connect VirtualBox Guest Additions via VirtualBox graphical interface press `Host+D` (`Host` is usually `Right Ctrl`).

CLI Example:

```
salt '*' vbox_guest.additions_mount
```

Returns True or OSError exception

salt.modules.vbox_guest.additions_remove(**kwargs)
Remove VirtualBox Guest Additions.

Firstly it tries to uninstall itself by executing `/opt/VBoxGuestAdditions-VERSION/uninstall.run uninstall`. It uses the CD, connected by VirtualBox if it fails.
CLI Example:

```
salt '*' vbox_guest.additions_remove
salt '*' vbox_guest.additions_remove force=True
```

Parameters **force** *(bool)* -- force VirtualBox Guest Additions removing

Returns True if VirtualBox Guest Additions were removed successfully else False

salt.modules.vbox_guest.additions_umount *(mount_point)*

Unmount VirtualBox Guest Additions CD from the temp directory.

CLI Example:

```
salt '*' vbox_guest.additions_umount
```

Parameters **mount_point** -- directory VirtualBox Guest Additions is mounted to

Returns True or an string with error

salt.modules.vbox_guest.additions_version *

Check VirtualBox Guest Additions version.

CLI Example:

```
salt '*' vbox_guest.additions_version
```

Returns version of VirtualBox Guest Additions or False if they are not installed

salt.modules.vbox_guest.grant_access_to_shared_folders_to *(name, users=None)*

Grant access to auto-mounted shared folders to the users.

User is specified by it's name. To grant access for several users use argument *users*. Access will be denied to the users not listed in *users* argument.

CLI Example:

```
salt '*' vbox_guest.grant_access_to_shared_folders_to fred
salt '*' vbox_guest.grant_access_to_shared_folders_to users ['fred', 'roman']
```

Parameters

- **name** *(str)* -- name of the user to grant access to auto-mounted shared folders to
- **users** *(list of str)* -- list of names of users to grant access to auto-mounted shared folders to (if specified, *name* will not be taken into account)

Returns list of users who have access to auto-mounted shared folders

salt.modules.vbox_guest.list_shared_folders_users *

List users who have access to auto-mounted shared folders.

CLI Example:

```
salt '*' vbox_guest.list_shared_folders_users
```

Returns list of users who have access to auto-mounted shared folders

19.9.407 salt.modules.vboxmanage module

Support for VirtualBox using the VBoxManage command
New in version 2016.3.0.

If the `vboxdrv` kernel module is not loaded, this module can automatically load it by configuring `autotoload_vboxdrv` in `/etc/salt/minion`:

The default for this setting is `False`.

**depends** virtualbox

```
salt.modules.vboxmanage.clonemedium(medium, uuid_in=None, file_in=None, uuid_out=None, file_out=None, mformat=None, variant=None, existing=False, **kwargs)
```

Clone a new VM from an existing VM

CLI Example:

```
salt 'hypervisor' vboxmanage.clonemedium <name> <new_name>
```

```
salt.modules.vboxmanage.clonevm(name=None, uuid=None, new_name=None, snapshot_uuid=None, snapshot_name=None, mode='machine', options=None, basefolder=None, new_uuid=None, register=False, groups=None, **kwargs)
```

Clone a new VM from an existing VM

CLI Example:

```
salt 'hypervisor' vboxmanage.clonevm <name> <new_name>
```

```
salt.modules.vboxmanage.create(name, groups=None, ostype=None, register=True, basefolder=None, new_uuid=None, **kwargs)
```

Create a new VM

CLI Example:

```
salt 'hypervisor' vboxmanage.create <name>
```

```
salt.modules.vboxmanage.destroy(name)
```

Unregister and destroy a VM

CLI Example:

```
salt '*' vboxmanage.destroy my_vm
```

```
salt.modules.vboxmanage.list_items(item, details=False, group_by='UUID')
```

Return a list of a specific type of item. The following items are available:

- vms
- runningvms
- ostypes
- hostdvds
- hostfloppies
- innets
- bridgedifs
- hostonlyifs
- natnets
- dhcpservers
- hostinfo
- hostcpuids
- hddbackends
- hdds
- dvds
- floppies
- usbhost
- usbfilters
- systemproperties
- extpacks
- groups
- webcams
- screenshotformats

CLI Example:

```
salt 'hypervisor' vboxmanage.items <item>
salt 'hypervisor' vboxmanage.items <item> details=True
salt 'hypervisor' vboxmanage.items <item> details=True group_by='Name'
```

Some items do not display well, or at all, unless `details` is set to `True`. By default, items are grouped by the UUID field, but not all items contain that field. In those cases, another field must be specified.

```
salt.modules.vboxmanage.list_nodes() 
```

Return a list of registered VMs

CLI Example:
salt '*' vboxmanage.list_nodes

salt.modules.vboxmanage.list_nodes_full()
   Return a list of registered VMs, with detailed information
   CLI Example:
   salt '*' vboxmanage.list_nodes_full

salt.modules.vboxmanage.list_nodes_min()
   Return a list of registered VMs, with minimal information
   CLI Example:
   salt '*' vboxmanage.list_nodes_min

salt.modules.vboxmanage.list_ostypes()
   List the available OS Types
   CLI Example:
   salt '*' vboxmanage.list_ostypes

salt.modules.vboxmanage.register(filename)
   Register a VM
   CLI Example:
   salt '*' vboxmanage.register my_vm_filename

salt.modules.vboxmanage.start(name)
   Start a VM
   CLI Example:
   salt '*' vboxmanage.start my_vm

salt.modules.vboxmanage.stop(name)
   Stop a VM
   CLI Example:
   salt '*' vboxmanage.stop my_vm

salt.modules.vboxmanage.unregister(name, delete=False)
   Unregister a VM
   CLI Example:
   salt '*' vboxmanage.unregister my_vm_filename

salt.modules.vboxmanage.vboxcmd()
   Return the location of the VBoxManage command
   CLI Example:
   salt '*' vboxmanage.vboxcmd
19.9.408 salt.modules.victorops

Support for VictorOps

New in version 2015.8.0.

Requires an api_key in /etc/salt/minion:

```
salt.modules.victorops.create_event(message_type=None, routing_key='everybody', **kwargs)
```

Create an event in VictorOps. Designed for use in states.

The following parameters are required:

- **message_type** -- One of the following values: INFO, WARNING, ACKNOWLEDGEMENT, CRITICAL, RECOVERY.

The following parameters are optional:

- **routing_key** -- The key for where messages should be routed. By default, sent to `everyone` route.
- **entity_id** -- The name of alerting entity. If not provided, a random name will be assigned.
- **timestamp** -- Timestamp of the alert in seconds since epoch. Defaults to the time the alert is received at VictorOps.

:func:`timestamp_fmt` The date format for the timestamp parameter.

- **state_start_time** -- The time this entity entered its current state (seconds since epoch). Defaults to the time alert is received.
- **state_start_time_fmt** -- The date format for the timestamp parameter.
- **state_message** -- Any additional status information from the alert item.
- **entity_is_host** -- Used within VictorOps to select the appropriate display format for the incident.
- **entity_display_name** -- Used within VictorOps to display a human-readable name for the entity.
- **ack_message** -- A user entered comment for the acknowledgment.
- **ack_author** -- The user that acknowledged the incident.

Returns A dictionary with result, entity_id, and message if result was failure.

CLI Example:

```
salt myminion victorops.create_event message_type='CRITICAL' routing_key='everyone'
entity_id='hostname/diskspace'
salt myminion victorops.create_event message_type='ACKNOWLEDGEMENT' routing_key='everyone'
entity_id='hostname/diskspace' ack_message='Acknowledged' ack_author='username'
salt myminion victorops.create_event message_type='RECOVERY' routing_key='everyone'
entity_id='hostname/diskspace'
```

The following parameters are required: message_type

19.9.409 salt.modules.virt

Work with virtual machines managed by libvirt

```
depends libvirt Python module
```

```
salt.modules.virt.cpu_baseline(full=False, migratable=False, out='libvirt')
```

Return the optimal `custom` CPU baseline config for VM's on this minion
New in version 2016.3.0.

Parameters

- **full** -- Return all CPU features rather than the ones on top of the closest CPU model
- **migratable** -- Exclude CPU features that are unmigratable (libvirt 2.13+)
- **out** -- `libvirt` (default) for usable libvirt XML definition, `salt` for nice dict

CLI Example:

```
salt '*' virt.cpu_baseline
```

salt.modules.virt.create_xml_path(path)
Start a domain based on the XML-file path passed to the function

CLI Example:

```
salt '*' virt.create_xml_path <path to XML file on the node>
```

salt.modules.virt.create_xml_str(xml)
Start a domain based on the XML passed to the function

CLI Example:

```
salt '*' virt.create_xml_str <XML in string format>
```

salt.modules.virt.ctrl_alt_del(vm_)
Sends CTRL+ALT+DEL to a VM

CLI Example:

```
salt '*' virt.ctrl_alt_del <domain>
```

salt.modules.virt.define_vol_xml_path(path)
Define a volume based on the XML-file path passed to the function

CLI Example:

```
salt '*' virt.define_vol_xml_path <path to XML file on the node>
```

salt.modules.virt.define_vol_xml_str(xml)
Define a volume based on the XML passed to the function

CLI Example:

```
salt '*' virt.define_vol_xml_str <XML in string format>
```

salt.modules.virt.define_xml_path(path)
Define a domain based on the XML-file path passed to the function

CLI Example:

```
salt '*' virt.define_xml_path <path to XML file on the node>
```

salt.modules.virt.define_xml_str(xml)
Define a domain based on the XML passed to the function

CLI Example:

```
salt '*' virt.define_xml_str <XML in string format>
```
salt.modules.virt.delete_snapshots(name, *names, **kwargs)
Delete one or more snapshots of the given VM.

Options:
*all*: Remove all snapshots. Values: True or False (default False).
New in version 2016.3.0.

CLI Example:
```
salt '*' virt.delete_snapshots <domain> all=True
salt '*' virt.delete_snapshots <domain> <snapshot>
salt '*' virt.delete_snapshots <domain> <snapshot1> <snapshot2> ...
```

salt.modules.virt.freecpu()
Return an int representing the number of unallocated cpus on this hypervisor

CLI Example:
```
salt '*' virt.freecpu
```

salt.modules.virt.freemem()
Return an int representing the amount of memory (in MB) that has not been given to virtual machines on this node

CLI Example:
```
salt '*' virt.freemem
```

salt.modules.virt.full_info()
Return the node_info, vm_info and freemem

CLI Example:
```
salt '*' virt.full_info
```

salt.modules.virt.get_disks(vm_)
Return the disks of a named vm

CLI Example:
```
salt '*' virt.get_disks <domain>
```

salt.modules.virt.get_graphics(vm_)
Returns the information on vnc for a given vm

CLI Example:
```
salt '*' virt.get_graphics <vm>
```

salt.modules.virt.get_macs(vm_)
Return a list off MAC addresses from the named vm

CLI Example:
```
salt '*' virt.get_macs <domain>
```

salt.modules.virt.get_nics(vm_)
Return info about the network interfaces of a named vm

CLI Example:
salt '*' virt.get_nics <domain>

```
salt.modules.virt.get_profiles(hypervisor=None)
Return the virt profiles for hypervisor.
Currently there are profiles for:
  • nic
  • disk
CLI Example:
salt '*' virt.get_profiles
salt '*' virt.get_profiles hypervisor=esxi
```

salt.modules.virt.get_xml(vm_)
Returns the XML for a given vm
CLI Example:
salt '*' virt.get_xml <domain>

salt.modules.virt.init(name, cpu, mem, image=None, nic='default', hypervisor='kvm',
start=True, disk='default', saltenv='base', seed=True, install=True,
pub_key=None, priv_key=None, seed_cmd='seed.apply', enable_vnc=False,
enable_qcow=False, **kwargs)
Initialize a new vm
CLI Example:
salt 'hypervisor' virt.init vm_name 4 512 salt://path/to/image.raw
salt 'hypervisor' virt.init vm_name 4 512 /var/lib/libvirt/images/img.raw
salt 'hypervisor' virt.init vm_name 4 512 nic=profile disk=profile

salt.modules.virt.is_hyper()
Returns a bool whether or not this node is a hypervisor of any kind
CLI Example:
salt '*' virt.is_hyper

salt.modules.virt.is_kvm_hyper()
Returns a bool whether or not this node is a KVM hypervisor
CLI Example:
salt '*' virt.is_kvm_hyper

salt.modules.virt.is_xen_hyper()
Returns a bool whether or not this node is a XEN hypervisor
CLI Example:
salt '*' virt.is_xen_hyper

salt.modules.virt.list_active_vms()
Return a list of names for active virtual machine on the minion
CLI Example:
salt '*' virt.list_active_vms

```
salt.modules.virt.list_domains()
    Return a list of available domains.
    CLI Example:
    salt '*' virt.list_domains
```

salt.modules.virt.list_inactive_vms()
    Return a list of names for inactive virtual machine on the minion
    CLI Example:
    salt '*' virt.list_inactive_vms

salt.modules.virt.list_snapshots(domain=None)
    List available snapshots for certain vm or for all.
    New in version 2016.3.0.
    CLI Example:
    salt '*' virt.list_snapshots
    salt '*' virt.list_snapshots <domain>

salt.modules.virt.migrate(vm_, target, ssh=False)
    Shared storage migration
    CLI Example:
    salt '*' virt.migrate <domain> <target hypervisor>

salt.modules.virt.migrate_non_shared(vm_, target, ssh=False)
    Attempt to execute non-shared storage "all" migration
    CLI Example:
    salt '*' virt.migrate_non_shared <vm name> <target hypervisor>

salt.modules.virt.migrate_non_shared_inc(vm_, target, ssh=False)
    Attempt to execute non-shared storage "all" migration
    CLI Example:
    salt '*' virt.migrate_non_shared_inc <vm name> <target hypervisor>

salt.modules.virt.node_info()
    Return a dict with information about this node
    CLI Example:
    salt '*' virt.node_info

salt.modules.virt.pause(vm_)
    Pause the named vm
    CLI Example:
salt 'x' virt.pause <domain>

**salt.modules.virt.purge**(vm_, dirs=False)
Recursively destroy and delete a virtual machine, pass True for dir's to also delete the directories containing the virtual machine disk images - USE WITH EXTREME CAUTION!

CLI Example:
```
salt 'x' virt.purge <domain>
```

salt.modules.virt.reboot(name)
Reboot a domain via ACPI request

CLI Example:
```
salt 'x' virt.reboot <domain>
```

salt.modules.virt.reset(vm_)
Reset a VM by emulating the reset button on a physical machine

CLI Example:
```
salt 'x' virt.reset <domain>
```

salt.modules.virt.resume(vm_)
Resume the named vm

CLI Example:
```
salt 'x' virt.resume <domain>
```

salt.modules.virt.revert_snapshot(name, snapshot=None, cleanup=False)
Revert snapshot to the previous from current (if available) or to the specific.

Options:
- **cleanup**: Remove all newer than reverted snapshots. Values: True or False (default False).
New in version 2016.3.0.

CLI Example:
```
salt 'x' virt.revert <domain>
salt 'x' virt.revert <domain> <snapshot>
```

salt.modules.virt.seed_non_shared_migrate(disks, force=False)
Non shared migration requires that the disks be present on the migration destination, pass the disks information via this function, to the migration destination before executing the migration.

CLI Example:
```
salt 'x' virt.seed_non_shared_migrate <disks>
```

salt.modules.virt.set_autostart(vm_, state='on')
Set the autostart flag on a VM so that the VM will start with the host system on reboot.

CLI Example:
```
salt "x" virt.set_autostart <domain> <on | off>
```
salt.modules.virt.setmem(*vm_, memory, config=False*)
Changes the amount of memory allocated to VM. The VM must be shutdown for this to work.
memory is to be specified in MB If config is True then we ask libvirt to modify the config as well
CLI Example:
```
salt '*' virt.setmem <domain> <size>
salt '*' virt.setmem my_domain 768
```

salt.modules.virt.setvcpus(*vm_, vcpus, config=False*)
Changes the amount of vcpus allocated to VM. The VM must be shutdown for this to work.
vcpus is an int representing the number to be assigned If config is True then we ask libvirt to modify the config as well
CLI Example:
```
salt '*' virt.setvcpus <domain> <amount>
salt '*' virt.setvcpus my_domain 4
```

salt.modules.virt.shutdown(*vm_*)
Send a soft shutdown signal to the named vm
CLI Example:
```
salt '*' virt.shutdown <domain>
```

salt.modules.virt.snapshot(domain, name=None, suffix=None)
Create a snapshot of a VM.
Options:
- **name**: Name of the snapshot. If the name is omitted, then will be used original domain name with ISO 8601 time as a suffix.
- **suffix**: Add suffix for the new name. Useful in states, where such snapshots can be distinguished from manually created.
New in version 2016.3.0.
CLI Example:
```
salt '*' virt.snapshot <domain>
```

salt.modules.virt.start(name)
Start a defined domain
CLI Example:
```
salt '*' virt.start <domain>
```

salt.modules.virt.stop(name)
Hard power down the virtual machine, this is equivalent to pulling the power.
CLI Example:
```
salt '*' virt.stop <domain>
```

salt.modules.virt.undefine(*vm_*)
Remove a defined vm, this does not purge the virtual machine image, and this only works if the vm is powered down
CLI Example:
salt '*' virt.undefine <domain>

salt.modules.virt.virt_type()

Returns the virtual machine type as a string

CLI Example:

salt '*' virt.virt_type

salt.modules.virt.vm_cputime(vm_=None)

Return cputime used by the vms on this hyper in a list of dicts:

```
[    
  'your-vm': {   
      'cputime' <int>,   
      'cputime_percent' <int>
  },
...
]
```

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

salt '*' virt.vm_cputime

salt.modules.virt.vm_diskstats(vm_=None)

Return disk usage counters used by the vms on this hyper in a list of dicts:

```
[    
  'your-vm': {   
      'rd_req' : 0,   
      'rd_bytes' : 0,   
      'wr_req' : 0,   
      'wr_bytes' : 0,   
      'errs' : 0
  },
...
]
```

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

salt '*' virt.vm_blockstats

salt.modules.virt.vm_info(vm_=None)

Return detailed information about the vms on this hyper in a list of dicts:

```
[    
  'your-vm': {   
      'cpu': <int>,   
      'maxMem': <int>,   
      'mem': <int>,   
      'state': '<state>',   
      'cputime' <int>
  },
...]
```
If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```
salt '*' virt.vm_info
```

salt.modules.virt.vm_netstats(vm_=None)

Return combined network counters used by the vms on this hyper in a list of dicts:

```
[
    'your-vm': {
        'rx_bytes': 0,
        'rx_packets': 0,
        'rx_errs': 0,
        'rx_drop': 0,
        'tx_bytes': 0,
        'tx_packets': 0,
        'tx_errs': 0,
        'tx_drop': 0
    },
    ...
]
```

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```
salt '*' virt.vm_netstats
```

salt.modules.virt.vm_state(vm_=None)

Return list of all the vms and their state.

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```
salt '*' virt.vm_state <domain>
```

19.9.410 salt.modules.virtualenv

Create virtualenv environments.

New in version 0.17.0.

salt.modules.virtualenv_mod.create(path, venv_bin=None, system_site_packages=False, distribute=False, clear=False, python=None, extra_search_dir=None, never_download=None, prompt=None, pip=False, symlinks=None, upgrade=None, user=None, use_vt=False, saltenv='base', **kwargs)

Create a virtualenv

path The path to the virtualenv to be created

19.9. execution modules
venv_bin  The name (and optionally path) of the virtualenv command. This can also be set globally in the
minion config file as virtualenv.venv_bin. Defaults to virtualenv.

system_site_packages  [False] Passthrough argument given to virtualenv or pyvenv

distribute  [False] Passthrough argument given to virtualenv

pip  [False] Install pip after creating a virtual environment. Implies distribute=True

clear  [False] Passthrough argument given to virtualenv or pyvenv

python  [None (default)] Passthrough argument given to virtualenv

extra_search_dir  [None (default)] Passthrough argument given to virtualenv

never_download  [None (default)] Passthrough argument given to virtualenv if True

prompt  [None (default)] Passthrough argument given to virtualenv if not None

symlinks  [None] Passthrough argument given to pyvenv if True

upgrade  [None] Passthrough argument given to pyvenv if True

user  [None] Set ownership for the virtualenv

Note:  On Windows you must also pass a password parameter. Additionally, the user must have
permissions to the location where the virtual environment is being created

runas  [None] Set ownership for the virtualenv

use_vt  [False] Use VT terminal emulation (see output while installing)

New in version 2015.5.0.

saltenv  ['base'] Specify a different environment. The default environment is base.

New in version 2014.1.0.

Note:  The runas argument is deprecated as of 2014.1.0. user should be used instead.

CLI Example:

```bash
salt '*' virtualenv.create /path/to/new/virtualenv
```

salt.modules.virtualenv_mod.get_distribution_path(venv, distribution)

Return the path to a distribution installed inside a virtualenv

New in version 2016.3.0.

venv  Path to the virtualenv.

distribution  Name of the distribution. Note, all non-alphanumeric characters will be converted to dashes.

CLI Example:

```bash
salt '*' virtualenv.get_distribution_path /path/to/my/venv my_distribution
```

salt.modules.virtualenv_mod.get_resource_content(venv, package=None, resource=None)

Return the content of a package resource installed inside a virtualenv

New in version 2015.5.0.

venv  Path to the virtualenv

package  Name of the package in which the resource resides

New in version 2016.3.0.

resource  Name of the resource of which the content is to be returned

New in version 2016.3.0.

CLI Example:
salt.modules.virtualenv_mod.get_resource_path(venv, package=None, resource=None)

Return the path to a package resource installed inside a virtualenv

New in version 2015.5.0.

venv  Path to the virtualenv
package  Name of the package in which the resource resides

New in version 2016.3.0.
resource  Name of the resource of which the path is to be returned

New in version 2016.3.0.

CLI Example:

```
salt '*' virtualenv.get_resource_path /path/to/my/venv my_package my/resource.xml
```

salt.modules.virtualenv_mod.get_site_packages(venv)

Return the path to the site-packages directory of a virtualenv

venv  Path to the virtualenv.

CLI Example:

```
salt '*' virtualenv.get_site_packages /path/to/my/venv
```

19.9.411 salt.modules.vsphere

Manage VMware vCenter servers and ESXi hosts.

New in version 2015.8.4.

codeauthor  Alexandru Bleotu <alexandru.bleotu@morganstaley.com>

Dependencies

- pyVmomi Python Module
- ESXCLI

pyVmomi

PyVmomi can be installed via pip:

```
pip install pyVmomi
```

Note: Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, Python 2.6, Python 2.7.9, or newer must be present. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the following:
pip install pyVmomi==5.5.0.2014.1.1

The 5.5.0.2014.1.1 is a known stable version that this original vSphere Execution Module was developed against.

ESXCLI

Currently, about a third of the functions used in the vSphere Execution Module require the ESXCLI package be installed on the machine running the Proxy Minion process.

The ESXCLI package is also referred to as the VMware vSphere CLI, or vCLI. VMware provides vCLI package installation instructions for vSphere 5.5 and vSphere 6.0.

Once all of the required dependencies are in place and the vCLI package is installed, you can check to see if you can connect to your ESXi host or vCenter server by running the following command:

```
esxcli -s <host-location> -u <username> -p <password> system syslog config get
```

If the connection was successful, ESXCLI was successfully installed on your system. You should see output related to the ESXi host’s syslog configuration.

**Note:** Be aware that some functionality in this execution module may depend on the type of license attached to a vCenter Server or ESXi host(s).

For example, certain services are only available to manipulate service state or policies with a VMware vSphere Enterprise or Enterprise Plus license, while others are available with a Standard license. The ntpd service is restricted to an Enterprise Plus license, while ssh is available via the Standard license.

Please see the vSphere Comparison page for more information.

About

This execution module was designed to be able to handle connections both to a vCenter Server, as well as to an ESXi host. It utilizes the pyVmomi Python library and the ESXCLI package to run remote execution functions against either the defined vCenter server or the ESXi host.

Whether or not the function runs against a vCenter Server or an ESXi host depends entirely upon the arguments passed into the function. Each function requires a host location, username, and password. If the credentials provided apply to a vCenter Server, then the function will be run against the vCenter Server. For example, when listing hosts using vCenter credentials, you’ll get a list of hosts associated with that vCenter Server:

```
# salt my-minion vsphere.list_hosts <vcenter-ip> <vcenter-user> <vcenter-password>
```

```
my-minion:
- esxi-1.example.com
- esxi-2.example.com
```

However, some functions should be used against ESXi hosts, not vCenter Servers. Functionality such as getting a host’s coredump network configuration should be performed against a host and not a vCenter server. If the authentication information you’re using is against a vCenter server and not an ESXi host, you can provide the host name that is associated with the vCenter server in the command, as a list, using the host_names or esxi_host kwarg. For example:

```
# salt my-minion vsphere.get_coredump_network_config <vcenter-ip> <vcenter-user> <vcenter-password> esxi_hosts=['esxi-1.example.com', 'esxi-2.example.com']
```
esxi-1.example.com:
----------
Coredump Config:
----------
enabled:
False
esxi-2.example.com:
----------
Coredump Config:
----------
enabled:
True
host_vnic:
  vmk0
ip:
coredump-location.example.com
port:
  6500

You can also use these functions against an ESXi host directly by establishing a connection to an ESXi host using the host’s location, username, and password. If ESXi connection credentials are used instead of vCenter credentials, the host_names and esxi_hosts arguments are not needed.

```
# salt my-minion vsphere.get_coredump_network_config esxi-1.example.com root <host-,
password>
local:
----------
10.4.28.150:
----------
Coredump Config:
----------
enabled:
True
host_vnic:
  vmk0
ip:
coredump-location.example.com
port:
  6500
```

salt.modules.vsphere.coredump_network_enable(host, username, password, enabled, protocol=None, port=None, esxi_hosts=None, credstore=None)

Enable or disable ESXi core dump collection. Returns True if coredump is enabled and returns False if core dump is not enabled. If there was an error, the error will be the value printed in the Error key dictionary for the given host.

- **host** The location of the host.
- **username** The username used to login to the host, such as root.
- **password** The password used to login to the host.
- **enabled** Python True or False to enable or disable coredumps.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is 443.
- **esxi_hosts** If host is a vCenter host, then use esxi_hosts to execute this function on a list of one or more ESXi machines.
- **credstore** Optionally set to path to the credential store file.
CLI Example:

```python
salt '*' vsphere.coredump_network_enable my.esxi.host root bad-password True
```

```python
salt '*' vsphere.coredump_network_enable my.vcenter.location root bad-password

# Used for connecting to a vCenter Server
esxi_hosts='[esxi-1.host.com, esxi-2.host.com]'
```

```python
salt.modules.vsphere.disconnect(*args, **kwargs)
```

```python
salt.modules.vsphere.enable_firewall_ruleset(host, username, password, ruleset_enable,

ruleset_name, protocol=None, port=None,

esxi_hosts=None, credstore=None)
```

Enable or disable an ESXi firewall rule set.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as `root`.
- **password**: The password used to login to the host.
- **ruleset_enable**: True to enable the ruleset, false to disable.
- **ruleset_name**: Name of ruleset to target.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is `443`.
- **esxi_hosts**: If `host` is a vCenter host, then use `esxi_hosts` to execute this function on a list of one or more ESXi machines.
- **credstore**: Optionally set to path to the credential store file.

Returns A standard cmd.run_all dictionary, per host.

CLI Example:

```python
salt '*' vsphere.enable_firewall_ruleset my.esxi.host root bad-password True

# Used for ESXi host connection information
syslog
```

```python
salt '*' vsphere.enable_firewall_ruleset my.vcenter.location root bad-password

# Used for connecting to a vCenter Server
esxi_hosts='[esxi-1.host.com, esxi-2.host.com]'
```

```python
salt.modules.vsphere.esxcli_cmd(cmd_str, host=None, username=None, password=None, protocol=None, port=None, esxi_hosts=None, credstore=None)
```

Run an ESXCLI command directly on the host or list of hosts.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as `root`.
- **password**: The password used to login to the host.
- **cmd_str**: The ESXCLI command to run. Note: This should not include the `-s`, `-u`, `-p`, `-h`, `--protocol`, or `--portnumber` arguments that are frequently passed when using a bare ESXCLI command from the command line. Those arguments are handled by this function via the other args and kwargs.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is `443`.
- **esxi_hosts**: If `host` is a vCenter host, then use `esxi_hosts` to execute this function on a list of one or more ESXi machines.
- **credstore**: Optionally set to path to the credential store file.

CLI Example:
# Used for ESXi host connection information
salt '*' vsphere.esxcli_cmd my.esxi.host root bad-password 'system
--coredump network get'

# Used for connecting to a vCenter Server
salt '*' vsphere.esxcli_cmd my.vcenter.location root bad-password
--'system coredump network get' esxi_hosts='[esxi-1.host.com, esxi-2.host.com]'

salt.modules.vsphere.get_coredump_network_config(host, username, password, protocol=None, port=None, esxi_hosts=None, credstore=None)

Retrieve information on ESXi or vCenter network dump collection and format it into a dictionary.

host The location of the host.
username The username used to login to the host, such as root.
password The password used to login to the host.
protocol Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
port Optionally set to alternate port if the host is not using the default port. Default port is 443.
esxi_hosts If host is a vCenter host, then use esxi_hosts to execute this function on a list of one or more ESXi machines.
credstore Optionally set to path to the credential store file.

Returns A dictionary with the network configuration, or, if getting the network config failed, an error message retrieved from the standard cmd.run_all dictionary, per host.

CLI Example:

# Used for ESXi host connection information
salt '*' vsphere.get_coredump_network_config my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.get_coredump_network_config my.vcenter.location root bad-password

salt.modules.vsphere.get_firewall_status(host, username, password, protocol=None, port=None, esxi_hosts=None, credstore=None)

Show status of all firewall rule sets.

host The location of the host.
username The username used to login to the host, such as root.
password The password used to login to the host.
protocol Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
port Optionally set to alternate port if the host is not using the default port. Default port is 443.
esxi_hosts If host is a vCenter host, then use esxi_hosts to execute this function on a list of one or more ESXi machines.
credstore Optionally set to path to the credential store file.

Returns Nested dictionary with two toplevel keys rulesets and success success will be True or False depending on query success rulesets will list the rulesets and their statuses if success was true, per host.

CLI Example:

# Used for ESXi host connection information
salt '*' vsphere.get_firewall_status my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt 'vsphere.get_firewall_status my.vcenter.location root bad-password
  → esxi_hosts='[esxi-1.host.com, esxi-2.host.com]'

salt.modules.vsphere.get_proxy_type()
Returns the proxy type

salt 'vsphere.get_proxy_type

salt.modules.vsphere.get_service_instance_via_proxy(*args, **kwargs)

salt.modules.vsphere.get_service_instance_via_proxy

salt.modules.vsphere.get_syslog_config(host, username, password, protocol=\None,
  port=\None, esxi_hosts=\None, credstore=\None)

Retrieve the syslog configuration.

host The location of the host.
username The username used to login to the host, such as root.
password The password used to login to the host.
protocol Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
port Optionally set to alternate port if the host is not using the default port. Default port is 443.
esxi_hosts If host is a vCenter host, then use esxi_hosts to execute this function on a list of one or more ESXi machines.
credstore Optionally set to path to the credential store file.

Returns Dictionary with keys and values corresponding to the syslog configuration, per host.

CLI Example:

# Used for ESXi host connection information
salt 'vsphere.get_syslog_config my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt 'vsphere.get_syslog_config my.vcenter.location root bad-password
  → esxi_hosts='[esxi-1.host.com, esxi-2.host.com]'

salt.modules.vsphere.get_service_instance_via_proxy(fn)

Decorator that connects to a target system (vCenter or ESXi host) using the proxy details and passes the
connection (vim.ServiceInstance) to the decorated function.

Notes

1. The decorated function must have a service_instance parameter or a **\kwarg type argument
   (name of argument is not important); 2. If the service_instance parameter is already defined, the value
   is passed through to the decorated function; 3. If the service_instance parameter in not defined, the
   connection is created using the proxy details and the service instance is returned.

CLI Example: None, this is a decorator

salt.modules.vsphere.reset_syslog_config(host, username, password, protocol=\None,
  port=\None, syslog_config=\None, esxi_hosts=\None, credstore=\None)

Reset the syslog service to its default settings.

Valid syslog_config values are logdir, loghost, logdir-unique, default-rotate, default-size,
default-timeout, or all for all of these.

host The location of the host.
username The username used to login to the host, such as root.
password  The password used to login to the host.
protocol  Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
port  Optionally set to alternate port if the host is not using the default port. Default port is 443.
syslog_config  List of parameters to reset, provided as a comma-delimited string, or `all' to reset all syslog configuration parameters. Required.
esxi_hosts  If host is a vCenter host, then use esxi_hosts to execute this function on a list of one or more ESXi machines.
credstore  Optionally set to path to the credential store file.

**Returns** Dictionary with a top-level key of `success' which indicates if all the parameters were reset, and individual keys for each parameter indicating which succeeded or failed, per host.

**CLI Example:**

```
syslog_config can be passed as a quoted, comma-separated string, e.g.

# Used for ESXi host connection information
salt '*' vsphere.reset_syslog_config my.esxi.host root bad-password
 =syslog_config='logdir,loghost'

# Used for connecting to a vCenter Server
salt '*' vsphere.reset_syslog_config my.vcenter.location root bad-password
 =syslog_config='logdir,loghost' esxi_hosts='[esxi-1.host.com, esxi-2.host.com]'
```

---

**salt.modules.vsphere.set_coredump_network_config**

```
salt.modules.vsphere.set_coredump_network_config(
    host, username, password, dump_ip,
    protocol=None, port=None,
    host_vnic='vmk0', dump_port=6500,
    esxi_hosts=None, credstore=None)
```

Set the network parameters for a network coredump collection. Note that ESXi requires that the dumps first be enabled (see coredump_network_enable) before these parameters may be set.

- **host**  The location of the host.
- **username**  The username used to login to the host, such as root.
- **password**  The password used to login to the host.
- **dump_ip**  IP address of host that will accept the dump.
- **protocol**  Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- **port**  Optionally set to alternate port if the host is not using the default port. Default port is 443.
- **esxi_hosts**  If host is a vCenter host, then use esxi_hosts to execute this function on a list of one or more ESXi machines.
- **host_vnic**  Host VNic port through which to communicate. Defaults to vmk0.
- **dump_port**  TCP port to use for the dump, defaults to 6500.
- **credstore**  Optionally set to path to the credential store file.

**Returns** A standard cmd.run_all dictionary with a success key added, per host. success will be True if the set succeeded, False otherwise.

**CLI Example:**

```
# Used for ESXi host connection information
salt '*' vsphere.set_coredump_network_config my.esxi.host root bad-password 'dump_ip.host.com'

# Used for connecting to a vCenter Server
salt '*' vsphere.set_coredump_network_config my.vcenter.location root bad-password
  'dump_ip.host.com' esxi_hosts='[esxi-1.host.com, esxi-2.host.com]'
```
salt.modules.vsphere.set_syslog_config(host, username, password, syslog_config, config_value, protocol=None, port=None, firewall=True, reset_service=True, esxi_hosts=None, credstore=None)

Set the specified syslog configuration parameter. By default, this function will reset the syslog service after the configuration is set.

- **host**: ESXi or vCenter host to connect to.
- **username**: User to connect as, usually root.
- **password**: Password to connect with.
- **syslog_config**: Name of parameter to set (corresponds to the command line switch for esxcli without the double dashes (--))
  - Valid syslog_config values are `logdir`, `loghost`, `default-rotate` `,``default-size`, `default-timeout`, and `logdir-unique`.
- **config_value**: Value for the above parameter. For `loghost`, URLs or IP addresses to use for logging. Multiple log servers can be specified by listing them, comma-separated, but without spaces before or after commas.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is `443`.
- **firewall**: Enable the firewall rule set for syslog. Defaults to `True`.
- **reset_service**: After a successful parameter set, reset the service. Defaults to `True`.
- **esxi_hosts**: If `host` is a vCenter host, then use `esxi_hosts` to execute this function on a list of one or more ESXi machines.
- **credstore**: Optionally set to path to the credential store file.

**Returns**: Dictionary with a top-level key of 'success' which indicates if all the parameters were reset, and individual keys for each parameter indicating which succeeded or failed, per host.

**CLI Example**:

```
# Used for ESXi host connection information
salt 'vSphere' vsphere.set_syslog_config my.esxi.host root bad-password
  -> loghost ssl://localhost:5432,tcp://10.1.0.1:1514

# Used for connecting to a vCenter Server
salt 'vSphere' vsphere.set_syslog_config my.vcenter.location root bad-password
  -> loghost ssl://localhost:5432,tcp://10.1.0.1:1514
  -> ['esxi-1.host.com, esxi-2.host.com']
```

salt.modules.vsphere.supports_proxies(proxy_types)

Decorator to specify which proxy types are supported by a function

- **proxy_types**: Arbitrary list of strings with the supported types of proxies

salt.modules.vsphere.syslog_service_reload(host, username, password, protocol=None, port=None, esxi_hosts=None, credstore=None)

Reload the syslog service so it will pick up any changes.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as `root`.
- **password**: The password used to login to the host.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is `443`.
**esxi_hosts** If host is a vCenter host, then use esxi_hosts to execute this function on a list of one or more ESXi machines.

**credstore** Optionally set to path to the credential store file.

**Returns** A standard cmd.run_all dictionary. This dictionary will at least have a `retcode` key. If `retcode` is 0 the command was successful.

CLI Example:

```bash
# Used for ESXi host connection information
salt '*' vsphere.syslog_service_reload my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.syslog_service_reload my.vcenter.location root bad-password
esxi_hosts='[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.test_vcenter_connection(*args, **kwargs)

### 19.9.412 salt.modules.win_autoruns

Module for listing programs that automatically run on startup (very alpha...not tested on anything but my Win 7x64)

salt.modules.win_autoruns.list()

Get a list of automatically running programs

CLI Example:

```bash
salt '*' autoruns.list
```

### 19.9.413 salt.modules.win_certutil module

This module allows you to install certificates into the windows certificate manager.

salt '*' certutil.add_store salt://cert.cer "TrustedPublisher"

salt.modules.certutil.add_store(source, store, saltenv='base')

Add the given cert into the given Certificate Store

- **source** The source certificate file this can be in the form salt://path/to/file
- **store** The certificate store to add the certificate to
- **saltenv** The salt environment to use this is ignored if the path is local

CLI Example:

```bash
salt '*' certutil.add_store salt://cert.cer TrustedPublisher
```

salt.modules.certutil.del_store(source, store, saltenv='base')

Delete the given cert into the given Certificate Store

- **source** The source certificate file this can be in the form salt://path/to/file
- **store** The certificate store to delete the certificate from
- **saltenv** The salt environment to use this is ignored if the path is local

CLI Example:

```bash
salt '*' certutil.del_store salt://cert.cer TrustedPublisher
```

salt.modules.certutil.get_cert_serial(cert_file)

Get the serial number of a certificate file
The certificate file to find the serial for
CLI Example:
```bash
salt '*' certutil.get_cert_serial <certificate name>
```

salt.modules.win_certutil.get_stored_cert_serials(store)
Get all of the certificate serials in the specified store
store The store to get all the certificate serials from
CLI Example:
```bash
salt '*' certutil.get_stored_cert_serials <store>
```

## 19.9.414 salt.modules.win_dacl

Manage DACLs on Windows

depends
  - winreg Python module

salt.modules.win_dacl.add_ace(path, objectType, user, permission, acetype, propagation)
add an ace to an object
  - path: path to the object (i.e. c:\temp\file, HKEY_LOCAL_MACHINE\SOFTWARE\KEY, etc)
  - user: user to add permission
  - permission: permissions for the user
  - acetype: either allow/deny for each user/permission (ALLOW, DENY)
  - propagation: how the ACE applies to children for Registry Keys and Directories (KEY, KEY&SUBKEYS, SUBKEYS)

CLI Example:
```bash
allow domain\fakeuser full control on HKLM\SOFTWARE\somekey, propagate to this key and subkeys
salt 'myminion' win_dacl.add_ace 'HKEY_LOCAL_MACHINE\SOFTWARE\somekey' 'Registry\domain\fakeuser' 'FULLCONTROL' 'ALLOW' 'KEY&SUBKEYS'
```

salt.modules.win_dacl.check_ace(path, objectType, user=None, permission=None, acetype=None, propagation=None, exactPermissionMatch=False)
Checks a path to verify the ACE (access control entry) specified exists
Parameters
  - path -- path to the file/reg key
  - objectType -- The type of object (FILE, DIRECTORY, REGISTRY)
  - user -- user that the ACL is for
  - permission -- permission to test for (READ, FULLCONTROL, etc)
  - acetype -- the type of ACE (ALLOW or DENY)
  - propagation -- the propagation type of the ACE (FILES, FOLDERS, KEY, KEY&SUBKEYS, SUBKEYS, etc)
  - exactPermissionMatch -- the ACL must match exactly, IE if READ is specified, the user must have READ exactly and not FULLCONTROL (which also has the READ permission obviously)

Returns (dict): `Exists' true if the ACE exists, false if it does not

CLI Example:
```bash
salt 'minion-id' win_dacl.check_ace c: emp directory <username> fullcontrol
```

salt.modules.win_dacl.check_inheritance(path, objectType, user=None)
Check a specified path to verify if inheritance is enabled
Parameters

• **path** -- path of the registry key or file system object to check
• **objectType** -- The type of object (FILE, DIRECTORY, REGISTRY)
• **user** -- if provided, will consider only the ACEs for that user

Returns (bool): 'Inheritance' of True/False

CLI Example:
```
salt 'minion-id' win_dacl.check_inheritance c: emp directory <username>
```

class salt.modules.win_dacl.daclConstants
DACL constants used throughout the module

  getAceTypeBit(t)
  returns the acetype bit of a text value

  getAceTypeText(t)
  returns the textual representation of a acetype bit

  getObjectTypeBit(t)
  returns the bit value of the string object type

  getPermissionBit(t, m)
  returns a permission bit of the string permission value for the specified object type

  getPermissionText(t, m)
  returns the permission textual representation of a specified permission bit/object type

  getPropagationBit(t, p)
  returns the propagation bit of a text value

  getPropagationText(t, p)
  returns the textual representation of a propagation bit

  getSecurityHkey(s)
  returns the necessary string value for an HKEY for the win32security module

  processPath(path, objectType)
  processes a path/object type combo and returns: registry types with the correct HKEY text representation files/directories with environment variables expanded

salt.modules.win_dacl.disable_inheritance(path, objectType, copy=True)
Disable inheritance on an object

Parameters

• **path** -- The path to the object
• **objectType** -- The type of object (FILE, DIRECTORY, REGISTRY)
• **copy** -- True will copy the Inherited ACEs to the DACL before disabling inheritance

Returns (dict): A dictionary containing the results

CLI Example:
```
salt 'minion-id' win_dacl.disable_inheritance c: emp directory
```

salt.modules.win_dacl.enable_inheritance(path, objectType, clear=False)
enable/disable inheritance on an object

Parameters

• **path** -- The path to the object
• **objectType** -- The type of object (FILE, DIRECTORY, REGISTRY)
• **clear** -- True will remove non-Inherited ACEs from the ACL
Retruns (dict): A dictionary containing the results

CLI Example:
```
salt 'minion-id' win_dacl.enable_inheritance c: emp directory
```

salt.modules.win_dacl.get(path, objectType, user=None)
Get the ACL of an object. Will filter by user if one is provided.
Parameters
- **path** -- The path to the object
- **objectType** -- The type of object (FILE, DIRECTORY, REGISTRY)
- **user** -- A user name to filter by

Returns (dict): A dictionary containing the ACL

CLI Example:
```
salt 'minion-id' win_dacl.get c: emp directory
```

salt.modules.win_dacl.rm_ace(path, objectType, user, permission=None, acetype=None, propagation=None)
remove an ace to an object

- **path**: path to the object (i.e. c:\temp\file, HKEY_LOCAL_MACHINE\SOFTWARE\KEY, etc)
- **user**: user to remove permission: permissions for the user acetypes: either allow/deny for each user/permission (ALLOW, DENY)
- **propagation**: how the ACE applies to children for Registry Keys and Directories (KEY, KEY&SUBKEYS, SUBKEYS)

If any of the optional parameters are omitted (or set to None) they act as wildcards.

CLI Example:
```
remove allow domain\fakeuser full control on HKLM\SOFTWARE\somekey propagated to this key and subkeys
salt 'myminion' win_dacl.rm_ace 'Registry' 'HKEY_LOCAL_MACHINE\SOFTWARE\somekey' 'domain\fakeuser' 'FULLCONTROL' 'ALLOW' 'KEY&SUBKEYS'
```

19.9.415 salt.modules.win_disk

Module for gathering disk information on Windows

depends
- win32api Python module

salt.modules.win_disk.usage()
Return usage information for volumes mounted on this minion

CLI Example:
```
salt '*' disk.usage
```

19.9.416 salt.modules.win_dism module

Install features/packages for Windows using DISM, which is useful for minions not running server versions of Windows. Some functions are only available on Windows 10.
salt.modules.win_dism.add_capability(capability, source=None, limit_access=False, image=None, restart=False)

Install a capability

Parameters

- **capability** *(str)* -- The capability to install
- **source** *(Optional[str]*) -- The optional source of the capability. Default is set by group policy and can be Windows Update.
- **limit_access** *(Optional[bool]*) -- Prevent DISM from contacting Windows Update for the source package
- **image** *(Optional[str]*) -- The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None.
- **restart** *(Optional[bool]*) -- Reboot the machine if required by the install

Raises

- **NotImplementedError** -- For all versions of Windows that are not Windows 10 and later. Server editions of Windows use ServerManager instead.

Returns

A dictionary containing the results of the command

Return type: dict

CLI Example:

```sh
salt '*' dism.add_capability Tools.Graphics.DirectX~~~~0.0.1.0
```

salt.modules.win_dism.add_feature(feature, package=None, source=None, limit_access=False, enable_parent=False, image=None, restart=False)

Install a feature using DISM

Parameters

- **feature** *(str)* -- The feature to install
- **package** *(Optional[str]*) -- The parent package for the feature. You do not have to specify the package if it is the Windows Foundation Package. Otherwise, use package to specify the parent package of the feature
- **source** *(Optional[str]*) -- The optional source of the capability. Default is set by group policy and can be Windows Update
- **limit_access** *(Optional[bool]*) -- Prevent DISM from contacting Windows Update for the source package
- **enable_parent** *(Optional[bool]*) -- True will enable all parent features of the specified feature
- **image** *(Optional[str]*) -- The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None.
- **restart** *(Optional[bool]*) -- Reboot the machine if required by the install

Returns

A dictionary containing the results of the command

Return type: dict

CLI Example:

```sh
salt '*' dism.add_feature NetFx3
```

salt.modules.win_dism.add_package(package, ignore_check=False, prevent_pending=False, image=None, restart=False)

Install a package using DISM

Parameters

- **package** *(str)* -- The package to install. Can be a .cab file, a .msu file, or a folder

Note: An .msu package is supported only when the target image is offline, either mounted or applied.

- **ignore_check** *(Optional[bool]*) -- Skip installation of the package if the ap-
Salt Documentation, Release 2017.7.8

plicability checks fail
• **prevent_pending** (Optional[bool]) -- Skip the installation of the package if there are pending online actions
• **image** (Optional[str]) -- The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None.
• **restart** (Optional[bool]) -- Reboot the machine if required by the install

Returns A dictionary containing the results of the command
Return type dict

CLI Example:
```
salt '*' dism.add_package C:\Packages\package.cab
```

**salt.modules.win_dism.available_capabilities** *(image=None)*
List the capabilities available on the system

Parameters **image** (Optional[str]) -- The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None.

Raises
- **NotImplementedError** -- For all versions of Windows that are not Windows 10 and later. Server editions of Windows use ServerManager instead.

Returns A list of available capabilities
Return type list

CLI Example:
```
salt '*' dism.installed_capabilities
```

**salt.modules.win_dism.available_features** *(image=None)*
List the features available on the system

Parameters **image** (Optional[str]) -- The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None.

Returns A list of available features
Return type list

CLI Example:
```
salt '*' dism.available_features
```

**salt.modules.win_dism.get_capabilities** *(image=None)*
List all capabilities on the system

Parameters **image** (Optional[str]) -- The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None.

Raises
- **NotImplementedError** -- For all versions of Windows that are not Windows 10 and later. Server editions of Windows use ServerManager instead.

Returns A list of capabilities
Return type list

CLI Example:
```
salt '*' dism.get_capabilities
```

**salt.modules.win_dism.get_features** *(package=None, image=None)*
List features on the system or in a package

Parameters
- **package** (Optional[str]) -- The full path to the package. Can be either a .cab file or a folder. Should point to the original source of the package, not to where the file is installed. You cannot use this command to get package information for .msu files

Returns A list of features
Return type list

CLI Example:
```
salt '*' dism.get_features
```
This can also be the name of a package as listed in `dism.installed_packages`.

- `image (Optional [str])` -- The path to the root directory of an offline Windows image. If `None` is passed, the running operating system is targeted. Default is `None`.

Returns: A list of features
Return type: `list`

CLI Example:
```
# Return all features on the system
salt '*' dism.get_features

# Return all features in package.cab
salt '*' dism.get_features C:\packages\package.cab

# Return all features in the calc package
salt '*' dism.get_features Microsoft.Windows.Calc.Demo~6595b6144ccf1df~x86~en~1.0.0.0
```

salt.modules.win_dism.installed_capabilities(image=None)
List the capabilities installed on the system

Parameters:
- `image (Optional [str])` -- The path to the root directory of an offline Windows image. If `None` is passed, the running operating system is targeted. Default is `None`.

Raises:
- `NotImplementedError` -- For all versions of Windows that are not Windows 10 and later. Server editions of Windows use ServerManager instead.

Returns: A list of installed capabilities
Return type: `list`

CLI Example:
```
salt '*' dism.installed_capabilities
```

salt.modules.win_dism.installed_features(image=None)
List the features installed on the system

Parameters:
- `image (Optional [str])` -- The path to the root directory of an offline Windows image. If `None` is passed, the running operating system is targeted. Default is `None`.

Returns: A list of installed features
Return type: `list`

CLI Example:
```
salt '*' dism.installed_features
```

salt.modules.win_dism.installed_packages(image=None)
List the packages installed on the system

Parameters:
- `image (Optional [str])` -- The path to the root directory of an offline Windows image. If `None` is passed, the running operating system is targeted. Default is `None`.

Returns: A list of installed packages
Return type: `list`

CLI Example:
```
salt '*' dism.installed_packages
```

salt.modules.win_dism.package_info(package, image=None)
Display information about a package

Parameters:
- `package (str)` -- The full path to the package. Can be either a .cab file or a folder. Should point to the original source of the package, not to where the file is installed. You cannot use this command to get package information for .msu files
**salt.modules.win_dism.remove_capability** *(capability, image=None, restart=False)*

Uninstall a capability

- **capability** *str* -- The capability to be removed
- **image** *Optional[str]* -- The path to the root directory of an offline Windows image. If *None* is passed, the running operating system is targeted. Default is *None*.
- **restart** *Optional[bool]* -- Reboot the machine if required by the install

**Raises**
- **NotImplementedError** -- For all versions of Windows that are not Windows 10 and later. Server editions of Windows use ServerManager instead.

**Returns** A dictionary containing the results of the command

**Return type** *dict*

**CLI Example:**

```
salt '*' dism.remove_capability Tools.Graphics.DirectX~~~~0.0.1.0
```

**salt.modules.win_dism.remove_feature** *(feature, remove_payload=False, image=None, restart=False)*

Disables the feature.

- **feature** *str* -- The feature to uninstall
- **remove_payload** *Optional[bool]* -- Remove the feature’s payload. Must supply source when enabling in the future.
- **image** *Optional[str]* -- The path to the root directory of an offline Windows image. If *None* is passed, the running operating system is targeted. Default is *None*.
- **restart** *Optional[bool]* -- Reboot the machine if required by the install

**Returns** A dictionary containing the results of the command

**Return type** *dict*

**CLI Example:**

```
salt '*' dism.remove_feature NetFx3
```

**salt.modules.win_dism.remove_package** *(package, image=None, restart=False)*

Uninstall a package

- **package** *str* -- The full path to the package. Can be either a .cab file or a folder. Should point to the original source of the package, not to where the file is installed. This can also be the name of a package as listed in dism.installed_packages
- **image** *Optional[str]* -- The path to the root directory of an offline Windows image. If *None* is passed, the running operating system is targeted. Default is *None*.
- **restart** *Optional[bool]* -- Reboot the machine if required by the install

**Returns** A dictionary containing the results of the command

**Return type** *dict*

**CLI Example:**

```
# Remove the Calc Package
salt '*' dism.remove_package Microsoft.Windows.Calc.Demo-6595b6144ccf1df-x86~en-1.----0.0.0
```
# Remove the package.cab (does not remove C:\packages\package.cab)
salt '*' dism.remove_package C:\packages\package.cab

## 19.9.417 salt.modules.win_dns_client

Module for configuring DNS Client on Windows systems

- `salt.modules.win_dns_client.add_dns(ip, interface='Local Area Connection', index=1)`
  Add the DNS server to the network interface (index starts from 1)
  
  Note: if the interface DNS is configured by DHCP, all the DNS servers will be removed from the interface and the requested DNS will be the only one

  CLI Example:

  ```
salt '*' win_dns_client.add_dns <ip> <interface> <index>
  ```

- `salt.modules.win_dns_client.dns_dhcp(interface='Local Area Connection')`
  Configure the interface to get its DNS servers from the DHCP server

  CLI Example:

  ```
salt '*' win_dns_client.dns_dhcp <interface>
  ```

- `salt.modules.win_dns_client.get_dns_config(interface='Local Area Connection')`
  Get the type of DNS configuration (dhcp / static)

  CLI Example:

  ```
salt '*' win_dns_client.get_dns_config 'Local Area Connection'
  ```

- `salt.modules.win_dns_client.get_dns_servers(interface='Local Area Connection')`
  Return a list of the configured DNS servers of the specified interface

  CLI Example:

  ```
salt '*' win_dns_client.get_dns_servers 'Local Area Connection'
  ```

- `salt.modules.win_dns_client.rm_dns(ip, interface='Local Area Connection')`
  Remove the DNS server from the network interface

  CLI Example:

  ```
salt '*' win_dns_client.rm_dns <ip> <interface>
  ```

## 19.9.418 salt.modules.win_dsc

This module is Alpha

Module for working with Windows PowerShell DSC ( Desired State Configuration)

This module applies DSC Configurations in the form of PowerShell scripts or MOF (Managed Object Format) schema files.

Use the `psget` module to manage PowerShell resources.

The idea is to leverage Salt to push DSC configuration scripts or MOF files to the Minion.

### 19.9. execution modules
depends
  • PowerShell 5.0

salt.modules.win_dsc.apply_config(path, source=None, salt_env='base')
Run an compiled DSC configuration (a folder containing a .mof file). The folder can be cached from the salt master using the source option.

Parameters
  • **path (str)** -- Local path to the directory that contains the .mof configuration file to apply. Required.
  • **source (str)** -- Path to the directory that contains the .mof file on the file_roots. The source directory will be copied to the path directory and then executed. If the path and source directories differ, the source directory will be applied. If source is not passed, the config located at path will be applied. Optional.
  • **salt_env (str)** -- The salt environment to use when copying your source. Default is 'base'

Returns True if successful, otherwise False
Return type bool

CLI Example:
To apply a config that already exists on the system

```
salt '*' dsc.apply_config C:\\DSC\\WebSiteConfiguration
```

To cache a configuration from the master and apply it:

```
salt '*' dsc.apply_config C:\\DSC\\WebSiteConfiguration salt://dsc/configs/\\WebSiteConfiguration
```

salt.modules.win_dsc.compile_config(path, source=None, config_name=None, config_data=None, config_data_source=None, script_parameters=None, salt_env='base')
Compile a config from a PowerShell script (.ps1)

Parameters
  • **path (str)** -- Path (local) to the script that will create the .mof configuration file. If no source is passed, the file must exist locally. Required.
  • **source (str)** -- Path to the script on file_roots to cache at the location specified by path. The source file will be cached locally and then executed. If source is not passed, the config script located at path will be compiled. Optional.
  • **config_name (str)** -- The name of the Configuration within the script to apply. If the script contains multiple configurations within the file a config_name must be specified. If the config_name is not specified, the name of the file will be used as the config_name to run. Optional.
  • **config_data (str)** -- Configuration data in the form of a hash table that will be passed to the ConfigurationData parameter when the config_name is compiled. This can be the path to a .psd1 file containing the proper hash table or the PowerShell code to create the hash table.

New in version 2017.7.0.

• **config_data_source (str)** -- The path to the .psd1 file on file_roots to cache at the location specified by config_data. If this is specified, config_data must be a local path instead of a hash table.

New in version 2017.7.0.

• **script_parameters (str)** -- Any additional parameters expected by the configuration script. These must be defined in the script itself.

New in version 2017.7.0.
- **salt_env**(str) -- The salt environment to use when copying the source. Default is 'base'
  
  Returns A dictionary containing the results of the compilation
  
  Return type dict

CLI Example:

To compile a config from a script that already exists on the system:

```bash
salt '*' dsc.compile_config C:\\DSC\\WebsiteConfig.ps1
```

To cache a config script to the system from the master and compile it:

```bash
salt '*' dsc.compile_config C:\\DSC\\WebsiteConfig.ps1 salt://dsc/configs/ WebsiteConfig.ps1
```

```
salt.modules.win_dsc.get_config()
Get the current DSC Configuration
  
  Returns A dictionary representing the DSC Configuration on the machine
  
  Return type dict
  
  Raises CommandExecutionError -- On failure

CLI Example:

```bash
salt '*' dsc.get_config
```

```
salt.modules.win_dsc.get_config_status()
Get the status of the current DSC Configuration
  
  Returns A dictionary representing the status of the current DSC Configuration on the machine
  
  Return type dict

CLI Example:

```bash
salt '*' dsc.get_config_status
```

```
salt.modules.win_dsc.get_lcm_config()
Get the current Local Configuration Manager settings
  
  Returns A dictionary representing the Local Configuration Manager settings on the machine
  
  Return type dict

CLI Example:

```bash
salt '*' dsc.get_lcm_config
```

```
salt.modules.win_dsc.remove_config(reset=False)
Remove the current DSC Configuration. Removes current, pending, and previous dsc configurations.

New in version 2017.7.5.
  
  Parameters reset(bool) -- Attempts to reset the DSC configuration by removing the following from C:\Windows\System32\Configuration:
    
    • File: DSCStatusHistory.mof
    • File: DSCEngineCache.mof
    • Dir: ConfigurationStatus
  
  Default is False
Warning: `remove_config` may fail to reset the DSC environment if any of the files in the `ConfigurationStatus` directory. If you wait a few minutes and run again, it may complete successfully.

**Returns**  True if successful  
**Return type**  `bool`  
**Raises**  CommandExecutionError -- On failure  

CLI Example:
```
salt '*' dsc.remove_config True
```

### `restore_config`

Applies the previous configuration.

**New in version 2017.7.5.**

**Note:** The current configuration will be come the previous configuration. If run a second time back-to-back it is like toggling between two configs.

**Returns**  True if successfully restored  
**Return type**  `bool`  
**Raises**  CommandExecutionError -- On failure  

CLI Example:
```
salt '*' dsc.restore_config
```

### `run_config`

Compile a DSC Configuration in the form of a PowerShell script (.ps1) and apply it. The PowerShell script can be cached from the master using the `source` option. If there is more than one config within the PowerShell script, the desired configuration can be applied by passing the name in the `config` option.

This command would be the equivalent of running `dsc.compile_config` followed by `dsc.apply_config`.

**Parameters**

- **path (`str`)** -- The local path to the PowerShell script that contains the DSC Configuration. Required.
- **source (`str`)** -- The path to the script on `file_roots` to cache at the location specified by path. The source file will be cached locally and then executed. If source is not passed, the config script located at path will be compiled. Optional.
- **config_name (`str`)** -- The name of the Configuration within the script to apply. If the script contains multiple configurations within the file a `config_name` must be specified. If the `config_name` is not specified, the name of the file will be used as the `config_name` to run. Optional.
- **config_data (`str`)** -- Configuration data in the form of a hash table that will be passed to the `ConfigurationData` parameter when the `config_name` is compiled. This can be the path to a `.psd1` file containing the proper hash table or the PowerShell code to create the hash table.

  **New in version 2017.7.0.**

- **config_data_source (`str`)** -- The path to the `.psd1` file on `file_roots` to cache at the location specified by `config_data`. If this is specified, `config_data` must be a local path instead of a hash table.
**New in version 2017.7.0.**

- **script_parameters**(str) -- Any additional parameters expected by the configuration script. These must be defined in the script itself.

**New in version 2017.7.0.**

- **salt_env**(str) -- The salt environment to use when copying the source. Default is `base`

**Returns** True if successfully compiled and applied, otherwise False

**Return type** bool

CLI Example:

To compile a config from a script that already exists on the system:

```
salt 'salt '*' dsc.run_config C:\DSC\WebsiteConfig.ps1
```

To cache a config script to the system from the master and compile it:

```
salt 'salt '*' dsc.run_config C:\DSC\WebsiteConfig.ps1 salt://dsc/configs/WebsiteConfig.ps1
```

**salt.modules.win_dsc.set_lcm_config**(*config_mode=None, config_mode_freq=None, refresh_freq=None, reboot_if_needed=None, action_after_reboot=None, certificate_id=None, configuration_id=None, allow_module_overwrite=None, debug_mode=False, status_retention_days=None*)

For detailed descriptions of the parameters see: [https://msdn.microsoft.com/en-us/PowerShell/DSC/metaConfig](https://msdn.microsoft.com/en-us/PowerShell/DSC/metaConfig)

**config_mode**(str): How the LCM applies the configuration. Valid values are:

- ApplyOnly
- ApplyAndMonitor
- ApplyAndAutoCorrect

**config_mode_freq**(int): How often, in minutes, the current configuration is checked and applied. Ignored if config_mode is set to ApplyOnly. Default is 15.

**refresh_mode**(str): How the LCM gets configurations. Valid values are:

- Disabled
- Push
- Pull

**refresh_freq**(int): How often, in minutes, the LCM checks for updated configurations. (pull mode only) Default is 30.

**reboot_if_needed**(bool): Reboot the machine if needed after a configuration is applied. Default is False.

**action_after_reboot**(str): Action to take after reboot. Valid values are:

- ContinueConfiguration
- StopConfiguration

**certificate_id**(guid): A GUID that specifies a certificate used to access the configuration. (pull mode)

**configuration_id**(guid): A GUID that identifies the config file to get from a pull server. (pull mode)

**allow_module_overwrite**(bool): New configs are allowed to overwrite old ones on the target node.

**debug_mode**(str): Sets the debug level. Valid values are:

- None
- ForceModuleImport
- All

**status_retention_days**(int): Number of days to keep status of the current config.

**Note:** Either **config_mode_freq** or **refresh_freq** needs to be a multiple of the other. See document-
Returns  True if successful, otherwise False
Return type  bool

CLI Example:

```
salt '*' dsc.set_lcm_config ApplyOnly
```

**salt.modules.win_dsc.test_config()**

Tests the current applied DSC Configuration

Returns  True if successfully applied, otherwise False
Return type  bool

CLI Example:

```
salt '*' dsc.test_config
```

### 19.9.419  salt.modules.win_file

Manage information about files on the minion, set/read user, group data, modify the ACL of files/directories

**depends**
- win32api
- win32file
- win32con
- salt.utils.win_dacl

**exception**  salt.modules.win_file.WindowsError

salt.modules.win_file.check_perms(path, ret=None, owner=None, grant_perms=None, deny_perms=None, inheritance=True)

Set owner and permissions for each directory created. Used mostly by the state system.

**Parameters**
- path *(str)* -- The full path to the directory.
- ret *(dict)* -- A dictionary to append changes to and return. If not passed, will create a new dictionary to return.
- owner *(str)* -- The owner of the directory. If not passed, it will be the account that created the directory, likely SYSTEM
- grant_perms *(dict)* -- A dictionary containing the user/group and the basic permissions to grant, ie: {‘user’: {‘perms’: ‘basic_permission’}}. You can also set the applies_to setting here. The default is this_folder_subfolders_files. Specify another applies_to setting like this:

```
{‘user’: {‘perms’: ‘full_control’, ‘applies_to’: ‘this_folder’}}
```

To set advanced permissions use a list for the perms parameter, ie:

```
{‘user’: {‘perms’: [‘read_attributes’, ‘read_ea’], ‘applies_to’: ‘this_folder’}}
```

- deny_perms *(dict)* -- A dictionary containing the user/group and permissions to deny along with the applies_to setting. Use the same format used for the
grant_perms parameter. Remember, deny permissions supersede grant permissions.

- **inheritance** *(bool)* -- If True the object will inherit permissions from the parent, if False, inheritance will be disabled. Inheritance setting will not apply to parent directories if they must be created

**Returns** A dictionary of changes made to the object

**Return type** `dict`

**Raises** `CommandExecutionError` -- If the object does not exist

CLI Example:

```py
# To grant the 'Users' group 'read & execute' permissions.
salt '*' file.check_perms C:\Temp\ Administrators "{'Users': {'perms': 'read_,
                                 'execute'}}"
```

```py
# Locally using salt call
salt-call file.check_perms C:\Temp\ Administrators "{'Users': {'perms': 'read_,
                                 'execute', 'applies_to': 'this_folder_only'}}"
```

```py
# Specify advanced attributes with a list
salt '*' file.check_perms C:\Temp\ Administrators "{'jsnuffy': {'perms': ['read_,
                              'attributes', 'read_ea'], 'applies_to': 'files_only'}}"
```

salt.modules.win_file.chgrp *(path, group)*
Change the group of a file

Under Windows, this will do nothing.

While a file in Windows does have a `primary group`, this rarely used attribute generally has no bearing on permissions unless intentionally configured and is only used to support Unix compatibility features (e.g. Services For Unix, NFS services).

Salt, therefore, remaps this function to do nothing while still being compatible with Unix behavior. When managing Windows systems, this function is superfluous and will generate an info level log entry if used directly.

If you do actually want to set the `primary group` of a file, use `file.chpgrp`.

To set group permissions use `file.set_perms`

**Parameters**

- **path** *(str)* -- The path to the file or directory
- **group** *(str)* -- The group (unused)

**Returns** None

CLI Example:

```py
salt '*' file.chpgrp c:\temp\test.txt administrators
```

salt.modules.win_file.chown *(path, user, group=None, pgroup=None, follow_symlinks=True)*
Chown a file, pass the file the desired user and group

Under Windows, the group parameter will be ignored.

This is because while files in Windows do have a `primary group` property, this is rarely used. It generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

If you do want to change the `primary group` property and understand the implications, pass the Windows only parameter, `pgroup`, instead.

**Parameters**

- **path** *(str)* -- The path to the file or directory
**user** *(str)* — The name of the user to own the file

**group** *(str)* — The group (not used)

**pgroup** *(str)* — The primary group to assign

**follow_symlinks** *(bool)* — If the object specified by path is a symlink, get attributes of the linked file instead of the symlink itself. Default is True

Returns: True if successful, otherwise error

Return type: bool

CLI Example:

```
salt '*' file.chown c:\temp\test.txt myusername
salt '*' file.chown c:\temp\test.txt myusername pgroup=Administrators
salt '*' file.chown c:\temp\test.txt myusername "pgroup='None'"
```

**salt.modules.win_file.chpgrp(path, group)**

Change the group of a file

Under Windows, this will set the rarely used primary group of a file. This generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

Ensure you know what you are doing before using this function.

Parameters

- **path** *(str)* — The path to the file or directory
- **pgroup** *(str)* — The primary group to assign

Returns: True if successful, otherwise error

Return type: bool

CLI Example:

```
salt '*' file.chpgrp c:\temp\test.txt Administrators
salt '*' file.chpgrp c:\temp\test.txt '"None'"
```

**salt.modules.win_file.get_attributes(path)**

Return a dictionary object with the Windows file attributes for a file.

Parameters **path** *(str)* — The path to the file or directory

Returns: A dictionary of file attributes

Return type: dict

CLI Example:

```
salt '*' file.get_attributes c:\temp\a.txt
```

**salt.modules.win_file.get_gid(path, follow_symlinks=True)**

Return the id of the group that owns a given file

Under Windows, this will return the uid of the file.

While a file in Windows does have a `primary group`, this rarely used attribute generally has no bearing on permissions unless intentionally configured and is only used to support Unix compatibility features (e.g. Services For Unix, NFS services).

Salt, therefore, remaps this function to provide functionality that somewhat resembles Unix behavior for API compatibility reasons. When managing Windows systems, this function is superfluous and will generate an info level log entry if used directly.

If you do actually want to access the `primary group` of a file, use **file.get_pgid**.

Parameters

- **path** *(str)* — The path to the file or directory
- **follow_symlinks** *(bool)* — If the object specified by path is a symlink, get attributes of the linked file instead of the symlink itself. Default is True
Returns The gid of the owner

Return type str

CLI Example:

```shell
salt '*' file.get_gid c:\temp\test.txt
```

`salt.modules.win_file.get_group(path, follow_symlinks=True)`

Return the group that owns a given file

Under Windows, this will return the user (owner) of the file.
While a file in Windows does have a `primary group', this rarely used attribute generally has no bearing on permissions unless intentionally configured and is only used to support Unix compatibility features (e.g. Services For Unix, NFS services).
Salt, therefore, remaps this function to provide functionality that somewhat resembles Unix behavior for API compatibility reasons. When managing Windows systems, this function is superfluous and will generate an info level log entry if used directly.
If you do actually want to access the `primary group' of a file, use `file.get_pgroup'.

Parameters

- `path` (str) -- The path to the file or directory
- `follow_symlinks` (bool) -- If the object specified by path is a symlink, get attributes of the linked file instead of the symlink itself. Default is True

Returns The name of the owner

Return type str

CLI Example:

```shell
salt '*' file.get_group c:\temp\test.txt
```

`salt.modules.win_file.get_mode(path)`

Return the mode of a file

Right now we’re just returning None because Windows’ doesn’t have a mode like Linux

Parameters `path` (str) -- The path to the file or directory

Returns None

CLI Example:

```shell
salt '*' file.get_mode /etc/passwd
```

`salt.modules.win_file.get_pgid(path, follow_symlinks=True)`

Return the id of the primary group that owns a given file (Windows only)

This function will return the rarely used primary group of a file. This generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).
Ensure you know what you are doing before using this function.

Parameters

- `path` (str) -- The path to the file or directory
- `follow_symlinks` (bool) -- If the object specified by path is a symlink, get attributes of the linked file instead of the symlink itself. Default is True

Returns The gid of the primary group

Return type str

CLI Example:

```shell
salt '*' file.get_pgid c:\temp\test.txt
```
salt.modules.win_file.get_pgroup(path, follow_symlinks=True)

Return the name of the primary group that owns a given file (Windows only)

This function will return the rarely used primary group of a file. This generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

Ensure you know what you are doing before using this function.

The return value may be `None', e.g. if the user is not on a domain. This is a valid group - do not confuse this with the Salt/Python value of None which means no value was returned. To be certain, use the get_pgid function which will return the SID, including for the system `None' group.

Parameters

- **path**(str) -- The path to the file or directory
- **follow_symlinks**(bool) -- If the object specified by path is a symlink, get attributes of the linked file instead of the symlink itself. Default is True

Returns The name of the primary group

Return type str

CLI Example:

```
salt '*' file.get_pgroup c:\temp\test.txt
```

salt.modules.win_file.get_uid(path, follow_symlinks=True)

Return the id of the user that owns a given file

Symlinks are followed by default to mimic Unix behavior. Specify **follow_symlinks=False** to turn off this behavior.

Parameters

- **path**(str) -- The path to the file or directory
- **follow_symlinks**(bool) -- If the object specified by path is a symlink, get attributes of the linked file instead of the symlink itself. Default is True

Returns The uid of the owner

Return type str

CLI Example:

```
salt '*' file.get_uid c:\temp\test.txt
salt '*' file.get_uid c:\temp\test.txt follow_symlinks=False
```

salt.modules.win_file.get_user(path, follow_symlinks=True)

Return the user that owns a given file

Symlinks are followed by default to mimic Unix behavior. Specify **follow_symlinks=False** to turn off this behavior.

Parameters

- **path**(str) -- The path to the file or directory
- **follow_symlinks**(bool) -- If the object specified by path is a symlink, get attributes of the linked file instead of the symlink itself. Default is True

Returns The name of the owner

Return type str

CLI Example:

```
salt '*' file.get_user c:\temp\test.txt
salt '*' file.get_user c:\temp\test.txt follow_symlinks=False
```

salt.modules.win_file.gid_to_group(gid)

Convert the group id to the group name on this system

Under Windows, because groups are just another ACL entity, this function behaves the same as uid_to_user.
For maintaining Windows systems, this function is superfluous and only exists for API compatibility with Unix. Use the uid_to_user function instead; an info level log entry will be generated if this function is used directly.

**Parameters**
- `gid (str)` -- The gid of the group

**Returns**
The name of the group

**Return type**
`str`

**CLI Example:**
```
salt '*' file.gid_to_group S-1-5-21-626487655-2533044672-482107328-1010
```

salt.modules.win_file.group_to_gid(group)
Convert the group to the gid on this system

Under Windows, because groups are just another ACL entity, this function behaves the same as user_to_uid, except if None is given, ‘’ is returned.

For maintaining Windows systems, this function is superfluous and only exists for API compatibility with Unix. Use the user_to_uid function instead; an info level log entry will be generated if this function is used directly.

**Parameters**
- `group (str)` -- The name of the group

**Returns**
The gid of the group

**Return type**
`str`

**CLI Example:**
```
salt '*' file.group_to_gid administrators
```

salt.modules.win_file.is_link(path)
Check if the path is a symlink

This is only supported on Windows Vista or later.

Inline with Unix behavior, this function will raise an error if the path is not a symlink, however, the error raised will be a SaltInvocationError, not an OSError.

**Parameters**
- `path (str)` -- The path to a file or directory

**Returns**
True if path is a symlink, otherwise False

**Return type**
`bool`

**CLI Example:**
```
salt '*' file.is_link /path/to/link
```

salt.modules.win_file.lchown(path, user=None, group=None, pgroup=None)
Chown a file, pass the file the desired user and group without following any symlinks.

Under Windows, the group parameter will be ignored.

This is because while files in Windows do have a `primary group' property, this is rarely used. It generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

If you do want to change the `primary group' property and understand the implications, pass the Windows only parameter, pgroup, instead.

To set the primary group to `None', it must be specified in quotes. Otherwise Salt will interpret it as the Python value of None and no primary group changes will occur. See the example below.

**Parameters**
- `path (str)` -- The path to the file or directory
- `user (str)` -- The name of the user to own the file
- `group (str)` -- The group (not used)
- `pgroup (str)` -- The primary group to assign
Returns  True if successful, otherwise error
Return type  bool

CLI Example:

```bash
salt '*' file.lchown c:\temp\test.txt myusername
salt '*' file.lchown c:\temp\test.txt myusername pgroup=Administrators
salt '*' file.lchown c:\temp\test.txt myusername "pgroup='None'"
```

salt.modules.win_file.makedirs_(path, owner=None, grant_perms=None, deny_perms=None, inheritance=True)

Ensure that the parent directory containing this path is available.

Parameters

- **path** *(str)* -- The full path to the directory.
- **owner** *(str)* -- The owner of the directory. If not passed, it will be the account that created the directory, likely SYSTEM
- **grant_perms** *(dict)* -- A dictionary containing the user/group and the basic permissions to grant, ie: `{user: {'perms': 'basic_permission'}`. You can also set the applies_to setting here. The default is this_folder_subfolders_files. Specify another applies_to setting like this:

  ```json
  {'user': {'perms': 'full_control', 'applies_to': 'this_folder'}}
  ```

  To set advanced permissions use a list for the perms parameter, ie:

  ```json
  {'user': {'perms': ['read_attributes', 'read_ea'], 'applies_to': 'this_folder'}}
  ```

- **deny_perms** *(dict)* -- A dictionary containing the user/group and permissions to deny along with the applies_to setting. Use the same format used for the grant_perms parameter. Remember, deny permissions supersede grant permissions.
- **inheritance** *(bool)* -- If True the object will inherit permissions from the parent, if False, inheritance will be disabled. Inheritance setting will not apply to parent directories if they must be created

**Note:** The path must end with a trailing slash otherwise the directory(s) will be created up to the parent directory. For example if path is C:\temp\test, then it would be treated as C:\temp\ but if the path ends with a trailing slash like C:\temp\test\, then it would be treated as C:\temp\test\.

Returns  True if successful
Return type  bool

CLI Example:

```bash
# To grant the 'Users' group 'read & execute' permissions.
salt '*' file.makedirs C:\Temp\ Administrators "{'Users': {'perms': 'read_execute'}}"

# Locally using salt-call
salt-call file.makedirs C:\Temp\ Administrators "{'Users': {'perms': 'read_execute', 'applies_to': 'this_folder_only'}}"

# Specify advanced attributes with a list
salt '*' file.makedirs C:\Temp\ Administrators "{'jsnuffy': {'perms': ['read_attributes', 'read_ea'], 'applies_to': 'this_folder_only'}}"
```
salt.modules.win_file.makedirs_perms(path, owner=None, grant_perms=None, deny_perms=None, inheritance=True)

Set owner and permissions for each directory created.

Parameters

- **path (str)** -- The full path to the directory.
- **owner (str)** -- The owner of the directory. If not passed, it will be the account that created the directory, likely SYSTEM
- **grant_perms (dict)** -- A dictionary containing the user/group and the basic permissions to grant, ie: {'user': {'perms': 'basic_permission'}}. You can also set the applies_to setting here. The default is this_folder_subfolders_files. Specify another applies_to setting like this:

```
{'user': {'perms': 'full_control', 'applies_to': 'this_folder'}}
```

To set advanced permissions use a list for the perms parameter, ie:

```
{'user': {'perms': ['read_attributes', 'read_ea'], 'applies_to': 'this_folder'}}
```

- **deny_perms (dict)** -- A dictionary containing the user/group and permissions to deny along with the applies_to setting. Use the same format used for the grant_perms parameter. Remember, deny permissions supersede grant permissions.
- **inheritance (bool)** -- If True the object will inherit permissions from the parent, if False, inheritance will be disabled. Inheritance setting will not apply to parent directories if they must be created

Returns True if successful, otherwise raises an error

Return type bool

CLI Example:

```
# To grant the 'Users' group 'read & execute' permissions.
salt '*' file.makedirs_perms C:\Temp\Administrators "{'Users': {'perms': 'read
execute'}}"
```

```
# Locally using salt-call
salt-call file.makedirs_perms C:\Temp\Administrators "{'Users': {'perms': 'read
execute', 'applies_to': 'this_folder_only'}}"
```

```
# Specify advanced attributes with a list
salt '*' file.makedirs_perms C:\Temp\Administrators "{'jsnuffy': {'perms': ['read_attributes', 'read_ea'], 'applies_to': 'this_folder_files'}}"
```

salt.modules.win_file.mkdir(path, owner=None, grant_perms=None, deny_perms=None, inheritance=True)

Ensure that the directory is available and permissions are set.

Parameters

- **path (str)** -- The full path to the directory.
- **owner (str)** -- The owner of the directory. If not passed, it will be the account that created the directory, likely SYSTEM
- **grant_perms (dict)** -- A dictionary containing the user/group and the basic permissions to grant, ie: {'user': {'perms': 'basic_permission'}}. You can also set the applies_to setting here. The default is this_folder_subfolders_files. Specify another applies_to setting like this:
To set advanced permissions use a list for the `perms` parameter, ie:

```
{'user': {'perms': ['read_attributes', 'read_ea'], 'applies_to': 'this_folder'}}
```

- **deny_perms (dict)** -- A dictionary containing the user/group and permissions to deny along with the `applies_to` setting. Use the same format used for the `grant_perms` parameter. Remember, deny permissions supersede grant permissions.
- **inheritance (bool)** -- If True the object will inherit permissions from the parent, if False, inheritance will be disabled. Inheritance setting will not apply to parent directories if they must be created.

**Returns**
- True if successful

**Return type**
- bool

**Raises**
- CommandExecutionError -- If unsuccessful

**CLI Example:**

```
# To grant the 'Users' group 'read & execute' permissions.
salt '*' file.mkdir C:\Temp\Administrators "{'Users': {'perms': 'read_execute'}}"

# Locally using salt call
salt-call file.mkdir C:\Temp\Administrators "{'Users': {'perms': 'read_execute', 'applies_to': 'this_folder_only'}}"

# Specify advanced attributes with a list
salt '*' file.mkdir C:\Temp\Administrators "{'jsnuffy': {'perms': ['read_attributes', 'read_ea'], 'applies_to': 'this_folder_only'}}"
```

**salt.modules.win_file.readlink(path)**

Return the path that a symlink points to.

This is only supported on Windows Vista or later.

Inline with Unix behavior, this function will raise an error if the path is not a symlink, however, the error raised will be a SaltInvocationError, not an OSError.

**Parameters**
- **path (str)** -- The path to the symlink

**Returns**
- The path that the symlink points to

**Return type**
- str

**CLI Example:**

```
salt '*' file.readlink /path/to/link
```

**salt.modules.win_file.remove(path, force=False)**

Remove the named file or directory

**Parameters**
- **path (str)** -- The path to the file or directory to remove.
- **force (bool)** -- Remove even if marked Read-Only. Default is False

**Returns**
- True if successful, False if unsuccessful

**Return type**
- bool

**CLI Example:**

```
salt '*' file.remove C:\Temp
```
salt.modules.win_file.set_attributes(path, archive=None, hidden=None, normal=None, notIndexed=None, readonly=None, system=None, temporary=None)

Set file attributes for a file. Note that the normal attribute means that all others are false. So setting it will clear all others.

Parameters
- path (str) -- The path to the file or directory
- archive (bool) -- Sets the archive attribute. Default is None
- hidden (bool) -- Sets the hidden attribute. Default is None
- normal (bool) -- Resets the file attributes. Cannot be used in conjunction with any other attribute. Default is None
- notIndexed (bool) -- Sets the indexed attribute. Default is None
- readonly (bool) -- Sets the readonly attribute. Default is None
- system (bool) -- Sets the system attribute. Default is None
- temporary (bool) -- Sets the temporary attribute. Default is None

Returns True if successful, otherwise False
Return type bool

CLI Example:
```bash
salt '*' file.set_attributes c:\temp\a.txt normal=True
salt '*' file.set_attributes c:\temp\a.txt readonly=True hidden=True
```

call.methods.win_file.set_mode(path, mode)

Set the mode of a file

This just calls get_mode, which returns None because we don't use mode on Windows

Parameters
- path -- The path to the file or directory
- mode -- The mode (not used)

Returns None

CLI Example:
```bash
salt '*' file.set_mode /etc/passwd 0644
```

call.methods.win_file.set_perms(path, grant_perms=None, deny_perms=None, inheritance=True)

Set permissions for the given path

Parameters
- path (str) -- The full path to the directory.
- grant_perms (dict) -- A dictionary containing the user/group and the basic permissions to grant, ie: {'user': {'perms': 'basic_permission'}}. You can also set the applies_to setting here. The default is this_folder_subfolders_files. Specify another applies_to setting like this:

  ```json
  {'user': {'perms': 'full_control', 'applies_to': 'this_folder'}}
  ```

To set advanced permissions use a list for the perms parameter, ie:

  ```json
  {'user': {'perms': ['read_attributes', 'read_ea'], 'applies_to': 'this_folder'}}
  ```

To see a list of available attributes and applies to settings see the documentation for salt.utils.win_dacl
- deny_perms (dict) -- A dictionary containing the user/group and permissions to deny along with the applies_to setting. Use the same format used for the
grant_perms parameter. Remember, deny permissions supersede grant permissions.

- inheritance (bool) -- If True the object will inherit permissions from the parent, if False, inheritance will be disabled. Inheritance setting will not apply to parent directories if they must be created

Returns True if successful, otherwise raise an error
Return type bool

CLI Example:

# To grant the 'Users' group 'read & execute' permissions.
salt '*' file.set_perms C:\Temp\ "{'Users': {'perms': 'read_execute'}}"

# Locally using salt call
salt-call file.set_perms C:\Temp\ "{'Users': {'perms': 'read_execute', 'applies_to': 'this_folder_only'}}"

# Specify advanced attributes with a list
salt '*' file.set_perms C:\Temp\ "{'jsnuffy': {'perms': ['read_attributes', 'read_ea'], 'applies_to': 'this_folder_only'}}"

```
salt.modules.win_file.stats(path, hash_type='sha256', follow_symlinks=True)
```

Return a dict containing the stats about a given file

Under Windows, gid will equal uid and group will equal user.

While a file in Windows does have a `primary group', this rarely used attribute generally has no bearing on permissions unless intentionally configured and is only used to support Unix compatibility features (e.g. Services For Unix, NFS services).

Salt, therefore, remaps these properties to keep some kind of compatibility with Unix behavior. If the `primary group' is required, it can be accessed in the pgroup and pgid properties.

Parameters

- path (str) -- The path to the file or directory
- hash_type (str) -- The type of hash to return
- follow_symlinks (bool) -- If the object specified by path is a symlink, get attributes of the linked file instead of the symlink itself. Default is True

Returns A dictionary of file/directory stats
Return type dict

CLI Example:

```
salt '*' file.stats /etc/passwd
```

```
salt.modules.win_file.symlink(src, link)
```

Create a symbolic link to a file

This is only supported with Windows Vista or later and must be executed by a user with the SeCreateSymbolicLink privilege.

The behavior of this function matches the Unix equivalent, with one exception - invalid symlinks cannot be created. The source path must exist. If it doesn't, an error will be raised.

Parameters

- src (str) -- The path to a file or directory
- link (str) -- The path to the link

Returns True if successful, otherwise False
Return type bool

CLI Example:
salt 'salt' file.symlink /path/to/file /path/to/link

salt.modules.win_file.uid_to_user(uid)
Convert a uid to a user name
Parameters
uid (str) -- The user id to lookup
Returns
The name of the user
Return type
str
CLI Example:
salt '*' file.uid_to_user S-1-5-21-626487655-2533044672-482107328-1010

salt.modules.win_file.user_to_uid(user)
Convert user name to a uid
Parameters
user (str) -- The user to lookup
Returns
The user id of the user
Return type
str
CLI Example:
salt '*' file.user_to_uid myusername

19.9.420 salt.modules.win_firewall

Module for configuring Windows Firewall using netsh
salt.modules.win_firewall.add_rule(name, localport, protocol='tcp', action='allow', dir='in', remoteip='any')
New in version 2015.5.0.
Add a new inbound or outbound rule to the firewall policy
Parameters
- name (str) -- The name of the rule. Must be unique and cannot be `all`. Required.
- localport (int) -- The port the rule applies to. Must be a number between 0 and 65535. Can be a range. Can specify multiple ports separated by commas. Required.
- protocol (Optional[str]) -- The protocol. Can be any of the following:
  - A number between 0 and 255
  - icmpv4
  - icmpv6
  - tcp
  - udp
  - any
- action (Optional[str]) -- The action the rule performs. Can be any of the following:
  - allow
  - block
  - bypass
- dir (Optional[str]) -- The direction. Can be in or out.
- remoteip (Optional [str]) -- The remote IP. Can be any of the following:
  - any
  - localhost
  - dns
  - dhcp
  - wins
  - defaultgateway
  - Any valid IPv4 address (192.168.0.12)
- Any valid subnet (192.168.1.0/24)
- Any valid range of IP addresses (192.168.0.1-192.168.0.12)
- A list of valid IP addresses
  Can be combinations of the above separated by commas.

Returns True if successful
Return type bool
Raises CommandExecutionError -- If the command fails

CLI Example:

```bash
salt '*' firewall.add_rule 'test' '8080' 'tcp'
salt '*' firewall.add_rule 'test' '1' 'icmpv4'
salt '*' firewall.add_rule 'test_remote_ip' '8000' 'tcp' 'allow' 'in' '192.168.0.1'
```

salt.modules.win_firewall.delete_rule(name=None, localport=None, protocol=None, dir=None, remoteip=None)

New in version 2015.8.0.

Delete an existing firewall rule identified by name and optionally by ports, protocols, direction, and remote IP.

Parameters
- **name** *(str)* -- The name of the rule to delete. If the name all is used you must specify additional parameters.
- **localport** *(Optional[str]*) -- The port of the rule. If protocol is not specified, protocol will be set to tcp.
- **protocol** *(Optional[str]*) -- The protocol of the rule. Default is tcp when localport is specified.
- **dir** *(Optional[str]*) -- The direction of the rule.
- **remoteip** *(Optional[str]*) -- The remote IP of the rule.

Returns True if successful
Return type bool
Raises CommandExecutionError -- If the command fails

CLI Example:

```bash
# Delete incoming tcp port 8080 in the rule named 'test'
salt '*' firewall.delete_rule 'test' '8080' 'tcp' 'in'

# Delete the incoming tcp port 8000 from 192.168.0.1 in the rule named # 'test_remote_ip'
salt '*' firewall.delete_rule 'test_remote_ip' '8000' 'tcp' 'in' '192.168.0.1'

# Delete all rules for local port 80:
salt '*' firewall.delete_rule all 80 tcp

# Delete a rule called 'allow80':
salt '*' firewall.delete_rule allow80
```

salt.modules.win_firewall.disable(profile='allprofiles')

Disable firewall profile

Parameters **profile** *(Optional[str])* -- The name of the profile to disable. Default is all-profiles. Valid options are:
- all-profiles
- domainprofile
- privateprofile
- publicprofile

Returns True if successful
Return type: bool
Raises: CommandExecutionError -- If the command fails

CLI Example:

```
salt '*' firewall.disable
```

**salt.modules.win_firewall.enable**(profile='allprofiles')</br>New in version 2015.5.0.

Enable firewall profile

Parameters: profile (Optional [str]) -- The name of the profile to enable. Default is all-profiles. Valid options are:
- allprofiles
- domainprofile
- privateprofile
- publicprofile

Returns: True if successful

**salt.modules.win_firewall.get_config()**

Get the status of all the firewall profiles

Returns: A dictionary of all profiles on the system

Return type: dict

Raises: CommandExecutionError -- If the command fails

CLI Example:

```
salt '*' firewall.get_config
```

**salt.modules.win_firewall.get_rule**(name='all')</br>New in version 2015.5.0.

Display all matching rules as specified by name

Parameters: name (Optional [str]) -- The full name of the rule. all will return all rules.

Returns: A dictionary of all rules or rules that match the name exactly

Return type: dict

Raises: CommandExecutionError -- If the command fails

CLI Example:

```
salt '*' firewall.get_rule 'MyAppPort'
```

**salt.modules.win_firewall.rule_exists**(name)</br>New in version 2016.11.6.

Checks if a firewall rule exists in the firewall policy

Parameters: name (str) -- The name of the rule

Returns: True if exists, otherwise False

Return type: bool

CLI Example:

```
# Is there a rule named RemoteDesktop
salt '*' firewall.rule_exists RemoteDesktop
```

19.9. execution modules
19.9.421 salt.modules.win_groupadd

Manage groups on Windows

**Important:** If you feel that Salt should be using this module to manage groups on a minion, and it is using a different module (or gives an error similar to `group.info` is not available), see [here](#).

```python
salt.modules.win_groupadd.add(name, **kwargs)
Add the specified group

Parameters
- `name` (str) -- The name of the group to add

Returns A dictionary of results

Return type dict

CLI Example:
salt '*' group.add foo
```

```python
salt.modules.win_groupadd.adduser(name, username, **kwargs)
Add a user to a group

Parameters
- `name` (str) -- The name of the group to modify
- `username` (str) -- The name of the user to add to the group

Returns A dictionary of results

Return type dict

CLI Example:
salt '*' group.adduser foo username
```

```python
salt.modules.win_groupadd.delete(name, **kwargs)
Remove the named group

Parameters
- `name` (str) -- The name of the group to remove

Returns A dictionary of results

Return type dict

CLI Example:
salt '*' group.delete foo
```

```python
salt.modules.win_groupadd.deluser(name, username, **kwargs)
Remove a user from a group

Parameters
- `name` (str) -- The name of the group to modify
- `username` (str) -- The name of the user to remove from the group

Returns A dictionary of results

Return type dict

CLI Example:
salt '*' group.deluser foo username
```

```python
salt.modules.win_groupadd.getent(refresh=False)
Return info on all groups

Parameters
- `refresh` (bool) -- Refresh the info for all groups in __context__. If False only the groups in __context__ will be returned. If True the __context__ will be refreshed with current data and returned. Default is False

Returns A list of groups and their information

CLI Example:
```
salt 'salt '*' group.getent

salt.modules.win_groupadd.info(name)
Return information about a group

Parameters name (str) -- The name of the group for which to get information

Returns A dictionary of information about the group

Return type dict

CLI Example:
salt 'salt '*' group.info foo

salt.modules.win_groupadd.list_groups(refresh=False)
Return a list of groups

Parameters refresh (bool) -- Refresh the info for all groups in __context__. If False only
the groups in __context__ will be returned. If True, the __context__ will be re-
freshed with current data and returned. Default is False

Returns A list of groups on the machine

Return type list

CLI Example:
salt 'salt '*' group.list_groups

salt.modules.win_groupadd.members(name, members_list, **kwargs)
Ensure a group contains only the members in the list

Parameters

• name (str) -- The name of the group to modify
• members_list (str) -- A single user or a comma separated list of users. The group
will contain only the users specified in this list.

Returns A dictionary of results

Return type dict

CLI Example:
salt 'salt '*' group.members foo 'user1,user2,user3'

19.9.422 salt.modules.win_iis module

Microsoft IIS site management via WebAdministration powershell module

maintainer Shane Lee <slee@saltstack.com>, Robert Booth <rbooth@saltstack.com>

platform Windows

depends PowerShell

depends WebAdministration module (PowerShell) (IIS)

New in version 2016.3.0.

salt.modules.win_iis.create_app(name, site, sourcepath, apppool=None)
Create an IIS application.

Note: This function only validates against the application name, and will return True even if the application
already exists with a different configuration. It will not modify the configuration of an existing application.

Parameters
• **name** (*str*) -- The IIS application.
• **site** (*str*) -- The IIS site name.
• **sourcepath** (*str*) -- The physical path.
• **apppool** (*str*) -- The name of the IIS application pool.

Returns: True if successful, otherwise False

Return type: bool

CLI Example:

```python
salt '*' win_iis.create_app name='app0' site='site0' sourcepath='C:\site0' apppool='site0'
```

salt.modules.win_iis.create_apppool(name)
Create an IIS application pool.

**Note:** This function only validates against the application pool name, and will return True even if the application pool already exists with a different configuration. It will not modify the configuration of an existing application pool.

Parameters

- **name** (*str*) -- The name of the IIS application pool.

Returns: True if successful, otherwise False

Return type: bool

CLI Example:

```python
salt '*' win_iis.create_apppool name='MyTestPool'
```

salt.modules.win_iis.create_backup(name)
Backup an IIS Configuration on the System.

New in version 2017.7.0.

**Note:** Backups are stored in the $env:Windir\System32\inetsrv\backup folder.

Parameters

- **name** (*str*) -- The name to give the backup

Returns: True if successful, otherwise False

Return type: bool

CLI Example:

```python
salt '*' win_iis.create_backup good_config_20170209
```

salt.modules.win_iis.create_binding(site, hostheader='', ipaddress='', port=80, protocol='http', sslflags=None)
Create an IIS Web Binding.

**Note:** This function only validates against the binding ipaddress:port:hostheader combination, and will return True even if the binding already exists with a different configuration. It will not modify the configuration of an existing binding.

Parameters

- **site** (*str*) -- The IIS site name.
- **hostheader** (*str*) -- The host header of the binding. Usually a hostname.
- **ipaddress** (*str*) -- The IP address of the binding.
• `port (int)` -- The TCP port of the binding.
• `protocol (str)` -- The application protocol of the binding.
• `sslflags (str)` -- The flags representing certificate type and storage of the binding.

Returns True if successful, otherwise False

Return type `bool`

CLI Example:
```bash
salt '*' win_iis.create_binding site='site0' hostheader='example.com' ipaddress='*' port='80'
```

salt.modules.win_iis.create_cert_binding(name, site, hostheader=quote, ipaddress=quote, port=443, sslflags=0)

Assign a certificate to an IIS Web Binding.

New in version 2016.11.0.

**Note:** The web binding that the certificate is being assigned to must already exist.

Parameters

• `name (str)` -- The thumbprint of the certificate.
• `site (str)` -- The IIS site name.
• `hostheader (str)` -- The host header of the binding.
• `ipaddress (str)` -- The IP address of the binding.
• `port (int)` -- The TCP port of the binding.
• `sslflags (int)` -- Flags representing certificate type and certificate storage of the binding.

Returns True if successful, otherwise False

Return type `bool`

CLI Example:
```bash
salt '*' win_iis.create_cert_binding name='AAA000' site='site0' hostheader=quote ipaddress=quote port='443'
```

salt.modules.win_iis.create_site(name, sourcepath=quote, apppool=quote, hostheader=quote, ipaddress=quote, port=80, protocol=quote)

Create a basic website in IIS.

**Note:** This function only validates against the site name, and will return True even if the site already exists with a different configuration. It will not modify the configuration of an existing site.

Parameters

• `name (str)` -- The IIS site name.
• `sourcepath (str)` -- The physical path of the IIS site.
• `apppool (str)` -- The name of the IIS application pool.
• `hostheader (str)` -- The host header of the binding. Usually the hostname or website name, ie: www.contoso.com
• `ipaddress (str)` -- The IP address of the binding.
• `port (int)` -- The TCP port of the binding.
• `protocol (str)` -- The application protocol of the binding. (http, https, etc.)

Returns True if successful, otherwise False.

Return type `bool`
Note: If an application pool is specified, and that application pool does not already exist, it will be created.

CLI Example:
```bash
salt '*' win_iis.create_site name='My Test Site' sourcepath='c:\stage' apppool='TestPool'
```

```
salt.modules.win_iis.create_vdir(name, site, sourcepath, app=u'/')
```

Create an IIS virtual directory.

Note: This function only validates against the virtual directory name, and will return True even if the virtual directory already exists with a different configuration. It will not modify the configuration of an existing virtual directory.

Parameters
- **name** (str) -- The virtual directory name.
- **site** (str) -- The IIS site name.
- **sourcepath** (str) -- The physical path.
- **app** (str) -- The IIS application.

Returns True if successful, otherwise False

Return type bool

CLI Example:
```bash
salt '*' win_iis.create_vdir name='vd0' site='site0' sourcepath='C:\inetpub\vdirs\vd0'
```

```
salt.modules.win_iis.get_container_setting(name, container, settings)
```

Get the value of the setting for the IIS container.

Parameters
- **name** (str) -- The name of the IIS container.
- **container** (str) -- The type of IIS container. The container types are: AppPools, Sites, SslBindings
- **settings** (dict) -- A dictionary of the setting names and their values.

Returns A dictionary of the provided settings and their values.

Return type dict

CLI Example:
```bash
salt '*' win_iis.get_container_setting name='MyTestPool' container='AppPools' settings="["processModel.identityType"]"
```

```
salt.modules.win_iis.get_webapp_settings(name, site, settings)
```

Get the value of the setting for the IIS web application.

Note: Params are case sensitive

Parameters
- **name** (str) -- The name of the IIS web application.
- **site** *(str)* -- The site name contains the web application. Example: Default Web Site
- **settings** *(str)* -- A dictionary of the setting names and their values. Available settings: physicalPath, applicationPool, userName, password

Returns A dictionary of the provided settings and their values.

Return type *dict*

CLI Example:

```
salt '*' win_iis.get_webapp_settings name='app0' site='Default Web Site' settings="[['physicalPath','applicationPool']]"
```

salt.modules.win_iis.list_apppools()

List all configured IIS application pools.

Returns A dictionary of IIS application pools and their details.

Return type *dict*

CLI Example:

```
salt '*' win_iis.list_apppools
```

salt.modules.win_iis.list_apps(site)

Get all configured IIS applications for the specified site.

Parameters **site** *(str)* -- The IIS site name.

Returns: A dictionary of the application names and properties.

CLI Example:

```
salt '*' win_iis.list_apps site
```

salt.modules.win_iis.list_backups()

List the IIS Configuration Backups on the System.

New in version 2017.7.0.

Note: Backups are made when a configuration is edited. Manual backups are stored in the $env:Windir\System32\inetsrv\backup folder.

Returns A dictionary of IIS Configurations backed up on the system.

Return type *dict*

CLI Example:

```
salt '*' win_iis.list_backups
```

salt.modules.win_iis.list_bindings(site)

Get all configured IIS bindings for the specified site.

Parameters **site** *(str)* -- The name if the IIS Site

Returns A dictionary of the binding names and properties.

Return type *dict*

CLI Example:

```
salt '*' win_iis.list_bindings site
```

salt.modules.win_iis.list_cert_bindings(site)

List certificate bindings for an IIS site.

New in version 2016.11.0.
Parameters **site** *(str)* -- The IIS site name.

Returns A dictionary of the binding names and properties.

Return type `dict`

CLI Example:

```
salt '*' win_iis.list_bindings site
```

salt.modules.win_iis.list_sites()

List all the currently deployed websites.

Returns A dictionary of the IIS sites and their properties.

Return type `dict`

CLI Example:

```
salt '*' win_iis.list_sites
```

salt.modules.win_iis.list_vdirs(*site, app=u'/*')

Get all configured IIS virtual directories for the specified site, or for the combination of site and application.

Parameters

- **site** *(str)* -- The IIS site name.
- **app** *(str)* -- The IIS application.

Returns A dictionary of the virtual directory names and properties.

Return type `dict`

CLI Example:

```
salt '*' win_iis.list_vdirs site
```

salt.modules.win_iis.list_worker_processes(apppool)

Returns a list of worker processes that correspond to the passed application pool.

New in version 2017.7.0.

Parameters **apppool** *(str)* -- The application pool to query

Returns A dictionary of worker processes with their process IDs

Return type `dict`

CLI Example:

```
salt '*' win_iis.list_worker_processes 'My App Pool'
```

salt.modules.win_iis.modify_binding(*site, binding, hostheader=None, ipaddress=None, port=None, sslflags=None)

Modify an IIS Web Binding. Use **site** and **binding** to target the binding.

New in version 2017.7.0.

Parameters

- **site** *(str)* -- The IIS site name.
- **binding** *(str)* -- The binding to edit. This is a combination of the IP address, port, and hostheader. It is in the following format: ipaddress:port:hostheader. For example, *:*80: or *:*80:salt.com
- **hostheader** *(str)* -- The host header of the binding. Usually the hostname.
- **ipaddress** *(str)* -- The IP address of the binding.
- **port** *(int)* -- The TCP port of the binding.
- **sslflags** *(str)* -- The flags representing certificate type and storage of the binding.

Returns True if successful, otherwise False

Return type `bool`

CLI Example:

The following will set the host header of binding *:*80: for site0 to example.com
**salt.modules.win_iis.modify_site** *(name, sourcepath=None, apppool=None)*
Modify a basic website in IIS.

New in version 2017.7.0.

**Parameters**
- `name` *(str)* -- The IIS site name.
- `sourcepath` *(str)* -- The physical path of the IIS site.
- `apppool` *(str)* -- The name of the IIS application pool.

**Returns**
True if successful, otherwise False.

**Return type** *bool*

**Note:** If an application pool is specified, and that application pool does not already exist, it will be created.

**CLI Example:**
```
salt '*' win_iis.modify_site name='My Test Site' sourcepath='c:\new_path' apppool='NewTestPool'
```

---

**salt.modules.win_iis.remove_app** *(name, site)*
Remove an IIS application.

**Parameters**
- `name` *(str)* -- The application name.
- `site` *(str)* -- The IIS site name.

**Returns**
True if successful, otherwise False.

**Return type** *bool*

**CLI Example:**
```
salt '*' win_iis.remove_app name='app0' site='site0'
```

---

**salt.modules.win_iis.remove_apppool** *(name)*
Remove an IIS application pool.

**Parameters**
- `name` *(str)* -- The name of the IIS application pool.

**Returns**
True if successful, otherwise False.

**Return type** *bool*

**CLI Example:**
```
salt '*' win_iis.remove_apppool name='MyTestPool'
```

---

**salt.modules.win_iis.remove_backup** *(name)*
Remove an IIS Configuration backup from the System.

New in version 2017.7.0.

**Parameters**
- `name` *(str)* -- The name of the backup to remove

**Returns**
True if successful, otherwise False.

**Return type** *bool*

**CLI Example:**
```
salt '*' win_iis.remove_backup backup_20170209
```

---

**salt.modules.win_iis.remove_binding** *(site, hostheader='*', ipaddress='*', port=80)*
Remove an IIS binding.

**Parameters**
- **site** *(str)* -- The IIS site name.
- **hostheader** *(str)* -- The host header of the binding.
- **ipaddress** *(str)* -- The IP address of the binding.
- **port** *(int)* -- The TCP port of the binding.

Returns: True if successful, otherwise False

Return type: bool

**CLI Example:**
```
salt '*' win_iis.remove_binding site='site0' hostheader='example.com' ipaddress='*' port=80'
```

salt.modules.win_iis.remove_cert_binding(name, site, hostheader=u'', ipaddress=u'', port=443)

Remove a certificate from an IIS Web Binding.

New in version 2016.11.0.

**Note:** This function only removes the certificate from the web binding. It does not remove the web binding itself.

Parameters
- **name** *(str)* -- The thumbprint of the certificate.
- **site** *(str)* -- The IIS site name.
- **hostheader** *(str)* -- The host header of the binding.
- **ipaddress** *(str)* -- The IP address of the binding.
- **port** *(int)* -- The TCP port of the binding.

Returns: True if successful, otherwise False

Return type: bool

**CLI Example:**
```
salt '*' win_iis.remove_cert_binding name='AAA000' site='site0' hostheader='example.com' ipaddress='*' port=443'
```

salt.modules.win_iis.remove_site(name)

Delete a website from IIS.

Parameters
- **name** *(str)* -- The IIS site name.

Returns: True if successful, otherwise False

Return type: bool

**Note:** This will not remove the application pool used by the site.

**CLI Example:**
```
salt '*' win_iis.remove_site name='My Test Site'
```

salt.modules.win_iis.remove_vdir(name, site, app=u'/')

Remove an IIS virtual directory.

Parameters
- **name** *(str)* -- The virtual directory name.
- **site** *(str)* -- The IIS site name.
- **app** *(str)* -- The IIS application.

Returns: True if successful, otherwise False

Return type: bool
salt.modules.win_iis.restart_apppool(name)
Restart an IIS application pool.
New in version 2016.11.0.
Parameters
- name (str) -- The name of the IIS application pool.
- Returns True if successful, otherwise False
- Return type bool
CLI Example:
salt '*' win_iis.restart_apppool name='MyTestPool'

salt.modules.win_iis.restart_site(name)
Restart a Web Site in IIS.
New in version 2017.7.0.
Parameters
- name (str) -- The name of the website to restart.
- Returns True if successful, otherwise False
- Return type bool
CLI Example:
salt '*' win_iis.restart_site name='My Test Site'

salt.modules.win_iis.set_container_setting(name, container, settings)
Set the value of the setting for an IIS container.
New in version 2016.11.0.
Parameters
- name (str) -- The name of the IIS container.
- container (str) -- The type of IIS container. The container types are: AppPools, Sites, SslBindings
- settings (dict) -- A dictionary of the setting names and their values.
- Returns True if successful, otherwise False
- Return type bool
CLI Example:
salt '*' win_iis.set_container_setting name='MyTestPool' container='AppPools'
settings="{'managedPipeLineMode': 'Integrated'}"

salt.modules.win_iis.set_webapp_settings(name, site, settings)
Configure an IIS application.
New in version 2017.7.0.
Configure an IIS application.

Note: This function only configures an existing app. Params are case sensitive.
Returns A boolean representing whether all changes succeeded.
Return type bool

CLI Example:
```
salt '*' win_iis.set_webapp_settings name='app0' site='site0' settings="{
    'physicalPath': 'C:\site0', 'apppool': 'site0'}"
```

salt.modules.win_iis.start_apppool(name)
Start an IIS application pool.
New in version 2017.7.0.
Parameters name (str) -- The name of the App Pool to start.
Returns True if successful, otherwise False
Return type bool
CLI Example:
```
salt '*' win_iis.start_apppool name='MyTestPool'
```

salt.modules.win_iis.start_site(name)
Start a Web Site in IIS.
New in version 2017.7.0.
Parameters name (str) -- The name of the website to start.
Returns True if successful, otherwise False
Return type bool
CLI Example:
```
salt '*' win_iis.start_site name='My Test Site'
```

salt.modules.win_iis.stop_apppool(name)
Stop an IIS application pool.
New in version 2017.7.0.
Parameters name (str) -- The name of the App Pool to stop.
Returns True if successful, otherwise False
Return type bool
CLI Example:
```
salt '*' win_iis.stop_apppool name='MyTestPool'
```

salt.modules.win_iis.stop_site(name)
Stop a Web Site in IIS.
New in version 2017.7.0.
Parameters name (str) -- The name of the website to stop.
Returns True if successful, otherwise False
Return type bool
CLI Example:
```
salt '*' win_iis.stop_site name='My Test Site'
```

19.9.423 salt.modules.win_ip
The networking module for Windows based systems
salt.modules.win_ip.disable(iface)
   Disable an interface
   CLI Example:
   ```
salt -G 'os_family:Windows' ip.disable 'Local Area Connection #2'
   ```

salt.modules.win_ip.enable(iface)
   Enable an interface
   CLI Example:
   ```
salt -G 'os_family:Windows' ip.enable 'Local Area Connection #2'
   ```

salt.modules.win_ip.get_all_interfaces()
   Return configs for all interfaces
   CLI Example:
   ```
salt -G 'os_family:Windows' ip.get_all_interfaces
   ```

salt.modules.win_ip.get_default_gateway()
   Set DNS source to DHCP on Windows
   CLI Example:
   ```
salt -G 'os_family:Windows' ip.get_default_gateway
   ```

salt.modules.win_ip.get_interface(iface)
   Return the configuration of a network interface
   CLI Example:
   ```
salt -G 'os_family:Windows' ip.get_interface 'Local Area Connection'
   ```

salt.modules.win_ip.get_subnet_length(mask)
   Convenience function to convert the netmask to the CIDR subnet length
   CLI Example:
   ```
salt -G 'os_family:Windows' ip.get_subnet_length 255.255.255.0
   ```

salt.modules.win_ip.is_disabled(iface)
   Returns True if interface is disabled, otherwise False
   CLI Example:
   ```
salt -G 'os_family:Windows' ip.is_disabled 'Local Area Connection #2'
   ```

salt.modules.win_ip.is_enabled(iface)
   Returns True if interface is enabled, otherwise False
   CLI Example:
   ```
salt -G 'os_family:Windows' ip.is_enabled 'Local Area Connection #2'
   ```

salt.modules.win_ip.raw_interface_configs()
   Return raw configs for all interfaces
   CLI Example:
salt -G 'os_family:Windows' ip.raw_interface_configs

salt.modules.win_ip.set_dhcp_all(iface)
Set both IP Address and DNS to DHCP

CLI Example:
salt -G 'os_family:Windows' ip.set_dhcp_all 'Local Area Connection'

salt.modules.win_ip.set_dhcp_dns(iface)
Set DNS source to DHCP on Windows

CLI Example:
salt -G 'os_family:Windows' ip.set_dhcp_dns 'Local Area Connection'

salt.modules.win_ip.set_dhcp_ip(iface)
Set Windows NIC to get IP from DHCP

CLI Example:
salt -G 'os_family:Windows' ip.set_dhcp_ip 'Local Area Connection'

salt.modules.win_ip.set_static_dns(iface, *addrs)
Set static DNS configuration on a Windows NIC

Parameters
• iface (str) -- The name of the interface to set
• addrs -- One or more DNS servers to be added. To clear the list of DNS servers pass an empty list ([]). If undefined or None no changes will be made.

Returns A dictionary containing the new DNS settings

Return type dict

CLI Example:
salt -G 'os_family:Windows' ip.set_static_dns 'Local Area Connection' '192.168.1.1'
salt -G 'os_family:Windows' ip.set_static_dns 'Local Area Connection' '192.168.1.252' '192.168.1.253'

salt.modules.win_ip.set_static_ip(iface, addr, gateway=None, append=False)
Set static IP configuration on a Windows NIC

iface The name of the interface to manage
addr IP address with subnet length (ex. 10.1.2.3/24). The ip.get_subnet_length function can be used to calculate the subnet length from a netmask.
gateway [None] If specified, the default gateway will be set to this value.
append [False] If True, this IP address will be added to the interface. Default is False, which overrides any existing configuration for the interface and sets addr as the only address on the interface.

CLI Example:
salt -G 'os_family:Windows' ip.set_static_ip 'Local Area Connection' 10.1.2.3/24
--gateway=10.1.2.1
salt -G 'os_family:Windows' ip.set_static_ip 'Local Area Connection' 10.1.2.4/24
--append=True

19.9.424 salt.modules.win_lgpo module

Manage Local Policy on Windows
This module allows configuring local group policy (i.e. gpedit.msc) on a Windows server. New in version 2016.11.0.

**Administrative Templates**

Administrative template policies are dynamically read from ADMX/ADML files on the server.

**Windows Settings**

Policies contained in the "Windows Settings" section of the gpedit.msc GUI are statically defined in this module. Each policy is configured for the section (Machine/User) in the module's _policy_info class. The _policy_info class contains a "policies" dict on how the module will configure the policy, where the policy resides in the GUI (for display purposes), data validation data, data transformation data, etc.

**Current known limitations**

- At this time, start/shutdown scripts policies are displayed, but are not configurable.
- Not all "Security Settings" policies exist in the _policy_info class

```python
salt.modules.win_lgpo.get(policy_class=None, return_full_policy_names=True, hierarchical_return=False, adml_language=u'en-US', return_not_configured=False)
```

Get a policy value

**Parameters**

- `policy_class (str)` -- Some policies are both user and computer, by default all policies will be pulled, but this can be used to retrieve only a specific policy class User/USER/user = retrieve user policies Machine/MACHINE/machine/Computer/COMPUTER/computer = retrieve machine/computer policies
- `return_full_policy_names (bool)` -- True/False to return the policy name as it is seen in the gpedit.msc GUI or to only return the policy key/id.
- `hierarchical_return (bool)` -- True/False to return the policy data in the hierarchy as seen in the gpedit.msc GUI. The default of False will return data split only into User/Computer configuration sections
- `adml_language (str)` -- The ADML language to use for processing display/descriptive names and enumeration values of ADMX template data, defaults to en-US
- `return_not_configured (bool)` -- Include Administrative Template policies that are 'Not Configured' in the return data

**Returns** A dictionary containing the policy values for the specified class

**Return type** dict

CLI Example:
salt '*' lgpo.get machine return_full_policy_names=True

salt.modules.win_lgpo.get_policy_info(policy_name, policy_class, admn_language=u'en-US')
Returns information about a specified policy
Parameters
- policy_name (str) -- The name of the policy to lookup
- policy_class (str) -- The class of policy, i.e. machine, user, both
- admn_language (str) -- The ADML language to use for Administrative Template
data lookup
Returns Information about the specified policy
Return type dict

CLI Example:
salt '*' lgpo.get_policy_info 'Maximum password age' machine

You can use lgpo.get_policy_info to get all the possible names that could be used in a state file or from the command line (along with elements that need to be set/etc). The key is to match the text you see in the gpedit.msc gui exactly, including quotes around words or phrases. The "full path" style is really only needed when there are multiple policies that use the same base name. For example, Access data sources across domains exists in ~10 different paths. If you put that through get_policy_info you'll get back a message that it is used for multiple policies and you need to be more specific.

CLI Example:
salt-call --local lgpo.get_policy_info ShellRemoveOrderPrints_2 machine

local: 
----------
message:
policy_aliases:
  - Turn off the "Order Prints" picture task
  - ShellRemoveOrderPrints_2
  - System\Internet Communication Management\Internet Communication
    \settings\Turn off the "Order Prints" picture task
policy_class:
machine
policy_elements:
policy_found:
  True
policy_name:
  ShellRemoveOrderPrints_2
rights_assignment:
  False

Escaping can get tricky in cmd/Powershell. The following is an example of escaping in Powershell using backquotes:

PS> salt-call --local lgpo.get_policy_info "Turn off the "\"Order Prints\"" picture task" machine

local: 
----------
message:
policy_aliases:
  - Turn off the "Order Prints" picture task
  - ShellRemoveOrderPrints_2
  - System\Internet Communication Management\Internet Communication\settings\Turn off the "Order Prints" picture task
This function can then be used to get the options available for specifying Group Policy Objects to be used in state files. Based on the above any of these should be usable:

```yaml
internet_communications_settings:
  lgpo.set:
    - computer_policy:
      Turn off the "Order Prints" picture task: Enabled
```

When using the full path, it might be a good idea to use single quotes around the path:

```yaml
internet_communications_settings:
  lgpo.set:
    - computer_policy:
      'System\Internet Communication Management\Internet Communication\settings\Turn off the "Order Prints" picture task': 'Enabled'
```

If you struggle to find the policy from get_policy_info using the name as you see in gpeedit.msc, the names such as `ShellRemoveOrderPrints_2` come from the .admx files. If you know nothing about .admx/.adml relationships (ADML holds what you see in the GUI, ADMX holds the more technical details), then this may be a little bit too much info, but here is an example with the above policy using Powershell:

```powershell
PS> Get-ChildItem -Path C:\Windows\PolicyDefinitions -Recurse -Filter *.adml | % Select-String "ShellRemoveOrderPrints"
```

From this grep, we can see id `ShellRemoveOrderPrints` is the ID of the string used to describe this policy, then we search for it in the ADMX:

```powershell
PS> Get-ChildItem -Path C:\Windows\PolicyDefinitions -Recurse -Filter *.admx | % Select-String "ShellRemoveOrderPrints"
```
Now we have two to pick from. And if you notice the `class="Machine"` and `class="User"` (which details if it is a computer policy or user policy respectively) the `ShellRemoveOrderPrints_2` is the `short name` we could use to pass through `get_policy_info` to see what the module itself is expecting.

```python
salt.modules.win_lgpo.set_(computer_policy=None, user_policy=None, cumulative_rights_assignments=True, adml_language=u'en-US')
```

Set a local server policy.

**Parameters**

- **computer_policy (dict)** -- A dictionary of `policyname: value` pairs of computer policies to set. `value` should be how it is displayed in the gpedit GUI, i.e. if a setting can be `Enabled'/"Disabled', then that should be passed

  Administrative Template data may require dicts within dicts, to specify each element of the Administrative Template policy. Administrative Templates policies are always cumulative.

  Policy names can be specified in a number of ways based on the type of policy:

  **Windows Settings Policies:**
  
  These policies can be specified using the GUI display name or the key name from the `_policy_info` class in this module.
  
  The GUI display name is also contained in the `_policy_info` class in this module.

  **Administrative Template Policies:**
  
  These can be specified using the policy name as displayed in the GUI (case sensitive). Some policies have the same name, but a different location (for example, `Access data sources across domains`). These can be differentiated by the `"path"` in the GUI (for example, `"Windows Components\Internet Explorer\Internet Control Panel\Security Page\Internet Zone\Access data sources across domains"`).

  Additionally, policies can be specified using the `"name"` and `"id"` attributes from the ADMX files.

  For Administrative Templates that have policy elements, each element can be specified using the text string as seen in the GUI or using the ID attribute from the ADMX file. Due to the way some of the GUI text is laid out, some policy element names could include descriptive text that appears before the policy element in the GUI.

  Use the `get_policy_info` function for the policy name to view the element ID/names that the module will accept.

- **user_policy (dict)** -- The same setup as the computer_policy, except with data to configure the local user policy.
- **cumulative_rights_assignments** *(bool)* -- Determine how user rights assignment policies are configured.

  If True, user right assignment specifications are simply added to the existing policy

  If False, only the users specified will get the right (any existing will have the right revoked)

- **adml_language** *(str)* -- The language files to use for looking up Administrative Template policy data (i.e. how the policy is displayed in the GUI). Defaults to `en-US` (U.S. English).

  Returns True is successful, otherwise False

  Return type bool

  CLI Example:

  ```
salt '*' lgpo.set computer_policy="{'LockoutDuration': 2, 'RestrictAnonymous': False, 'AuditProcessTracking': 'Success, Failure'}"
  ```

  ```
salt.modules.win_lgpo.set_computer_policy(name, setting, cumulative_rights_assignments=True, adml_language=u'en-US')
  ```

  Set a single computer policy

  Parameters

  - **name** *(str)* -- The name of the policy to configure
  - **setting** *(str)* -- The setting to configure the named policy with
  - **cumulative_rights_assignments** *(bool)* -- Determine how user rights assignment policies are configured. If True, user right assignment specifications are simply added to the existing policy. If False, only the users specified will get the right (any existing will have the right revoked)
  - **adml_language** *(str)* -- The language files to use for looking up Administrative Template policy data (i.e. how the policy is displayed in the GUI). Defaults to `en-US` (U.S. English).

  Returns True if successful, otherwise False

  Return type bool

  CLI Example:

  ```
salt '*' lgpo.set_computer_policy LockoutDuration 1440
  ```

  ```
salt.modules.win_lgpo.set_user_policy("Control Panel\Display\Disable the Display Control Panel", Enabled)
  ```

  Set a single user policy

  Parameters

  - **name** *(str)* -- The name of the policy to configure
  - **setting** *(str)* -- The setting to configure the named policy with
  - **adml_language** *(str)* -- The language files to use for looking up Administrative Template policy data (i.e. how the policy is displayed in the GUI). Defaults to `en-US` (U.S. English).

  Returns True if successful, Otherwise False

  Return type bool

  CLI Example:

  ```
salt '*' lgpo.set_user_policy "Control Panel\Display\Disable the Display Control Panel", Enabled
  ```

19.9.425 salt.modules.win_license module

This module allows you to manage windows licensing via slmgr.vbs
salt '*' license.install XXXXX-XXXXX-XXXXX-XXXXX-XXXXX

salt.modules.win_license.activate()

Attempt to activate the current machine via Windows Activation

CLI Example:

```
salt '*' license.activate
```

salt.modules.win_license.info()

Return information about the license, if the license is not correctly activated this will return None.

CLI Example:

```
salt '*' license.info
```

salt.modules.win_license.install(product_key)

Install the given product key

CLI Example:

```
salt '*' license.install XXXXX-XXXXX-XXXXX-XXXXX-XXXXX
```

salt.modules.win_license.installed(product_key)

Check to see if the product key is already installed.

Note: This is not 100% accurate as we can only see the last 5 digits of the license.

CLI Example:

```
salt '*' license.installed XXXXX-XXXXX-XXXXX-XXXXX-XXXXX
```

salt.modules.win_license.licensed()

Return true if the current machine is licensed correctly

CLI Example:

```
salt '*' license.licensed
```

salt.modules.win_license.uninstall()

Uninstall the current product key

CLI Example:

```
salt '*' license.uninstall
```

19.9.426 salt.modules.win_network

Module for gathering and managing network information

salt.modules.win_network.connect(host, port=None, **kwargs)

Test connectivity to a host using a particular port from the minion.

New in version 2016.3.0.

CLI Example:

```
salt '*' network.connect archlinux.org 80
```

```
salt '*' network.connect archlinux.org 80 timeout=3
```
salt '*/' network.connect archlinux.org 80 timeout=3 family=ipv4
salt '*/' network.connect google-public-dns-a.google.com port=53 proto=udp timeout=3

salt.modules.win_network.dig(host)
Performs a DNS lookup with dig
Note: dig must be installed on the Windows minion
CLI Example:
salt '*/' network.dig archlinux.org

salt.modules.win_network.get_route(ip)
Return routing information for given destination ip
New in version 2016.11.5.
CLI Example:
salt '*/' network.get_route 10.10.10.10

salt.modules.win_network.hw_addr(iface)
Return the hardware address (a.k.a. MAC address) for a given interface
CLI Example:
salt '*/' network.hw_addr 'Wireless Connection #1'

salt.modules.win_network.hwaddr(iface)
This function is an alias of hw_addr.
Return the hardware address (a.k.a. MAC address) for a given interface
CLI Example:
salt '*/' network.hw_addr 'Wireless Connection #1'

salt.modules.win_network.in_subnet(cidr)
Returns True if host is within specified subnet, otherwise False
CLI Example:
salt '*/' network.in_subnet 10.0.0.0/16

salt.modules.win_network.interfaces()
Return a dictionary of information about all the interfaces on the minion
CLI Example:
salt '*/' network.interfaces

salt.modules.win_network.interfaces_names()
Return a list of all the interfaces names
CLI Example:
salt '*/' network.interfaces_names
salt.modules.win_network.ip_addrs(interface=None, include_loopback=False)

Returns a list of IPv4 addresses assigned to the host. 127.0.0.1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned.

CLI Example:
```
salt '*' network.ip_addrs
```

salt.modules.win_network.ip_addrs6(interface=None, include_loopback=False)

Returns a list of IPv6 addresses assigned to the host. ::1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned.

CLI Example:
```
salt '*' network.ip_addrs6
```

salt.modules.win_network.ipaddrs(interface=None, include_loopback=False)

This function is an alias of ip_addrs.

Returns a list of IPv4 addresses assigned to the host. 127.0.0.1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned.

CLI Example:
```
salt '*' network.ip_addrs
```

salt.modules.win_network.ipaddrs6(interface=None, include_loopback=False)

This function is an alias of ip_addrs6.

Returns a list of IPv6 addresses assigned to the host. ::1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned.

CLI Example:
```
salt '*' network.ip_addrs6
```

salt.modules.win_network.netstat()

Return information on open ports and states

CLI Example:
```
salt '*' network.netstat
```

salt.modules.win_network.nslookup(host)

Query DNS for information about a domain or ip address

CLI Example:
```
salt '*' network.nslookup archlinux.org
```

salt.modules.win_network.ping(host, timeout=False, return_boolean=False)

Performs a ping to a host

CLI Example:
```
salt '*' network.ping archlinux.org
```

New in version 2016.11.0.

Return a True or False instead of ping output.
salt '*' network.ping archlinux.org \(\text{return boolean}=\text{True}\)

Set the time to wait for a response in seconds.

salt '*' network.ping archlinux.org \(\text{timeout}=3\)

salt.modules.win_network\(\text{.\textbf{subnets}}()\)

Returns a list of subnets to which the host belongs

CLI Example:

salt '*' network.subnets

salt.modules.win_network\(\text{.\textbf{traceroute}}(\text{host})\)

Performs a traceroute to a 3rd party host

CLI Example:

salt '*' network.traceroute archlinux.org

---

19.9.427 salt.modules.win_ntp

Management of NTP servers on Windows

New in version 2014.1.0.

salt.modules.win_ntp\(\text{.\textbf{get_servers}}()\)

Get list of configured NTP servers

CLI Example:

salt '*' ntp.get_servers

salt.modules.win_ntp\(\text{.\textbf{set_servers}}(\text{\textquoteleft \textquoteleft servers})\)

Set Windows to use a list of NTP servers

CLI Example:

salt '*' ntp.set_servers 'pool.ntp.org' 'us.pool.ntp.org'

---

19.9.428 salt.modules.win_path

Manage the Windows System PATH

Note that not all Windows applications will rehash the PATH environment variable, Only the ones that listen to the WM_SETTINGCHANGE message http://support.microsoft.com/kb/104011

salt.modules.win_path\(\text{.\textbf{add}}(\text{\textquoteleft \textquoteleft path}, \text{\textit{index=}0})\)

Add the directory to the SYSTEM path in the index location

\textbf{Returns} \ \textbf{boolean True} if successful, \textbf{False} if unsuccessful

CLI Example:

```bash
# Will add to the beginning of the path
salt '*' win_path.add 'c:\python27' 0
```

```bash
# Will add to the end of the path
salt '*' win_path.add 'c:\python27' index='-1'
```
salt.modules.win_path.exists(path)
Check if the directory is configured in the SYSTEM path Case-insensitive and ignores trailing backslash
Returns boolean True if path exists, False if not

CLI Example:

```
salt '*' win_path.exists 'c:\python27'
salt '*' win_path.exists 'c:\\python27' 
salt '*' win_path.exists 'C:\pyThon27'
```

salt.modules.win_path.get_path()
Returns a list of items in the SYSTEM path

CLI Example:

```
salt '*' win_path.get_path
```

salt.modules.win_path.rehash()
Send a WM_SETTINGCHANGE Broadcast to Windows to refresh the Environment variables for new processes.

**Note:** This will only affect new processes that aren't launched by services. To apply changes to the path to services, the host must be restarted. The salt-minion, if running as a service, will not see changes to the environment until the system is restarted. See MSDN Documentation

CLI Example:

```
... code-block:: bash
    salt '*' win_path.rehash
```

salt.modules.win_path.remove(path)
Remove the directory from the SYSTEM path
Returns boolean True if successful, False if unsuccessful

CLI Example:

```
# Will remove C:\Python27 from the path
salt '*' win_path.remove 'c:\\python27'
```

### 19.9.429 salt.modules.win_pkg

A module to manage software on Windows

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install` is not available), see [here](#).

The following functions require the existence of a windows repository metadata DB, typically created by running `pkg.refresh_db`:

- `pkg.get_repo_data`
- `pkg.install`
- `pkg.latest_version`
- `pkg.list_available`
- `pkg.list_pkgs`
• `pkg.list_upgrades`
• `pkg.remove`

If a metadata DB does not already exist and one of these functions is run, then one will be created from the repo SLS files that are present.

As the creation of this metadata can take some time, the `winrepo_cache_expire_min` minion config option can be used to suppress refreshes when the metadata is less than a given number of seconds old.

**Note:** Version numbers can be `version number string`, `latest` and `Not Found`, where `Not Found` means this module was not able to determine the version of the software installed, it can also be used as the version number in sls definitions file in these cases. Versions numbers are sorted in order of `0`, `Not Found`, order `version numbers,...,latest`.

```python
salt.modules.win_pkg.compare_versions(ver1=u'`, oper=u'='', ver2=u'`)
```

**Parameters**

- `ver1` *(str)* -- A software version to compare
- `oper` *(str)* -- The operand to use to compare
- `ver2` *(str)* -- A software version to compare

**Returns**
True if the comparison is valid, otherwise False

**Return type** bool

**CLI Example:**
```
salt '*' pkg.compare_versions 1.2 >= 1.3
```

```python
salt.modules.win_pkg.genrepo(**kwargs)
```

Generate package metedata db based on files within the `winrepo_source_dir`

**Kwargs:**
- `saltenv` *(str)*: Salt environment. Default: base
- `verbose` *(bool)*: Return verbose data structure which includes `success_list`, a list of all sls files and the package names contained within. Default False.
- `failhard` *(bool)*: If True, an error will be raised if any repo SLS files failed to process. If False, no error will be raised, and a dictionary containing the full results will be returned.

**Note:**
- Hidden directories (directories beginning with `\`, such as `.git`) will be ignored.

**Returns**
A dictionary of the results of the command

**Return type** dict

**CLI Example:**
```
salt-run pkg.genrepo
salt -G 'os:windows' pkg.genrepo verbose=true failhard=false
salt -G 'os:windows' pkg.genrepo saltenv=base
```

```python
salt.modules.win_pkg.get_repo_data(saltenv=u'base')
```

Returns the existing package metedata db. Will create it, if it does not exist, however will not refresh it.

**Parameters**
- `saltenv` *(str)* -- Salt environment. Default base

**Returns**
A dict containing contents of metadata db.

**Return type** dict

**CLI Example:**
salt '*' pkg.get_repo_data

salt.modules.win_pkg.install(name=None, refresh=False, pkgs=None, **kwargs)

Install the passed package(s) on the system using winrepo

Parameters

- **name (str)** -- The name of a single package, or a comma-separated list of packages to install. (no spaces after the commas)
- **refresh (bool)** -- Boolean value representing whether or not to refresh the winrepo db. Default False.
- **pkgs (list)** -- A list of packages to install from a software repository. All packages listed under pkgs will be installed via a single command.

You can specify a version by passing the item as a dict:

CLI Example:

```bash
# will install the latest version of foo and bar
salt '*' pkg.install pkgs='["foo", "bar"]'

# will install the latest version of foo and version 1.2.3 of bar
salt '*' pkg.install pkgs='["foo", {"bar": "1.2.3"}]'
```

Kwargs:

- **version (str)**: The specific version to install. If omitted, the latest version will be installed. Recommend for use when installing a single package.

  If passed with a list of packages in the pkgs parameter, the version will be ignored.

  CLI Example:

  ```bash
  # Version is ignored
  salt '*' pkg.install pkgs='["foo", "bar"]' version=1.2.3
  ```

  If passed with a comma separated list in the name parameter, the version will apply to all packages in the list.

  CLI Example:

  ```bash
  # Version 1.2.3 will apply to packages foo and bar
  salt '*' pkg.install foo,bar version=1.2.3
  ```

- **extra_install_flags (str)**: Additional install flags that will be appended to the install_flags defined in the software definition file. Only applies when single package is passed.

- **saltenv (str)**: Salt environment. Default 'base'

- **report_reboot_exit_codes (bool)**: If the installer exits with a recognized exit code indicating that a reboot is required, the module function

  ```bash
  win_system.set_reboot_required_witnessed
  ```

  will be called, preserving the knowledge of this event for the remainder of the current boot session. For the time being, 3010 is the only recognized exit code. The value of this param defaults to True.

  New in version 2016.11.0.

Returns

Return a dict containing the new package names and versions

If the package is installed by pkg.install:

```python
{"<package>": {"old": '<old-version>',
               "new": '<new-version>'}}
```
If the package is already installed:

```python
{'<package>': {'current': '<current-version>'}}
```

**Return type**  
dict

The following example will refresh the winrepo and install a single package, 7zip.

**CLI Example:**

```bash
salt '*' pkg.install 7zip refresh=True
```

**CLI Example:**

```bash
salt '*' pkg.install 7zip
salt '*' pkg.install 7zip, filezilla
salt '*' pkg.install pkgs='["7zip","filezilla"]'
```

**WinRepo Definition File Examples:**

The following example demonstrates the use of `cache_file`. This would be used if you have multiple installers in the same directory that use the same `install.ini` file and you don't want to download the additional installers.

```json
ntp:
  4.2.8:
    installer: 'salt://win/repo/ntp/ntp-4.2.8-win32-setup.exe'
    full_name: Meinberg NTP Windows Client
    locale: en_US
    reboot: False
    cache_file: 'salt://win/repo/ntp/install.ini'
    install_flags: '/USEFILE=C:\salt\var\cache\salt\minion\files\base\win\repo\ntp\install.ini'
    uninstaller: 'NTP/uninst.exe'
```

The following example demonstrates the use of `cache_dir`. It assumes a file named `install.ini` resides in the same directory as the installer.

```json
ntp:
  4.2.8:
    installer: 'salt://win/repo/ntp/ntp-4.2.8-win32-setup.exe'
    full_name: Meinberg NTP Windows Client
    locale: en_US
    reboot: False
    cache_dir: True
    install_flags: '/USEFILE=C:\salt\var\cache\salt\minion\files\base\win\repo\ntp\install.ini'
    uninstaller: 'NTP/uninst.exe'
```

```python
salt.modules.win_pkg.latest_version(*names, **kwargs)
```

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

**Parameters**

- `names`  
  A single or multiple names to lookup

**Kwargs:**

- `saltenv (str)` -- A single or multiple names to lookup
- `refresh (bool)` -- Refresh package metadata. Default `True`

**Returns**  
A dictionary of packages with the latest version available

**Return type**  
dict
CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

```
salt.modules.win_pkg.list_available('names', **kwargs)
```

Return a list of available versions of the specified package.

**Parameters**
- **names** *(str)* -- One or more package names

**Kwargs:**
- saltenv *(str)*: The salt environment to use. Default `base`.
- return_dict_always *(bool)*: Default `False` dict when a single package name is queried.

**Returns**
The package name with its available versions

**Return type**
dict

```
{'<package name>': ['<version>', '<version>', ]}
```

CLI Example:

```
salt '*' pkg.list_available <package name> return_dict_always=True
salt '*' pkg.list_available <package name01> <package name02>
```

```
salt.modules.win_pkg.list_pkgs(versions_as_list=False, **kwargs)
```

List the packages currently installed

**version_as_list** *(bool)*: Returns the versions as a list

**saltenv** *(str)*: The salt environment to use. Default `base`.

**refresh** *(bool)*: Refresh package metadata. Default `False`.

**Returns**
A dictionary of installed software with versions installed

**Return type**
dict

```
{'<package_name>': '<version>'}
```

CLI Example:

```
salt '*' pkg.list_pkgs
salt '*' pkg.list_pkgs versions_as_list=True
```

```
salt.modules.win_pkg.list_upgrades(refresh=True, **kwargs)
```

List all available package upgrades on this system

**Parameters**
- **refresh** *(bool)* -- Refresh package metadata. Default `True`

**Kwargs:**
- saltenv *(str)*: Salt environment. Default `base`

**Returns**
A dictionary of packages with available upgrades

**Return type**
dict

CLI Example:

```
salt '*' pkg.list_upgrades
```

```
salt.modules.win_pkg.purge(name=None, pkgs=None, **kwargs)
```

Package purges are not supported, this function is identical to `remove()`.

New in version 0.16.0.

**Parameters**
- **name** *(str)* -- The name of the package to be deleted.
• **version** *(str)* -- The version of the package to be deleted. If this option is used in combination with the *pkgs* option below, then this version will be applied to all targeted packages.

• **pkgs** *(list)* -- A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

**Kwargs:**

<table>
<thead>
<tr>
<th>Key</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>saltenv</td>
<td>(str)</td>
<td>Salt environment. Default is <em>base</em>.</td>
</tr>
<tr>
<td>refresh</td>
<td>(bool)</td>
<td>Refresh package metadata. Default is <em>False</em>.</td>
</tr>
</tbody>
</table>

**Returns**

A dict containing the changes.

**Return type**

dict

**CLI Example:**

```bash
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'
```

```python
salt.modules.win_pkg.refresh_db(**kwargs)
```

Generates the local software metadata database (*winrepo.p*) on the minion. The database is stored in a serialized format located by default at the following location:

```
C:saltvarcachesaltminionfilesbasewinrepo-ngwinrepo.p
```

This module performs the following steps to generate the software metadata database:

- Fetch the package definition files (*sls*) from *winrepo_source_dir* (default: *salt://win/repo-ng*) and cache them in *<cachedir>-files<saltenv><winrepo_source_dir>* (default: *C:saltvarcachesaltminionfilesbasewinrepo-ng*).
- Call `pkg.genrepo` to parse the package definition files and generate the repository metadata database file (*winrepo.p*).
- Return the report received from `pkg.genrepo`.

The default *winrepo* directory on the master is */srv/salt/win/repo-ng*. All files that end with *sls* in this and all subdirectories will be used to generate the repository metadata database (*winrepo.p*).

**Note:**

- Hidden directories (directories beginning with `.`) will be ignored.

---

**Note:** There is no need to call `pkg.refresh_db` every time you work with the `pkg` module. Automatic refresh will occur based on the following minion configuration settings:

- `winrepo_cache_expire_min`
- `winrepo_cache_expire_max`

However, if the package definition files have changed, as would be the case if you are developing a new package definition, this function should be called to ensure the minion has the latest information about packages available to it.

**Warning:** Directories and files fetched from `<winrepo_source_dir>` (*/srv/salt/win/repo-ng*) will be processed in alphabetical order. If two or more software definition files contain the same name, the last one processed replaces all data from the files processed before it.

For more information see *Windows Software Repository*

**Arguments:**
saltenv (str): Salt environment. Default: base
verbose (bool): Return a verbose data structure which includes `success_list`, a list of all sls files and the package names contained within. Default is `False`
failhard (bool): If True, an error will be raised if any repo SLS files fails to process. If False, no error will be raised, and a dictionary containing the full results will be returned.

Returns A dictionary containing the results of the database refresh.
Return type dict

Note: A result with a total: 0 generally means that the files are in the wrong location on the master. Try running the following command on the minion: salt-call -l debug pkg.refresh saltenv=base

Warning: When calling this command from a state using module.run be sure to pass failhard: False. Otherwise the state will report failure if it encounters a bad software definition file.

CLI Example:
salt '*' pkg.refresh_db
salt '*' pkg.refresh_db saltenv=base

salt.modules.win_pkg.remove(name=None, pkgs=None, **kwargs)
Remove the passed package(s) from the system using winrepo

New in version 0.16.0.

Parameters
- **name** (str) -- The name(s) of the package(s) to be uninstalled. Can be a single package or a comma delimited list of packages, no spaces.
- **pkgs** (list) -- A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

Kwargs:
- **version** (str): The version of the package to be uninstalled. If this option is used to to uninstall multiple packages, then this version will be applied to all targeted packages. Recommended using only when uninstalling a single package. If this parameter is omitted, the latest version will be uninstalled.

Returns

Returns a dict containing the changes.

If the package is removed by pkg.remove:

```
{`<package>`: `{`old`: `<old-version>`, `new`: `<new-version>`}`}
```

If the package is already uninstalled:

```
{`<package>`: `{`current`: `not installed'}`}
```

Return type dict

CLI Example:
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
salt.modules.win_pkg.upgrade(**kwargs)
Upgrade all software. Currently not implemented

Kwarg:

**Note:** This feature is not yet implemented for Windows.

Returns Empty dict, until implemented
Return type dict

CLI Example:
salt '*' pkg.upgrade

salt.modules.win_pkg.upgrade_available(name, **kwargs)
Check whether or not an upgrade is available for a given package

Parameters name (str) -- The name of a single package

Kwarg:
refresh (bool): Refresh package metadata. Default True

Returns True if new version available, otherwise False
Return type bool

CLI Example:
salt '*' pkg.upgrade_available <package name>

salt.modules.win_pkg.version(*names, **kwargs)
Return a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

Parameters name (str) -- One or more package names

Kwarg:

Returns version string when a single package is specified. dict: The package name(s) with the installed versions.
Return type str

CLI Example:
salt '*' pkg.version <package name>
salt '*' pkg.version <package name01> <package name02>

19.9.430 salt.modules.win_pki module

platform Windows
depends

- PowerShell 4
- PKI Client Module (Windows 8+ / Windows Server 2012+)

New in version 2016.11.0.

salt.modules.win_pki.export_cert(name, thumbprint, cert_format='cer', context='LocalMachine', store='My', password='')

Export the certificate to a file from the given certificate store.

Parameters

- name (str) -- The destination path for the exported certificate file.
- thumbprint (str) -- The thumbprint value of the target certificate.
- cert_format (str) -- The certificate format. Specify `cer' for X.509, or `pfx' for PKCS #12.
- context (str) -- The name of the certificate store location context.
- store (str) -- The name of the certificate store.
- password (str) -- The password of the certificate. Only applicable to pfx format.

Note that if used interactively, the password will be seen by all minions. To protect the password, use a state and get the password from pillar.

Returns A boolean representing whether all changes succeeded.

Return type bool

CLI Example:

```bash
salt '*' win_pki.export_cert name='C:\certs\example.cer' thumbprint='AAA000'
```

salt.modules.win_pki.get_cert_file(name, cert_format='cer', password='')

Get the details of the certificate file.

Parameters

- name (str) -- The filesystem path of the certificate file.
- cert_format (str) -- The certificate format. Specify `cer' for X.509, or `pfx' for PKCS #12.
- password (str) -- The password of the certificate. Only applicable to pfx format.

Note that if used interactively, the password will be seen by all minions. To protect the password, use a state and get the password from pillar.

Returns A dictionary of the certificate thumbprints and properties.

Return type dict

CLI Example:

```bash
salt '*' win_pki.get_cert_file name='C:\certs\example.cer'
```

salt.modules.win_pki.get_certs(context='LocalMachine', store='My')

Get the available certificates in the given store.

Parameters

- context (str) -- The name of the certificate store location context.
- store (str) -- The name of the certificate store.

Returns A dictionary of the certificate thumbprints and properties.

Return type dict

CLI Example:

```bash
salt '*' win_pki.get_certs
```

salt.modules.win_pki.get_stores()

Get the certificate location contexts and their corresponding stores.

Returns A dictionary of the certificate location contexts and stores.

Return type dict
CLI Example:

```
salt '*' win_pki.get_stores
```

**salt.modules.win_pki.import_cert(name, cert_format='cer', context='LocalMachine', store='My',
exportable=True, password='`, saltenv='base')**

Import the certificate file into the given certificate store.

**Parameters**

- **name (str)** -- The path of the certificate file to import.
- **cert_format (str)** -- The certificate format. Specify 'cer' for X.509, or 'pfx' for PKCS #12.
- **context (str)** -- The name of the certificate store location context.
- **store (str)** -- The name of the certificate store.
- **exportable (bool)** -- Mark the certificate as exportable. Only applicable to pfx format.
- **password (str)** -- The password of the certificate. Only applicable to pfx format.
  Note that if used interactively, the password will be seen by all minions. To protect the password, use a state and get the password from pillar.
- **saltenv (str)** -- The environment the file resides in.

**Returns** A boolean representing whether all changes succeeded.

**Return type** bool

CLI Example:

```
salt '*' win_pki.import_cert name='salt://cert.cer'
```

**salt.modules.win_pki.remove_cert(thumbprint, context='LocalMachine', store='My')**

Remove the certificate from the given certificate store.

**Parameters**

- **thumbprint (str)** -- The thumbprint value of the target certificate.
- **context (str)** -- The name of the certificate store location context.
- **store (str)** -- The name of the certificate store.

**Returns** A boolean representing whether all changes succeeded.

**Return type** bool

CLI Example:

```
salt '*' win_pki.remove_cert thumbprint='AAA000'
```

**salt.modules.win_pki.test_cert(thumbprint, context='LocalMachine', store='My',
untrusted_root=False, dns_name='`, eku='`)**

Check the certificate for validity.

**Parameters**

- **thumbprint (str)** -- The thumbprint value of the target certificate.
- **context (str)** -- The name of the certificate store location context.
- **store (str)** -- The name of the certificate store.
- **untrusted_root (bool)** -- Whether the root certificate is required to be trusted in chain building.
- **dns_name (str)** -- The DNS name to verify as valid for the certificate.
- **eku (str)** -- The enhanced key usage object identifiers to verify for the certificate chain.

**Returns** A boolean representing whether the certificate was considered valid.

**Return type** bool

CLI Example:

```
salt '*' win_pki.test_cert thumbprint='AAA000' dns_name='example.test'
```
19.9.431 salt.modules.win_powercfg

This module allows you to control the power settings of a windows minion via powercfg.

New in version 2015.8.0.

```bash
# Set monitor to never turn off on Battery power
salt '*' powercfg.set_monitor_timeout 0 power=dc
# Set disk timeout to 120 minutes on AC power
salt '*' powercfg.set_disk_timeout 120 power=ac
```

salt.modules.win_powercfg.get_disk_timeout(scheme=None)

Get the current disk timeout of the given scheme

**Parameters**

  scheme (str) -- The scheme to use, leave as None to use the current. Default is None. This can be the GUID or the Alias for the Scheme. Known Aliases are:

  - SCHEME_BALANCED - Balanced
  - SCHEME_MAX - Power saver
  - SCHEME_MIN - High performance

**Returns**

  A dictionary of both the AC and DC settings

**Return type**

dict

**CLI Example:**

```
salt '*' powercfg.get_disk_timeout
```

salt.modules.win_powercfg.get_hibernate_timeout(scheme=None)

Get the current hibernate timeout of the given scheme

**Parameters**

  scheme (str): The scheme to use, leave as None to use the current. Default is None. This can be the GUID or the Alias for the Scheme. Known Aliases are:

  - SCHEME_BALANCED - Balanced
  - SCHEME_MAX - Power saver
  - SCHEME_MIN - High performance

**Returns**

  A dictionary of both the AC and DC settings

**Return type**

dict

**CLI Example:**

```
salt '*' powercfg.get_hibernate_timeout
```

salt.modules.win_powercfg.get_monitor_timeout(scheme=None)

Get the current monitor timeout of the given scheme

**Parameters**

  scheme (str) -- The scheme to use, leave as None to use the current. Default is None. This can be the GUID or the Alias for the Scheme. Known Aliases are:

  - SCHEME_BALANCED - Balanced
  - SCHEME_MAX - Power saver
  - SCHEME_MIN - High performance

**Returns**

  A dictionary of both the AC and DC settings

**Return type**

dict

**CLI Example:**

```
salt '*' powercfg.get_monitor_timeout
```

salt.modules.win_powercfg.get_standby_timeout(scheme=None)

Get the current standby timeout of the given scheme

**Parameters**

  scheme (str): The scheme to use, leave as None to use the current. Default is None. This can be the GUID or the Alias for the Scheme. Known Aliases are:

  - SCHEME_BALANCED - Balanced
Salt Documentation, Release 2017.7.8

- SCHEME_MAX - Power saver
- SCHEME_MIN - High performance

**Returns** A dictionary of both the AC and DC settings

**Return type** `dict`

**CLI Example:**
```bash
salt '*' powercfg.get_standby_timeout
```

`salt.modules.win_powercfg.set_disk_timeout(timeout, power='ac', scheme=None)`
Set the disk timeout in minutes for the given power scheme

**Parameters**
- `timeout (int)` -- The amount of time in minutes before the disk will timeout
- `power (str)` -- Set the value for AC or DC power. Default is `ac`. Valid options are:
  - `ac` (AC Power)
  - `dc` (Battery)
- `scheme (str)` -- The scheme to use, leave as `None` to use the current. Default is `None`. This can be the GUID or the Alias for the Scheme. Known Aliases are:
  - SCHEME_BALANCED - Balanced
  - SCHEME_MAX - Power saver
  - SCHEME_MIN - High performance

**Returns** `True` if successful, otherwise `False`

**Return type** `bool`

**CLI Example:**
```bash
# Sets the disk timeout to 30 minutes on battery
salt '*' powercfg.set_disk_timeout 30 power=dc
```

`salt.modules.win_powercfg.set_hibernate_timeout(timeout, power='ac', scheme=None)`
Set the hibernate timeout in minutes for the given power scheme

**Parameters**
- `timeout (int)` -- The amount of time in minutes before the computer hibernates
- `power (str)` -- Set the value for AC or DC power. Default is `ac`. Valid options are:
  - `ac` (AC Power)
  - `dc` (Battery)
- `scheme (str)` -- The scheme to use, leave as `None` to use the current. Default is `None`. This can be the GUID or the Alias for the Scheme. Known Aliases are:
  - SCHEME_BALANCED - Balanced
  - SCHEME_MAX - Power saver
  - SCHEME_MIN - High performance

**Returns** `True` if successful, otherwise `False`

**Return type** `bool`

**CLI Example:**
```bash
# Sets the hibernate timeout to 30 minutes on Battery
salt '*' powercfg.set_hibernate_timeout 30 power=dc
```

`salt.modules.win_powercfg.set_monitor_timeout(timeout, power='ac', scheme=None)`
Set the monitor timeout in minutes for the given power scheme

**Parameters**
- `timeout (int)` -- The amount of time in minutes before the monitor will timeout
- `power (str)` -- Set the value for AC or DC power. Default is `ac`. Valid options are:
  - `ac` (AC Power)
  - `dc` (Battery)
- **scheme** *(str)* -- The scheme to use, leave as *None* to use the current. Default is *None*. This can be the GUID or the Alias for the Scheme. Known Aliases are:
  - SCHEME_BALANCED - Balanced
  - SCHEME_MAX - Power saver
  - SCHEME_MIN - High performance

Returns True if successful, otherwise False

Return type **bool**

CLI Example:

```bash
# Sets the monitor timeout to 30 minutes
salt '*' powercfg.set_monitor_timeout 30
```

**salt.modules.win_powercfg.set_standby_timeout** *(timeout, power='ac', scheme=None)*

Set the standby timeout in minutes for the given power scheme

Parameters

- **timeout** *(int)* -- The amount of time in minutes before the computer sleeps
- **power** *(str)* -- Set the value for AC or DC power. Default is *ac*. Valid options are:
  - *ac* (AC Power)
  - *dc* (Battery)
- **scheme** *(str)* -- The scheme to use, leave as *None* to use the current. Default is *None*. This can be the GUID or the Alias for the Scheme. Known Aliases are:
  - SCHEME_BALANCED - Balanced
  - SCHEME_MAX - Power saver
  - SCHEME_MIN - High performance

Returns True if successful, otherwise False

Return type **bool**

CLI Example:

```bash
# Sets the system standby timeout to 30 minutes on Battery
salt '*' powercfg.set_standby_timeout 30 power=dc
```

### 19.9.432 salt.modules.win_psget module

Module for managing PowerShell through PowerShellGet (PSGet)

* depends
  - PowerShell 5.0
  - PSGet

Support for PowerShell

**salt.modules.win_psget.avail_modules** *(desc=False)*

List available modules in registered Powershell module repositories.

Parameters **desc** *(bool)* -- If *True*, the verbose description will be returned.

CLI Example:

```bash
salt 'win01' psget.avail_modules
salt 'win01' psget.avail_modules desc=True
```

**salt.modules.win_psget.bootstrap** *

Make sure that nuget-anycpu.exe is installed. This will download the official nuget-anycpu.exe from the internet.

CLI Example:
salt 'win01' psget.bootstrap

salt.modules.win_psget.get_repository(name)
Get the details of a local PSGet repository
Parameters name (str) -- Name of the repository
CLI Example:
salt 'win01' psget.get_repository MyRepo

salt.modules.win_psget.install(name, minimum_version=None, required_version=None, scope=None, repository=None)
Install a Powershell module from powershell gallery on the system.
Parameters
- name (str) -- Name of a Powershell module
- minimum_version (str) -- The maximum version to install, e.g. 1.23.2
- required_version (str) -- Install a specific version
- scope (str) -- The scope to install the module to, e.g. CurrentUser, Computer
- repository (str) -- The friendly name of a private repository, e.g. MyREpo
CLI Example:
salt 'win01' psget.install PowerPlan

salt.modules.win_psget.list_modules(desc=False)
List currently installed PSGet Modules on the system.
Parameters desc (bool) -- If True, the verbose description will be returned.
CLI Example:
salt 'win01' psget.list_modules
salt 'win01' psget.list_modules desc=True

salt.modules.win_psget.psversion()
Returns the Powershell version
This has been deprecated and has been replaced by cmd.shell_info
Note the minimum version return is 5 as dsc is not available for version less than 5. This function will be removed in `Oxygen' release.
CLI Example:
salt 'win01' dsc.psversion

salt.modules.win_psget.register_repository(name, location, installation_policy=None)
Register a PSGet repository on the local machine
Parameters
- name (str) -- The name for the repository
- location (str) -- The URI for the repository
- installation_policy (str) -- The installation policy for packages, e.g. Trusted, Untrusted
CLI Example:
salt 'win01' psget.register_repository MyRepo https://myrepo.mycompany.com/

salt.modules.win_psget.remove(name)
Remove a Powershell DSC module from the system.
Parameters name (str) -- Name of a Powershell DSC module
CLI Example:
salt 'win01' psget.remove PowerPlan

salt.modules.win_psget.update(name, maximum_version=None, required_version=None)
  Update a PowerShell module to a specific version, or the newest
  Parameters
  • name (str) -- Name of a Powershell module
  • maximum_version (str) -- The maximum version to install, e.g. 1.23.2
  • required_version (str) -- Install a specific version

CLI Example:
salt 'win01' psget.update PowerPlan

19.9.433  salt.modules.win_repo

Module to manage Windows software repo on a Standalone Minion

file_client: local must be set in the minion config file.

For documentation on Salt's Windows Repo feature, see here.

salt.modules.win_repo.genrepo()
  Generate winrepo_cachefile based on sls files in the winrepo_dir

  CLI Example:
  salt-call winrepo.genrepo

salt.modules.win_repo.show_sls(name, saltenv='base')
  New in version 2015.8.0.
  Display the rendered software definition from a specific sls file in the local winrepo cache. This will parse all
  Jinja. Run pkg.refresh_db to pull the latest software definitions from the master.

  Note: This function does not ask a master for an sls file to render. Instead it directly processes the file
  specified in name

  Parameters
  • str (saltenv) -- The name/path of the package you want to view. This can be the
  • path to a file on the minion file system or a file on the
  local (full) --
  • cache. (minion) --
  • str -- The default environment is base

  Returns Returns a dictionary containing the rendered data structure
  Return type dict

  Note: To use a file from the minion cache start from the local winrepo root
  (C:\salt\var\cache\salt\minion\files\base\win\repo-ng). If you have .sls files
  organized in subdirectories you'll have to denote them with .. For example, if you have a test directory
  in the winrepo root with a gvim.sls file inside, would target that file like so: test.gvim. Directories can
  be targeted as well as long as they contain an init.sls inside. For example, if you have a node directory
  with an init.sls inside, target that like so: node.
salt.modules.win_repo.update_git_repos(clean=False)

Checkout git repos containing *Windows Software Package Definitions*.

**Important:** This function requires *Git for Windows* to be installed in order to work. When installing, make sure to select an installation option which permits the git executable to be run from the Command Prompt.

**clean** [False] Clean repo cachedirs which are not configured under *winrepo_remotes*.

**Note:** This option only applies if either *pygit2* or *GitPython* is installed into Salt's bundled Python.

**Warning:** This argument should not be set to True if a mix of git and non-git repo definitions are being used, as it will result in the non-git repo definitions being removed.

New in version 2015.8.0.

CLI Example:

```
salt-call winrepo.update_git_repos
```

### 19.9.434 salt.modules.win_servermanager

Manage Windows features via the ServerManager powershell module

salt.modules.win_servermanager.install(feature, recurse=False, restart=False, source=None, exclude=None)

Install a feature

**Note:** Some features require reboot after un/installation, if so until the server is restarted other features can not be installed!

**Note:** Some features take a long time to complete un/installation, set -t with a long timeout

**Parameters**

- **feature** (*str*) -- The name of the feature to install
- **recurse** (*bool*) -- Install all sub-features. Default is False
- **source** (*str*) -- Path to the source files if missing from the target system. None means that the system will use windows update services to find the required files. Default is None
- **restart** (*bool*) -- Restarts the computer when installation is complete, if required by the role/feature installed. Default is False
- **exclude** (*str*) -- The name of the feature to exclude when installing the named feature.
Note: As there is no exclude option for the Add-WindowsFeature command, the feature will be installed with other sub-features and will then be removed.

- **restart** -- Restarts the computer when installation is complete, if required by the role feature installed.

  Returns A dictionary containing the results of the install
  Return type dict

CLI Example:

```
salt '*' win_servermanager.install Telnet-Client
salt '*' win_servermanager.install SNMP-Service True
salt '*' win_servermanager.install TFTP-Client source=d:\side-by-side
```

```python
salt.modules.win_servermanager.list_available()
```

List available features to install

- Returns A list of available features
- Return type list

CLI Example:

```
salt '*' win_servermanager.list_available
```

```python
salt.modules.win_servermanager.list_installed()
```

List installed features. Supported on Windows Server 2008 and Windows 8 and newer.

- Returns A list of installed features
- Return type list

CLI Example:

```
salt '*' win_servermanager.list_installed
```

```python
salt.modules.win_servermanager.remove(feature, remove_payload=False, restart=False)
```

Remove an installed feature

Note: Some features require a reboot after installation/uninstallation. If one of these features are modified, then other features cannot be installed until the server is restarted. Additionally, some features take a while to complete installation/uninstallation, so it is a good idea to use the -t option to set a longer timeout.

Parameters

- **feature (str)** -- The name of the feature to remove
- **remove_payload (bool)** -- True will cause the feature to be removed from the side-by-side store (%SystemDrive%:\Windows\WinSxS). Default is False
- **restart (bool)** -- Restarts the computer when uninstall is complete, if required by the role/feature removed. Default is False

- Returns A dictionary containing the results of the uninstall
- Return type dict

CLI Example:

```
salt -t 600 '*' win_servermanager.remove Telnet-Client
```

19.9.435 salt.modules.win_service

Windows Service module.
Changed in version 2016.11.0: - Rewritten to use PyWin32

```python
salt.modules.win_service.available(name)
```

Check if a service is available on the system.

**Parameters**

- `name (str)` -- The name of the service to check

**Returns**

- `True` if the service is available, `False` otherwise

**Return type**

`bool`

**CLI Example:**

```
salt '*' service.available <service name>
```

```python
salt.modules.win_service.config(name, bin_path=None, display_name=None, svc_type=None, start_type=None, error=None, group=None, tag=None, depend=None, obj=None, password=None, **kwargs)
```

Deprecated since version 2016.11.0: Use `service.modify` instead

Modify the named service. Because this is deprecated it will use the passed parameters to run `service.modify` instead.

**Parameters**

- `name (str)` -- Specifies the service name. This is not the `display_name` of the service.

- `bin_path (str)` -- Specifies the path to the service binary file. Backslashes must be escaped, e.g.: C:\path\to\binary.exe

- `display_name (str)` -- The name to be displayed in the service manager

- `svc_type (str)` -- Specifies the service type. Default is `own`. Valid options are as follows:
  - `kernel`: Driver service
  - `filesystem`: File system driver service
  - `adapter`: Adapter driver service (reserved)
  - `recognizer`: Recognizer driver service (reserved)
  - `own (default)`: Service runs in its own process
  - `share`: Service shares a process with one or more other services

- `start_type (str)` -- Specifies the service start type. Valid options are as follows:
  - `boot`: Device driver that is loaded by the boot loader
  - `system`: Device driver that is started during kernel initialization
  - `auto`: Service that automatically starts
  - `manual (default)`: Service must be started manually
  - `disabled`: Service cannot be started

- `error (str)` -- The severity of the error, and action taken, if this service fails to start. Valid options are as follows:
  - `normal (normal)`: Error is logged and a message box is displayed
  - `severe`: Error is logged and computer attempts a restart with the last known good configuration
  - `critical`: Error is logged, computer attempts to restart with the last known good configuration, system halts on failure
  - `ignore`: Error is logged and startup continues, no notification is given to the user

- `group` -- The name of the load order group to which this service belongs

- `depend (list)` -- A list of services or load ordering groups that must start before this service

- `obj (str)` -- The name of the account under which the service should run. For `own` type services this should be in the `domain\username` format. The following are examples of valid built-in service accounts:
  - `NT Authority\LocalService`
  - `NT Authority\NetworkService`
  - `NT Authority\LocalSystem`
- `.\LocalSystem`

- **password (str)** -- The password for the account name specified in account_name. For the above built-in accounts, this can be None. Otherwise a password must be specified.

Returns a dictionary of changes made

Returns a dictionary of changes made

**Return type** dict

**CLI Example:**

```
salt '*' service.config <service name> <path to exe> display_name='display name'
```

**salt.modules.win_service.create**

```
salt.modules.win_service.create(name, bin_path, exe_args=None, display_name=None, description=None, service_type='own', start_type='manual', start_delayed=False, error_control='normal', load_order_group=None, dependencies=None, account_name='.\LocalSystem', account_password=None, run_interactive=False, **kwargs)
```

Create the named service.

New in version 2015.8.0.

**Parameters**

- **name (str)** -- Specifies the service name. This is not the display_name
- **bin_path (str)** -- Specifies the path to the service binary file. Backslashes must be escaped, eg: C:\path\to\binary.exe
- **exe_args (str)** -- Any additional arguments required by the service binary.
- **display_name (str)** -- The name to be displayed in the service manager. If not passed, the name will be used
- **description (str)** -- A description of the service
- **service_type (str)** -- Specifies the service type. Default is own. Valid options are as follows:
  - kernel: Driver service
  - filesystem: File system driver service
  - adapter: Adapter driver service (reserved)
  - recognizer: Recognizer driver service (reserved)
  - own (default): Service runs in its own process
  - share: Service shares a process with one or more other services
- **start_type (str)** -- Specifies the service start type. Valid options are as follows:
  - boot: Device driver that is loaded by the boot loader
  - system: Device driver that is started during kernel initialization
  - auto: Service that automatically starts
  - manual (default): Service must be started manually
  - disabled: Service cannot be started
- **start_delayed (bool)** -- Set the service to Auto(Delayed Start). Only valid if the start_type is set to Auto. If service_type is not passed, but the service is already set to Auto, then the flag will be set. Default is False
- **error_control (str)** -- The severity of the error, and action taken, if this service fails to start. Valid options are as follows:
  - normal (normal): Error is logged and a message box is displayed
  - severe: Error is logged and computer attempts a restart with the last known good configuration
  - critical: Error is logged, computer attempts to restart with the last known good configuration, system halts on failure
  - ignore: Error is logged and startup continues, no notification is given to the user
- **load_order_group (str)** -- The name of the load order group to which this service belongs
• **dependencies** *(list)* -- A list of services or load ordering groups that must start before this service

• **account_name** *(str)* -- The name of the account under which the service should run. For *own* type services this should be in the `domain\username` format. The following are examples of valid built-in service accounts:
  - NT Authority\LocalService
  - NT Authority\NetworkService
  - NT Authority\LocalSystem
  - .\LocalSystem

• **account_password** *(str)* -- The password for the account name specified in `account_name`. For the above built-in accounts, this can be None. Otherwise a password must be specified.

• **run_interactive** *(bool)* -- If this setting is True, the service will be allowed to interact with the user. Not recommended for services that run with elevated privileges.

**Returns** A dictionary containing information about the new service

**Return type** `dict`

**CLI Example:**
```
salt '*' service.create <service name> <path to exe> display_name='<display name>'
```

salt.modules.win_service.create_win_salt_restart_task()
Create a task in Windows task scheduler to enable restarting the salt-minion

**Returns** True if successful, otherwise False

**Return type** `bool`

**CLI Example:**
```
salt '*' service.create_win_salt_restart_task()
```

salt.modules.win_service.delete*(name, timeout=90)*
Delete the named service

**Parameters**

• **name** *(str)* -- The name of the service to delete

• **timeout** *(int)* -- The time in seconds to wait for the service to be deleted before returning. This is necessary because a service must be stopped before it can be deleted. Default is 90 seconds

**Returns**

**True** if successful, otherwise **False**. Also returns **True** if the service is not present

**Return type** `bool`

**CLI Example:**
```
salt '*' service.delete <service name>
```

salt.modules.win_service.disable*(name, **kwargs)*
Disable the named service to start at boot

**Parameters**

• **name** *(str)* -- The name of the service to disable

**Returns** True if disabled, False otherwise

**Return type** `bool`

**CLI Example:**
```
salt '*' service.disable <service name>
```

salt.modules.win_service.disabled*(name)*
Check to see if the named service is disabled to start on boot
Parameters **name** (str) -- The name of the service to check
Returns True if the service is disabled
Return type bool
CLI Example:
```
salt '*' service.disabled <service name>
```

salt.modules.win_service.enable(name, **kwargs)
Enable the named service to start at boot
Parameters **name** (str) -- The name of the service to enable.
Returns True if successful, False otherwise
Return type bool
CLI Example:
```
salt '*' service.enable <service name>
```

salt.modules.win_service.enabled(name, **kwargs)
Check to see if the named service is enabled to start on boot
Parameters **name** (str) -- The name of the service to check
Returns True if the service is set to start
Return type bool
CLI Example:
```
salt '*' service.enabled <service name>
```

salt.modules.win_service.execute_salt_restart_task()
Run the Windows Salt restart task
Returns True if successful, otherwise False
Return type bool
CLI Example:
```
salt '*' service.execute_salt_restart_task()
```

salt.modules.win_service.get_all()
Return all installed services
Returns Returns a list of all services on the system.
Return type list
CLI Example:
```
salt '*' service.get_all
```

salt.modules.win_service.get_disabled()
Return a list of disabled services. Disabled is defined as a service that is marked 'Disabled' or 'Manual'.
Returns A list of disabled services.
Return type list
CLI Example:
```
salt '*' service.get_disabled
```

salt.modules.win_service.get_enabled()
Return a list of enabled services. Enabled is defined as a service that is marked to Auto Start.
Returns A list of enabled services
Return type list
CLI Example:
**salt '*** service.get_enabled**

salt.modules.win_service.get_service_name(*args*)

The Display Name is what is displayed in Windows when services.msc is executed. Each Display Name has an associated Service Name which is the actual name of the service. This function allows you to discover the Service Name by returning a dictionary of Display Names and Service Names, or filter by adding arguments of Display Names.

If no args are passed, return a dict of all services where the keys are the service Display Names and the values are the Service Names.

If arguments are passed, create a dict of Display Names and Service Names

    Returns A dictionary of display names and service names
    Return type dict

CLI Examples:

salt '***' service.get_service_name
salt '***' service.get_service_name 'Google Update Service (gupdate)' 'DHCP Client'

salt.modules.win_service.getsid(name)

Return the SID for this windows service

    Parameters name (str) -- The name of the service for which to return the SID
    Returns A string representing the SID for the service
    Return type str

CLI Example:

salt '***' service.getsid <service name>

salt.modules.win_service.info(name)

Get information about a service on the system

    Parameters name (str) -- The name of the service. This is not the display name. Use get_service_name to find the service name.
    Returns A dictionary containing information about the service.
    Return type dict

CLI Example:

salt '***' service.info spooler

salt.modules.win_service.missing(name)

The inverse of service.available.

    Parameters name (str) -- The name of the service to check
    Returns True if the service is missing, False otherwise
    Return type bool

CLI Example:

salt '***' service.missing <service name>

salt.modules.win_service.modify(name, bin_path=None, exe_args=None, display_name=None, description=None, service_type=None, start_type=None, start_delayed=None, error_control=None, load_order_group=None, dependencies=None, account_name=None, account_password=None, run_interactive=None)

Modify a service's parameters. Changes will not be made for parameters that are not passed.

New in version 2016.11.0.
Parameters

- **name (str)** -- The name of the service. Can be found using the `service.get_service_name` function
- **bin_path (str)** -- The path to the service executable. Backslashes must be escaped, eg: C:\path\to\binary.exe
- **exe_args (str)** -- Any arguments required by the service executable
- **display_name (str)** -- The name to display in the service manager
- **description (str)** -- The description to display for the service
- **service_type (str)** -- Specifies the service type. Default is `own`. Valid options are as follows:
  - kernel: Driver service
  - filesystem: File system driver service
  - adapter: Adapter driver service (reserved)
  - recognizer: Recognizer driver service (reserved)
  - own (default): Service runs in its own process
  - share: Service shares a process with one or more other services
- **start_type (str)** -- Specifies the service start type. Valid options are as follows:
  - boot: Device driver that is loaded by the boot loader
  - system: Device driver that is started during kernel initialization
  - auto: Service that automatically starts
  - manual: Service must be started manually
  - disabled: Service cannot be started
- **start_delayed (bool)** -- Set the service to Auto(Delayed Start). Only valid if the start_type is set to Auto. If service_type is not passed, but the service is already set to Auto, then the flag will be set.
- **error_control (str)** -- The severity of the error, and action taken, if this service fails to start. Valid options are as follows:
  - normal: Error is logged and a message box is displayed
  - severe: Error is logged and computer attempts a restart with the last known good configuration
  - critical: Error is logged, computer attempts to restart with the last known good configuration, system halts on failure
  - ignore: Error is logged and startup continues, no notification is given to the user
- **load_order_group (str)** -- The name of the load order group to which this service belongs
- **dependencies (list)** -- A list of services or load ordering groups that must start before this service
- **account_name (str)** -- The name of the account under which the service should run. For `own` type services this should be in the domain\username format. The following are examples of valid built-in service accounts:
  - NT Authority\LocalService
  - NT Authority\NetworkService
  - NT Authority\LocalSystem
  - .LocalSystem
- **account_password (str)** -- The password for the account name specified in account_name. For the above built-in accounts, this can be None. Otherwise a password must be specified.
- **run_interactive (bool)** -- If this setting is True, the service will be allowed to interact with the user. Not recommended for services that run with elevated privileges.

Returns a dictionary of changes made

Return type dict

CLI Example:
salt '*' service.modify spooler start_type=disabled

salt.modules.win_service.restart(name, timeout=90)
Restart the named service. This issues a stop command followed by a start.

Parameters
- name -- The name of the service to restart.

**Note:** If the name passed is salt-minion a scheduled task is created and executed to restart the salt-minion service.

- timeout (int) -- The time in seconds to wait for the service to stop and start before returning. Default is 90 seconds

**Note:** The timeout is cumulative meaning it is applied to the stop and then to the start command. A timeout of 90 could take up to 180 seconds if the service is long in stopping and starting

New in version 2017.7.9, 2018.3.4.

Returns
- True if successful, otherwise False

Return type: bool

CLI Example:
```bash
salt '*' service.restart <service name>
```

salt.modules.win_service.start(name, timeout=90)
Start the specified service.

**Warning:** You cannot start a disabled service in Windows. If the service is disabled, it will be changed to Manual start.

Parameters
- name (str) -- The name of the service to start
- timeout (int) -- The time in seconds to wait for the service to start before returning. Default is 90 seconds

New in version 2017.7.9, 2018.3.4.

Returns
- True if successful, otherwise False. Also returns True if the service is already started

Return type: bool

CLI Example:
```bash
salt '*' service.start <service name>
```

salt.modules.win_service.status(name, *args, **kwargs)
Return the status for a service

Parameters
- name (str) -- The name of the service to check

Returns
- True if running, False otherwise

Return type: bool

CLI Example:
```bash
salt '*' service.status <service name> [service signature]
```
salt.modules.win_service.stop(name, timeout=90)
Stop the specified service
Parameters
• name (str) -- The name of the service to stop
• timeout (int) -- The time in seconds to wait for the service to stop before returning.
   Default is 90 seconds
Returns
   True if successful, otherwise False. Also returns True if the service is already stopped
Return type bool
CLI Example:

    salt '*' service.stop <service name>

19.9.436  salt.modules.win_shadow

Manage the shadow file

Important: If you feel that Salt should be using this module to manage passwords on a minion, and it is using a different module (or gives an error similar to `shadow.info' is not available), see here.

salt.modules.win_shadow.info(name)
Return information for the specified user This is just returns dummy data so that salt states can work.
Parameters name (str) -- The name of the user account to show.
CLI Example:

    salt '*' shadow.info root

salt.modules.win_shadow.require_password_change(name)
Require the user to change their password the next time they log in.
Parameters name -- The name of the user account to require a password change.
Returns True if successful. False if unsuccessful.
Return type bool
CLI Example:

    salt '*' shadow.require_password_change <username>

salt.modules.win_shadow.set_expire(name, expire)
Set the expiration date for a user account.
Parameters
• name -- The name of the user account to edit.
• expire -- The date the account will expire.
Returns True if successful. False if unsuccessful.
Return type bool
CLI Example:

    salt '*' shadow.set_expire <username> 2016/7/1

salt.modules.win_shadow.set_password(name, password)
Set the password for a named user.
Parameters
- **name** *(str)* -- The name of the user account
- **password** *(str)* -- The new password

Returns: True if successful. False if unsuccessful.

Return type: *bool*

CLI Example:

```bash
salt '*' shadow.set_password root mysecretpassword
```

salt.modules.win_shadow.unlock_account*(name)*

Unlocks a user account.

Parameters: name -- The name of the user account to unlock.

Returns: True if successful. False if unsuccessful.

Return type: *bool*

CLI Example:

```bash
salt '*' shadow.unlock_account <username>
```

19.9.437 **salt.modules.win_smtp_server module**

Module for managing IIS SMTP server configuration on Windows servers. The Windows features 'SMTP-Server' and 'Web-WMI' must be installed.

```
depends: wmi
```

salt.modules.win_smtp_server.get_connection_ip_list*(as_wmi_format=False,
server='SmtpSvc/1')*

Get the IPGrant list for the SMTP virtual server.

Parameters:

- **as_wmi_format** *(bool)* -- Returns the connection IPs as a list in the format WMI expects.
- **server** *(str)* -- The SMTP server name.

Returns: A dictionary of the IP and subnet pairs.

Return type: *dict*

CLI Example:

```bash
salt '*' win_smtp_server.get_connection_ip_list
```

salt.modules.win_smtp_server.get_log_format*(server='SmtpSvc/1')*

Get the active log format for the SMTP virtual server.

Parameters: server -- The SMTP server name.

Returns: A string of the log format name.

Return type: *str*

CLI Example:

```bash
salt '*' win_smtp_server.get_log_format
```

salt.modules.win_smtp_server.get_log_format_types()

Get all available log format names and ids.

Returns: A dictionary of the log format names and ids.

Return type: *dict*

CLI Example:

```bash
salt '*' win_smtp_server.get_log_format_types
```
salt.modules.win_smtp_server.get_relay_ip_list(server='SmtpSvc/1')
Get the RelayIpList list for the SMTP virtual server.
Parameters
   server (str) -- The SMTP server name.
Returns
   A list of the relay IPs.
Return type
list

Note: A return value of None corresponds to the restrictive `Only the list below' GUI parameter with an
empty access list, and setting an empty list/tuple corresponds to the more permissive `All except the list below'
GUI parameter.

CLI Example:
```
salt '*' win_smtp_server.get_relay_ip_list
```

salt.modules.win_smtp_server.get_server_setting(settings, server='SmtpSvc/1')
Get the value of the setting for the SMTP virtual server.
Parameters
   • settings (str) -- A list of the setting names.
   • server (str) -- The SMTP server name.
Returns
   A dictionary of the provided settings and their values.
Return type
dict
CLI Example:
```
salt '*' win_smtp_server.get_server_setting settings="['MaxRecipients']"
```

salt.modules.win_smtp_server.get_servers()
Get the SMTP virtual server names.
Returns
   A list of the SMTP virtual servers.
Return type
list
CLI Example:
```
salt '*' win_smtp_server.get_servers
```

salt.modules.win_smtp_server.set_connection_ip_list(addresses=None,
grant_by_default=False,
service='SmtpSvc/1')
Set the IPGrant list for the SMTP virtual server.
Parameters
   • addresses (str) -- A dictionary of IP + subnet pairs.
   • grant_by_default (bool) -- Whether the addresses should be a blacklist or
     whitelist.
   • server (str) -- The SMTP server name.
Returns
   A boolean representing whether the change succeeded.
Return type
bool
CLI Example:
```
salt '*' win_smtp_server.set_connection_ip_list addresses="{'127.0.0.1': '255.255.255.255'}"
```

salt.modules.win_smtp_server.set_log_format(log_format, service='SmtpSvc/1')
Set the active log format for the SMTP virtual server.
Parameters
   • log_format (str) -- The log format name.
   • server (str) -- The SMTP server name.
Returns
   A boolean representing whether the change succeeded.
Return type: \texttt{bool}

CLI Example:

```
salt '*\ win smtp_server.set_log_format 'Microsoft IIS Log File Format'
```

\texttt{salt.modules.win smtp_server.set relay ip list}(\texttt{addresses=None, server='SmtpSvc/1'})

Set the RelayIpList list for the SMTP virtual server.

Due to the unusual way that Windows stores the relay IPs, it is advisable to retrieve the existing list you wish to set from a pre-configured server.

For example, setting `127.0.0.1` as an allowed relay IP through the GUI would generate an actual relay IP list similar to the following:

```
['24.0.0.128', '32.0.0.128', '60.0.0.128', '68.0.0.128', '1.0.0.0', '76.0.0.0', '0.0.0.0', '0.0.0.0', '1.0.0.0', '2.0.0.0', '4.0.0.0', '0.0.0.0', '76.0.0.128', '0.0.0.0', '0.0.0.0', '0.0.0.0', '0.0.0.0', '127.0.0.1']
```

\textbf{Note:} Setting the list to None corresponds to the restrictive `Only the list below` GUI parameter with an empty access list configured, and setting an empty list/tuple corresponds to the more permissive `All except the list below` GUI parameter.

Parameters

- \texttt{addresses (str)} -- A list of the relay IPs. The order of the list is important.
- \texttt{server (str)} -- The SMTP server name.

Returns: A boolean representing whether the change succeeded.

Return type: \texttt{bool}

CLI Example:

```
salt '*\ win smtp_server.set relay ip list addresses="[192.168.1.1', '172.16.1.1 ...']"
```

\texttt{salt.modules.win smtp_server.set server setting}(\texttt{settings, server='SmtpSvc/1'})

Set the value of the setting for the SMTP virtual server.

\textbf{Note:} The setting names are case-sensitive.

Parameters

- \texttt{settings (str)} -- A dictionary of the setting names and their values.
- \texttt{server (str)} -- The SMTP server name.

Returns: A boolean representing whether all changes succeeded.

Return type: \texttt{bool}

CLI Example:

```
salt '*\ win smtp_server.set server setting settings="{'MaxRecipients': '500'}"
```

\textbf{19.9.438 salt.modules.win snmp module}

Module for managing SNMP service settings on Windows servers. The Windows feature `SNMP-Service` must be installed.
salt.modules.win_snmp.get_agent_service_types()
Get the sysServices types that can be configured.
Returns A list of service types.
Return type list
CLI Example:
salt '*' win_snmp.get_agent_service_types

salt.modules.win_snmp.get_agent_settings()
Determine the value of the SNMP sysContact, sysLocation, and sysServices settings.
Returns A dictionary of the agent settings.
Return type dict
CLI Example:
salt '*' win_snmp.get_agent_settings

salt.modules.win_snmp.get_auth_traps_enabled()
Determine whether the host is configured to send authentication traps.
Returns True if traps are enabled, otherwise False
Return type bool
CLI Example:
salt '*' win_snmp.get_auth_traps_enabled

salt.modules.win_snmp.get_community_names()
Get the current accepted SNMP community names and their permissions.
If community names are being managed by Group Policy, those values will be returned instead like this:
TestCommunity:
    Managed by GPO
Community names managed normally will denote the permission instead:
TestCommunity:
    Read Only
Returns A dictionary of community names and permissions.
Return type dict
CLI Example:
salt '*' win_snmp.get_community_names

salt.modules.win_snmp.get_permission_types()
Get the permission types that can be configured for communities.
Returns A list of permission types.
Return type list
CLI Example:
salt '*' win_snmp.get_permission_types

salt.modules.win_snmp.set_agent_settings(contact=None, location=None, services=None)
Manage the SNMP sysContact, sysLocation, and sysServices settings.
Parameters
- contact (str, optional) -- The SNMP contact.
- location (str, optional) -- The SNMP location.
- `services` *(list, optional)* -- A list of selected services. The possible service names can be found via `win_snmp.get_agent_service_types`. To disable all services pass a list of None, i.e: `['None']`

  **Returns** True if successful, otherwise False
  **Return type** bool

  CLI Example:

  ```
salt '*' win_snmp.set_agent_settings contact='Contact Name' location='Place' --services='["Physical"]'
  ```

salt.modules.win_snmp.set_auth_traps_enabled(*status=True*)
Manage the sending of authentication traps.

  **Parameters**

  - `status` *(bool)* -- True to enable traps. False to disable.
  
  **Returns** True if successful, otherwise False
  **Return type** bool

  CLI Example:

  ```
salt '*' win_snmp.set_auth_traps_enabled status='True'
  ```

salt.modules.win_snmp.set_community_names(*communities*)
Manage the SNMP accepted community names and their permissions.

  **Note:** Settings managed by Group Policy will always take precedence over those set using the SNMP interface. Therefore if this function finds Group Policy settings it will raise a CommandExecutionError

  **Parameters**

  - `communities` *(dict)* -- A dictionary of SNMP community names and permissions. The possible permissions can be found via `win_snmp.get_permission_types`.
  
  **Returns** True if successful, otherwise False
  **Return type** bool
  **Raises** CommandExecutionError -- If SNMP settings are being managed by Group Policy

  CLI Example:

  ```
salt '*' win_snmp.set_community_names communities='{"TestCommunity": "Read Only"}'
  ```

**19.9.439 salt.modules.win_status**

Module for returning various status data about a minion. These data can be useful for compiling into stats later, or for problem solving if your minion is having problems.

New in version 0.12.0.

  **depends**

  - wmi

salt.modules.win_status.cpuload()  
New in version 2015.8.0.

Return the processor load as a percentage

  CLI Example:

  ```
salt '*' status.cpuload
  ```
salt.modules.win_status.diskusage(human_readable=False, path=None)
New in version 2015.8.0.
Return the disk usage for this minion
human_readable [False] If True, usage will be in KB/MB/GB etc.
CLI Example:
salt '*' status.diskusage path=c:/salt

salt.modules.win_status.master(master=None, connected=True)
New in version 2015.5.0.
Fire an event if the minion gets disconnected from its master. This function is meant to be run via a scheduled
job from the minion. If master_ip is an FQDN/Hostname, is must be resolvable to a valid IPv4 address.
CLI Example:
salt '*' status.master

salt.modules.win_status.procs(count=False)
Return the process data
count [False] If True, this function will simply return the number of processes.
New in version 2015.8.0.
CLI Example:
salt '*' status.procs
salt '*' status.procs count

salt.modules.win_status.saltmem(human_readable=False)
New in version 2015.8.0.
Returns the amount of memory that salt is using
human_readable [False] return the value in a nicely formatted number
CLI Example:
salt '*' status.saltmem
salt '*' status.saltmem human_readable=True

salt.modules.win_status.uptime(human_readable=False)
New in version 2015.8.0.
Return the system uptime for the machine

Parameters
human_readable (bool) -- Return uptime in human readable format if True,
otherwise return seconds. Default is False

Note: Human readable format is days,hours:min:sec. Days will only be displayed
if more than 0

Returns The uptime in seconds or human readable format depending on the value of hu-
man_readable
Return type str
CLI Example:
salt '*' status.uptime
salt '*' status.uptime human_readable=True
19.9.440 salt.modules.win_system

Module for managing windows systems.

depends
  - pythoncom
  - pywintypes
  - win32api
  - win32con
  - win32net
  - wmi

Support for reboot, shutdown, etc

salt.modules.win_system.get_computer_desc()
Get the Windows computer description
  Returns  Returns the computer description if found. Otherwise returns False.
  Return type  str

CLI Example:
```
salt 'minion-id' system.get_computer_desc
```

salt.modules.win_system.get_computer_name()
Get the Windows computer name
  Returns  Returns the computer name if found. Otherwise returns False.
  Return type  str

CLI Example:
```
salt 'minion-id' system.get_computer_name
```

salt.modules.win_system.get_domain_workgroup()
Get the domain or workgroup the computer belongs to.

New in version 2015.5.7.
New in version 2015.8.2.
  Returns  The name of the domain or workgroup
  Return type  str

CLI Example:
```
salt 'minion-id' system.get_domain_workgroup
```

salt.modules.win_system.get_hostname()
Get the hostname of the windows minion

New in version 2016.3.0.
  Returns  Returns the hostname of the windows minion
  Return type  str

CLI Example:
```
salt 'minion-id' system.get_hostname
```

salt.modules.win_system.get_pending_component_servicing()
Determine whether there are pending Component Based Servicing tasks that require a reboot.

New in version 2016.11.0.
Salt Documentation, Release 2017.7.8

Returns  True if there are pending Component Based Servicing tasks, otherwise False
Return type  bool
CLI Example:

```
salt '*' system.get_pending_component_servicing
```

salt.modules.win_system.get_pending_computer_name()
Get a pending computer name. If the computer name has been changed, and the change is pending a system reboot, this function will return the pending computer name. Otherwise, None will be returned. If there was an error retrieving the pending computer name, False will be returned, and an error message will be logged to the minion log.

Returns  Returns the pending name if pending restart. Returns None if not pending restart.
Return type  str
CLI Example:

```
salt 'minion-id' system.get_pending_computer_name
```

salt.modules.win_system.get_pending_domain_join()
Determine whether there is a pending domain join action that requires a reboot.

New in version 2016.11.0.

Returns  True if there is a pending domain join action, otherwise False
Return type  bool
CLI Example:

```
salt '*' system.get_pending_domain_join
```

salt.modules.win_system.get_pending_file_rename()
Determine whether there are pending file rename operations that require a reboot.

New in version 2016.11.0.

Returns  True if there are pending file rename operations, otherwise False
Return type  bool
CLI Example:

```
salt '*' system.get_pending_file_rename
```

salt.modules.win_system.get_pending_reboot()
Determine whether there is a reboot pending.

New in version 2016.11.0.

Returns  True if the system is pending reboot, otherwise False
Return type  bool
CLI Example:

```
salt '*' system.get_pending_reboot
```

salt.modules.win_system.get_pending_servermanager()
Determine whether there are pending Server Manager tasks that require a reboot.

New in version 2016.11.0.

Returns  True if there are pending Server Manager tasks, otherwise False
Return type  bool
CLI Example:

```
salt '*' system.get_pending_servermanager
```

2302 Chapter 19. Salt Module Reference
salt.modules.win_system.get_pending_update()
Determine whether there are pending updates that require a reboot.

New in version 2016.11.0.

Returns True if there are pending updates, otherwise False
Return type bool

CLI Example:
salt '*' system.get_pending_update

salt.modules.win_system.get_reboot_required_witnessed()
Determine if at any time during the current boot session the salt minion witnessed an event indicating that a reboot is required.

This function will return True if an install completed with exit code 3010 during the current boot session and can be extended where appropriate in the future.

New in version 2016.11.0.

Returns True if the Requires reboot registry flag is set to 1, otherwise False
Return type bool

CLI Example:
salt '*' system.get_reboot_required_witnessed

salt.modules.win_system.get_system_date()
Get the Windows system date

Returns Returns the system date
Return type str

CLI Example:
salt '*' system.get_system_date

salt.modules.win_system.get_system_info()
Get system information.

Returns Dictionary containing information about the system to include name, description, version, etc...
Return type dict

CLI Example:
salt 'minion-id' system.get_system_info

salt.modules.win_system.get_system_time()
Get the system time.

Returns Returns the system time in HH:MM:SS AM/PM format.
Return type str

CLI Example:
salt 'minion-id' system.get_system_time

salt.modules.win_system.halt( timeout=5, in_seconds=False )
Halt a running system.

Parameters
- timeout (int) -- Number of seconds before halting the system. Default is 5 seconds.
- in_seconds (bool) -- Whether to treat timeout as seconds or minutes.

New in version 2015.8.0.
Returns  True if successful, otherwise False
Return type  bool

CLI Example:
```
salt '*' system.halt 5 True
```

`salt.modules.win_system.init(runlevel)`  
Change the system runlevel on sysV compatible systems. Not applicable to Windows

CLI Example:
```
salt '*' system.init 3
```

`salt.modules.win_system.join_domain(domain, username=None, password=None, account_ou=None, account_exists=False, restart=False)`  
Join a computer to an Active Directory domain. Requires a reboot.

Parameters
- `domain (str)` -- The domain to which the computer should be joined, e.g. example.com
- `username (str)` -- Username of an account which is authorized to join computers to the specified domain. Needs to be either fully qualified like user@domain.tld or simply user
- `password (str)` -- Password of the specified user
- `account_ou (str)` -- The DN of the OU below which the account for this computer should be created when joining the domain, e.g. ou=computers,ou=departm_432,dc=my-company,dc=com
- `account_exists (bool)` -- If set to True the computer will only join the domain if the account already exists. If set to False the computer account will be created if it does not exist, otherwise it will use the existing account. Default is False
- `restart (bool)` -- True will restart the computer after a successful join. Default is False

New in version 2015.8.2/2015.5.7.

Returns  Returns a dictionary if successful, otherwise False
Return type  dict

CLI Example:
```
salt 'minion-id' system.join_domain domain='domain.tld' \ 
    username='joinuser' password='joinpassword' \ 
    account_ou='ou=clients,ou=org,dc=domain,dc=tld' \ 
    account_exists=False, restart=True
```

`salt.modules.win_system.lock()`  
Lock the workstation.

Returns  True if successful, otherwise False
Return type  bool

CLI Example:
```
salt 'minion-id' system.lock
```

`salt.modules.win_system.poweroff(timeout=5, in_seconds=False)`  
Power off a running system.

Parameters
- `timeout (int)` -- Number of seconds before powering off the system. Default is 5 seconds.
- `in_seconds (bool)` -- Whether to treat timeout as seconds or minutes.
New in version 2015.8.0.

Returns True if successful, otherwise False

Return type bool

CLI Example:

```
salt '*' system.poweroff 5
```

```
salt.modules.win_system.reboot(timeout=5,  in_seconds=False,  wait_for_reboot=False,
only_on_pending_reboot=False)
```

Reboot a running system.

Parameters

- **timeout** (int) -- The number of minutes/seconds before rebooting the system. Use of minutes or seconds depends on the value of `in_seconds`. Default is 5 minutes.
- **in_seconds** (bool) --
  True will cause the `timeout` parameter to be in seconds. False will be in minutes. Default is False.
  New in version 2015.8.0.
- **wait_for_reboot** (bool) -- True will sleep for `timeout` + 30 seconds after reboot has been initiated. This is useful for use in a highstate. For example, you may have states that you want to apply only after the reboot. Default is False.
  New in version 2015.8.0.
- **only_on_pending_reboot** (bool) -- If this is set to True, then the reboot will only proceed if the system reports a pending reboot. Setting this parameter to True could be useful when calling this function from a final housekeeping state intended to be executed at the end of a state run (using `order: last`). Default is False.

Returns True if successful (a reboot will occur), otherwise False

Return type bool

CLI Example:

```
salt '*' system.reboot 5
salt '*' system.reboot 5 True
```

Invoking this function from a final housekeeping state:

```
final_housekeeping:
  module.run:
    - name: system.reboot
    - only_on_pending_reboot: True
    - order: last
```

```
salt.modules.win_system.set_computer_desc(desc=None)
```

Set the Windows computer description

Parameters **desc** (str) -- The computer description

Returns Description if successful, otherwise False

Return type str

CLI Example:

```
salt 'minion-id' system.set_computer_desc 'This computer belongs to Dave!'
```

salt.modules.win_system.set_computer_name(name)

Set the Windows computer name

Parameters **name** (str) -- The new name to give the computer. Requires a reboot to take effect.

Returns Returns a dictionary containing the old and new names if successful. False if not.

Return type dict

CLI Example:
salt 'minion-id' system.set_computer_name 'DavesComputer'

```
salt.modules.win_system.set_hostname(hostname)
Set the hostname of the windows minion, requires a restart before this will be updated.

New in version 2016.3.0.
Parameters hostname (str) -- The hostname to set
Returns True if successful, otherwise False
Return type bool
```

CLI Example:

```
salt 'minion-id' system.set_hostname newhostname
```

salt.modules.win_system.set_reboot_required_witnessed()
This function is used to remember that an event indicating that a reboot is required was witnessed. This function relies on the salt-minion's ability to create the following volatile registry key in the HKLM hive:
\[SYSTEM\CurrentControlSet\Services\salt-minion\Volatile-Data\]
Because this registry key is volatile, it will not persist beyond the current boot session. Also, in the scope of this key, the name ‘Reboot required’ will be assigned the value of 1.
For the time being, this function is being used whenever an install completes with exit code 3010 and can be extended where appropriate in the future.

New in version 2016.11.0.
Returns True if successful, otherwise False
Return type bool
CLI Example:

```
salt '*' system.set_reboot_required_witnessed
```

salt.modules.win_system.set_system_date(newdate)
Set the Windows system date. Use <mm-dd-yy> format for the date.

```
Parameters newdate (str) -- The date to set. Can be any of the following formats
  • YYYY-MM-DD
  • MM-DD-YYYY
  • MM-DD-YY
  • MM/DD/YYYY
  • MM/DD/YY
  • YYYY/MM/DD

Returns True if successful, otherwise False
Return type bool
```

CLI Example:

```
salt '*' system.set_system_date '03-28-13'
```

salt.modules.win_system.set_system_date_time(years=None, months=None, days=None, hours=None, minutes=None, seconds=None)
Set the system date and time. Each argument is an element of the date, but not required. If an element is not passed, the current system value for that element will be used. For example, if you don't pass the year, the current system year will be used. (Used by set_system_date and set_system_time)

```
Parameters
  • years (int) -- Years digit, ie: 2015
  • months (int) -- Months digit: 1 - 12
  • days (int) -- Days digit: 1 - 31
  • hours (int) -- Hours digit: 0 - 23
```

```
- **minutes** *(int)* -- Minutes digit: 0 - 59
- **seconds** *(int)* -- Seconds digit: 0 - 59

Returns True if successful, otherwise False

Return type **bool**

CLI Example:

```
salt '*' system.set_system_date_time 2015 5 12 11 37 53
```

**salt.modules.win_system.set_system_time**(newtime)

Set the system time.

Parameters

- **newtime** *(str)* -- The time to set. Can be any of the following formats:
  - HH:MM:SS AM/PM
  - HH:MM AM/PM
  - HH:MM:SS (24 hour)
  - HH:MM (24 hour)

Returns True if successful, otherwise False

Return type **bool**

CLI Example:

```
salt 'minion-id' system.set_system_time 12:01
```

**salt.modules.win_system.shutdown**(message=None, **timeout=5**,** force_close=True,** reboot=False,** in_seconds=False,** only_on_pending_reboot=False)

Shutdown a running system.

Parameters

- **message** *(str)* -- The message to display to the user before shutting down.
- **timeout** *(int)* -- The length of time (in seconds) that the shutdown dialog box should be displayed. While this dialog box is displayed, the shutdown can be aborted using the system.shutdown_abort function.

If timeout is not zero, InitiateSystemShutdown displays a dialog box on the specified computer. The dialog box displays the name of the user who called the function, the message specified by the lpMessage parameter, and prompts the user to log off. The dialog box beeps when it is created and remains on top of other windows (system modal). The dialog box can be moved but not closed. A timer counts down the remaining time before the shutdown occurs.

If timeout is zero, the computer shuts down immediately without displaying the dialog box and cannot be stopped by system.shutdown_abort.

Default is 5 minutes

- **in_seconds** *(bool)* --
  - **True** will cause the **timeout** parameter to be in seconds. **False** will be in minutes. Default is **False**.
  
New in version 2015.8.0.

- **force_close** *(bool)* -- **True** will force close all open applications. **False** will display a dialog box instructing the user to close open applications. Default is **True**.

- **reboot** *(bool)* -- **True** restarts the computer immediately after shutdown. **False** powers down the system. Default is **False**.

- **only_on_pending_reboot** *(bool)* -- If this is set to **True**, then the shutdown will only proceed if the system reports a pending reboot. To optionally shutdown in a highstate, consider using the shutdown state instead of this module.

- **only_on_pending_reboot** *(bool)* -- If **True** the shutdown will only proceed if there is a reboot pending. **False** will shutdown the system. Default is **False**.

Returns True if successful (a shutdown or reboot will occur), otherwise False

Return type **bool**

19.9. execution modules 2307
Salt Documentation, Release 2017.7.8

CLI Example:

```
salt '*' system.shutdown "System will shutdown in 5 minutes"
```

salt.modules.win_system.shutdown_abort()

Abort a shutdown. Only available while the dialog box is being displayed to the user. Once the shutdown has initiated, it cannot be aborted.

Returns True if successful, otherwise False

Return type bool

CLI Example:

```
salt 'minion-id' system.shutdown_abort
```

salt.modules.win_system.shutdown_hard()

Shutdown a running system with no timeout or warning.

Returns True if successful, otherwise False

Return type bool

CLI Example:

```
salt '*' system.shutdown_hard
```

salt.modules.win_system.start_time_service()

Start the Windows time service

Returns True if successful, otherwise False

Return type bool

CLI Example:

```
salt '*' system.start_time_service
```

salt.modules.win_system.stop_time_service()

Stop the Windows time service

Returns True if successful, otherwise False

Return type bool

CLI Example:

```
salt '*' system.stop_time_service
```

salt.modules.win_system.unjoin_domain(username=None, password=None, domain=None, workgroup='WORKGROUP', disable=False, restart=False)

Unjoin a computer from an Active Directory Domain. Requires a restart.

Parameters

- **username** (str) -- Username of an account which is authorized to manage computer accounts on the domain. Needs to be a fully qualified name like user@domain.tld or domain.tld\user. If the domain is not specified, the passed domain will be used. If the computer account doesn't need to be disabled after the computer is unjoined, this can be None.
- **password** (str) -- The password of the specified user
- **domain** (str) -- The domain from which to unjoin the computer. Can be None
- **workgroup** (str) -- The workgroup to join the computer to. Default is WORKGROUP

New in version 2015.8.2/2015.5.7.

- **disable** (bool) -- True to disable the computer account in Active Directory. Default is False
• **restart**(bool) -- True will restart the computer after successful unjoin. Default is False

New in version 2015.8.2/2015.5.7.

**Returns** Returns a dictionary if successful, otherwise False

**Return type** dict

CLI Example:

```
salt 'minion-id' system.unjoin_domain restart=True
salt 'minion-id' system.unjoin_domain username='unjoinuser' \ password='unjoinpassword' disable=True \ restart=True
```

### 19.9.441 salt.modules.win_task module

Windows Task Scheduler Module .. versionadded:: 2016.3.0

A module for working with the Windows Task Scheduler. You can add and edit existing tasks. You can add and clear triggers and actions. You can list all tasks, folders, triggers, and actions.

```
salt.modules.win_task.add_action(name=None, location='\', action_type='Execute', **kwargs)
```

Add an action to a task.

**Parameters**

- **name**(str) -- The name of the task to which to add the action.
- **location**(str) -- A string value representing the location of the task. Default is `\` which is the root for the task scheduler (C:WindowsSystem32tasks).
- **action_type**(str) -- The type of action to add. There are three action types. Each one requires its own set of Keyword Arguments (kwargs). Valid values are:
  - Execute
  - Email
  - Message

Required arguments for each action_type:

**Execute** - Execute a command or an executable

**Parameters**

- **cmd**(str) -- (required) The command / executable to run.
- **arguments**(str) -- (optional) Arguments to be passed to the command / executable. To launch a script the first command will need to be the interpreter for the script. For example, to run a vbscript you would pass `cscript.exe` in the `cmd` parameter and pass the script in the `arguments` parameter as follows:
  - `cmd='cscript.exe' arguments='c:\scripts\myscript.vbs'`

  Batch files do not need an interpreter and may be passed to the cmd parameter directly.

- **start_in**(str) -- (optional) The current working directory for the command.

**Email** - Send and email. Requires server, from, and to or cc.

**Parameters**

- **from**(str) -- The sender
- **reply_to**(str) -- Who to reply to
- **to**(str) -- The recipient
- **cc**(str) -- The CC recipient
- **bcc**(str) -- The BCC recipient
- **subject**(str) -- The subject of the email
- **body**(str) -- The Message Body of the email
- **server**(str) -- The server used to send the email

19.9. execution modules
• **attachments** *(list)* -- A list of attachments. These will be the paths to the files to attach. IE: `attachments=['C:\attachment1.txt','C:\attachment2.txt']`

**Message** - Display a dialog box. The task must be set to ``Run only when user is logged on`` in order for the dialog box to display. Both parameters are required.

**Parameters**

• **title** *(str)* -- The dialog box title.

• **message** *(str)* -- The dialog box message body

**Returns** True if successful, False if unsuccessful

**Return type** bool

**CLI Example:**

```bash
salt 'minion-id' task.add_action <task_name> cmd='del /Q /S C:\\Temp'
```

```python
salt.modules.win_task.add_trigger(name=None, location='\', trigger_type=None, trigger_enabled=True, start_date=None, start_time=None, end_date=None, end_time=None, random_delay=None, repeat_interval=None, repeat_duration=None, repeat_stop_at_duration_end=False, execution_time_limit=None, **kwargs)
```

**Parameters**

• **name** *(str)* -- The name of the task to which to add the trigger.

• **location** *(str)* -- A string value representing the location of the task. Default is `'\' which is the root for the task scheduler (C:\Windows\System32\tasks).

• **trigger_type** *(str)* -- The type of trigger to create. This is defined when the trigger is created and cannot be changed later. Options are as follows:

  • Event
  • Once
  • Daily
  • Weekly
  • Monthly
  • MonthlyDay
  • OnIdle
  • OnTaskCreation
  • OnBoot
  • OnLogon
  • OnSessionChange

**Parameters**

• **trigger_enabled** *(bool)* -- Boolean value that indicates whether the trigger is enabled.

• **start_date** *(str)* -- The date when the trigger is activated. If no value is passed, the current date will be used. Can be one of the following formats:

  • %Y-%m-%d
  • %m-%d-%y
  • %m-%d-%Y
  • %m/%d/%y
  • %m/%d/%Y
  • %Y/%m/%d

• **start_time** *(str)* -- The time when the trigger is activated. If no value is passed, midnight will be used. Can be one of the following formats:

  • %I:%M:%S %p
  • %I:%M %p
Parameters **end_date** *(str)* -- The date when the trigger is deactivated. The trigger cannot start the task after it is deactivated. Can be one of the following formats:

- %Y-%m-%d
- %m-%d-%y
- %m-%d-%Y
- %m/%d/%y
- %m/%d/%Y
- %Y/%m/%d

Parameters **end_time** *(str)* -- The time when the trigger is deactivated. If the this is not passed with **end_date** it will be set to midnight. Can be one of the following formats:

- %I:%M:%S %p
- %I:%M %p
- %H:%M:%S
- %H:%M

Parameters **random_delay** *(str)* -- The delay time that is randomly added to the start time of the trigger. Valid values are:

- 30 seconds
- 1 minute
- 30 minutes
- 1 hour
- 8 hours
- 1 day

Parameters **repeat_interval** *(str)* -- The amount of time between each restart of the task. Valid values are:

- 5 minutes
- 10 minutes
- 15 minutes
- 30 minutes
- 1 hour

Parameters **repeat_duration** *(str)* -- How long the pattern is repeated. Valid values are:

- Indefinitely
- 15 minutes
- 30 minutes
- 1 hour
- 12 hours
- 1 day

Parameters

- **repeat_stop_at_duration_end** *(bool)* -- Boolean value that indicates if a running instance of the task is stopped at the end of the repetition pattern duration.
- **execution_time_limit** *(str)* -- The maximum amount of time that the task launched by the trigger is allowed to run. Valid values are:

- 30 minutes
- 1 hour
- 2 hours
- 4 hours
- 8 hours

19.9. execution modules
• 12 hours
• 1 day
• 3 days (default)

kwargs
There are optional keyword arguments determined by the type of trigger being defined. They are as follows:

Event
Parameters `subscription (str)` -- An event definition in xml format that fires the trigger.
The easiest way to get this would is to create an event in windows task scheduler and then copy the xml text.

Once
No special parameters required.

Daily
Parameters `days_interval (int)` -- The interval between days in the schedule. An interval of 1 produces a daily schedule. An interval of 2 produces an every-other day schedule. If no interval is specified, 1 is used. Valid entries are 1 - 999.

Weekly
Parameters `weeks_interval (int)` -- The interval between weeks in the schedule. An interval of 1 produces a weekly schedule. An interval of 2 produces an every-other week schedule. If no interval is specified, 1 is used. Valid entries are 1 - 52.

param list `days_of_week`: Sets the days of the week on which the task runs. Should be a list. ie: ['Monday','Wednesday','Friday']. Valid entries are the names of the days of the week.

Monthly
Parameters
  • `months_of_year (list)` -- Sets the months of the year during which the task runs. Should be a list. ie: ['January','July']. Valid entries are the full names of all the months.
  • `days_of_month (list)` -- Sets the days of the month during which the task runs. Should be a list. ie: [1, 15, 'Last']. Options are all days of the month 1 - 31 and the word 'Last' to indicate the last day of the month.
  • `last_day_of_month (bool)` -- Boolean value that indicates that the task runs on the last day of the month regardless of the actual date of that day.

You can set the task to run on the last day of the month by either including the word `Last` in the list of days, or setting the parameter `last_day_of_month` equal to True.

MonthlyDay
Parameters
  • `months_of_year (list)` -- Sets the months of the year during which the task runs. Should be a list. ie: ['January','July']. Valid entries are the full names of all the months.
  • `weeks_of_month (list)` -- Sets the weeks of the month during which the task runs. Should be a list. ie: ['First','Third']. Valid options are:
    • First
    • Second
    • Third
    • Fourth
  • `last_week_of_month (bool)` -- Boolean value that indicates that the task runs on the last week of the month.
  • `days_of_week (list)` -- Sets the days of the week during which the task runs. Should be a list. ie: ['Monday','Wednesday','Friday']. Valid entries are the names of the
the days of the week.

**OnIdle** No special parameters required.

**OnTaskCreation** No special parameters required.

**OnBoot** No special parameters required.

**OnLogon** No special parameters required.

**OnSessionChange**

Parameters

- `session_user_name (str)` -- Sets the user for the Terminal Server session. When a session state change is detected for this user, a task is started. To detect session status change for any user, do not pass this parameter.

- `state_change (str)` -- Sets the kind of Terminal Server session change that would trigger a task launch. Valid options are:
  - `ConsoleConnect`: When you connect to a user session (switch users)
  - `ConsoleDisconnect`: When you disconnect a user session (switch users)
  - `RemoteConnect`: When a user connects via Remote Desktop
  - `RemoteDisconnect`: When a user disconnects via Remote Desktop
  - `SessionLock`: When the workstation is locked
  - `SessionUnlock`: When the workstation is unlocked

Returns True if successful, False if unsuccessful

Return type `bool`

CLI Example:

```
salt 'minion-id' task.add_trigger <task_name> trigger_type=Once trigger_*enabled=True start_date=2016/12/1 start_time=12:01
```

**salt.modules.win_task.clear_triggers(name, location='\')**

Remove all triggers from the task.

Parameters

- `name (str)` -- The name of the task from which to clear all triggers.

- `location (str)` -- A string value representing the location of the task. Default is `\` which is the root for the task scheduler (C:WindowsSystem32tasks).

Returns True if successful, False if unsuccessful

Return type `bool`

CLI Example:

```
salt 'minion-id' task.clear_trigger <task_name>
```

**salt.modules.win_task.create_folder(name, location='\')**

Create a folder in which to create tasks.

Parameters

- `name (str)` -- The name of the folder. This will be displayed in the task scheduler.

- `location (str)` -- A string value representing the location in which to create the folder. Default is `\` which is the root for the task scheduler (C:WindowsSystem32tasks).

Returns True if successful, False if unsuccessful

Return type `bool`

CLI Example:

```
salt 'minion-id' task.create_folder <folder_name>
```

19.9. execution modules
salt.modules.win_task.create_task

Create a new task in the designated location. This function has many keyword arguments that are not listed here. For additional arguments see:

- `edit_task()`
- `add_action()`
- `add_trigger()`

**Parameters**

- `name` *(str)* -- The name of the task. This will be displayed in the task scheduler.
- `location` *(str)* -- A string value representing the location in which to create the task. Default is `\` which is the root for the task scheduler (C:WindowsSystem32tasks).
- `user_name` *(str)* -- The user account under which to run the task. To specify the 'System' account, use 'System'. The password will be ignored.
- `password` *(str)* -- The password to use for authentication. This should set the task to run whether the user is logged in or not, but is currently not working.
- `force` *(bool)* -- If the task exists, overwrite the existing task.

**Returns**

True if successful, False if unsuccessful

**Return type**

bool

**CLI Example:**

```
salt 'minion-id' task.create_task <task_name> user_name=System force=True action_type=Execute cmd='del /Q /S C:\\Temp' trigger_type=Once start_date=2016-12-10 start_time=01:00
```

salt.modules.win_task.create_task_from_xml

Create a task based on XML. Source can be a file or a string of XML.

**Parameters**

- `name` *(str)* -- The name of the task. This will be displayed in the task scheduler.
- `location` *(str)* -- A string value representing the location in which to create the task. Default is `\` which is the root for the task scheduler (C:WindowsSystem32tasks).
- `xml_text` *(str)* -- A string of xml representing the task to be created. This will be overridden by `xml_path` if passed.
- `xml_path` *(str)* -- The path to an XML file on the local system containing the xml that defines the task. This will override `xml_text`
- `user_name` *(str)* -- The user account under which to run the task. To specify the 'System' account, use 'System'. The password will be ignored.
- `password` *(str)* -- The password to use for authentication. This should set the task to run whether the user is logged in or not, but is currently not working.

**Returns**

True if successful, False if unsuccessful

**Return type**

bool

**CLI Example:**

```
salt 'minion-id' task.create_task_from_xml <task_name> xml_path=C:\\task.xml
```

salt.modules.win_task.delete_folder

Delete a folder from the task scheduler.

**Parameters**

- `name` *(str)* -- The name of the folder to delete.
- `location` *(str)* -- A string value representing the location of the folder. Default is `\` which is the root for the task scheduler (C:WindowsSystem32tasks).
Returns True if successful, False if unsuccessful
Return type bool

CLI Example:

```
salt 'minion-id' task.delete_folder <folder_name>
```

salt.modules.win_task.delete_task(name, location='\')
Delete a task from the task scheduler.
Parameters
• name (str) -- The name of the task to delete.
• location (str) -- A string value representing the location of the task. Default is '\ which is the root for the task scheduler (C:WindowsSystem32tasks).

Returns True if successful, False if unsuccessful
Return type bool

CLI Example:

```
salt 'minion-id' task.delete_task <task_name>
```

salt.modules.win_task.edit_task(name=None, location='\', user_name=None, password=None, description=None, enabled=None, hidden=None, run_if_idle=None, idle_duration=None, idle_wait_timeout=None, idle_stop_on_end=None, idle_restart=None, ac_only=None, stop_if_on_batteries=None, wake_to_run=None, run_if_network=None, network_id=None, network_name=None, allow_demand_start=None, start_when_available=None, restart_every=None, restart_count=3, execution_time_limit=None, force_stop=None, delete_after=None, multiple_instances=None, **kwargs)
Edit the parameters of a task. Triggers and Actions cannot be edited yet.
Parameters
• name (str) -- The name of the task. This will be displayed in the task scheduler.
• location (str) -- A string value representing the location in which to create the task. Default is '\ which is the root for the task scheduler (C:WindowsSystem32tasks).
• user_name (str) -- The user account under which to run the task. To specify the 'System' account, use 'System'. The password will be ignored.
• password (str) -- The password to use for authentication. This should set the task to run whether the user is logged in or not, but is currently not working.

Note: The combination of user_name and password determine how the task runs. For example, if a username is passed without at password the task will only run when the user is logged in. If a password is passed as well the task will run whether the user is logged on or not. If you pass 'System' as the username the task will run as the system account (the password parameter is ignored.)

Parameters
• description (str) -- A string representing the text that will be displayed in the description field in the task scheduler.
• enabled (bool) -- A boolean value representing whether or not the task is enabled.
• hidden (bool) -- A boolean value representing whether or not the task is hidden.
• run_if_idle (bool) -- Boolean value that indicates that the Task Scheduler will run the task only if the computer is in an idle state.
• idle_duration (str) -- A value that indicates the amount of time that the computer must be in an idle state before the task is run. Valid values are:
  • 1 minute
Parameters

idle_wait_timeout (str) -- A value that indicates the amount of time that the
Task Scheduler will wait for an idle condition to occur. Valid values are:

• Do not wait
• 1 minute
• 5 minutes
• 10 minutes
• 15 minutes
• 30 minutes
• 1 hour
• 2 hours

Parameters

idle_stop_on_end (bool) -- Boolean value that indicates that the Task Sched-
uler will terminate the task if the idle condition ends before the task is completed.

idle_restart (bool) -- Boolean value that indicates whether the task is restarted
when the computer cycles into an idle condition more than once.

ac_only (bool) -- Boolean value that indicates that the Task Scheduler will launch
the task only while on AC power.

stop_if_on_batteries (bool) -- Boolean value that indicates that the task
will be stopped if the computer begins to run on battery power.

wake_to_run (bool) -- Boolean value that indicates that the Task Scheduler will
wake the computer when it is time to run the task.

run_if_network (bool) -- Boolean value that indicates that the Task Scheduler
will run the task only when a network is available.

network_id (guid) -- GUID value that identifies a network profile.

network_name (str) -- Sets the name of a network profile. The name is used for
display purposes.

allow_demand_start (bool) -- Boolean value that indicates that the task can
be started by using either the Run command or the Context menu.

start_when_available (bool) -- Boolean value that indicates that the Task
Scheduler can start the task at any time after its scheduled time has passed.

restart_every -- A value that specifies the interval between task restart at-
ttempts. Valid values are:

• False (to disable)
• 1 minute
• 5 minutes
• 10 minutes
• 15 minutes
• 30 minutes
• 1 hour
• 2 hours

Parameters

restart_count (int) -- The number of times the Task Scheduler will attempt to
restart the task. Valid values are integers 1 - 999.

execution_time_limit -- The amount of time allowed to complete the task.
Valid values are:

• False (to disable)
• 1 hour
• 2 hours
• 4 hours
• 8 hours
• 12 hours
• 1 day
• 3 days

Parameters

• **force_stop** *(bool)* -- Boolean value that indicates that the task may be terminated by using TerminateProcess.

• **delete_after** -- The amount of time that the Task Scheduler will wait before deleting the task after it expires. Requires a trigger with an expiration date. Valid values are:

  • False (to disable)
  • Immediately
  • 30 days
  • 90 days
  • 180 days
  • 365 days

Parameters **multiple_instances**(str) -- Sets the policy that defines how the Task Scheduler deals with multiple instances of the task. Valid values are:

• Parallel
• Queue
• No New Instance
• Stop Existing

Returns True if successful, False if unsuccessful

Return type bool

CLI Example:
```
salt 'minion-id' task.edit_task <task_name> description='This task is awesome'
```

**salt.modules.win_task.info**(name, *location='\'*)

Get the details about a task in the task scheduler.

Parameters

• **name**(str) -- The name of the task for which to return the status

• **location**(str) -- A string value representing the location of the task. Default is `\` which is the root for the task scheduler (C:WindowsSystem32tasks).

Returns

Return type dict

CLI Example:
```
salt 'minion-id' task.info <task_name>
```

**salt.modules.win_task.list_actions**(name, *location='\'*)

List all actions that pertain to a task in the specified location.

Parameters

• **name**(str) -- The name of the task for which list actions.

• **location**(str) -- A string value representing the location of the task from which to list actions. Default is `\` which is the root for the task scheduler (C:WindowsSystem32tasks).

Returns Returns a list of actions.

Return type list
CLI Example:

```bash
salt 'minion-id' task.list_actions <task_name>
```

`salt.modules.win_task.list_folders(location='\')`
List all folders located in a specific location in the task scheduler.

**Parameters**
- `location` *(str)* -- A string value representing the folder from which you want to list tasks. Default is `\` which is the root for the task scheduler (C:WindowsSystem32tasks).

**Returns**
Returns a list of folders.

**Return type** `list`

CLI Example:

```bash
salt 'minion-id' task.list_folders
```

`salt.modules.win_task.list_tasks(location='\')`
List all tasks located in a specific location in the task scheduler.

**Parameters**
- `location` *(str)* -- A string value representing the folder from which you want to list tasks. Default is `\` which is the root for the task scheduler (C:WindowsSystem32tasks).

**Returns**
Returns a list of tasks.

**Return type** `list`

CLI Example:

```bash
salt 'minion-id' task.list_tasks
```

`salt.modules.win_task.list_triggers(name, location='\')`
List all triggers that pertain to a task in the specified location.

**Parameters**
- `name` *(str)* -- The name of the task for which list triggers.
- `location` *(str)* -- A string value representing the location of the task from which to list triggers. Default is `\` which is the root for the task scheduler (C:WindowsSystem32tasks).

**Returns**
Returns a list of triggers.

**Return type** `list`

CLI Example:

```bash
salt 'minion-id' task.list_triggers <task_name>
```

`salt.modules.win_task.run(name, location='\')`
Run a scheduled task manually.

**Parameters**
- `name` *(str)* -- The name of the task to run.
- `location` *(str)* -- A string value representing the location of the task. Default is `\` which is the root for the task scheduler (C:WindowsSystem32tasks).

**Returns**
True if successful, False if unsuccessful

**Return type** `bool`

CLI Example:

```bash
salt 'minion-id' task.run <task_name>
```

`salt.modules.win_task.run_wait(name, location='\')`
Run a scheduled task and return when the task finishes

**Parameters**
- `name` *(str)* -- The name of the task to run.
- `location` *(str)* -- A string value representing the location of the task. Default is `\` which is the root for the task scheduler (C:WindowsSystem32tasks).
Returns  True if successful, False if unsuccessful
Return type  bool

CLI Example:

```shell
salt 'minion-id' task.list_run_wait <task_name>
```

salt.modules.win_task.status(name, location='\')

Determine the status of a task. Is it Running, Queued, Ready, etc.

Parameters

- name (str) -- The name of the task for which to return the status
- location (str) -- A string value representing the location of the task. Default is `\` which is the root for the task scheduler (C:\Windows\System32\tasks).

Returns  The current status of the task. Will be one of the following:

- Unknown
- Disabled
- Queued
- Ready
- Running

Return type  string

CLI Example:

```shell
salt 'minion-id' task.list_status <task_name>
```

salt.modules.win_task.stop(name, location='\')

Stop a scheduled task.

Parameters

- name (str) -- The name of the task to stop.
- location (str) -- A string value representing the location of the task. Default is `\` which is the root for the task scheduler (C:\Windows\System32\tasks).

Returns  True if successful, False if unsuccessful
Return type  bool

CLI Example:

```shell
salt 'minion-id' task.list_stop <task_name>
```

19.9.442  salt.modules.win_timezone

Module for managing timezone on Windows systems.

salt.modules.win_timezone.get_hwclock()

Get current hardware clock setting (UTC or localtime)

CLI Example:

```shell
salt '*' timezone.get_hwclock
```

salt.modules.win_timezone.get_offset()

Get current numeric timezone offset from UCT (i.e. -0700)

CLI Example:

```shell
salt '*' timezone.get_offset
```
salt.modules.win_timezone.get_zone()
Get current timezone (i.e. America/Denver)

CLI Example:
```
salt '*' timezone.get_zone
```

salt.modules.win_timezone.get_zonecode()
Get current timezone (i.e. PST, MDT, etc)

CLI Example:
```
salt '*' timezone.get_zonecode
```

salt.modules.win_timezone.set_hwclock(clock)
Sets the hardware clock to be either UTC or localtime

CLI Example:
```
salt '*' timezone.set_hwclock UTC
```

salt.modules.win_timezone.set_zone(timezone)
Unlinks, then symlinks /etc/localtime to the set timezone.

The timezone is crucial to several system processes, each of which SHOULD be restarted (for instance, whatever you system uses as its cron and syslog daemons). This will not be magically done for you!

CLI Example:
```
salt '*' timezone.set_zone 'America/Denver'
```

salt.modules.win_timezone.zone_compare(timezone)
Checks the md5sum between the given timezone, and the one set in /etc/localtime. Returns True if they match, and False if not. Mostly useful for running state checks.

Example:
```
salt '*' timezone.zone_compare 'America/Denver'
```

19.9.443 salt.modules.win_update

Module for running windows updates.

This module is being deprecated and will be removed in Salt Fluorine. Please use the win_wua module instead.

depends

- win32com
- win32con
- win32api
- pywintypes

New in version 2014.7.0.

Set windows updates to run by category. Default behavior is to install all updates that do not require user interaction to complete. Optionally set categories to a category of your choice to only install certain updates. Default is to set to install all available but driver updates. The following example will install all Security and Critical Updates, and download but not install standard updates.
You can also specify a number of features about the update to have a fine grain approach to specific types of updates. These are the following features/states of updates available for configuring:

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'UI'</td>
<td>User interaction required, skipped by default</td>
</tr>
<tr>
<td>'downloaded'</td>
<td>Already downloaded, included by default</td>
</tr>
<tr>
<td>'present'</td>
<td>Present on computer, included by default</td>
</tr>
<tr>
<td>'installed'</td>
<td>Already installed, skipped by default</td>
</tr>
<tr>
<td>'reboot'</td>
<td>Reboot required, included by default</td>
</tr>
<tr>
<td>'hidden'</td>
<td>Skip hidden updates, skipped by default</td>
</tr>
<tr>
<td>'software'</td>
<td>Software updates, included by default</td>
</tr>
<tr>
<td>'driver'</td>
<td>Driver updates, included by default</td>
</tr>
</tbody>
</table>

The following example installs all updates that don’t require a reboot:

```bash
salt '*' win_update.install_updates categories=["Critical Updates", 'Security Updates']
```

Once installed Salt will return a similar output:

```
2 : Windows Server 2012 Update (KB123456)
4 : Internet Explorer Security Update (KB098765)
2 : Malware Definition Update (KB321456)
... 
```

The number at the beginning of the line is an OperationResultCode from the Windows Update Agent, it’s enumeration is described here: [https://msdn.microsoft.com/en-us/library/windows/desktop/aa387095(v=vs.85).aspx](https://msdn.microsoft.com/en-us/library/windows/desktop/aa387095(v=vs.85).aspx). The result code is then followed by the update name and its KB identifier.

```python
class salt.modules.win_update.PyWinUpdater(categorie...SkipDriverUpdates=False, skipHidden=True)
```

**AutoSearch()**
- this function generates a search string, simplifying the search function while still providing as many features as possible.

**Download()**

**GetAvailableCategories()**

**GetCategories()**

**GetDownloadResults()**

**GetInstallationResults()**
- this gets results of installation process.

**GetInstallationResultsPretty()**
- converts the installation results into a pretty print.

**GetSearchResults(fields=\None)\**
- Reduce full updates information to the most important information.

**GetSearchResultsVerbose()**

**Install()**

**Search(searchString)**

19.9. execution modules
**SetCategories** *(categories)*

**SetSkip** *(skip, state)*

**SetSkips** *(skips)*

salt.modules.win_update.download_updates *(skips=None, retries=5, categories=None)*

Downloads all available updates, skipping those that require user interaction.

Various aspects of the updates can be included or excluded. This feature is still in development.

- **retries** Number of retries to make before giving up. This is total, not per step.
- **categories** Specify the categories to update. Must be passed as a list.

```bash
salt '*' win_update.download_updates categories="['Updates']"
```

Categories include the following:

- Updates
- Windows 7
- Critical Updates
- Security Updates
- Update Rollups

CLI Examples:

```bash
# Normal Usage
salt '*' win_update.download_updates

# Download critical updates only
salt '*' win_update.download_updates categories="['Critical Updates']"
```

salt.modules.win_update.install_updates *(skips=None, retries=5, categories=None)*

Downloads and installs all available updates, skipping those that require user interaction.

Add cached to only install those updates which have already been downloaded.

```bash
salt '*' win_update.install_updates categories="['Updates']"
```

Categories include the following:

- Updates
- Windows 7
- Critical Updates
- Security Updates
- Update Rollups

CLI Examples:

```bash
# Normal Usage
salt '*' win_update.install_updates

# Install all critical updates
salt '*' win_update.install_updates categories="['Critical Updates']"
```

salt.modules.win_update.list_updates *(verbose=False, fields=None, skips=None, retries=5, categories=None)*

Returns a summary of available updates, grouped into their non-mutually exclusive categories.
verbose  Return full set of results, including several fields from the COM.
fields  Return a list of specific fields for each update. The optional values here are those at the root level of
        the verbose list. This is superseded by the verbose option.
retries  Number of retries to make before giving up. This is total, not per step.
categories  Specify the categories to list. Must be passed as a list.

        `salt '*' win_update.list_updates categories="['Updates']"`

Categories include, but are not limited to, the following:
    • Updates
    • Windows 7
    • Critical Updates
    • Security Updates
    • Update Rollups

CLI Examples:

# Normal Usage
salt '*' win_update.list_updates

# Specific Fields
salt '*' win_update.list_updates fields="['Title', 'Description']"

# List all critical updates list in verbose detail
salt '*' win_update.list_updates categories="['Critical Updates']" verbose=True

19.9.444  salt.modules.win_useradd

Module for managing Windows Users

Important:  If you feel that Salt should be using this module to manage users on a minion, and it is using a different
module (or gives an error similar to `user.info' is not available), see here.

depends
    • pythoncom
    • pywintypes
    • win32api
    • win32con
    • win32net
    • win32netcon
    • win32profile
    • win32security
    • win32ts
    • wmi

Note:  This currently only works with local user accounts, not domain accounts

19.9.  execution modules
salt.modules.win_useradd.add(name, password=None, fullname=None, description=None, groups=None, home=None, homedrive=None, profile=None, logonscript=None)

Add a user to the minion.

Parameters

- **name** *(str)* -- User name
- **password** *(str, optional)* -- User's password in plain text.
- **fullname** *(str, optional)* -- The user's full name.
- **description** *(str, optional)* -- A brief description of the user account.
- **groups** *(str, optional)* -- A list of groups to add the user to. (see chgroups)
- **home** *(str, optional)* -- The path to the user's home directory.
- **homedrive** *(str, optional)* -- The drive letter to assign to the home directory. Must be the Drive Letter followed by a colon. ie: U:
- **profile** *(str, optional)* -- An explicit path to a profile. Can be a UNC or a folder on the system. If left blank, windows uses it's default profile directory.
- **logonscript** *(str, optional)* -- Path to a login script to run when the user logs on.

Returns True if successful. False is unsuccessful.

Return type *bool*

CLI Example:

```sh
salt '*' user.add name password
```

salt.modules.win_useradd.addgroup(name, group)

Add user to a group

Parameters

- **name** *(str)* -- The user name to add to the group
- **group** *(str)* -- The name of the group to which to add the user

Returns True if successful, otherwise False

Return type *bool*

CLI Example:

```sh
salt '*' user.addgroup jsnuffy 'Power Users'
```

salt.modules.win_useradd.chfullname(name, fullname)

Change the full name of the user

Parameters

- **name** *(str)* -- The user name for which to change the full name
- **fullname** *(str)* -- The new value for the full name

Returns True if successful, otherwise False

Return type *bool*

CLI Example:

```sh
salt '*' user.chfullname user 'First Last'
```

salt.modules.win_useradd.chgroups(name, groups, append=True)

Change the groups this user belongs to, add append=False to make the user a member of only the specified groups

Parameters

- **name** *(str)* -- The user name for which to change groups
- **groups** *(str, list)* -- A single group or a list of groups to assign to the user. For multiple groups this can be a comma delimited string or a list.
- **append** *(bool, optional)* -- True adds the passed groups to the user's current groups. False sets the user's groups to the passed groups only. Default is True.

Returns True if successful, otherwise False
Return type: bool

CLI Example:

```
salt '*' user.chgroups jsnuffy Administrators,Users True
```

```
salt.modules.win_useradd.chhome(name, home, **kwargs)
```

Change the home directory of the user, pass True for persist to move files to the new home directory if the old home directory exist.

Parameters:
- `name (str)` -- The name of the user whose home directory you wish to change
- `home (str)` -- The new location of the home directory

Returns: True if successful, otherwise False

Return type: bool

CLI Example:

```
salt '*' user.chhome foo \fileserv\home\foo True
```

```
salt.modules.win_useradd.chprofile(name, profile)
```

Change the profile directory of the user

Parameters:
- `name (str)` -- The name of the user whose profile you wish to change
- `profile (str)` -- The new location of the profile

Returns: True if successful, otherwise False

Return type: bool

CLI Example:

```
salt '*' user.chprofile foo \fileserv\profiles\foo
```

```
salt.modules.win_useradd.current(sam=False)
```

Get the username that salt-minion is running under. If salt-minion is running as a service it should return the Local System account. If salt is running from a command prompt it should return the username that started the command prompt.

New in version 2015.5.6.

Parameters:
- `sam (bool, optional)` -- False returns just the username without any domain notation. True returns the domain with the username in the SAM format. Ie: domain\username

Returns: Returns username

Return type: str

CLI Example:

```
salt '*' user.current
```

```
salt.modules.win_useradd.delete(name, purge=False, force=False)
```

Remove a user from the minion

Parameters:
- `name (str)` -- The name of the user to delete
- `purge (bool, optional)` -- Boolean value indicating that the user profile should also be removed when the user account is deleted. If set to True the profile will be removed. Default is False.
- `force (bool, optional)` -- Boolean value indicating that the user account should be deleted even if the user is logged in. True will log the user out and delete user.

Returns: True if successful, otherwise False

Return type: bool
CLI Example:

```
salt '*' user.delete name
```

```
salt.modules.win_useradd.getUserSid(username)
```
Get the Security ID for the user
  Parameters **username** *(str)* -- The user name for which to look up the SID
  Returns The user SID
  Return type **str**

CLI Example:

```
salt '*' user.getUserSid jsnuffy
```

```
salt.modules.win_useradd.getent(refresh=False)
```
Return the list of all info for all users
  Parameters **refresh** *(bool, optional)* -- Refresh the cached user information. Useful when used from within a state function. Default is False.
  Returns A dictionary containing information about all users on the system
  Return type **dict**

CLI Example:

```
salt '*' user.getent
```

```
salt.modules.win_useradd.info(name)
```
Return user information
  Parameters **name** *(str)* -- Username for which to display information
  Returns A dictionary containing user information
    • **fullname**
    • **username**
    • **SID**
    • **passwd** (will always return None)
    • **comment** (same as description, left here for backwards compatibility)
    • **description**
    • **active**
    • **logonscript**
    • **profile**
    • **home**
    • **homedrive**
    • **groups**
    • **password_changed**
    • **successful_logon_attempts**
    • **failed_logon_attempts**
    • **last_logon**
    • **account_disabled**
    • **account_locked**
    • **password_neverExpires**
    • **disallow_change_password**
    • **gid**
  Return type **dict**

CLI Example:

```
salt '*' user.info jsnuffy
```

```
salt.modules.win_useradd.list_groups(name)
```

Return a list of groups the named user belongs to

```python
Parameters name (str) -- The user name for which to list groups
Returns A list of groups to which the user belongs
Return type list
```

CLI Example:
```
salt '*' user.list_groups foo
```

salt.modules.win_useradd.list_users()

Return a list of all users on Windows

```python
Returns A list of all users on the system
Return type list
```

CLI Example:
```
salt '*' user.list_users
```

salt.modules.win_useradd.removegroup(name, group)

Remove user from a group

```python
Parameters
  • name (str) -- The user name to remove from the group
  • group (str) -- The name of the group from which to remove the user
Returns True if successful, otherwise False
Return type bool
```

CLI Example:
```
salt '*' user.removegroup jsnuffy 'Power Users'
```

salt.modules.win_useradd.rename(name, new_name)

Change the username for a named user

```python
Parameters
  • name (str) -- The user name to change
  • new_name (str) -- The new name for the current user
Returns True if successful, otherwise False
Return type bool
```

CLI Example:
```
salt '*' user.rename jsnuffy jshmoe
```

salt.modules.win_useradd.setpassword(name, password)

Set the user's password

```python
Parameters
  • name (str) -- The user name for which to set the password
  • password (str) -- The new password
Returns True if successful, otherwise False
Return type bool
```

CLI Example:
```
salt '*' user.setpassword jsnuffy sup3rs3cr3t
```

salt.modules.win_useradd.update(name, password=None, fullname=None, description=None, home=None, homedrive=None, logonscript=None, profile=None, expiration_date=None, expired=None, account_disabled=None, unlock_account=None, password_neverExpires=None, disallow_change_password=None)

Updates settings for the windows user. Name is the only required parameter. Settings will only be changed if the parameter is passed a value.
New in version 2015.8.0.

Parameters

- **name** (*str*) -- The user name to update.
- **password** (*str*, *optional*) -- New user password in plain text.
- **fullname** (*str*, *optional*) -- The user's full name.
- **description** (*str*, *optional*) -- A brief description of the user account.
- **home** (*str*, *optional*) -- The path to the user's home directory.
- **homedrive** (*str*, *optional*) -- The drive letter to assign to the home directory. Must be the Drive Letter followed by a colon. ie: U:
- **logonscript** (*str*, *optional*) -- The path to the logon script.
- **profile** (*str*, *optional*) -- The path to the user's profile directory.
- **expiration_date** (*date*, *optional*) -- The date and time when the account expires. Can be a valid date/time string. To set to never expire pass the string ‘Never’.
- **expired** (*bool*, *optional*) -- Pass True to expire the account. The user will be prompted to change their password at the next logon. Pass False to mark the account as ‘not expired’. You can’t use this to negate the expiration if the expiration was caused by the account expiring. You’ll have to change the expiration_date as well.
- **account_disabled** (*bool*, *optional*) -- True disables the account. False enables the account.
- **unlock_account** (*bool*, *optional*) -- True unlocks a locked user account. False is ignored.
- **password_never_expires** (*bool*, *optional*) -- True sets the password to never expire. False allows the password to expire.
- **disallow_change_password** (*bool*, *optional*) -- True blocks the user from changing the password. False allows the user to change the password.

Returns  True if successful. False is unsuccessful.

Return type  bool

CLI Example:

```
salt '*' user.update bob password=secret profile=C:\Users\Bob
home=\\server\homeshare\bob homedrive=U:
```
The `get` function expects a name in the form of a GUID, KB, or Title and should return information about a single update. The other functions accept either a single item or a list of items for downloading/installing/uninstalling a specific list of items.

The `win_wua.list` and `win_wua.get` functions are utility functions. In addition to returning information about updates they can also download and install updates by setting `download=True` or `install=True`. So, with `py:func:win_wua.list <salt.modules.win_wua.list_>` for example, you could run the function with the filters you want to see what is available. Then just add `install=True` to install everything on that list.

If you want to download, install, or uninstall specific updates, use `win_wua.download`, `win_wua.install`, or `win_wua.uninstall`. To update your system with the latest updates use `win_wua.list` and set `install=True`

You can also adjust the Windows Update settings using the `win_wua.set_wu_settings` function. This function is only supported on the following operating systems:

- Windows Vista / Server 2008
- Windows 7 / Server 2008R2
- Windows 8 / Server 2012
- Windows 8.1 / Server 2012R2

As of Windows 10 and Windows Server 2016, the ability to modify the Windows Update settings has been restricted. The settings can be modified in the Local Group Policy using the `lgpo` module.

New in version 2015.8.0.

```
depends  salt.utils.win_update
salt.modules.win_wua.available(software=True,  
    drivers=True,  
    summary=False,  
    skip_installed=True,  
    skip_hidden=True,  
    skip_mandatory=False,  
    skip_reboot=False,  
    categories=None,  
    severities=None)
```

New in version 2017.7.0.

List updates that match the passed criteria. This allows for more filter options than `list()`. Good for finding a specific GUID or KB.

**Parameters**

- `software (bool)` -- Include software updates in the results (default is True)
- `drivers (bool)` -- Include driver updates in the results (default is True)
- `summary (bool)` --
  - True: Return a summary of updates available for each category.
  - False (default): Return a detailed list of available updates.
- `skip_installed (bool)` -- Skip updates that are already installed. Default is False.
- `skip_hidden (bool)` -- Skip updates that have been hidden. Default is True.
- `skip_mandatory (bool)` -- Skip mandatory updates. Default is False.
- `skip_reboot (bool)` -- Skip updates that require a reboot. Default is False.
- `categories (list)` -- Specify the categories to list. Must be passed as a list. All categories returned by default.

Categories include the following:

- Critical Updates
- Definition Updates
- Drivers (make sure you set `drivers=True`)
- Feature Packs
- Security Updates
- Update Rollups
- Updates
- Update Rollups
- Windows 7
- Windows 8.1
- Windows 8.1 drivers
- Windows 8.1 and later drivers
- Windows Defender

- **severities** *(list)* -- Specify the severities to include. Must be passed as a list.
  All severities returned by default.

  Severities include the following:
  - Critical
  - Important

Returns

Returns a dict containing either a summary or a list of updates:

```
List of Updates:
{'<GUID>': {'Title': <title>,
  'KB': <KB>,
  'GUID': <the globally unique identifier for the update>,
  'Description': <description>,
  'Downloaded': <has the update been downloaded>,
  'Installed': <has the update been installed>,
  'Mandatory': <is the update mandatory>,
  'UserInput': <is user input required>,
  'EULAAccepted': <has the EULA been accepted>,
  'Severity': <update severity>,
  'NeedsReboot': <is the update installed and awaiting reboot>,
  'RebootBehavior': <will the update require a reboot>,
  'Categories': [ '<category 1>',
                  '<category 2>',
                  ...]
}

Summary of Updates:
{'Total': <total number of updates returned>,
 'Available': <updates that are not downloaded or installed>,
 'Downloaded': <updates that are downloaded but not installed>,
 'Installed': <updates installed (usually 0 unless installed=True)>,
 'Categories': { '<category 1>: <total for that category>',
                  '<category 2>: <total for category 2>',
                  ... }
}
```

Return type: **dict**

CLI Examples:

```
# Normal Usage (list all software updates)
salt '*' win_wua.available

# List all updates with categories of Critical Updates and Drivers
salt '*' win_wua.available categories=['Critical Updates','Drivers']

# List all Critical Security Updates
salt '*' win_wua.available categories=['Security Updates'] severities=['Critical']

# List all updates with a severity of Critical
salt '*' win_wua.available severities=['Critical']
```
salt.modules.win_wua.download(names)

New in version 2017.7.0.

Downloads updates that match the list of passed identifiers. It's easier to use this function by using list_updates and setting install=True.

Parameters names (str, list) -- A single update or a list of updates to download. This can be any combination of GUIDs, KB numbers, or names. GUIDs or KBs are preferred.

Note: An error will be raised if there are more results than there are items in the names parameter

Returns A dictionary containing the details about the downloaded updates

Return type dict

CLI Examples:

```
# Normal Usage
salt '*' win_wua.download names=['12345678-abcd-1234-abcd-1234567890ab', 'KB2131232']
```

salt.modules.win_wua.download_update(name)

Deprecated since version 2017.7.0: Use download() instead

Downloads a single update.

Parameters name (str) -- The name of the update to download. This can be a GUID, a KB number, or any part of the name. To ensure a single item is matched the GUID is preferred.

Note: If more than one result is returned an error will be raised.

Returns A dictionary containing the results of the download

Return type dict

CLI Examples:

```
salt '*' win_wua.download_update 12345678-abcd-1234-abcd-1234567890ab
salt '*' win_wua.download_update KB12312321
```

salt.modules.win_wua.download_updates(names)

Deprecated since version 2017.7.0: Use download() instead

Downloads updates that match the list of passed identifiers. It's easier to use this function by using list_updates and setting install=True.

Parameters names (list) -- A list of updates to download. This can be any combination of GUIDs, KB numbers, or names. GUIDs or KBs are preferred.

Returns A dictionary containing the details about the downloaded updates

Return type dict

CLI Examples:
# Normal Usage

```python
salt '*' win_wua.download_updates guid=['12345678-abcd-1234-abcd-1234567890ab',
    'KB2131233']
```

```python
salt.modules.win_wua.get(name, download=False, install=False)
```

New in version 2017.7.0.

Returns details for the named update

Parameters

- `name` (str) -- The name of the update you're searching for. This can be the GUID, a KB number, or any part of the name of the update. GUIDs and KBs are preferred. Run `list` to get the GUID for the update you're looking for.

- `download` (bool) -- Download the update returned by this function. Run this function first to see if the update exists, then set `download=True` to download the update.

- `install` (bool) -- Install the update returned by this function. Run this function first to see if the update exists, then set `install=True` to install the update.

Returns

Returns a dict containing a list of updates that match the name if download and install are both set to False. Should usually be a single update, but can return multiple if a partial name is given.

If download or install is set to true it will return the results of the operation.

```
List of Updates:
{ '<GUID>': {'Title': <title>,
    'KB': <KB>,
    'GUID': <the globally unique identifier for the update>
    'Description': <description>,
    'Downloaded': <has the update been downloaded>,
    'Installed': <has the update been installed>,
    'Mandatory': <is the update mandatory>,
    'UserInput': <is user input required>,
    'EULAAccepted': <has the EULA been accepted>,
    'Severity': <update severity>,
    'NeedsReboot': <is the update installed and awaiting reboot>,
    'RebootBehavior': <will the update require a reboot>,
    'Categories': ['<category 1>',
        '<category 2>',
        ...]
    }
}
```

Return type: `dict`

CLI Examples:

```bash
# Recommended Usage using GUID without braces
# Use this to find the status of a specific update
salt '*' win_wua.get 12345678-abcd-1234-abcd-1234567890ab

# Use the following if you don't know the GUID:

# Using a KB number
# Not all updates have an associated KB
salt '*' win_wua.get KB3030298
```
```python
salt.modules.win_wua.get_needs_reboot()

Determines if the system needs to be rebooted.

Returns  True if the system requires a reboot, otherwise False

Return type  bool

CLI Examples:

salt '*' win_wua.get_needs_reboot

salt.modules.win_wua.get_wu_settings()

Get current Windows Update settings.

Returns

A dictionary of Windows Update settings:

- **Featured Updates**: Boolean value that indicates whether to display notifications for featured updates.
- **Group Policy Required (Read-only)**: Boolean value that indicates whether Group Policy requires the Automatic Updates service.
- **Microsoft Update**: Boolean value that indicates whether to turn on Microsoft Update for other Microsoft Products
- **Needs Reboot**: Boolean value that indicates whether the machine is in a reboot pending state.
- **Non Admins Elevated**: Boolean value that indicates whether non-administrators can perform some update-related actions without administrator approval.
- **Notification Level**: Number 1 to 4 indicating the update level:
  1. Never check for updates
  2. Check for updates but let me choose whether to download and install them
  3. Download updates but let me choose whether to install them
  4. Install updates automatically
- **Read Only (Read-only)**: Boolean value that indicates whether the Automatic Update settings are read-only.
- **Recommended Updates**: Boolean value that indicates whether to include optional or recommended updates when a search for updates and installation of updates is performed.
- **Scheduled Day**: Days of the week on which Automatic Updates installs or uninstalls updates.
- **Scheduled Time**: Time at which Automatic Updates installs or uninstalls updates.

Return type  dict

CLI Examples:

salt '*' win_wua.get_wu_settings

salt.modules.win_wua.install(names)

New in version 2017.7.0.

Installs updates that match the list of identifiers. It may be easier to use the list_updates function and set install=True.

Parameters names (str, list) -- A single update or a list of updates to install. This can be any combination of GUIDs, KB numbers, or names. GUIDs or KBs are preferred.
**salt.modules.win_wua.install_update**(*name*)

- **Deprecated since version 2017.7.0:** Use **install()** instead

Installs a single update

**Parameters**

- **name (str)** -- The name of the update to install. This can be a GUID, a KB or any part of the name. To ensure a single item is matched the **(number,)** --

**is preferred. (GUID) --**

**Note:** If no results or more than one result is returned an error will be raised.

**Returns** A dictionary containing the results of the install

**Return type** dict

**CLI Examples:**

```
salt '.*' win_wua.install_update 12345678-abcd-1234-abcd-1234567890ab
salt '.*' win_wua.install_update KB12312231
```

**salt.modules.win_wua.install_updates**(*names*)

- **Deprecated since version 2017.7.0:** Use **install()** instead

Installs updates that match the list of identifiers. It may be easier to use the list_updates function and set install=True.

**Parameters**

- **names (list)** -- A list of updates to install. This can be any combination GUIDs, KB numbers, or names. GUIDs or KBs are preferred.

**Returns** A dictionary containing the details about the installed updates

**Return type** dict

**CLI Examples:**

```
# Normal Usage
salt '.*' win_wua.install_updates guid=['12345678-abcd-1234-abcd-1234567890ab', 'KB12323211']
```

**salt.modules.win_wua.list_**(*software=True, drivers=False, summary=False, skip_installed=True, categories=None, severities=None, download=False, install=False*)

- **New in version 2017.7.0.**

Returns a detailed list of available updates or a summary. If download or install is True the same list will be downloaded and/or installed.

**Parameters**

- **software (bool)** -- Include software updates in the results (default is True)
• **drivers** *(bool)* -- Include driver updates in the results (default is False)

• **summary** *(bool)* --
  - True: Return a summary of updates available for each category.
  - False (default): Return a detailed list of available updates.

• **skip_installed** *(bool)* -- Skip installed updates in the results (default is False)

• **download** *(bool)* -- (Overrides reporting functionality) Download the list of updates returned by this function. Run this function first with `download=False` to see what will be downloaded, then set `download=True` to download the updates.

• **install** *(bool)* -- (Overrides reporting functionality) Install the list of updates returned by this function. Run this function first with `install=False` to see what will be installed, then set `install=True` to install the updates.

• **categories** *(list)* -- Specify the categories to list. Must be passed as a list. All categories returned by default.

Categories include the following:
- Critical Updates
- Definition Updates
- Drivers (make sure you set `drivers=True`)
- Feature Packs
- Security Updates
- Update Rollups
- Updates
- Update Rollups
- Windows 7
- Windows 8.1
- Windows 8.1 drivers
- Windows 8.1 and later drivers
- Windows Defender

• **severities** *(list)* -- Specify the severities to include. Must be passed as a list. All severities returned by default.

Severities include the following:
- Critical
- Important

**Returns**

Returns a dict containing either a summary or a list of updates:

```python
List of Updates:
{'<GUID>': {'Title': <title>,
             'KB': <KB>,
             'GUID': <the globally unique identifier for the update>
             'Description': <description>,
             'Downloaded': <has the update been downloaded>,
             'Installed': <has the update been installed>,
             'Mandatory': <is the update mandatory>,
             'UserInput': <is user input required>,
             'EULAAccepted': <has the EULA been accepted>,
             'Severity': <update severity>,
             'NeedsReboot': <is the update installed and awaiting reboot>,
             'RebootBehavior': <will the update require a reboot>,
             'Categories': [ '<category 1>',
                           '<category 2>',
                           ...]
             }
```
Summary of Updates:
{'Total': <total number of updates returned>,
'Available': <updates that are not downloaded or installed>,
'Downloaded': <updates that are downloaded but not installed>,
'Installed': <updates installed (usually 0 unless installed=True)>,
'Categories': { <category 1>: <total for that category>,
               <category 2>: <total for category 2>,
               ... }}

Return type  dict

CLI Examples:

```python
# Normal Usage (list all software updates)
salt '*' win_wua.list

# List all updates with categories of Critical Updates and Drivers
salt '*' win_wua.list categories=['Critical Updates','Drivers']

# List all Critical Security Updates
salt '*' win_wua.list categories=['Security Updates'] severities=['Critical']

# List all updates with a severity of Critical
salt '*' win_wua.list severities=['Critical']

# A summary of all available updates
salt '*' win_wua.list summary=True

# A summary of all Feature Packs and Windows 8.1 Updates
salt '*' win_wua.list categories=['Feature Packs','Windows 8.1'] summary=True
```

```
salt.modules.win_wua.list_update(name, download=False, install=False)

Depreciated since version 2017.7.0: Use get() instead

Returns details for all updates that match the search criteria

Parameters

- **name** *(str)* -- The name of the update you're searching for. This can be the GUID, a KB number, or any part of the name of the update. GUIDs and KBs are preferred. Run list_updates to get the GUID for the update you're looking for.

- **download** *(bool)* -- Download the update returned by this function. Run this function first to see if the update exists, then set download=True to download the update.

- **install** *(bool)* -- Install the update returned by this function. Run this function first to see if the update exists, then set install=True to install the update.

Returns

Returns a dict containing a list of updates that match the name if download and install are both set to False. Should usually be a single update, but can return multiple if a partial name is given.

If download or install is set to true it will return the results of the operation.

List of Updates:
{'<GUID>': {'Title': <title>,
            'KB': <KB>,
            'GUID': <the globally unique identifier for the update>,
            'Description': <description>},
{'Downloaded': <has the update been downloaded>,
'Installed': <has the update been installed>,
'Mandatory': <is the update mandatory>,
'UserInput': <is user input required>,
'EULAAccepted': <has the EULA been accepted>,
'Severity': <update severity>,
'NeedsReboot': <is the update installed and awaiting reboot>,
'RebootBehavior': <will the update require a reboot>,
'Categories': [ '<category 1>',
'category 2>',
...]
}

Return type: dict

CLI Examples:

```python
# Recommended Usage using GUID without braces
# Use this to find the status of a specific update
salt '*' win_wua.list_update 12345678-abcd-1234-abcd-1234567890ab

# Use the following if you don't know the GUID:
# Using a KB number (could possibly return multiple results)
# Not all updates have an associated KB
salt '*' win_wua.list_update KB3030298

# Using part or all of the name of the update
# Could possibly return multiple results
# Not all updates have an associated KB
salt '*' win_wua.list_update 'Microsoft Camera Codec Pack'
```

```python
salt.modules.win_wua.list_updates(software=True, drivers=False, summary=False,
skip_installed=True, categories=None, severities=None,
download=False, install=False)
```

Deprecated since version 2017.7.0: Use list() instead

Returns a detailed list of available updates or a summary. If download or install is True the same list will be downloaded and/or installed.

Parameters

- **software** *(bool)* -- Include software updates in the results (default is True)
- **drivers** *(bool)* -- Include driver updates in the results (default is False)
- **summary** *(bool)* --
  - True: Return a summary of updates available for each category.
  - False (default): Return a detailed list of available updates.
- **skip_installed** *(bool)* -- Skip installed updates in the results (default is False)
- **download** *(bool)* -- (Overrides reporting functionality) Download the list of updates returned by this function. Run this function first with download=False to see what will be downloaded, then set download=True to download the updates.
- **install** *(bool)* -- (Overrides reporting functionality) Install the list of updates returned by this function. Run this function first with install=False to see what will be installed, then set install=True to install the updates.
- **categories** *(list)* -- Specify the categories to list. Must be passed as a list. All categories returned by default.

Categories include the following:
- Critical Updates
- Definition Updates
- Drivers (make sure you set drivers=True)
- Feature Packs
- Security Updates
- Update Rollups
- Updates
- Update Rollups
- Windows 7
- Windows 8.1
- Windows 8.1 drivers
- Windows 8.1 and later drivers
- Windows Defender

- **severities** *(list)* -- Specify the severities to include. Must be passed as a list.

  All severities returned by default.

  Severities include the following:
  - Critical
  - Important

**Returns**

Returns a dict containing either a summary or a list of updates:

```python
List of Updates:
{'<GUID>': {'Title': <title>,
            'KB': <KB>,
            'GUID': <the globally unique identifier for the update>,
            'Description': <description>,
            'Downloaded': <has the update been downloaded>,
            'Installed': <has the update been installed>,
            'Mandatory': <is the update mandatory>,
            'UserInput': <is user input required>,
            'EULAAccepted': <has the EULA been accepted>,
            'Severity': <update severity>,
            'NeedsReboot': <is the update installed and awaiting reboot>,
            'RebootBehavior': <will the update require a reboot>,
            'Categories': [ '<category 1>',
                            '<category 2>',
                            ... ]
          }
}
```

Summary of Updates:
```python
{'Total': <total number of updates returned>,
 'Available': <updates that are not downloaded or installed>,
 'Downloaded': <updates that are downloaded but not installed>,
 'Installed': <updates installed (usually 0 unless installed=True)>,
 'Categories': { '<category 1>': <total for that category>,
                 '<category 2>': <total for category 2>,
                 ... }
}
```
salt.modules.win_wua.set_wu_settings(level=None, recommended=None, featured=None, elevated=None, msupdate=None, day=None, time=None)

Change Windows Update settings. If no parameters are passed, the current value will be returned.

Supported:
- Windows Vista / Server 2008
- Windows 7 / Server 2008R2
- Windows 8 / Server 2012
- Windows 8.1 / Server 2012R2

Parameters
- **level (int)** -- Number from 1 to 4 indicating the update level:
  1. Never check for updates
  2. Check for updates but let me choose whether to download and install them
  3. Download updates but let me choose whether to install them
  4. Install updates automatically
- **recommended (bool)** -- Boolean value that indicates whether to include optional or recommended updates when a search for updates and installation of updates is performed.
- **featured (bool)** -- Boolean value that indicates whether to display notifications for featured updates.
- **elevated (bool)** -- Boolean value that indicates whether non-administrators can perform some update-related actions without administrator approval.
- **msupdate (bool)** -- Boolean value that indicates whether to turn on Microsoft Update for other Microsoft products
- **day (str)** -- Days of the week on which Automatic Updates installs or uninstalls updates. Accepted values:
  - Everyday
  - Monday
  - Tuesday
  - Wednesday
  - Thursday
  - Friday
  - Saturday
- **time (str)** -- Time at which Automatic Updates installs or uninstalls updates. Must be in the #HH## 24hr format, eg. 3:00 PM would be 15:00. Must be in 1 hour increments.

Returns Returns a dictionary containing the results.
Return type dict

CLI Examples:
salt 'salt '*' win_wua.set_wu_settings level=4 recommended=True featured=False

salt.modules.win_wua.uninstall(names)
New in version 2017.7.0.
Uninstall updates.

Parameters names (str, list) -- A single update or a list of updates to uninstall. This can be any combination of GUIDs, KB numbers, or names. GUIDs or KBs are preferred.

Returns A dictionary containing the details about the uninstalled updates

Return type dict

CLI Examples:

# Normal Usage
salt 'salt '*' win_wua.uninstall KB3121212

# As a list
salt 'salt '*' win_wua.uninstall guid=["12345678-abcd-1234-abcd-1234567890ab", "KB1231231"]

19.9.446 salt.modules.x509

Manage X509 certificates
New in version 2015.8.0.

depends M2Crypto

salt.modules.x509.create_certificate(path=None, text=False, overwrite=True, ca_server=None, **kwargs)
Create an X509 certificate.

path: Path to write the certificate to.
text: If True, return the PEM text without writing to a file. Default False.
overwrite: If True(default), create_certificate will overwrite the entire pem file. Set False to preserve existing private keys and dh params that may exist in the pem file.
kwarg: Any of the properties below can be included as additional keyword arguments.
ca_server: Request a remotely signed certificate from ca_server. For this to work, a signing_policy must be specified, and that same policy must be configured on the ca_server. See signing_policy for details. Also the salt master must permit peers to call the sign_remote_certificate function.

Example:
/etc/salt/master.d/peer.conf

```
peer:
  .*:  
    - x509.sign_remote_certificate
```

subject properties: Any of the values below can be included to set subject properties Any other subject properties supported by OpenSSL should also work.

C: 2 letter Country code
CN: Certificate common name, typically the FQDN.
Email: Email address
GN: Given Name
L: Locality
O: Organization
OU: Organization Unit
SN: SurName
ST: State or Province

signing_private_key: A path or string of the private key in PEM format that will be used to sign this certificate. If neither signing_cert, public_key, or csr are included, it will be assumed that this is a self-signed certificate, and the public key matching signing_private_key will be used to create the certificate.

signing_private_key_passphrase: Passphrase used to decrypt the signing_private_key.

signing_cert: A certificate matching the private key that will be used to sign this certificate. This is used to populate the issuer values in the resulting certificate. Do not include this value for self-signed certificates.

public_key: The public key to be included in this certificate. This can be sourced from a public key, certificate, csr or private key. If a private key is used, the matching public key from the private key will be generated before any processing is done. This means you can request a certificate from a remote CA using a private key file as your public_key and only the public key will be sent across the network to the CA. If neither public_key or csr are specified, it will be assumed that this is a self-signed certificate, and the public key derived from signing_private_key will be used. Specify either public_key or csr, not both. Because you can input a CSR as a public key or as a CSR, it is important to understand the difference. If you import a CSR as a public key, only the public key will be added to the certificate, subject or extension information in the CSR will be lost.

public_key_passphrase: If the public key is supplied as a private key, this is the passphrase used to decrypt it.

csr: A file or PEM string containing a certificate signing request. This will be used to supply the subject, extensions and public key of a certificate. Any subject or extensions specified explicitly will overwrite any in the CSR.

basicConstraints: X509v3 Basic Constraints extension.

extensions: The following arguments set X509v3 Extension values. If the value starts with critical, the extension will be marked as critical.

Some special extensions are subjectKeyIdentifier and authorityKeyIdentifier.

subjectKeyIdentifier can be an explicit value or it can be the special string hash. hash will set the subjectKeyIdentifier equal to the SHA1 hash of the modulus of the public key in this certificate. Note that this is not the exact same hashing method used by OpenSSL when using the hash value.

authorityKeyIdentifier Use values acceptable to the openssl CLI tools. This will automatically populate authorityKeyIdentifier with the subjectKeyIdentifier of signing_cert. If this is a self-signed cert these values will be the same.

basicConstraints: X509v3 Basic Constraints
keyUsage: X509v3 Key Usage
extendedKeyUsage: X509v3 Extended Key Usage
subjectKeyIdentifier: X509v3 Subject Key Identifier
issuerAltName: X509v3 Issuer Alternative Name
subjectAltName: X509v3 Subject Alternative Name
crlDistributionPoints: X509v3 CRL distribution points
issuingDistributionPoint: X509v3 Issuing Distribution Point
certificatePolicies: X509v3 Certificate Policies
policyConstraints: X509v3 Policy Constraints
inhibitAnyPolicy: X509v3 Inhibit Any Policy
nameConstraints: X509v3 Name Constraints
noCheck: X509v3 OCSP No Check
nsComment: Netscape Comment
nsCertType: Netscape Certificate Type
days_valid: The number of days this certificate should be valid. This sets the notAfter property of the certificate. Defaults to 365.

version: The version of the X509 certificate. Defaults to 3. This is automatically converted to the version value, so version=3 sets the certificate version field to 0x2.
serial_number: The serial number to assign to this certificate. If omitted a random serial number of size
serial_bits is generated.
serial_bits: The number of bits to use when randomly generating a serial number. Defaults to 64.
algorithm: The hashing algorithm to be used for signing this certificate. Defaults to sha256.
copypath: An additional path to copy the resulting certificate to. Can be used to maintain a copy of all
certificates issued for revocation purposes.
prepend_cn: If set to True, the CN and a dash will be prepended to the copypath's filename.
Example: /etc/pki/issued_certs/wwwexample.com-DE:CA:FB:AD:00:00:00:00.crt
signing_policy: A signing policy that should be used to create this certificate. Signing policies should be
deferred in the minion configuration, or in a minion pillar. It should be a yaml formatted list of arguments
which will override any arguments passed to this function. If the minions key is included in the
signing policy, only minions matching that pattern will be permitted to remotely request certificates
from that policy.
Example:

```
x509_signing_policies:
  www:
    - minions: 'www*'
    - signing_private_key: /etc/pki/ca.key
    - signing_cert: /etc/pki/ca.crt
    - C: US
    - ST: Utah
    - L: Salt Lake City
    - basicConstraints: "critical CA:false"
    - keyUsage: "critical cRLSign, keyCertSign"
    - subjectKeyIdentifier: hash
    - authorityKeyIdentifier: keyid,issuer:always
    - days_valid: 90
    - copypath: /etc/pki/issued_certs/
```

The above signing policy can be invoked with signing_policy=www
CLI Example:

```
salt '*' x509.create_certificate path=/etc/pki/myca.crt signing_private_key='/etc/
  pki/myca.key' csr='/etc/pki/myca.csr'}
```

salt.modules.x509.create_crl(path=None, text=False, signing_private_key=None, sign-
ing_private_key_passphrase=None, signing_cert=None, re-
voked=None, include_expired=False, days_valid=100, digest='')

Create a CRL

Depends

- PyOpenSSL Python module

path: Path to write the crl to.
text: If True, return the PEM text without writing to a file. Default False.
signing_private_key: A path or string of the private key in PEM format that will be used to sign this crl. This
is required.
signing_private_key_passphrase: Passphrase to decrypt the private key.
signing_cert: A certificate matching the private key that will be used to sign this crl. This is required.
revoked: A list of dicts containing all the certificates to revoke. Each dict represents one certificate. A dict
must contain either the key serial_number with the value of the serial number to revoke, or cer-
tificate with either the PEM encoded text of the certificate, or a path to the certificate to revoke.

The dict can optionally contain the revocation_date key. If this key is omitted the revocation date
will be set to now. If should be a string in the format "%Y-%m-%d %H:%M:%S".

The dict can also optionally contain the not_after key. This is redundant if the certificate
Salt Documentation, Release 2017.7.8

key is included. If the Certificate key is not included, this can be used for the logic behind the include_expired parameter. If should be a string in the format "%Y-%m-%d %H:%M:%S".

The dict can also optionally contain the reason key. This is the reason code for the revocation. Available choices are unspecified, keyCompromise, CACompromise, affiliationChanged, superseded, cessationOfOperation and certificateHold.

include_expired: Include expired certificates in the CRL. Default is False.
days_valid: The number of days that the CRL should be valid. This sets the Next Update field in the CRL.
digest: The digest to use for signing the CRL. This has no effect on versions of pyOpenSSL less than 0.14

CLI Example:

```
salt '*' x509.create_crl path=/etc/pki/mykey.key signing_private_key=/etc/pki/ca.key signing_cert=/etc/pki/ca.crt revoked="{'compromized-web-key': {'certificate': '/etc/pki/certs/www1.crt', 'revocation_date': '2015-03-01 00:00:00'}}"
```

salt.modules.x509.create_csr(path=None, text=False, **kwargs)

Create a certificate signing request.

path: Path to write the certificate to.
text: If True, return the PEM text without writing to a file. Default False.
algorithm: The hashing algorithm to be used for this request. Defaults to sha256.
kwargs: The subject, extension and version arguments from x509.create_certificate can be used.

CLI Example:

```
salt '*' x509.create_csr path=/etc/pki/myca.csr public_key='/etc/pki/myca.key' CN='My Cert'
```

salt.modules.x509.create_private_key(path=None, text=False, bits=2048, passphrase=None, cipher='aes_128_cbc', verbose=True)

Creates a private key in PEM format.

path: The path to write the file to, either path or text are required.
text: If True, return the PEM text without writing to a file. Default False.
bits: Length of the private key in bits. Default 2048
passphrase: Passphrase for encrypting the private key
cipher: Cipher for encrypting the private key. Has no effect if passphrase is None.
verbose: Provide visual feedback on stdout. Default True

New in version 2016.11.0.

CLI Example:

```
salt '*' x509.create_private_key path=/etc/pki/mykey.key
```

salt.modules.x509.expired(certificate)

Returns a dict containing limited details of a certificate and whether the certificate has expired.

New in version 2016.11.0.
certificate: The certificate to be read. Can be a path to a certificate file, or a string containing the PEM formatted text of the certificate.

CLI Example:

```
salt '*' x509.expired '/etc/pki/mycert.crt'
```

salt.modules.x509.get_pem_entries(glob_path)

Returns a dict containing PEM entries in files matching a glob

glob_path: A path to certificates to be read and returned.

CLI Example:
salt 'x' x509.get_pem_entries "*/etc/pki/x.crt"

salt.modules.x509.get_pem_entry(text, pem_type=None)
Returns a properly formatted PEM string from the input text fixing any whitespace or line-break issues.

- **text**: Text containing the X509 PEM entry to be returned or path to a file containing the text.
- **pem_type**: If specified, this function will only return a pem of a certain type, for example `CERTIFICATE` or `CERTIFICATE REQUEST`.

CLI Example:
salt 'x' x509.get_pem_entry "-----BEGIN CERTIFICATE REQUEST-----MIICyzCC Ar8CAQI...-
                                     -----END CERTIFICATE REQUEST"

salt.modules.x509.get_private_key_size(private_key, passphrase=None)
Returns the bit length of a private key in PEM format.

- **private_key**: A path or PEM encoded string containing a private key.

CLI Example:
salt 'x' x509.get_private_key_size /etc/pki/mycert.key

salt.modules.x509.get_public_key(key, passphrase=None, asObj=False)
Returns a string containing the public key in PEM format.

- **key**: A path or PEM encoded string containing a CSR, Certificate or Private Key from which a public key can be retrieved.

CLI Example:
salt 'x' x509.get_public_key /etc/pki/mycert.cer

salt.modules.x509.get_signing_policy(signing_policy_name)
Returns the details of a names signing policy, including the text of the public key that will be used to sign it. Does not return the private key.

CLI Example:
salt 'x' x509.get_signing_policy www

salt.modules.x509.read_certificate(certificate)
Returns a dict containing details of a certificate. Input can be a PEM string or file path.

- **certificate**: The certificate to be read. Can be a path to a certificate file, or a string containing the PEM formatted text of the certificate.

CLI Example:
salt 'x' x509.read_certificate /etc/pki/mycert.crt

salt.modules.x509.read_certificates(glob_path)
Returns a dict containing details of all certificates matching a glob.

- **glob_path**: A path to certificates to be read and returned.

CLI Example:
salt 'x' x509.read_certificates "*/etc/pki/.*.crt"

salt.modules.x509.read_crl(crl)
Returns a dict containing details of a certificate revocation list. Input can be a PEM string or file path.

- **crl**: A path or PEM encoded string containing the CSL to read.

Depends
- OpenSSL command line tool

---

Chapter 19. Salt Module Reference
salt.modules.x509.read_crl(csr)
Returns a dict containing details of a certificate request.

Depends
  • OpenSSL command line tool

csr: A path or PEM encoded string containing the CSR to read.

CLI Example:
```
salt '*' x509.read_crl /etc/pki/mycrl.crl
```

salt.modules.x509.read_csr(csr)
Returns a dict containing details of a certificate request.

Depends
  • OpenSSL command line tool

csr: A path or PEM encoded string containing the CSR to read.

CLI Example:
```
salt '*' x509.read_csr /etc/pki/mycert.csr
```

salt.modules.x509.sign_remote_certificate(argdic, **kwargs)
Request a certificate to be remotely signed according to a signing policy.

argdic: A dict containing all the arguments to be passed into the create_certificate function. This will become
kwargs when passed to create_certificate.

kwargs: kwargs delivered from publish.publish

CLI Example:
```
salt '*' x509.sign_remote_certificate argdic="{'public_key': '/etc/pki/www.key',
    'signing_policy': 'www'}" __pub_id='www1'
```

salt.modules.x509.verify_crl(crl, cert)
Validate a CRL against a certificate. Parses openssl command line output, this is a workaround for M2Crypto's
inability to get them from CSR objects.

crl: The CRL to verify

cert: The certificate to verify the CRL against

CLI Example:
```
salt '*' x509.verify_crl crl=/etc/pki/myca.crl cert=/etc/pki/myca.crt
```

salt.modules.x509.verify_private_key(private_key, public_key, passphrase=None)
Verify that `private_key' matches `public_key'

private_key: The private key to verify, can be a string or path to a private key in PEM format.

certificate: The certificate to verify. Can be a path or string containing a PEM formatted certificate.

public_key: The public key to verify, can be a string or path to a PEM formatted certificate, csr, or another
private key.

passphrase: Passphrase to decrypt the private key.

CLI Example:
```
salt '*' x509.verify_private_key private_key=/etc/pki/myca.key \
    public_key=/etc/pki/myca.crt
```

salt.modules.x509.verify_signature(certificate, signing_pub_key=None, signing_pub_key_passphrase=None)
Verify that certificate has been signed by signing_pub_key

certificate: The certificate to verify. Can be a path or string containing a PEM formatted certificate.

signing_pub_key: The public key to verify, can be a string or path to a PEM formatted certificate, csr, or private key.

signing_pub_key_passphrase: Passphrase to the signing_pub_key if it is an encrypted private key.

CLI Example:
```
salt '*' x509.verify_signature /etc/pki/mycert.pem \
    signing_pub_key=/etc/pki/myca.crt
```

19.9. execution modules
Salt Documentation, Release 2017.7.8

salt.modules.x509.will_expire(certificate, days)

Returns a dict containing details of a certificate and whether the certificate will expire in the specified number of days. Input can be a PEM string or file path.

New in version 2016.11.0.

certificate: The certificate to be read. Can be a path to a certificate file, or a string containing the PEM formatted text of the certificate.

CLI Example:

```bash
salt '*' x509.will_expire "/etc/pki/mycert.crt" days=30
```

salt.modules.x509.write_pem(text, path, overwrite=True, pem_type=None)

Writes out a PEM string fixing any formatting or whitespace issues before writing.

text: PEM string input to be written out.

path: Path of the file to write the pem out to.

overwrite: If True (default), write_pem will overwrite the entire pem file. Set False to preserve existing private keys and dh params that may exist in the pem file.

pem_type: The PEM type to be saved, for example CERTIFICATE or PUBLIC KEY. Adding this will allow the function to take input that may contain multiple pem types.

CLI Example:

```bash
salt '*' x509.write_pem "-----BEGIN CERTIFICATE-----MIIGMzCCBBugA..." path=/etc/pki/mycert.crt
```

19.9.447 salt.modules.xapi

This module (mostly) uses the XenAPI to manage Xen virtual machines.

Big fat warning: the XenAPI used in this file is the one bundled with Xen Source, NOT XenServer nor Xen Cloud Platform. As a matter of fact it will fail under those platforms. From what I've read, little work is needed to adapt this code to XS/XCP, mostly playing with XenAPI version, but as XCP is not taking precedence on Xen Source on many platforms, please keep compatibility in mind.

Useful documentation:

- [http://downloads.xen.org/Wiki/XenAPI/xenapi-1.0.6.pdf](http://downloads.xen.org/Wiki/XenAPI/xenapi-1.0.6.pdf)
- [http://docs.vmd.citrix.com/XenServer/6.0.0/1.0/en_gb/api/](http://docs.vmd.citrix.com/XenServer/6.0.0/1.0/en_gb/api/)
- [https://github.com/xapi-project/xen-api/tree/master/scripts/examples/python](https://github.com/xapi-project/xen-api/tree/master/scripts/examples/python)
- [http://xenbits.xen.org/gitweb/?p=xen.git;a=tree;f=tools/python/xen/xm;hb=HEAD](http://xenbits.xen.org/gitweb/?p=xen.git;a=tree;f=tools/python/xen/xm;hb=HEAD)

salt.modules.xapi.freecpu()

Return an int representing the number of unallocated cpus on this hypervisor

CLI Example:

```bash
salt '*' virt.freecpu
```

salt.modules.xapi.freemem()

Return an int representing the amount of memory that has not been given to virtual machines on this node

CLI Example:

```bash
salt '*' virt.freemem
```

salt.modules.xapi.full_info()

Return the node_info, vm_info and freemem

CLI Example:
salt '.*' virt.full_info

salt.modules.xapi.get_disks(vm_)
  Return the disks of a named vm
  CLI Example:
  `salt '.*' virt.get_disks <vm name>`

salt.modules.xapi.get_macs(vm_)
  Return a list off MAC addresses from the named vm
  CLI Example:
  `salt '.*' virt.get_macs <vm name>`

salt.modules.xapi.get_nics(vm_)
  Return info about the network interfaces of a named vm
  CLI Example:
  `salt '.*' virt.get_nics <vm name>`

salt.modules.xapi.is_hyper()
  Returns a bool whether or not this node is a hypervisor of any kind
  CLI Example:
  `salt '.*' virt.is_hyper`

salt.modules.xapi.list_domains()
  Return a list of virtual machine names on the minion
  CLI Example:
  `salt '.*' virt.list_domains`

salt.modules.xapi.migrate(vm_, target, live=1, port=0, node=-1, ssl=None, change_home_server=0)
  Migrates the virtual machine to another hypervisor
  CLI Example:
  `salt '.*' virt.migrate <vm name> <target hypervisor> [live] [port] [node] [ssl] [change_home_server]`

  Optional values:
  live  Use live migration
  port  Use a specified port
  node  Use specified NUMA node on target
  ssl  use ssl connection for migration
  change_home_server  change home server for managed domains

salt.modules.xapi.node_info()
  Return a dict with information about this node
  CLI Example:
  `salt '.*' virt.node_info`
salt.modules.xapi.pause(vm_)
  Pause the named vm
  
  CLI Example:
  
  salt '*' virt.pause <vm name>

salt.modules.xapi.reboot(vm_)
  Reboot a domain via ACPI request
  
  CLI Example:
  
  salt '*' virt.reboot <vm name>

salt.modules.xapi.reset(vm_)
  Reset a VM by emulating the reset button on a physical machine
  
  CLI Example:
  
  salt '*' virt.reset <vm name>

salt.modules.xapi.resume(vm_)
  Resume the named vm
  
  CLI Example:
  
  salt '*' virt.resume <vm name>

salt.modules.xapi.setmem(vm_, memory)
  Changes the amount of memory allocated to VM.
  Memory is to be specified in MB
  
  CLI Example:
  
  salt '*' virt.setmem myvm 768

salt.modules.xapi.setvcpus(vm_, vcpus)
  Changes the amount of vcpus allocated to VM.
  vcpus is an int representing the number to be assigned
  
  CLI Example:
  
  salt '*' virt.setvcpus myvm 2

salt.modules.xapi.shutdown(vm_)
  Send a soft shutdown signal to the named vm
  
  CLI Example:
  
  salt '*' virt.shutdown <vm name>

salt.modules.xapi.start(config_)
  Start a defined domain
  
  CLI Example:
  
  salt '*' virt.start <path to Xen cfg file>
salt.modules.xapi.stop(vm_)
Hard power down the virtual machine, this is equivalent to pulling the power

CLI Example:
```
salt '*' virt.stop <vm name>
```

salt.modules.xapi.vcpu_pin(vm_, vcpu, cpus)
Set which CPUs a VCPU can use.

CLI Example:
```
salt 'foo' virt.vcpu_pin domU-id 2 1
salt 'foo' virt.vcpu_pin domU-id 2 2-6
```

salt.modules.xapi.vm_cputime(vm_=None)
Return cputime used by the vms on this hyper in a list of dicts:
```
[
    'your-vm': {
        'cputime' <int>,
        'cputime_percent' <int>,
    },
    ...
]
```

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:
```
salt '*' virt.vm_cputime
```

salt.modules.xapi.vm_diskstats(vm_=None)
Return disk usage counters used by the vms on this hyper in a list of dicts:
```
[
    'your-vm': {
        'io_read_kbs' : 0,
        'io_write_kbs' : 0,
    },
    ...
]
```

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:
```
salt '*' virt.vm_diskstats
```

salt.modules.xapi.vm_info(vm_=None)
Return detailed information about the vms.

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:
salt '*' virt.vm_info

salt.modules.xapi.vm_netstats(vm_=None)
Return combined network counters used by the vms on this hyper in a list of dicts:

```python
[
    {'your-vm': {
        'io_read_kbs': 0,
        'io_total_read_kbs': 0,
        'io_total_write_kbs': 0,
        'io_write_kbs': 0
    },
    ...
]
```

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```
salt '*' virt.vm_netstats
```

salt.modules.xapi.vm_state(vm_=None)
Return list of all the vms and their state.

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```
salt '*' virt.vm_state <vm name>
```

### 19.9.448 salt.modules.xbpspkg module

Package support for XBPS package manager (used by VoidLinux)

New in version 2016.11.0.

salt.modules.xbpspkg.add_repo(repo, conffile='/usr/share/xbps.d/15-saltstack.conf')
Add an XBPS repository to the system.
repo url of repo to add (persistent).
conffile path to xbps conf file to add this repo default: /usr/share/xbps.d/15-saltstack.conf

CLI Examples:

```
salt '*' pkg.add_repo <repo url> [conffile=/path/to/xbps/repo.conf]
```

salt.modules.xbpspkg.available_version(*names, **kwargs)
Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```
salt.modules.xbpspkg.del_repo(repo)
Remove an XBPS repository from the system.
repo  url of repo to remove (persistent).

CLI Examples:
```
salt '*' pkg.del_repo <repo url>
```

salt.modules.xbpspkg.get_repo(repo,**kwargs)
Display information about the repo.

CLI Examples:
```
salt '*' pkg.get_repo 'repo-url'
```

salt.modules.xbpspkg.install(name=None, refresh=False, fromrepo=None, pkgs=None, sources=None,**kwargs)
Install the passed package
name  The name of the package to be installed.
refresh Whether or not to refresh the package database before installing.
fromrepo Specify a package repository (url) to install from.

Multiple Package Installation Options:
pkgs  A list of packages to install from a software repository. Must be passed as a python list.

CLI Example:
```
salt '*' pkg.install pkgs='["foo","bar"]'
```
sources  A list of packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

CLI Example:
```
salt '*' pkg.install sources='[{"foo": "salt://foo.deb"},{"bar": "salt://bar.deb"}]'
```

Return a dict containing the new package names and versions:
```
{ '<package>': { 'old': '<old-version>', 'new': '<new-version>' }}
```

CLI Example:
```
salt '*' pkg.install <package name>
```

salt.modules.xbpspkg.latest_version(names,**kwargs)
Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:
```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

salt.modules.xbpspkg.list_pkgs(versions_as_list=False,**kwargs)
List the packages currently installed as a dict:
```
{ '<package_name>': '<version>' }
```
Salt Documentation, Release 2017.7.8

CLI Example:

```
salt '*' pkg.list_pkgs
```

`salt.modules.xbpspkg.list_repos()`  
List all repos known by XBPS  

CLI Example:

```
salt '*' pkg.list_repos
```

`salt.modules.xbpspkg.list_upgrades(refresh=True)`  
Check whether or not an upgrade is available for all packages  

CLI Example:

```
salt '*' pkg.list_upgrades
```

`salt.modules.xbpspkg.refresh_db()`  
Update list of available packages from installed repos  

CLI Example:

```
salt '*' pkg.refresh_db
```

`salt.modules.xbpspkg.remove(name=None, pkgs=None, recursive=True, **kwargs)`  
- **name** The name of the package to be deleted.  
- **recursive** Also remove dependent packages (not required elsewhere). Default mode: enabled.  
- **pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.  

Returns a list containing the removed packages.  

CLI Example:

```
salt '*' pkg.remove <package name> [recursive=False]
salt '*' pkg.remove <package1>,<package2>,<package3> [recursive=False]
salt '*' pkg.remove pkgs=['"foo", "bar"]' [recursive=False]
```

`salt.modules.xbpspkg.upgrade(refresh=True)`  
Run a full system upgrade  
- **refresh** Whether or not to refresh the package database before installing. Default is `True`.  

Returns a dictionary containing the changes:

```
{'<package>': {'old': '<old-version>',  
              'new': '<new-version>'}}
```

CLI Example:

```
salt '*' pkg.upgrade
```

`salt.modules.xbpspkg.upgrade_available(name)`  
Check whether or not an upgrade is available for a given package  

CLI Example:

```
salt '*' pkg.upgrade_available <package name>
```
salt.modules.xbpspkg.version(*names, **kwargs)
Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:
```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

19.9.449 salt.modules.xfs
Module for managing XFS file systems.
salt.modules.xfs.defragment(device)
Defragment mounted XFS filesystem. In order to mount a filesystem, device should be properly mounted and writable.

CLI Example:
```
salt '*' xfs.defragment /dev/sda1
```
salt.modules.xfs.devices()
Get known XFS formatted devices on the system.

CLI Example:
```
salt '*' xfs.devices
```
salt.modules.xfs.dump(device, destination, level=0, label=None, noerase=None)
Dump filesystem device to the media (file, tape etc).
Required parameters:
- `device`: XFS device, content of which to be dumped.
- `destination`: Specifies a dump destination.

Valid options are:
- `label`: Label of the dump. Otherwise automatically generated label is used.
- `level`: Specifies a dump level of 0 to 9.
- `noerase`: Pre-erase media.

Other options are not used in order to let xfsdump use its default values, as they are most optimal. See the xfsdump(8) manpage for a more complete description of these options.

CLI Example:
```
salt '*' xfs.dump /dev/sda1 /destination/on/the/client
salt '*' xfs.dump /dev/sda1 /destination/on/the/client label='Company accountancy'
salt '*' xfs.dump /dev/sda1 /destination/on/the/client noerase=True
```
salt.modules.xfs.estimate(path)
Estimate the space that an XFS filesystem will take. For each directory estimate the space that directory would take if it were copied to an XFS filesystem. Estimation does not cross mount points.

CLI Example:
```
salt '*' xfs.estimate /path/to/file
salt '*' xfs.estimate /path/to/dir/*
```
salt.modules.xfs.info(device)
Get filesystem geometry information.
CLI Example:
```
salt '*' xfs.info /dev/sda1
```

**salt.modules.xfs.inventory()**
Display XFS dump inventory without restoration.

CLI Example:
```
salt '*' xfs.inventory
```

**salt.modules.xfs.mkfs**(device, label=None, ssize=None, noforce=None, bso=None, gmo=None,  
dso=None, iso=None, rso=None, nmo=None, dso=None)
Create a file system on the specified device. By default wipes out with force.

General options:
- **label**: Specify volume label.
- **ssize**: Specify the fundamental sector size of the filesystem.
- **noforce**: Do not force create filesystem, if disk is already formatted.

Filesystem geometry options:
- **bso**: Block size options.
- **gmo**: Global metadata options.
- **dso**: Data section options. **These options specify the location, size, and other parameters of the data section of the filesystem.**
- **ino**: Inode options to specify the inode size of the filesystem, and other inode allocation parameters.
- **iso**: Log section options.
- **nmo**: Naming options.
- **rso**: Realtime section options.

See the `mkfs.xfs(8)` manpage for a more complete description of corresponding options description.

CLI Example:
```
salt '*' xfs.mkfs /dev/sda1  
salt '*' xfs.mkfs /dev/sda1 dso='su=32k,sw=6' noforce=True  
salt '*' xfs.mkfs /dev/sda1 dso='su=32k,sw=6' lso='logdev=/dev/sda2,size=10000b'
```

**salt.modules.xfs.modify**(device, label=None, lazy_counting=None, uuid=None)**
Modify parameters of an XFS filesystem.

CLI Example:
```
salt '*' xfs.modify /dev/sda1 label='My backup' lazy_counting=False  
salt '*' xfs.modify /dev/sda1 uuid=False  
salt '*' xfs.modify /dev/sda1 uuid=True
```

**salt.modules.xfs.prune_dump**(sessionid)
Prunes the dump session identified by the given session id.

CLI Example:
```
salt '*' xfs.prune_dump b74a3586-e52e-4a4a-8775-c3334fa8ea2c
```

19.9.450 **salt.modules.xmpp**
Module for Sending Messages via XMPP (a.k.a. Jabber)

New in version 2014.1.0.
depends

- sleekxmpp>=1.3.1
- pyasn1
- pyasn1-modules
- dnspython

configuration

This module can be used by either passing a jid and password directly to send_message,
or by specifying the name of a configuration profile in the minion config, minion pillar, or master config.

For example:

```bash
my-xmpp-login:
    xmpp.jid: myuser@jabber.example.org/resourcename
    xmpp.password: verybadpass
```

The resourcename refers to the resource that is using this account. It is user-definable, and optional. The following configurations are both valid:

```bash
my-xmpp-login:
    xmpp.jid: myuser@jabber.example.org/salt
    xmpp.password: verybadpass

my-xmpp-login:
    xmpp.jid: myuser@jabber.example.org
    xmpp.password: verybadpass
```

class salt.modules.xmpp.SendMsgBot(jid, password, recipient, msg)

classmethod create_multi(jid, password, msg, recipients=None, rooms=None, nick='SaltStackBot')

Alternate constructor that accept multiple recipients and rooms

start(event)

class salt.modules.xmpp.SleekXMPPMUC(name='')

filter(record)

class salt.modules.xmpp.send_msg(recipient, message, jid=None, password=None, profile=None)

Send a message to an XMPP recipient. Designed for use in states.

CLI Examples:

```bash
xmpp.send_msg 'admins@xmpp.example.com' 'This is a salt module test'
  profile='my-xmpp-account'

xmpp.send_msg 'admins@xmpp.example.com' 'This is a salt module test'
  jid='myuser@xmpp.example.com/salt' password='verybadpass'
```

class salt.modules.xmpp.send_msg_multi(message, recipients=None, rooms=None, jid=None, password=None, nick='SaltStack Bot', profile=None)

Send a message to an XMPP recipient, support send message to multiple recipients or chat room.

CLI Examples:
**19.9.451 salt.modules.yumpkg**

Support for YUM/DNF

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install` is not available), see [here](#).

**Note:** DNF is fully supported as of version 2015.5.10 and 2015.8.4 (partial support for DNF was initially added in 2015.8.0), and DNF is used automatically in place of YUM in Fedora 22 and newer.

salt.modules.yumpkg.clean_metadata(**kwargs**)

New in version 2014.1.0.

Cleans local yum metadata. Functionally identical to `refresh_db()`.

CLI Example:

```
salt '*' pkg.clean_metadata
```

salt.modules.yumpkg.del_repo(repo, basedir=None, **kwargs**)

Delete a repo from <basedir> (default basedir: all dirs in reposdir yum option).

If the .repo file in which the repo exists does not contain any other repo configuration, the file itself will be deleted.

CLI Examples:

```
salt '*' pkg.del_repo myrepo
salt '*' pkg.del_repo myrepo basedir=/path/to/dir
salt '*' pkg.del_repo myrepo basedir=/path/to/dir,/path/to/another/dir
```

salt.modules.yumpkg.diff(*paths*)

Return a formatted diff between current files and original in a package. NOTE: this function includes all files (configuration and not), but does not work on binary content.

**Parameters**

- `path` -- Full path to the installed file

**Returns**

Difference string or raises and exception if examined file is binary.

CLI example:

```
salt '*' pkg.diff /etc/apache2/httpd.conf /etc/sudoers
```

salt.modules.yumpkg.download(*packages*)

New in version 2015.5.0.

Download packages to the local disk. Requires yumdownloader from yum-utils package.
Note: yum-utils will already be installed on the minion if the package was installed from the Fedora / EPEL repositories.

CLI example:

```bash
salt '*' pkg.download httpd
salt '*' pkg.download httpd postfix
```

**salt.modules.yumpkg.file_dict('packages')**

New in version 2014.1.0.

List the files that belong to a package, grouped by package. Not specifying any packages will return a list of every file on the system's rpm database (not generally recommended).

CLI Examples:

```bash
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

**salt.modules.yumpkg.file_list('packages')**

New in version 2014.1.0.

List the files that belong to a package. Not specifying any packages will return a list of every file on the system's rpm database (not generally recommended).

CLI Examples:

```bash
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

**salt.modules.yumpkg.get_repo(name, basedir=None, **kwargs)**

Display a repo from <basedir> (default basedir: all dirs in reposdir yum option).

CLI Examples:

```bash
salt '*' pkg.get_repo myrepo
salt '*' pkg.get_repo myrepo basedir=/path/to/dir
salt '*' pkg.get_repo myrepo basedir=/path/to/dir,/path/to/another/dir
```

**salt.modules.yumpkg.group_diff(name)**

New in version 2014.1.0.

Changed in version 2016.3.0, 2015.8.4, 2015.5.10: Environment groups are now supported. The key names have been renamed, similar to the changes made in pkg.group_info.

Lists which of a group's packages are installed and which are not installed

CLI Example:

```bash
salt '*' pkg.group_diff 'Perl Support'
```

**salt.modules.yumpkg.group_info(name, expand=False)**

New in version 2014.1.0.

Changed in version 2016.3.0, 2015.8.4, 2015.5.10: The return data has changed. A new key type has been added to distinguish environment groups from package groups. Also, keys for the group name and group ID have been added. The mandatory packages, optional packages, and default packages keys have
been renamed to mandatory, optional, and default for accuracy, as environment groups include other
groups, and not packages. Finally, this function now properly identifies conditional packages.

Lists packages belonging to a certain group

name Name of the group to query

expand [False] If the specified group is an environment group, then the group will be expanded and the
return data will include package names instead of group names.

New in version 2016.3.0.

CLI Example:

```
salt '*' pkg.group_info 'Perl Support'
```

salt.modules.yumpkg.group_install(name, skip=(), include=(), **kwargs)
New in version 2014.1.0.

Install the passed package group(s). This is basically a wrapper around pkg.install, which performs
package group resolution for the user. This function is currently considered experimental, and should be
expected to undergo changes.

name Package group to install. To install more than one group, either use a comma-separated list or pass the
value as a python list.

CLI Examples:

```
salt '*' pkg.group_install 'Group 1'
salt '*' pkg.group_install 'Group 1,Group 2'
salt '*' pkg.group_install ['"Group 1", "Group 2"]'
```

skip Packages that would normally be installed by the package group (``default'' packages), which should
not be installed. Can be passed either as a comma-separated list or a python list.

CLI Examples:

```
salt '*' pkg.group_install 'My Group' skip='foo,bar'
salt '*' pkg.group_install 'My Group' skip=['"foo", "bar"]'
```

include Packages which are included in a group, which would not normally be installed by a yum groupin-
stall (``optional'' packages). Note that this will not enforce group membership; if you include pack-
gages which are not members of the specified groups, they will still be installed. Can be passed either
as a comma-separated list or a python list.

CLI Examples:

```
salt '*' pkg.group_install 'My Group' include='foo,bar'
salt '*' pkg.group_install 'My Group' include=['"foo", "bar"]'
```

Note: Because this is essentially a wrapper around pkg.install, any argument which can be passed to
pkg.install may also be included here, and it will be passed along wholesale.

salt.modules.yumpkg.group_list()
New in version 2014.1.0.

Lists all groups known by yum on this system

CLI Example:

```
salt '*' pkg.group_list
```

salt.modules.yumpkg.hold(name=None, pkgs=None, sources=None, normalize=True, **kwargs)
New in version 2014.7.0.
Version-lock packages

**Note:** Requires the appropriate versionlock plugin package to be installed:
- On RHEL 5: yum-versionlock
- On RHEL 6 & 7: yum-plugin-versionlock
- On Fedora: python-dnf-plugins-extras-versionlock

**name** The name of the package to be held.

Multiple Package Options:

**pkgs** A list of packages to hold. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

Returns a dict containing the changes.

CLI Example:

```bash
salt '*' pkg.hold <package name>
salt '*' pkg.hold pkgs='["foo", "bar"]'
```

`salt.modules.yumpkg.info_installed(names)`

Return the information of the named package(s), installed on the system.

CLI example:

```bash
salt '*' pkg.info_installed <package1>
salt '*' pkg.info_installed <package1> <package2> <package3> ...
```

`salt.modules.yumpkg.install(name=None, refresh=False, skip_verify=False, pkgs=None, sources=None, downloadonly=False, reinstall=False, normalize=True, update_holds=False, saltenv='base', **kwargs)`

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any yum/dnf commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Install the passed package(s), add refresh=True to clean the yum database before package is installed.

**name** The name of the package to be installed. Note that this parameter is ignored if either `''pkgs''` or `''sources''` is passed. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the `''sources''` option.

32-bit packages can be installed on 64-bit systems by appending the architecture designation (.i686, .i586, etc.) to the end of the package name.

CLI Example:

```bash
salt '*' pkg.install <package name>
```

**refresh** Whether or not to update the yum database before executing.

**reinstall** Specifying reinstall=True will use `yum reinstall` rather than `yum install` for requested packages that are already installed.

If a version is specified with the requested package, then `yum reinstall` will only be used if the installed version matches the requested version.
Works with sources when the package header of the source can be matched to the name and version of an installed package.

New in version 2014.7.0.

skip_verify Skip the GPG verification check (e.g., --nogpgcheck)
downloadonly Only download the packages, do not install.
version Install a specific version of the package, e.g. 1.2.3-4.el5. Ignored if `pkgs` or `sources` is passed.
update_holds [False] If True, and this function would update the package version, any packages held using the yum/dnf `versionlock` plugin will be unheld so that they can be updated. Otherwise, if this function attempts to update a held package, the held package(s) will be skipped and an error will be raised.

New in version 2016.11.0.

Repository Options:
fromrepo Specify a package repository (or repositories) from which to install. (e.g., yum --disablerepo='*' --enablerepo='somerepo')
enablerepo (ignored if fromrepo is specified) Specify a disabled package repository (or repositories) to enable. (e.g., yum --enablerepo='somerepo')
disablerepo (ignored if fromrepo is specified) Specify an enabled package repository (or repositories) to disable. (e.g., yum --disablerepo='somerepo')
disableexcludes Disable exclude from main, for a repo or for everything. (e.g., yum --disableexcludes='main')

New in version 2014.7.0.

Multiple Package Installation Options:
pkgs A list of packages to install from a software repository. Must be passed as a python list. A specific version number can be specified by using a single-element dict representing the package and its version.

CLI Examples:

```
salt '*' pkg.install pkgs='["foo", "bar"]'
salt '*' pkg.install pkgs='["foo", {"bar": "1.2.3-4.el5"}]'
```

sources A list of RPM packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

CLI Example:

```
salt '*' pkg.install sources=[{"foo": "salt://foo.rpm"}, {"bar": "salt://bar.rpm"}]
```

normalize [True] Normalize the package name by removing the architecture. This is useful for poorly created packages which might include the architecture as an actual part of the name such as kernel modules which match a specific kernel version.

```
salt -G role:nsd pkg.install gpfs.gplbin-2.6.32-279.31.1.el6.x86_64
-normalize=False
```

New in version 2014.7.0.

Returns a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
              'new': '<new-version>'}}
```

salt.modules.yumpkg.latest_version(*names, **kwargs)

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.
A specific repo can be requested using the `fromrepo` keyword argument, and the `disableexcludes` option is also supported.

New in version 2014.7.0: Support for the `disableexcludes` option

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package name> fromrepo=epel-testing
salt '*' pkg.latest_version <package name> disableexcludes=main
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

```
salt.modules.yumpkg.list_downloaded()
New in version 2017.7.0.
List prefetched packages downloaded by Yum in the local disk.

CLI example:

```
salt '*' pkg.list_downloaded
```

```
salt.modules.yumpkg.list_holds(pattern='[w+\([.\-][^\-]+\]*)', full=True)
Changed in version 2016.3.0,2015.8.4,2015.5.10: Function renamed from pkg.get_locked_pkgs to pkg.list_holds.
List information on locked packages

**Note:** Requires the appropriate `versionlock` plugin package to be installed:
- On RHEL 5: `yum-versionlock`
- On RHEL 6 & 7: `yum-plugin-versionlock`
- On Fedora: `python-dnf-plugins-extras-versionlock`

```
pattern ['w+\([.\-][^\-]+\)'] Regular expression used to match the package name
full [True] Show the full hold definition including version and epoch. Set to False to return just the name of the package(s) being held.

CLI Example:

```
salt '*' pkg.list_holds
salt '*' pkg.list_holds full=False
```

```
salt.modules.yumpkg.list_installed_patches()
New in version 2017.7.0.
List installed advisory patches on the system.

CLI Examples:

```
salt '*' pkg.list_installed_patches
```

```
salt.modules.yumpkg.list_patches(refresh=False)
New in version 2017.7.0.
List all known advisory patches from available repos.
refresh force a refresh if set to True. If set to False (default) it depends on yum if a refresh is executed.

CLI Examples:

```
salt '*' pkg.list_patches
```

19.9. execution modules
salt.modules.yumpkg.list_pkgs(versions_as_list=False, **kwargs)

List the packages currently installed in a dict:

```
{ '<package_name>': '<version>' }
```

CLI Example:

```
salt '*' pkg.list_pkgs
```

salt.modules.yumpkg.list_repo_pkgs(*args, **kwargs)

New in version 2014.1.0.

Changed in version 2014.7.0: All available versions of each package are now returned. This required a slight modification to the structure of the return dict. The return data shown below reflects the updated return dict structure. Note that packages which are version-locked using `pkg.hold` will only show the currently-installed version, as locking a package will make other versions appear unavailable to yum/dnf.

Changed in version 2017.7.0: By default, the versions for each package are no longer organized by repository. To get results organized by repository, use `byrepo=True`.

Returns all available packages. Optionally, package names (and name globs) can be passed and the results will be filtered to packages matching those names. This is recommended as it speeds up the function considerably.

- **Warning**: Running this function on RHEL/CentOS 6 and earlier will be more resource-intensive, as the version of yum that ships with older RHEL/CentOS has no yum subcommand for listing packages from a repository. Thus, a `yum list installed` and `yum list available` are run, which generates a lot of output, which must then be analyzed to determine which package information to include in the return data.

This function can be helpful in discovering the version or repo to specify in a `pkg.installed` state.

The return data will be a dictionary mapping package names to a list of version numbers, ordered from newest to oldest. If `byrepo` is set to `True`, then the return dictionary will contain repository names at the top level, and each repository will map packages to lists of version numbers. For example:

```
# With byrepo=False (default)
{
    'bash': ['4.1.2-15.el6_5.2',
             '4.1.2-15.el6_5.1',
             '4.1.2-15.el6_4'],
    'kernel': ['2.6.32-431.29.2.el6',
               '2.6.32-431.23.3.el6',
               '2.6.32-431.20.5.el6',
               '2.6.32-431.20.3.el6',
               '2.6.32-431.17.1.el6',
               '2.6.32-431.11.2.el6',
               '2.6.32-431.5.1.el6',
               '2.6.32-431.3.1.el6',
               '2.6.32-431.2.0.1.el6',
               '2.6.32-431.el6']
}

# With byrepo=True
{
    'base': {
        'bash': ['4.1.2-15.el6_4'],
        'kernel': ['2.6.32-431.el6']
    },
```
'updates': {
    'bash': ['4.1.2-15.el6_5.2', '4.1.2-15.el6_5.1'],
    'kernel': ['2.6.32-431.29.2.el6',
               '2.6.32-431.23.3.el6',
               '2.6.32-431.20.5.el6',
               '2.6.32-431.20.3.el6',
               '2.6.32-431.17.1.el6',
               '2.6.32-431.11.2.el6',
               '2.6.32-431.5.1.el6',
               '2.6.32-431.3.1.el6',
               '2.6.32-431.1.2.0.1.el6']
}

fromrepo  [None] Only include results from the specified repo(s). Multiple repos can be specified, comma-separated.

enablerepo (ignored if fromrepo is specified) Specify a disabled package repository (or repositories) to enable. (e.g., yum --enablerepo='somerepo')

New in version 2017.7.0.

disablerepo (ignored if fromrepo is specified) Specify an enabled package repository (or repositories) to disable. (e.g., yum --disablerepo='somerepo')

New in version 2017.7.0.

byrepo  [False] When True, the return data for each package will be organized by repository.

New in version 2017.7.0.

cacheonly  [False] When True, the repo information will be retrieved from the cached repo metadata. This is equivalent to passing the -C option to yum/dnf.

New in version 2017.7.0.

CLI Examples:
salt '*' pkg.list_repo_pkgs
salt '*' pkg.list_repo_pkgs foo bar baz
salt '*' pkg.list_repo_pkgs 'samba4*' fromrepo=base,updates
salt '*' pkg.list_repo_pkgs 'python2-*' byrepo=True

salt.modules.yumpkg.list_repos( basedir=None )
Lists all repos in <basedir> (default: all dirs in reposdir yum option).

CLI Example:
salt '*' pkg.list_repos
salt '*' pkg.list_repos basedir=/path/to/dir
salt '*' pkg.list_repos basedir=/path/to/dir,/path/to/another/dir

salt.modules.yumpkg.list_upgrades( refresh=True, **kwargs )
Check whether or not an upgrade is available for all packages

The fromrepo, enablerepo, and disablerepo arguments are supported, as used in pkg states, and the disableexcludes option is also supported.

New in version 2014.7.0: Support for the disableexcludes option

CLI Example:
salt '*' pkg.list_upgrades
salt.modules.yumpkg.mod_repo(repo, basedir=None, **kwargs)

Modify one or more values for a repo. If the repo does not exist, it will be created, so long as the following values are specified:
- repo: name by which the yum refers to the repo
- name: a human-readable name for the repo
- baseurl: the URL for yum to reference
- mirrorlist: the URL for yum to reference

Key/Value pairs may also be removed from a repo's configuration by setting a key to a blank value. Bear in mind that a name cannot be deleted, and a baseurl can only be deleted if a mirrorlist is specified (or vice versa).

CLI Examples:

```
salt '*' pkg.mod_repo reponame enabled=1 gpgcheck=1
dsalt '*' pkg.mod_repo reponame basedir=/path/to/dir enabled=1
dsalt '*' pkg.mod_repo reponame baseurl= mirrorlist=http://host.com/
```

salt.modules.yumpkg.modified(*packages, **flags)

List the modified files that belong to a package. Not specifying any packages will return a list of all modified files on the system's RPM database.

New in version 2015.5.0.

Filtering by flags (True or False):
- size: Include only files where size changed.
- mode: Include only files which file's mode has been changed.
- checksum: Include only files which MD5 checksum has been changed.
- device: Include only files which major and minor numbers has been changed.
- symlink: Include only files which are symbolic link contents.
- owner: Include only files where owner has been changed.
- group: Include only files where group has been changed.
- time: Include only files where modification time of the file has been changed.
- capabilities: Include only files where capabilities differ or not. Note: supported only on newer RPM versions.

CLI Examples:

```
salt '*' pkg.modified
salt '*' pkg.modified httpd
salt '*' pkg.modified httpd postfix
salt '*' pkg.modified httpd owner=True group=False
```

salt.modules.yumpkg.normalize_name(name)

Strips the architecture from the specified package name, if necessary. Circumstances where this would be done include:
- If the arch is 32 bit and the package name ends in a 32-bit arch.
- If the arch matches the OS arch, or is noarch.

CLI Example:

```
salt '*' pkg.normalize_name zsh.x86_64
```

salt.modules.yumpkg.owner(*paths)

New in version 2014.7.0.

Return the name of the package that owns the file. Multiple file paths can be passed. Like `pkg.version`, if a single path is passed, a string will be returned, and if multiple paths are passed, a dictionary of file/package name pairs will be returned.

If the file is not owned by a package, or is not present on the minion, then an empty string will be returned for that path.
CLI Examples:

```
salt '*' pkg.owner /usr/bin/apachectl
salt '*' pkg.owner /usr/bin/apachectl /etc/httpd/conf/httpd.conf
```

```python
salt.modules.yumpkg.purge(name=None, pkgs=None, **kwargs)
```

Salt Documentation, Release 2017.7.8

---

### salt.modules.yumpkg.purge

**name=** `None`, **pkgs=** `None`, **kwargs**

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, *systemd-run(1)* is now used to isolate commands which modify installed packages from the salt-minion daemon’s control group. This is done to keep systemd from killing any yum/dnf commands spawned by Salt when the salt-minion service is restarted. (see `KillMode` in the `systemd.kill(5)` manpage for more information). If desired, usage of *systemd-run(1)* can be suppressed by setting a config option called `systemd.scope`, with a value of `False` (no quotes).

Package purges are not supported by yum, this function is identical to `pkg.remove`.

- **name** The name of the package to be purged
- **pkgs** A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs=['"foo", "bar"]'
```

```python
salt.modules.yumpkg.refresh_db(**kwargs)
```

Check the yum repos for updated packages

Returns:
- **True**: Updates are available
- **False**: An error occurred
- **None**: No updates are available

- **repo** Refresh just the specified repo
- **disablerepo** Do not refresh the specified repo
- **enablerepo** Refresh a disabled repo using this option
- **branch** Add the specified branch when refreshing
- **disableexcludes** Disable the excludes defined in your config files. Takes one of three options: - `all` - disable all excludes - `main` - disable excludes defined in [main] in yum.conf - `repoId` - disable excludes defined for that repo

CLI Example:

```
salt '*' pkg.refresh_db
```

```python
salt.modules.yumpkg.remove(name=None, pkgs=None, **kwargs)
```

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, *systemd-run(1)* is now used to isolate commands which modify installed packages from the salt-minion daemon’s control group. This is done to keep systemd from killing any yum/dnf commands spawned by Salt when the salt-minion service is restarted. (see `KillMode` in the `systemd.kill(5)` manpage for more information). If desired, usage of *systemd-run(1)* can be suppressed by setting a config option called `systemd.scope`, with a value of `False` (no quotes).

Remove packages

- **name** The name of the package to be removed
- **pkgs** A list of packages to delete. Must be passed as a python list.

Multiple Package Options:

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs=['"foo", "bar"]'
```
**pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```bash
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

**salt.modules.yumpkg.unhold(name=None, pkgs=None, sources=None, **kwargs)**

New in version 2014.7.0.

Remove version locks

**Note:** Requires the appropriate versionlock plugin package to be installed:
- On RHEL 5: `yum-versionlock`
- On RHEL 6 & 7: `yum-plugin-versionlock`
- On Fedora: `python-dnf-plugins-extras-versionlock`

**name** The name of the package to be unheld

Multiple Package Options:

**pkgs** A list of packages to unhold. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

Returns a dict containing the changes.

CLI Example:

```bash
salt '*' pkg.unhold <package name>
salt '*' pkg.unhold pkgs='["foo", "bar"]'
```

**salt.modules.yumpkg.upgrade(name=None, pkgs=None, refresh=True, skip_verify=False, normalize=True, **kwargs)**

Run a full system upgrade (a `yum upgrade` or `dnf upgrade`), or upgrade specified packages. If the packages aren't installed, they will not be installed.

Changed in version 2014.7.0.

Changed in version 2015.8.12, 2016.3.3, 2016.11.0: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any yum/dnf commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the `systemd.kill(5)` manpage for more information). If desired, usage of `systemd-run(1)` can be suppressed by setting a config option called `systemd.scope`, with a value of False (no quotes).

Run a full system upgrade, a yum upgrade

Returns a dictionary containing the changes:

```json
{ '<package>': { 'old': '<old-version>',
               'new': '<new-version>' }}
```

CLI Example:

```bash
salt '*' pkg.upgrade
salt '*' pkg.upgrade name=openssl
```
Repository Options:

fromrepo Specify a package repository (or repositories) from which to install. (e.g., yum --disablerepo='*' --enablerepo='somerepo')

enablerepo (ignored if fromrepo is specified) Specify a disabled package repository (or repositories) to enable. (e.g., yum --enablerepo='somerepo')

disablerepo (ignored if fromrepo is specified) Specify an enabled package repository (or repositories) to disable. (e.g., yum --disablerepo='somerepo')

disableexcludes Disable exclude from main, for a repo or for everything. (e.g., yum --disableexcludes='main')

New in version 2014.7.

name The name of the package to be upgraded. Note that this parameter is ignored if ``pkgs'' is passed.

32-bit packages can be upgraded on 64-bit systems by appending the architecture designation (.i686, .i586, etc.) to the end of the package name.

Warning: if you forget `name=' and run pkg.upgrade openssl, ALL packages are upgraded. This will be addressed in next releases.

CLI Example:

```
salt '*' pkg.upgrade name=openssl
```

New in version 2016.3.0.

pkgs A list of packages to upgrade from a software repository. Must be passed as a python list. A specific version number can be specified by using a single-element dict representing the package and its version. If the package was not already installed on the system, it will not be installed.

CLI Examples:

```
salt '*' pkg.upgrade pkgs='["foo", "bar"]'
salt '*' pkg.upgrade pkgs='["foo", {"bar": "1.2.3-4.el5"}]'
```

New in version 2016.3.0.

normalize [True] Normalize the package name by removing the architecture. This is useful for poorly created packages which might include the architecture as an actual part of the name such as kernel modules which match a specific kernel version.

```
salt -G role:nsd pkg.upgrade gpfs.gplbin-2.6.32-279.31.1.el6.x86_64
--normalize=False
```

New in version 2016.3.0.

Note: To add extra arguments to the yum upgrade command, pass them as key word arguments. For arguments without assignments, pass True

```
salt '*' pkg.upgrade security=True exclude='kernel*'
```

salt.modules.yumpkg.upgrade_available(name)
Check whether or not an upgrade is available for a given package

CLI Example:

```
salt '*' pkg.upgrade_available <package name>
```

salt.modules.yumpkg.verify(*names, **kwargs)
New in version 2014.1.0.
Runs an rpm -Va on a system, and returns the results in a dict.

Pass options to modify rpm verify behavior using the verify_options keyword argument.

Files with an attribute of config, doc, ghost, license or readme in the package header can be ignored using the ignore_types keyword argument.

**CLI Example:**

```bash
salt '*' pkg.verify
salt '*' pkg.verify httpd
salt '*' pkg.verify 'httpd postfix' ignore_types=['config', 'doc']
salt '*' pkg.verify 'httpd postfix' verify_options=['nodeps', 'nosize']
```

### salt.modules.yumpkg.version

`salt.modules.yumpkg.version('names', **kwargs)`

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

**CLI Example:**

```bash
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

### salt.modules.yumpkg.version_cmp

`salt.modules.yumpkg.version_cmp(pkg1, pkg2, ignore_epoch=False)`

New in version 2015.5.4.

Do a cmp-style comparison on two packages. Return -1 if pkg1 < pkg2, 0 if pkg1 == pkg2, and 1 if pkg1 > pkg2. Return None if there was a problem making the comparison.

- **ignore_epoch** [False] Set to True to ignore the epoch when comparing versions.

**New in version 2015.8.10,2016.3.2.**

**CLI Example:**

```bash
salt '*' pkg.version_cmp '0.2-001' '0.2.0.1-002'
```

### 19.9.452 salt.modules.zabbix module

Support for Zabbix

- **optdepends**
  - zabbix server

- **configuration** This module is not usable until the zabbix user and zabbix password are specified either in a pillar or in the minion’s config file. Zabbix url should be also specified.

```
zabbix.user: Admin
zabbix.password: mypassword
zabbix.url: http://127.0.0.1/zabbix/api_jsonrpc.php
```

Connection arguments from the minion config file can be overridden on the CLI by using arguments with _connection_ prefix.

```
zabbix.apiinfo_version _connection_user=Admin _connection_password=zabbix _connection_url=http://host/zabbix/
```

codeauthor Jiri Kotlin <jiri.kotlin@ultimum.io>
salt.modules.zabbix.apiinfo_version(**connection_args)

Retrieve the version of the Zabbix API.

New in version 2016.3.0.

Parameters

- `_connection_user` -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- `_connection_password` -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- `_connection_url` -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

Returns

On success string with Zabbix API version, False on failure.

CLI Example:
```
salt `*` zabbix.apiinfo_version
```

salt.modules.zabbix.host_create(host, groups, interfaces, **connection_args)

New in version 2016.3.0.

Create new host

**Note:** This function accepts all standard host properties: keyword argument names differ depending on your zabbix version, see [here](#).

Parameters

- `host` -- technical name of the host
- `groups` -- groupids of host groups to add the host to
- `interfaces` -- interfaces to be created for the host
- `_connection_user` -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- `_connection_password` -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- `_connection_url` -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)
- `visible_name` -- string with visible name of the host, use `visible_name` instead of `name` parameter to not mess with value supplied from Salt sls file.

Return: ID of the created host.

CLI Example:
```
salt '*' zabbix.host_create technicalname 4
    interfaces='{type: 1, main: 1, useip: 1, ip: "192.168.3.1", dns: "", port: 10050}'
    visible_name='Host Visible Name'
```

salt.modules.zabbix.host_delete(hostids, **connection_args)

Delete hosts.

New in version 2016.3.0.

Parameters

- `hostids` -- Hosts (hostids) to delete.
- `_connection_user` -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- `_connection_password` -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- `_connection_url` -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)
**Returns** IDs of the deleted hosts.

```bash
salt '*' zabbix.host_delete 10106
```

```python
salt.modules.zabbix.host_exists(host=None, hostid=None, name=None, node=None, nodeids=None, **connection_args)
```

Checks if at least one host that matches the given filter criteria exists.

New in version 2016.3.0.

**Parameters**

- `host` -- technical name of the host
- `hostids` -- Hosts (hostids) to delete.
- `name` -- visible name of the host
- `node` -- name of the node the hosts must belong to (zabbix API < 2.4)
- `nodeids` -- IDs of the node the hosts must belong to (zabbix API > 2.4)
- `_connection_user` -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- `_connection_password` -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- `_connection_url` -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

**Returns** IDs of the deleted hosts, False on failure.

```bash
salt '*' zabbix.host_get `Zabbix server'
```

```python
salt.modules.zabbix.host_get(host=None, name=None, hostids=None, **connection_args)
```

Retrieve hosts according to the given parameters

New in version 2016.3.0.

**Note:** This function accepts all optional host.get parameters: keyword argument names differ depending on your zabbix version, see [here](#).

**Parameters**

- `host` -- technical name of the host
- `name` -- visible name of the host
- `hostids` -- ids of the hosts
- `_connection_user` -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- `_connection_password` -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- `_connection_url` -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

**Returns** Array with convenient hosts details, False if no host found or on failure.

```bash
salt '*' zabbix.host_list(**connection_args)
```

Retrieve all hosts.

New in version 2016.3.0.

**Parameters**

- `_connection_user` -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- `_connection_password` -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
• `_connection_url` -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

Returns Array with details about hosts, False on failure.

CLI Example: .. code-block:: bash
salt '*' zabbix.host_list

salt.modules.zabbix.host_update(hostid, **connection_args)
New in version 2016.3.0.
Update existing hosts

Note: This function accepts all standard host and host.update properties: keyword argument names differ depending on your zabbix version, see the documentation for host objects and the documentation for updating hosts.

Parameters

- `hostid` -- ID of the host to update
- `_connection_user` -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- `_connection_password` -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- `_connection_url` -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)
- `visible_name` -- string with visible name of the host, use `visible_name` instead of `name` parameter to not mess with value supplied from Salt sls file.

Returns ID of the updated host.

CLI Example: .. code-block:: bash
salt '*' zabbix.host_update 10084 name='Zabbix server2'

salt.modules.zabbix.hostgroup_create(name, **connection_args)
New in version 2016.3.0.
Create a host group

Note: This function accepts all standard host group properties: keyword argument names differ depending on your zabbix version, see here.

Parameters

- `name` -- name of the host group
- `_connection_user` -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- `_connection_password` -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- `_connection_url` -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

Returns ID of the created host group.

CLI Example: .. code-block:: bash
salt '*' zabbix.hostgroup_create MyNewGroup

salt.modules.zabbix.hostgroup_delete(hostgroupids, **connection_args)
Delete the host group.

New in version 2016.3.0.

Parameters
**hostgroupids** -- IDs of the host groups to delete

**_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)

**_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)

**_connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

**Returns**

ID of the deleted host groups, False on failure.

CID Example:

```
salt `*` zabbix.hostgroup_delete 23
```

**salt.modules.zabbix.hostgroup_exists**(name=None, groupid=None, node=None, nodeids=None, **connection_args)**

Checks if at least one host group that matches the given filter criteria exists.

New in version 2016.3.0.

**Parameters**

- **name** -- names of the host groups
- **groupid** -- host group IDs
- **node** -- name of the node the host groups must belong to (zabbix API < 2.4)
- **nodeids** -- IDs of the nodes the host groups must belong to (zabbix API < 2.4)
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

**Returns**

True if at least one host group exists, False if not or on failure.

CID Example:

```
salt `*` zabbix.hostgroup_exists MyNewGroup
```

**salt.modules.zabbix.hostgroup_get**(name=None, groupids=None, hostids=None, **connection_args)**

New in version 2016.3.0.

Retrieve host groups according to the given parameters

**Note:** This function accepts all standard hostgroup.get properties: keyword argument names differ depending on your zabbix version, see [here](#).

**Parameters**

- **name** -- names of the host groups
- **groupid** -- host group IDs
- **node** -- name of the node the host groups must belong to
- **nodeids** -- IDs of the nodes the host groups must belong to
- **hostids** -- return only host groups that contain the given hosts
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

**Returns**

Array with host groups details, False if no convenient host group found or on failure.

CID Example:

```
salt `*` zabbix.hostgroup_get MyNewGroup
```
salt.modules.zabbix.hostgroup_list(**connection_args)**
Retrieve all host groups.

New in version 2016.3.0.

**Parameters**
- `_connection_user` -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- `_connection_password` -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- `_connection_url` -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

**Returns**
Array with details about host groups, False on failure.

CLI Example: .. code-block:: bash
salt '*' zabbix.hostgroup_list

salt.modules.zabbix.hostgroup_update(groupid, name=None, **connection_args)**
Update existing hosts group

**Note:** This function accepts all standard host group properties: keyword argument names differ depending on your zabbix version, see here.

**Parameters**
- `groupid` -- ID of the host group to update
- `name` -- name of the host group
- `_connection_user` -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- `_connection_password` -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- `_connection_url` -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

**Returns**
IDs of updated host groups.

CLI Example: .. code-block:: bash
salt '*' zabbix.hostgroup_update 24 name='Renamed Name'

salt.modules.zabbix.hostinterface_create(hostid, ip, dns='`, main=1, type=1, useip=1, port=None, **connection_args)**
Create new host interface

**Note:** This function accepts all standard host group interface: keyword argument names differ depending on your zabbix version, see here.

**Parameters**
- `hostid` -- ID of the host the interface belongs to
- `ip` -- IP address used by the interface
- `dns` -- DNS name used by the interface
- `main` -- whether the interface is used as default on the host (0 - not default, 1 - default)
- `port` -- port number used by the interface
- `type` -- Interface type (1 - agent; 2 - SNMP; 3 - IPMI; 4 - JMX)
- **useip** -- Whether the connection should be made via IP (0 - connect using host DNS name; 1 - connect using host IP address for this host interface)
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

Returns ID of the created host interface, False on failure.

CLI Example: .. code-block:: bash
salt `*` zabbix.hostinterface_create 10105 192.193.194.197

salt.modules.zabbix.hostinterface_delete(interfaceids, **connection_args)
Delete host interface

New in version 2016.3.0.

Parameters
- **interfaceids** -- IDs of the host interfaces to delete
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

Returns ID of deleted host interfaces, False on failure.

CLI Example: .. code-block:: bash
salt `*` zabbix.hostinterface_delete 50

salt.modules.zabbix.hostinterface_get(hostids, **connection_args)
Retrieve host groups according to the given parameters

New in version 2016.3.0.

Parameters
- **hostids** -- Return only host interfaces used by the given hosts.
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

Returns Array with host interfaces details, False if no convenient host interfaces found or on failure.

CLI Example: .. code-block:: bash
salt `*` zabbix.hostinterface_get 101054

salt.modules.zabbix.hostinterface_update(interfaceid, **connection_args)
Update host interface

New in version 2016.3.0.
Note: This function accepts all standard hostinterface: keyword argument names differ depending on your zabbix version, see here.

Parameters

- **interfaceid** -- ID of the hostinterface to update
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

Returns: ID of the updated host interface, False on failure.

CLI Example: .. code-block:: bash

    salt `*` zabbix.hostinterface_update 6 ip=0.0.2

salt.modules.zabbix.mediatype_create(name, mediatype, **connection_args)

Create new mediatype

Note: This function accepts all standard mediatype properties: keyword argument names differ depending on your zabbix version, see here.

Parameters

- **mediatype** -- media type - 0: email, 1: script, 2: sms, 3: Jabber, 100: Ez Texting
- **exec_path** -- exec path - Required for script and Ez Texting types, see Zabbix API docs
- **gsm_modem** -- exec path - Required for sms type, see Zabbix API docs
- **smtp_email** -- email address from which notifications will be sent, required for email type
- **smtp_helo** -- SMTP HELO, required for email type
- **smtp_server** -- SMTP server, required for email type
- **status** -- whether the media type is enabled - 0: enabled, 1: disabled
- **username** -- authentication user, required for Jabber and Ez Texting types
- **passwd** -- authentication password, required for Jabber and Ez Texting types
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

return: ID of the created mediatype.

CLI Example:

salt `*` zabbix.mediatype_create 'Email' 0 smtp_email='noreply@example.com' smtp_server='mailserver.example.com' smtp_helo='zabbix.example.com'

salt.modules.zabbix.mediatype_delete(mediatypeids, **connection_args)

Delete mediatype

Parameters

- **interfaceids** -- IDs of the mediatypes to delete
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
• `_connection_password` -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
• `_connection_url` -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

**Returns**
ID of deleted mediatype, False on failure.

CLI Example: .. code-block:: bash
salt `*` zabbix.mediatype_delete 3

```python
salt.modules.zabbix.mediatype_get(name=None, mediatypeids=None, **connection_args)
```

Retrieve mediatypes according to the given parameters.

**Parameters**
- `name` -- Name or description of the mediatype
- `mediatypeids` -- ids of the mediatypes
- `connection_args` *(optional)* -- _connection_user: zabbix user (can also be set in opts or pillar, see module's docstring) _connection_password: zabbix password (can also be set in opts or pillar, see module's docstring) _connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's docstring)

all optional mediatype.get parameters: keyword argument names differ depending on your zabbix version, see:

https://www.zabbix.com/documentation/2.2/manual/api/reference/mediatype/get

**Returns**
Array with mediatype details, False if no mediatype found or on failure.

CLI Example: .. code-block:: bash
salt `*` zabbix.mediatype_get name='Email' salt `*` zabbix.mediatype_get mediatypeids='[1,2,3]'

```python
salt.modules.zabbix.mediatype_update(mediatypeid, name=False, mediatype=False, **connection_args)
```

Update existing mediatype

**Note:** This function accepts all standard mediatype properties: keyword argument names differ depending on your zabbix version, see here.

**Parameters**
- `mediatypeid` -- ID of the mediatype to update
- `_connection_user` -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- `_connection_password` -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- `_connection_url` -- Optional - url of zabbix frontend (can also be set in opts or pillar, see module's docstring)

**Returns**
IDs of the updated mediatypes, False on failure.

CLI Example: .. code-block:: bash
salt `*` zabbix.usergroup_update 8 name="Email update"

```python
salt.modules.zabbix.run_query(method, params, **connection_args)
```

Send Zabbix API call

**Parameters**
- `method` -- actual operation to perform via the API
- `params` -- parameters required for specific method
- `connection_args` *(optional)* -- _connection_user: zabbix user (can also be set in opts or pillar, see module's docstring) _connection_password: zabbix password (can also be set in opts or pillar, see module's docstring) _connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's docstring)
all optional template.get parameters: keyword argument names differ depending on your zabbix version, see:

https://www.zabbix.com/documentation/2.4/manual/api/reference/template/get

**Returns** Response from Zabbix API

CLI Example: .. code-block:: bash

    salt '*' zabbix.run_query proxy.create '{'host': 'zabbixproxy.domain.com', 'status': '5'}'

salt.modules.zabbix.template_get(name=None, host=None, templateids=None, **connection_args)

Retrieve templates according to the given parameters.

Parameters

- **host** -- technical name of the template
- **name** -- visible name of the template
- **hostids** -- ids of the templates
- **connection_args** *(optional)* -- connection_user: zabbix user (can also be set in opts or pillar, see module's docstring) connection_password: zabbix password (can also be set in opts or pillar, see module's docstring) connection_url: url of zabbix frontend (can also be set in opts or pillar, see module's docstring)

all optional template.get parameters: keyword argument names differ depending on your zabbix version, see:

https://www.zabbix.com/documentation/2.4/manual/api/reference/template/get

**CLI Example:** .. code-block:: bash

    salt '*' zabbix.template_get name='Template OS Linux'
    salt '*' zabbix.template_get templateids='[10050,10001]'

salt.modules.zabbix.user_addmedia(userids, active, mediatypeid, period, sendto, severity, **connection_args)

Add new media to multiple users.

New in version 2016.3.0.

Parameters

- **userids** -- ID of the user that uses the media
- **active** -- Whether the media is enabled (0 enabled, 1 disabled)
- **mediatypeid** -- ID of the media type used by the media
- **period** -- Time when the notifications can be sent as a time period
- **sendto** -- Address, user name or other identifier of the recipient
- **severity** -- Trigger severities to send notifications about
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

**Returns** IDs of the created media.

CLI Example: .. code-block:: bash

    salt '*' zabbix.user_addmedia 4 active=0 mediatypeid=1 period='1-7,00:00-24:00'
    sendto='support2@example.com' severity=63

salt.modules.zabbix.user_create(alias, passwd, usrgrps, **connection_args)

New in version 2016.3.0.

Create new zabbix user

**Note:** This function accepts all standard user properties: keyword argument names differ depending on your
Parameters

- **alias** -- user alias
- **passwd** -- user's password
- **usrgrps** -- user groups to add the user to
- **connection_user** -- zabbix user (can also be set in opts or pillar, see module's docstring)
- **connection_password** -- zabbix password (can also be set in opts or pillar, see module's docstring)
- **connection_url** -- url of zabbix frontend (can also be set in opts or pillar, see module's docstring)
- **firstname** -- string with firstname of the user, use 'firstname' instead of 'name' parameter to not mess with value supplied from Salt sls file.

Returns

On success string with id of the created user.

CLI Example: .. code-block:: bash

    salt `*' zabbix.user_create james password007 [7, 12]' firstname='James Bond'

salt.modules.zabbix.user_delete(**connection_args**)

Delete zabbix users.

New in version 2016.3.0.

Parameters

- **users** -- array of users (userid) to delete
- **connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **connection_url** -- Optional - url of zabbix front end (can also be set in opts or pillar, see module's docstring)

Returns

On success array with userids of deleted users.

CLI Example: .. code-block:: bash

    salt `*' zabbix.user_delete 15

salt.modules.zabbix.user_deletemedia(**connection_args**)

Delete media by id.

New in version 2016.3.0.

Parameters

- **mediaids** -- IDs of the media to delete
- **connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **connection_url** -- Optional - url of zabbix frontend (can also be set in opts or pillar, see module's docstring)

Returns

IDs of the deleted media, False on failure.

CLI Example: .. code-block:: bash

    salt `*' zabbix.user_deletemedia 27

salt.modules.zabbix.user_exists(**connection_args**)

Checks if user with given alias exists.

New in version 2016.3.0.

Parameters

- **alias** -- user alias
• _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
• _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
• _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

Returns True if user exists, else False.

CLI Example: .. code-block:: bash
salt '*' zabbix.user_exists james

salt.modules.zabbix.user_get

Retrieve users according to the given parameters.

New in version 2016.3.0.

Parameters

• alias -- user alias
• userids -- return only users with the given IDs
• _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
• _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
• _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

Returns Array with details of convenient users, False on failure of if no user found.

CLI Example: .. code-block:: bash
salt '*' zabbix.user_getmedia(userids=None, **connection_args)

Retrieve media according to the given parameters

New in version 2016.3.0.

Parameters

• userids -- return only media that are used by the given users
• _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
• _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
• _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

Returns List of retrieved media, False on failure.

CLI Example: .. code-block:: bash
salt '*' zabbix.user_list(**connection_args)

Retrieve all of the configured users.

New in version 2016.3.0.

Parameters

• _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
The `zabbix.user_update` function is used to update existing users.

**Parameters**
- `userid` -- id of the user to update
- `_connection_user` -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- `_connection_password` -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- `_connection_url` -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

**Returns**
Id of the updated user on success.

**CLI Example**
```
salt '*' zabbix.user_update 16 visible_name='James Brown'
```

The `zabbix.usergroup_create` function is used to create new user groups.

**Parameters**
- `name` -- name of the user group
- `_connection_user` -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- `_connection_password` -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- `_connection_url` -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

**Returns**
IDs of the created user groups.

**CLI Example**
```
salt '*' zabbix.usergroup_create GroupName
```

The `zabbix.usergroup_delete` function is used to delete user groups.

**Parameters**
- `usergroupids` -- IDs of the user groups to delete

**CLI Example**
```
salt.modules.zabbix.usergroup_delete(usergroupids, **connection_args)
```
Returns IDs of the deleted user groups.

CLI Example: .. code-block:: bash

    salt `*` zabbix.usergroup_delete 28

salt.modules.zabbix.usergroup_exists(name=None, node=None, nodeids=None, **connection_args)

Checks if at least one user group that matches the given filter criteria exists

New in version 2016.3.0.

Parameters

- **name** -- names of the user groups
- **node** -- name of the node the user groups must belong to (This will override the nodeids parameter.)
- **nodeids** -- IDs of the nodes the user groups must belong to
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts or pillar, see module's docstring)

Returns True if at least one user group that matches the given filter criteria exists, else False.

CLI Example: .. code-block:: bash

    salt `*` zabbix.usergroup_exists Guests

salt.modules.zabbix.usergroup_get(name=None, usgrgid=None, userids=None, **connection_args)

Retrieve user groups according to the given parameters

Note: This function accepts all usergroup_get properties: keyword argument names differ depending on your zabbix version, see here.

Parameters

- **name** -- names of the user groups
- **usgrgid** -- return only user groups with the given IDs
- **userids** -- return only user groups that contain the given users
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts or pillar, see module's docstring)

Returns Array with convenient user groups details, False if no user group found or on failure.

CLI Example: .. code-block:: bash

    salt `*` zabbix.usergroup_get Guests

salt.modules.zabbix.usergroup_list(**connection_args)

Retrieve all enabled user groups.
New in version 2016.3.0.

Parameters

• `_connection_user` -- Optional - zabbix user (can also be set in opts or pillar, see
module's docstring)
• `_connection_password` -- Optional - zabbix password (can also be set in opts
or pillar, see module's docstring)
• `_connection_url` -- Optional - url of zabbix frontend (can also be set in opts,
piller, see module's docstring)

Returns Array with enabled user groups details, False on failure.

CLI Example: .. code-block:: bash
salt `*` zabbix.usergroup_list

salt.modules.zabbix.usergroup_update(usrgrpid, **connection_args)

New in version 2016.3.0.
Update existing user group

Note: This function accepts all standard user group properties: keyword argument names differ depending
on your zabbix version, see here.

Parameters

• `usrgrpid` -- ID of the user group to update.
• `_connection_user` -- Optional - zabbix user (can also be set in opts or pillar, see
module's docstring)
• `_connection_password` -- Optional - zabbix password (can also be set in opts
or pillar, see module's docstring)
• `_connection_url` -- Optional - url of zabbix frontend (can also be set in opts,
piller, see module's docstring)

Returns IDs of the updated user group, False on failure.

CLI Example: .. code-block:: bash
salt `*` zabbix.usergroup_update 8 name=guestsRenamed

19.9.453 salt.modules.zcbuildout

Management of zc.buildout

New in version 2014.1.0.

This module is inspired by minitage's buildout maker

Note: The zc.buildout integration is still in beta; the API is subject to change

General notes

You have those following methods:

• upgrade_bootstrap
• bootstrap
• run_buildout
• buildout
salt.modules.zcbuildout.bootstrap(*a, **kw)
Run the buildout bootstrap dance (python bootstrap.py).

directory  directory to execute in
config    alternative buildout configuration file to use
runas    User used to run buildout as
env       environment variables to set when running
buildout_ver  force a specific buildout version (1 | 2)
test_release buildout accept test release
offline    are we executing buildout in offline mode
distribute    Forcing use of distribute
new_st    Forcing use of setuptools &lt;= 0.7
python    path to a python executable to use in place of default (salt one)
onlyif    Only execute cmd if statement on the host return 0
unless    Do not execute cmd if statement on the host return 0
use_vt    Use the new salt VT to stream output [experimental]

CLI Example:
```
salt '*' buildout.bootstrap /srv/mybuildout
```

salt.modules.zcbuildout.buildout(*a, **kw)
Run buildout in a directory.

directory  directory to execute in
config    buildout config to use
parts    specific buildout parts to run
runas    user used to run buildout as
env       environment variables to set when running
buildout_ver  force a specific buildout version (1 | 2)
test_release buildout accept test release
new_st    Forcing use of setuptools &gt;= 0.7
distribute    use distribute over setuptools if possible
offline    does buildout run offline
python    python to use
debug    run buildout with -D debug flag
onlyif    Only execute cmd if statement on the host return 0
unless    Do not execute cmd if statement on the host return 0
newest    run buildout in newest mode
verbose    run buildout in verbose mode (-vvvvv)
use_vt    Use the new salt VT to stream output [experimental]

CLI Example:
```
salt '*' buildout.buildout /srv/mybuildout
```

salt.modules.zcbuildout.run_buildout(*a, **kw)
Run a buildout in a directory.

directory  directory to execute in
config    alternative buildout configuration file to use
offline    are we executing buildout in offline mode
runas    user used to run buildout as
env       environment variables to set when running
onlyif    Only execute cmd if statement on the host return 0
unless    Do not execute cmd if statement on the host return 0
newest    run buildout in newest mode
verbose    run buildout in verbose mode (-vvvvv)
use_vt    Use the new salt VT to stream output [experimental]
### salt.modules.zcbuildout

#### upgrade_bootstrap(*a, **kw)

Upgrade current bootstrap.py with the last released one.

Indeed, when we first run a buildout, a common source of problem is to have a locally stale bootstrap, we just try to grab a new copy

- **directory** directory to execute in
- **offline** are we executing buildout in offline mode
- **buildout_ver** forcing to use a specific buildout version (1 | 2)
- **onlyif** Only execute cmd if statement on the host return 0
- **unless** Do not execute cmd if statement on the host return 0

#### CLI Example:

```
salt '*' buildout.run_buildout /srv/mybuildout
```

```
salt.modules.zcbuildout.upgrade_bootstrap(*a, **kw)
```

### 19.9.454 salt.modules.zenoss

Module for working with the Zenoss API

New in version 2016.3.0.

- **depends** requests

- **configuration** This module requires a `zenoss' entry in the master/minion config.

For example:

```
zenoss:
  hostname: https://zenoss.example.com
  username: admin
  password: admin123
```

#### salt.modules.zenoss.add_device(device=None, device_class=None, collector='localhost', prod_state=1000)

A function to connect to a zenoss server and add a new device entry.

- **device** -- (Optional) Will use the grain `fqdn' by default.
- **device_class** -- (Optional) The device class to use. If none, will determine based on kernel grain.
- **collector** -- (Optional) The collector to use for this device. Defaults to `localhost'.
- **prod_state** -- (Optional) The prodState to set on the device. If none, defaults to 1000 (production)

#### CLI Example:

```
salt '*' zenoss.add_device
```

#### salt.modules.zenoss.device_exists(device=None)

Check to see if a device already exists in Zenoss.

- **device** -- (Optional) Will use the grain `fqdn' by default

#### CLI Example:

```
salt '*' zenoss.device_exists
```

#### salt.modules.zenoss.find_device(device=None)

Find a device in Zenoss. If device not found, returns None.

- **device** -- (Optional) Will use the grain `fqdn' by default

#### CLI Example:

```
salt '*' zenoss.find_device
```

---

2384 Chapter 19. Salt Module Reference
salt.modules.zenoss.setProdState(prod_state, device=None)
A function to set the prod_state in zenoss.

Parameters

- **prod_state** -- (Required) Integer value of the state
- **device** -- (Optional) Will use the grain `fqdn` by default.

CLI Example: salt zenoss.set_prod_state 1000 hostname

19.9.455 salt.modules.zfs

Salt interface to ZFS commands

codeauthor Nitin Madhok <nmadhok@clemson.edu>

salt.modules.zfs.bookmark(snapshot, bookmark)
New in version 2016.3.0.

Creates a bookmark of the given snapshot

**Note:** Bookmarks mark the point in time when the snapshot was created, and can be used as the incremental source for a zfs send command.

This feature must be enabled to be used. See zpool-features(5) for details on ZFS feature flags and the bookmarks feature.

snapshot [string] name of snapshot to bookmark
bookmark [string] name of bookmark

CLI Example:

```
salt '*' zfs.bookmark myzpool/mydataset@yesterday myzpool/mydataset#complete
```

salt.modules.zfs.clone(name_a, name_b, **kwargs)
New in version 2016.3.0.

Creates a clone of the given snapshot.

name_a [string] name of snapshot
name_b [string] name of filesystem or volume
create_parent [boolean] creates all the non-existing parent datasets. any property specified on the command line using the -o option is ignored.
properties [dict] additional zfs properties (-o)

**Note:** ZFS properties can be specified at the time of creation of the filesystem by passing an additional argument called `properties` and specifying the properties with their respective values in the form of a python dictionary:

```
properties="{"property1": 'value1', "property2": 'value2'}"
```

CLI Example:

```
salt '*' zfs.clone myzpool/mydataset@yesterday myzpool/mydataset_yesterday
```

salt.modules.zfs.create(name, **kwargs)
New in version 2015.5.0.

Changed in version 2016.3.0.
Create a ZFS File System.

- **name** [string] name of dataset or volume
- **volume_size** [string] if specified, a zvol will be created instead of a dataset
- **sparse** [boolean] create sparse volume
- **create_parent** [boolean] creates all the non-existing parent datasets. any property specified on the command line using the `-o` option is ignored.
- **properties** [dict] additional zfs properties (-o)

**Note:** ZFS properties can be specified at the time of creation of the filesystem by passing an additional argument called `properties` and specifying the properties with their respective values in the form of a python dictionary:

```python
properties = {'property1': 'value1', 'property2': 'value2'}
```

**CLI Example:**

```bash
salt '*' zfs.create myzpool/mydataset
```
Check if a ZFS filesystem or volume or snapshot exists.

`name` [string] name of dataset

`type` [string] also check if dataset is of a certain type, valid choices are: filesystem, snapshot, volume, bookmark, or all.

CLI Example:

```
salt '*' zfs.exists myzpool/mydataset
salt '*' zfs.exists myzpool/myvolume type=volume
```

```
salt.modules.zfs.get("dataset", **kwargs)
```

New in version 2016.3.0.

Displays properties for the given datasets.

`dataset` [string] name of snapshot(s), filesystem(s), or volume(s)

`properties` [string] comma-separated list of properties to list, defaults to all

`recursive` [boolean] recursively list children

`depth` [int] recursively list children to depth

`fields` [string] comma-separated list of fields to include, the name and property field will always be added

`type` [string] comma-separated list of types to display, where type is one of filesystem, snapshot, volume, bookmark, or all.

`source` [string] comma-separated list of sources to display. Must be one of the following: local, default, inherited, temporary, and none. The default value is all sources.

**Note:** If no datasets are specified, then the command displays properties for all datasets on the system.

CLI Example:

```
salt '*' zfs.get
salt '*' zfs.get myzpool/mydataset [recursive=True|False]
salt '*' zfs.get myzpool/mydataset properties="sharenfs,mountpoint"
  →[recursive=True|False]
salt '*' zfs.get myzpool/mydataset myzpool/myotherdataset properties=available
  →fields=value depth=1
```

```
salt.modules.zfs.hold(tag, *snapshot, **kwargs)
```

New in version 2016.3.0.

Add a single reference, named with the tag argument, to the specified snapshot or snapshots.

**Note:** Each snapshot has its own tag namespace, and tags must be unique within that space.

If a hold exists on a snapshot, attempts to destroy that snapshot by using the zfs destroy command return EBUSY.

`tag` [string] name of tag

`snapshot` [string] name of snapshot(s)

`recursive` [boolean] specifies that a hold with the given tag is applied recursively to the snapshots of all descendent file systems.

**Note:** A comma-separated list can be provided for the tag parameter to hold multiple tags.

CLI Example:
salt ']* zfs.hold mytag myzpool/mydataset@mysnapshot [recursive=True]
salt ']* zfs.hold mytag,myothertag myzpool/mydataset@mysnapshot
salt ']* zfs.hold mytag myzpool/mydataset@mysnapshot myzpool/
   --mydataset/myothersnapshot

salt.modules.zfs.hold(snapshot, **kwargs)
New in version 2016.3.0.
Lists all existing user references for the given snapshot or snapshots.
snapshot [string] name of snapshot
recursive [boolean] lists the holds that are set on the named descendent snapshots also.
CLI Example:
salt ']* zfs.hold myzpool/mydataset@baseline

salt.modules.zfs.inherit(prop, name, **kwargs)
New in version 2016.3.0.
Clears the specified property
prop [string] name of property
name [string] name of the filesystem, volume, or snapshot
recursive [boolean] recursively inherit the given property for all children.
revert [boolean] revert the property to the received value if one exists; otherwise operate as if the -S option
   was not specified.
CLI Example:
salt ']* zfs.inherit canmount myzpool/mydataset [recursive=True|False]

salt.modules.zfs.list_(name=None, **kwargs)
New in version 2015.5.0.
Changed in version 2016.3.0.
Return a list of all datasets or a specified dataset on the system and the values of their used, available, refe-
   renced, and mountpoint properties.
nname [string] name of dataset, volume, or snapshot
recursive [boolean] recursively list children
depth [int] limit recursion to depth
properties [string] comma-separated list of properties to list, the name property will always be added
type [string] comma-separated list of types to display, where type is one of filesystem, snapshot, volume,
   bookmark, or all.
sort [string] property to sort on (default = name)
order [string [ascending|descending]] sort order (default = ascending)
CLI Example:
salt ']* zfs.list
salt ']* zfs.list myzpool/mydataset [recursive=True|False]
salt ']* zfs.list myzpool/mydataset properties="sharenfs,mountpoint"

salt.modules.zfs.mount(name='a'; **kwargs)
New in version 2016.3.0.
Mounts ZFS file systems
name [string] name of the filesystem, you can use '-a' to mount all unmounted filesystems. (this is the default)
overlay [boolean] perform an overlay mount.
options [string] optional comma-separated list of mount options to use temporarily for the duration of the
mount.
CLI Example:

salt '*' zfs.mount
salt '*' zfs.mount myzpool/mydataset
salt '*' zfs.mount myzpool/mydataset options=ro

salt.modules.zfs.promote(name)
New in version 2016.3.0.
Promotes a clone file system to no longer be dependent on its ``origin'' snapshot.

**Note:** This makes it possible to destroy the file system that the clone was created from. The clone parent-
child dependency relationship is reversed, so that the origin file system becomes a clone of the specified file
system.

The snapshot that was cloned, and any snapshots previous to this snapshot, are now owned by the promoted
clone. The space they use moves from the origin file system to the promoted clone, so enough space must
be available to accommodate these snapshots. No new space is consumed by this operation, but the space
accounting is adjusted. The promoted clone must not have any conflicting snapshot names of its own. The
rename subcommand can be used to rename any conflicting snapshots.

name [string] name of clone-filesystem
CLI Example:

salt '*' zfs.promote myzpool/myclone

salt.modules.zfs.release(tag, *snapshot, **kwargs)
New in version 2016.3.0.
Removes a single reference, named with the tag argument, from the specified snapshot or snapshots.

**Note:** The tag must already exist for each snapshot. If a hold exists on a snapshot, attempts to destroy that
snapshot by using the zfs destroy command return EBUSY.

tag [string] name of tag
snapshot [string] name of snapshot(s)
recursive [boolean] recursively releases a hold with the given tag on the snapshots of all descendent file
systems.

**Note:** A comma-separated list can be provided for the tag parameter to release multiple tags.

CLI Example:

salt '*' zfs.release mytag myzpool/mydataset@mysnapshot [recursive=True]
salt '*' zfs.release mytag myzpool/mydataset@mysnapshot myzpool/
   !mydataset@myothersnapshot

salt.modules.zfs.rename(name, new_name, **kwargs)
New in version 2016.3.0.

Changed in version 2016.3.0.
Rename or Relocate a ZFS File System.

- **name** [string] name of dataset, volume, or snapshot
- **new_name** [string] new name of dataset, volume, or snapshot
- **force** [boolean] force unmount any filesystems that need to be unmounted in the process.
- **create_parent** [boolean] creates all the nonexistent parent datasets. Datasets created in this manner are automatically mounted according to the mountpoint property inherited from their parent.
- **recursive** [boolean] recursively rename the snapshots of all descendent datasets. Snapshots are the only dataset that can be renamed recursively.

CLI Example:

```shell
salt '*' zfs.rename myzpool/mydataset myzpool/renameddataset
```

salt.modules.zfs.rollback(name, **kwargs)

New in version 2016.3.0.

Roll back the given dataset to a previous snapshot.

**Warning:** When a dataset is rolled back, all data that has changed since the snapshot is discarded, and the dataset reverts to the state at the time of the snapshot. By default, the command refuses to roll back to a snapshot other than the most recent one.

In order to do so, all intermediate snapshots and bookmarks must be destroyed by specifying the -r option.

- **name** [string] name of snapshot
- **recursive** [boolean] destroy any snapshots and bookmarks more recent than the one specified.
- **recursive_all** [boolean] destroy any more recent snapshots and bookmarks, as well as any clones of those snapshots.
- **force** [boolean] used with the -R option to force an unmount of any clone file systems that are to be destroyed.

CLI Example:

```shell
salt '*' zfs.rollback myzpool/mydataset@yesterday
```

salt.modules.zfs.set(*dataset, **kwargs)

New in version 2016.3.0.

Sets the property or list of properties to the given value(s) for each dataset.

- **dataset** [string] name of snapshot(s), filesystem(s), or volume(s)
- **properties** [string] additional zfs properties pairs

**Note:** properties are passed as key-value pairs. e.g.

```shell
compression=off
```

- **Note:** Only some properties can be edited.

See the Properties section for more information on what properties can be set and acceptable values.

Numeric values can be specified as exact values, or in a human-readable form with a suffix of B, K, M, G, T, P, E, Z (for bytes, kilobytes, megabytes, gigabytes, terabytes, petabytes, exabytes, or zettabytes, respectively).

CLI Example:

```shell
salt '*' zfs.set myzpool/mydataset compression=off
salt '*' zfs.set myzpool/mydataset myzpool/myotherdataset compression=off
salt '*' zfs.set myzpool/mydataset myzpool/myotherdataset compression=lz4
    canmount=off
```
salt.modules.zfs.snapshot(*snapshot, **kwargs)
New in version 2016.3.0.
Creates snapshots with the given names.

**snapshot** [string] name of snapshot(s)
**recursive** [boolean] recursively create snapshots of all descendent datasets.
**properties** [dict] additional zfs properties (-o)

**Note:** ZFS properties can be specified at the time of creation of the filesystem by passing an additional argument called `"properties"` and specifying the properties with their respective values in the form of a python dictionary:

```
properties = '{property1': 'value1', 'property2': 'value2'}
```

CLI Example:
```
salt '*' zfs.snapshot myzpool/mydataset@yesterday [recursive=True]
salt '*' zfs.snapshot myzpool/mydataset@yesterday myzpool/→myotherdataset@yesterday [recursive=True]
```

salt.modules.zfs.unmount(name, **kwargs)
New in version 2016.3.0.
Unmounts ZFS file systems

**name** [string] name of the filesystem, you can use `-a' to unmount all mounted filesystems.
**force** [boolean] forcefully unmount the file system, even if it is currently in use.

**Warning:** Using `-a` for the name parameter will probably break your system, unless your rootfs is not on zfs.

CLI Example:
```
salt '*' zfs.unmount myzpool/mydataset [force=True|False]
```

19.9.456 salt.modules.zk_concurrency

Concurrency controls in zookeeper

This module allows you to acquire and release a slot. This is primarily useful for ensuring that no more than N hosts take a specific action at once. This can also be used to coordinate between masters.

salt.modules.zk_concurrency.lock(path, zk_hosts, identifier=None, max_concurrency=1, timeout=None, ephemeral_lease=False, force=False)

Get lock (with optional timeout)

**path** The path in zookeeper where the lock is
**zk_hosts** zookeeper connect string
**identifier** Name to identify this minion, if unspecified defaults to the hostname
**max_concurrency** Maximum number of lock holders
**timeout** timeout to wait for the lock. A None timeout will block forever
**ephemeral_lease** Whether the locks in zookeeper should be ephemeral
**force** Forcibly acquire the lock regardless of available slots
Example:

```bash
... code-block: bash
  salt minion zk_concurrency.lock /lock/path host1:1234,host2:1234
```

```python
salt.modules.zk_concurrency.lock_holders(path, zk_hosts, identifier=None, max_concurrency=1, ephemeral_lease=False, timeout=None)
```

Return an un-ordered list of lock holders

- **path**: The path in zookeeper where the lock is
- **zk_hosts**: zookeeper connect string
- **identifier**: Name to identify this minion, if unspecified defaults to hostname
- **max_concurrency**: Maximum number of lock holders
- **timeout**: timeout to wait for the lock. A None timeout will block forever
- **ephemeral_lease**: Whether the locks in zookeeper should be ephemeral

Example:

```bash
... code-block: bash
  salt minion zk_concurrency.lock_holders /lock/path host1:1234,host2:1234
```

```python
salt.modules.zk_concurrency.party_members(path, zk_hosts, min_nodes=1, blocking=False)
```

Get the List of identifiers in a particular party, optionally waiting for the specified minimum number of nodes (min_nodes) to appear

- **path**: The path in zookeeper where the lock is
- **zk_hosts**: zookeeper connect string
- **min_nodes**: The minimum number of nodes expected to be present in the party
- **blocking**: The boolean indicating if we need to block until min_nodes are available

Example:

```bash
... code-block: bash
  salt minion zk_concurrency.party_members /lock/path host1:1234,host2:1234
  salt minion zk_concurrency.party_members /lock/path host1:1234,host2:1234 min_nodes=3 blocking=True
```

```python
salt.modules.zk_concurrency.unlock(path, zk_hosts=None, identifier=None, max_concurrency=1, ephemeral_lease=False, timeout=None)
```

Remove lease from semaphore

- **path**: The path in zookeeper where the lock is
- **zk_hosts**: zookeeper connect string
- **identifier**: Name to identify this minion, if unspecified defaults to hostname
- **max_concurrency**: Maximum number of lock holders
- **timeout**: timeout to wait for the lock. A None timeout will block forever
- **ephemeral_lease**: Whether the locks in zookeeper should be ephemeral

Example:

```bash
... code-block: bash
  salt minion zk_concurrency.unlock /lock/path host1:1234,host2:1234
```

## 19.9.457 salt.modules.znc

**znc** - An advanced IRC bouncer

New in version 2014.7.0.

Provides an interface to basic ZNC functionality

```python
salt.modules.znc.buildmod(*modules)
```

Build module using znc-buildmod

CLI Example:
salt.modules.znc.dumpconf()
Write the active configuration state to config file
CLI Example:
salt '*' znc.dumpconf

salt.modules.znc.rehashconf()
Rehash the active configuration state from config file
CLI Example:
salt '*' znc.rehashconf

salt.modules.znc.version()
Return server version from znc --version
CLI Example:
salt '*' znc.version

19.9.458 salt.modules.zoneadm

Module for Solaris 10's zoneadm

maintainer Jorge Schrauwen <sjorge@blackdot.be>
maturity new
platform OmniOS,OpenIndiana,SmartOS,OpenSolaris,Solaris 10
New in version 2017.7.0.

Warning: Oracle Solaris 11's zoneadm is not supported by this module!

salt.modules.zoneadm.attach(zone, force=False, brand_opts=None)
Attach the specified zone.
zone [string] name of the zone
force [boolean] force the zone into the "installed" state with no validation
brand_opts [string] brand specific options to pass
CLI Example:
salt '*' zoneadm.attach lawrence
salt '*' zoneadm.attach lawrence True

salt.modules.zoneadm.boot(zone, single=False, altinit=None, smf_options=None)
Boot (or activate) the specified zone.
zone [string] name or uuid of the zone
single [boolean] boots only to milestone svc:/milestone/single-user:default.
altinit [string] valid path to an alternative executable to be the primordial process.
smf_options [string] include two categories of options to control booting behavior of the service management facility: recovery options and messages options.
CLI Example:
Salt modules.describe

**salt.modules.zoneadm.clone**(zone, source, snapshot=None)

Install a zone by copying an existing installed zone.

- **zone** [string] name of the zone
- **source** [string] zone to clone from
- **snapshot** [string] optional name of snapshot to use as source

**CLI Example:**
```
salt '*' zoneadm.clone clementine dolores
```

**salt.modules.zoneadm.detach**(zone)

Detach the specified zone.

- **zone** [string] name or uuid of the zone

**CLI Example:**
```
salt '*' zoneadm.detach kissy
```

**salt.modules.zoneadm.halt**(zone)

Halt the specified zone.

- **zone** [string] name or uuid of the zone

**Note:** To cleanly shutdown the zone use the shutdown function.

**CLI Example:**
```
salt '*' zoneadm.halt hector
```

**salt.modules.zoneadm.install**(zone, nodataset=False, brand_opts=None)

Install the specified zone from the system.

- **zone** [string] name of the zone
- **nodataset** [boolean] do not create a ZFS file system
- **brand_opts** [string] brand specific options to pass

**CLI Example:**
```
salt '*' zoneadm.install dolores
salt '*' zoneadm.install teddy True
```

**salt.modules.zoneadm.list_zones**(verbose=True, installed=False, configured=False, hide_global=True)

List all zones

- **verbose** [boolean] display additional zone information
- **installed** [boolean] include installed zones in output
- **configured** [boolean] include configured zones in output
- **hide_global** [boolean] do not include global zone

**CLI Example:**
```
salt '*' zoneadm.list
```

**salt.modules.zoneadm.move**(zone, zonepath)

Move zone to new zonepath.

- **zone** [string] name or uuid of the zone
- **zonepath** [string] new zonepath
salt.modules.zoneadm.ready(zone)
Prepares a zone for running applications.
zone [string] name or uuid of the zone
CLI Example:
salt '*' zoneadm.ready clementine

salt.modules.zoneadm.reboot(zone, single=False, altinit=None, smf_options=None)
Restart the zone. This is equivalent to a halt boot sequence.
zone [string] name or uuid of the zone
single [boolean] boots only to milestone svc:/milestone/single-user:default.
altinit [string] valid path to an alternative executable to be the primordial process.
smf_options [string] include two categories of options to control booting behavior of the service management facility: recovery options and messages options.
CLI Example:
salt '*' zoneadm.reboot dolores	salt '*' zoneadm.reboot teddy single=True

salt.modules.zoneadm.shutdown(zone, reboot=False, single=False, altinit=None, smf_options=None)
Gracefully shutdown the specified zone.
zone [string] name or uuid of the zone
reboot [boolean] reboot zone after shutdown (equivalent of shutdown -i6 -g0 -y)
single [boolean] boots only to milestone svc:/milestone/single-user:default.
altinit [string] valid path to an alternative executable to be the primordial process.
smf_options [string] include two categories of options to control booting behavior of the service management facility: recovery options and messages options.
CLI Example:
salt '*' zoneadm.shutdown peter	salt '*' zoneadm.shutdown armistice reboot=True

salt.modules.zoneadm.uninstall(zone)
Uninstall the specified zone from the system.
zone [string] name of the zone
Warning: The -F flag is always used to avoid the prompts when uninstalling.

CLI Example:
salt '*' zoneadm.uninstall teddy

salt.modules.zoneadm.verify(zone)
Check to make sure the configuration of the specified zone can safely be installed on the machine.
zone [string] name of the zone
CLI Example:
salt '*' zoneadm.verify dolores
19.9.459 salt.modules.zonecfg

Module for Solaris 10's zonecfg

- maintainer: Jorge Schrauwen <sjorge@blackdot.be>
- maturity: new
- platform: OmniOS, OpenIndiana, SmartOS, OpenSolaris, Solaris 10
- depend: salt.modules.file

New in version 2017.7.0.

**Warning:** Oracle Solaris 11's zonecfg is not supported by this module!

```python
salt.modules.zonecfg.add_resource(zone, resource_type, **kwargs)
```

Add a resource

- `zone` [string] name of zone
- `resource_type` [string] type of resource
- `kwargs` [string|int...] resource properties

CLI Example:

```bash
salt '*' zonecfg.add_resource tallgeese rctl
name=zone.max-locked-memory value="'(priv=privileged,limit=33554432,action=deny)'"
```

```python
salt.modules.zonecfg.clear_property(zone, key)
```

Clear a property

- `zone` [string] name of zone
- `key` [string] name of property

CLI Example:

```bash
salt '*' zonecfg.clear_property deathscythe cpu-shares
```

```python
salt.modules.zonecfg.create(zone, brand, zonepath, force=False)
```

Create an in-memory configuration for the specified zone.

- `zone` [string] name of zone
- `brand` [string] brand name
- `zonepath` [string] path of zone
- `force` [boolean] overwrite configuration

CLI Example:

```bash
salt '*' zonecfg.create deathscythe ipkg /zones/deathscythe
```

```python
salt.modules.zonecfg.create_from_template(zone, template)
```

Create an in-memory configuration from a template for the specified zone.

- `zone` [string] name of zone
- `template` [string] name of template

**Warning:** existing config will be overwritten!

CLI Example:

```bash
salt '*' zonecfg.create_from_template leo tallgeese
```
salt.modules.zonecfg.delete(zone)
Delete the specified configuration from memory and stable storage.
zone [string] name of zone

CLI Example:
salt '*' zonecfg.delete epyon

salt.modules.zonecfg.export(zone, path=None)
Export the configuration from memory to stable storage.
zone [string] name of zone
path [string] path of file to export to

CLI Example:
salt '*' zonecfg.export epyon
salt '*' zonecfg.export epyon /zones/epyon.cfg

salt.modules.zonecfg.import_(zone, path)
Import the configuration to memory from stable storage.
zone [string] name of zone
path [string] path of file to export to

CLI Example:
salt '*' zonecfg.import epyon /zones/epyon.cfg

salt.modules.zonecfg.info(zone, show_all=False)
Display the configuration from memory
zone [string] name of zone
show_all [boolean] also include calculated values like capped-cpu, cpu-shares, ...

CLI Example:
salt '*' zonecfg.info tallgeese

salt.modules.zonecfg.remove_resource(zone, resource_type, resource_key, resource_value)
Remove a resource
zone [string] name of zone
resource_type [string] type of resource
resource_key [string] key for resource selection
resource_value [string] value for resource selection

Note: Set resource_selector to None for resource that do not require one.

CLI Example:
salt '*' zonecfg.remove_resource tallgeese rctl name zone.max-locked-memory

salt.modules.zonecfg.set_property(zone, key, value)
Set a property
zone [string] name of zone
key [string] name of property
value [string] value of property

CLI Example:
salt '*' zonecfg.set_property deathscythe cpu-shares 100

salt.modules.zonecfg.update_resource(zone, resource_type, resource_selector, **kwargs)
Add a resource
zone [string] name of zone
resource_type [string] type of resource
resource_selector [string] unique resource identifier
kwargs [string|int|...] resource properties

Note: Set resource_selector to None for resource that do not require one.

CLI Example:

```
salt '*' zonecfg.update_resource tallgeese rctl name name=zone.max-locked-memory
  !value='(priv=privileged,limit=33554432,action=deny)'
```

19.9.460 salt.modules.zpool

Module for running ZFS zpool command

codeauthor Nitin Madhok <nmadhok@clemson.edu>

salt.modules.zpool.add(zpool, *vdevs, **kwargs)

Changed in version 2016.3.0.
Add the specified vdevs to the given storage pool
zpool [string] name of storage pool
vdevs [string] one or more devices
force [boolean] forces use of device

CLI Example:

```
salt '*' zpool.add myzpool /path/to/vdev1 /path/to/vdev2 [...]
```

salt.modules.zpool.attach(zpool, device, new_device, force=False)

Changed in version 2016.3.0.
Attach specified device to zpool
zpool [string] name of storage pool
device [string] device to attach too
new_device [string] device to attach
force [boolean] forces use of device

CLI Example:

```
salt '*' zpool.attach myzpool /path/to/vdev1 /path/to/vdev2 [...]
```

salt.modules.zpool.create(zpool, *vdevs, **kwargs)

New in version 2015.5.0.
Changed in version 2016.3.0.
Create a simple zpool, a mirrored zpool, a zpool having nested VDEVs, a hybrid zpool with cache, spare and log drives or a zpool with RAIDZ-1, RAIDZ-2 or RAIDZ-3
zpool [string] name of storage pool
vdevs [string] one or more devices
force [boolean] forces use of vdevs, even if they appear in use or specify a conflicting replication level.
mountpoint [string] sets the mount point for the root dataset
altroot [string] equivalent to ``-o cachefile=none,altroot=root''
properties [dict] additional pool properties
filesystem_properties [dict] additional filesystem properties

CLI Example:
salt 'Salt Doc Release 2017.7.8'

```python
salt '*' zpool.create myzpool /path/to/vdev1 [...] [force=True|False]
salt '*' zpool.create myzpool mirror /path/to/vdev1 /path/to/vdev2 [...] [force=True|False]
salt '*' zpool.create myzpool raidz1 /path/to/vdev1 /path/to/vdev2 raidz2 /path/to/vdev3 /path/to/vdev4 /path/to/vdev5 [...] [force=True|False]
salt '*' zpool.create myzpool mirror /path/to/vdev1 [...] mirror /path/to/vdev2 /path/to/vdev3 [...] [force=True|False]
salt '*' zpool.create myhybridzpool mirror /tmp/file1 [...] log mirror /path/to/vdev1 [...] cache /path/to/vdev2 [...] spare /path/to/vdev3 [...] [force=True|False]
```

**Note:** Zpool properties can be specified at the time of creation of the pool by passing an additional argument called `"properties"` and specifying the properties with their respective values in the form of a python dictionary:

```python
properties=
{
'property1': 'value1',
'property2': 'value2'
}
```

Filesystem properties can be specified at the time of creation of the pool by passing an additional argument called `"filesystem_properties"` and specifying the properties with their respective values in the form of a python dictionary:

```python
filesystem_properties=
{
'property1': 'value1',
'property2': 'value2'
}
```

**Example:**

```python
salt '*' zpool.create myzpool /path/to/vdev1 [...] properties="{'property1': 'value1', 'property2': 'value2'}"
```

**salt.modules.zpool.create_file_vdev(size, *vdevs)**

Changed in version 2016.3.0.

Creates file based virtual devices for a zpool

**vdevs** is a list of full paths for mkfile to create

**CLI Example:**

```python
salt '*' zpool.create_file_vdev 7g /path/to/vdev1 [...] properties="{'property1': 'value1', 'property2': 'value2'}"
```

**Note:** Depending on file size, the above command may take a while to return.

**salt.modules.zpool.destroy(zpool, force=False)**

Changed in version 2016.3.0.

Destroys a storage pool

**zpool** [string] name of storage pool

**force** [boolean] force destroy of pool

**CLI Example:**

```python
salt '*' zpool.destroy myzpool
```

**salt.modules.zpool.detach(zpool, device)**

Changed in version 2016.3.0.

Detach specified device to zpool
zpool [string] name of storage pool
device [string] device to detach

CLI Example:
salt '*' zpool.detach myzpool /path/to/vdev1

salt.modules.zpool.exists(zpool)
Check if a ZFS storage pool is active
zpool [string] name of storage pool

CLI Example:
salt '*' zpool.exists myzpool

salt.modules.zpool.export(*pools, **kwargs)
New in version 2015.5.0.
Changed in version 2016.3.0.
Export storage pools
pools [string] one or more storage pools to export
force [boolean] force export of storage pools

CLI Example:
salt '*' zpool.export myzpool ... [force=True|False]
salt '*' zpool.export myzpool2 myzpool2 ... [Force=True|False]

salt.modules.zpool.get(zpool, prop=None, show_source=False)
New in version 2016.3.0.
Retrieves the given list of properties
zpool [string] name of storage pool
prop [string] optional name of property to retrieve
show_source [boolean] show source of property

CLI Example:
salt '*' zpool.get myzpool

salt.modules.zpool.healthy()
New in version 2016.3.0.
Check if all zpools are healthy

CLI Example:
salt '*' zpool.healthy

salt.modules.zpool.history(zpool=None, internal=False, verbose=False)
New in version 2016.3.0.
Displays the command history of the specified pools or all pools if no pool is specified
zpool [string] optional storage pool
internal [boolean] toggle display of internally logged ZFS events
verbose [boolean] toggle display of the user name, the hostname, and the zone in which the operation was performed

CLI Example:
salt '*' zpool.upgrade myzpool
salt.modules.zpool.import_(zpool=None, new_name=None, **kwargs)

New in version 2015.5.0.

Import storage pools or list pools available for import

zpool [string] optional name of storage pool
new_name [string] optional new name for the storage pool
mntopts [string] comma-separated list of mount options to use when mounting datasets within the pool.
force [boolean] forces import, even if the pool appears to be potentially active.
altroot [string] equivalent to `"-o cachefile=none,altroot=root"`
dir [string] searches for devices or files in dir, multiple dirs can be specified as follows:: dir="dir1,dir2"
no_mount [boolean] import the pool without mounting any file systems.
only_destroyed [boolean] imports destroyed pools only. this also sets force=True.
properties [dict] additional pool properties

Note: Zpool properties can be specified at the time of creation of the pool by passing an additional argument called `"properties"` and specifying the properties with their respective values in the form of a python dictionary:

```
properties="{"property1": 'value1', 'property2': 'value2'}"
```

CLI Example:

```
salt '*' zpool.import [force=True|False]
salt '*' zpool.import myzpool [mynewzpool] [force=True|False]
salt '*' zpool.import myzpool dir="/tmp"
```

salt.modules.zpool.iostat(zpool=None, sample_time=0)

Changed in version 2016.3.0.

Display I/O statistics for the given pools

zpool [string] optional name of storage pool
sample_time [int] seconds to capture data before output

CLI Example:

```
salt '*' zpool.iostat myzpool
```

salt.modules.zpool.list_(properties='size, alloc, free, cap, frag, health', zpool=None)

New in version 2015.5.0.

Changed in version 2016.3.0.

Return information about (all) storage pools

zpool [string] optional name of storage pool
properties [string] comma-separated list of properties to list

Note: the `name' property will always be included, the `frag' property will get removed if not available

zpool [string] optional zpool

Note: multiple storage pool can be provided as a space separated list

CLI Example:
salt '*' zpool.list

salt.modules.zpool.offline(zpool, 'vdevs, **kwargs)
    New in version 2015.5.0.
    Changed in version 2016.3.0.
    Ensure that the specified devices are offline

    Warning: By default, the OFFLINE state is persistent. The device remains offline when the system is rebooted. To temporarily take a device offline, use temporary=True.

    zpool [string] name of storage pool
    vdevs [string] one or more devices
    temporary [boolean] enable temporarily offline

    CLI Example:
    salt '*' zpool.offline myzpool /path/to/vdev1 [...] [temporary=True|False]

salt.modules.zpool.online(zpool, 'vdevs, **kwargs)
    New in version 2015.5.0.
    Changed in version 2016.3.0.
    Ensure that the specified devices are online

    zpool [string] name of storage pool
    vdevs [string] one or more devices
    expand [boolean] Expand the device to use all available space.

    Note: If the device is part of a mirror or raidz then all devices must be expanded before the new space will become available to the pool.

    CLI Example:
    salt '*' zpool.online myzpool /path/to/vdev1 [...] 

salt.modules.zpool.reguid(zpool)
    New in version 2016.3.0.
    Generates a new unique identifier for the pool

    Warning: You must ensure that all devices in this pool are online and healthy before performing this action.

    zpool [string] name of storage pool

    CLI Example:
    salt '*' zpool.reguid myzpool

salt.modules.zpool.reopen(zpool)
    New in version 2016.3.0.
    Reopen all the vdevs associated with the pool

    zpool [string] name of storage pool
CLI Example:

```
salt '*' zpool.reopen myzpool
```

```
salt.modules.zpool.replace(zpool, old_device, new_device=None, force=False)
```

Changed in version 2016.3.0.
Replaces old_device with new_device.

**Note:** This is equivalent to attaching new_device, waiting for it to resilver, and then detaching old_device.
The size of new_device must be greater than or equal to the minimum size of all the devices in a mirror or raidz configuration.

```
zpool [string] name of storage pool
old_device [string] old device to replace
new_device [string] optional new device
force [boolean] Forces use of new_device, even if its appears to be in use.
```

CLI Example:

```
salt '*' zpool.replace myzpool /path/to/vdev1 /path/to/vdev2
```

```
salt.modules.zpool.scrub(zpool, stop=False)
```

Changed in version 2016.3.0.
Scrub a storage pool
```
zpool [string] name of storage pool
stop [boolean] if true, cancel ongoing scrub
```

CLI Example:

```
salt '*' zpool.scrub myzpool
```

```
salt.modules.zpool.set(zpool, prop, value)
```

New in version 2016.3.0.
Sets the given property on the specified pool
```
zpool [string] name of storage pool
prop [string] name of property
value [string] value to set property to
```

CLI Example:

```
salt '*' zpool.set myzpool readonly yes
```

```
salt.modules.zpool.status(zpool=None)
```

Changed in version 2016.3.0.
Return the status of the named zpool
```
zpool [string] optional name of storage pool
```

CLI Example:

```
salt '*' zpool.status myzpool
```

```
salt.modules.zpool.upgrade(zpool=None, version=None)
```

New in version 2016.3.0.
Enables all supported features on the given pool
Warning: Once this is done, the pool will no longer be accessible on systems that do not support feature flags. See zpool-features(5) for details on compatibility with systems that support feature flags, but do not support all features enabled on the pool.

zpool [string] optional storage pool, applies to all otherwise
version [int] version to upgrade to, if unspecified upgrade to the highest possible

CLI Example:
salt '*' zpool.upgrade myzpool

19.9.461 salt.modules.zypper

Package support for openSUSE via the zypper package manager

depends

• rpm Python module. Install with zypper install rpm-python

Important: If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to 'pkg.install' is not available), see here.

class salt.modules.zypperWildcard(zypper)
New in version 2017.7.0.

Converts string wildcard to a zypper query. .. rubric:: Example

```
'1.2.3.4*' is `1.2.3.4.whatever.is.here' and is equal to: `1.2.3.4 >= and < 1.2.3.5'
```

Parameters ptn -- Pattern

Returns Query range

Z_OP = ['<', `<=', `=', `>=', `>']

salt.modules.zypper.add_lock(packages, **kwargs)

Add a package lock. Specify packages to lock by exact name.

CLI Example:
salt '*' pkg.add_lock <package name>
salt '*' pkg.add_lock <package1>,<package2>,<package3>
salt '*' pkg.add_lock pkgs='["foo", "bar"]'

salt.modules.zypper.clean_locks()

Remove unused locks that do not currently (with regard to repositories used) lock any package.

CLI Example:
salt '*' pkg.clean_locks

salt.modules.zypper.del_repo(repo)

Delete a repo.

CLI Examples:
salt '*' pkg.del_repo alias
salt.modules.zypper.diff('paths')
Return a formatted diff between current files and original in a package. NOTE: this function includes all files
(configuration and not), but does not work on binary content.

Parameters
path -- Full path to the installed file

Returns
Difference string or raises and exception if examined file is binary.

CLI example:
```
salt '*' pkg.diff /etc/apache2/httpd.conf /etc/sudoers
```

salt.modules.zypper.download('packages', **kwargs)
Download packages to the local disk.

refresh force a refresh if set to True. If set to False (default) it depends on zypper if a refresh is executed.

CLI example:
```
salt '*' pkg.download httpd
salt '*' pkg.download httpd postfix
```

salt.modules.zypper.file_dict('packages')
List the files that belong to a package, grouped by package. Not specifying any packages will return a list of
every file on the system's rpm database (not generally recommended).

CLI Examples:
```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

salt.modules.zypper.file_list('packages')
List the files that belong to a package. Not specifying any packages will return a list of every file on the
system's rpm database (not generally recommended).

CLI Examples:
```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

salt.modules.zypper.get_repo(repo, **kwargs)
Display a repo.

CLI Example:
```
salt '*' pkg.get_repo alias
```

salt.modules.zypper.info_available('names', **kwargs)
Return the information of the named package available for the system.

refresh force a refresh if set to True (default). If set to False it depends on zypper if a refresh is executed or not.

CLI example:
```
salt '*' pkg.info_available <package1>
salt '*' pkg.info_available <package1> <package2> <package3> ...
```

salt.modules.zypper.info_installed('names', **kwargs)
Return the information of the named package(s), installed on the system.

Parameters
- names -- Names of the packages to get information about.
• **attr** -- Comma-separated package attributes. If no `attr` is specified, all available attributes returned.
  **Valid attributes are:** version, vendor, release, build_date, build_date_time_t, install_date, install_date_time_t, build_host, group, source_rpm, arch, epoch, size, license, signature, packager, url, summary, description.

• **errors** -- Handle RPM field errors. If `ignore` is chosen, then various mistakes are simply ignored and omitted from the texts or strings. If `report` is chosen, then a field with a mistake is not returned, instead a `N/A (broken)' (not available, broken) text is placed.
  **Valid attributes are:** ignore, report

CLI example:
```
salt '*' pkg.info_installed <package1>
salt '*' pkg.info_installed <package1> <package2> <package3> ...
salt '*' pkg.info_installed <package1> <package2> <package3> ...  
   attr=version,vendor
salt '*' pkg.info_installed <package1> <package2> <package3> ...  
   attr=version,vendor
salt '*' pkg.info_installed <package1> <package2> <package3> ...  
   attr=version,vendor errors=ignore
salt '*' pkg.info_installed <package1> <package2> <package3> ...  
   attr=version,vendor errors=report
```

```
salt.modules.zypper.install(name=None, refresh=False, fromrepo=None, pkgs=None, sources=None, downloadonly=None, skip_verify=False, ignore_repo_failure=False, **kwargs)
```

Changed in version 2015.8.12,2016.3.3,2016.11.0: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any zypper commands spawned by Salt when the salt-minion service is restarted. (see `KillMode` in the `systemd.kill(5)` manpage for more information). If desired, usage of `systemd-run(1)` can be suppressed by setting a `config` option called `systemd.scope`, with a value of `False` (no quotes).

Install the passed package(s), add refresh=True to force a `zypper refresh` before package is installed.

**name** The name of the package to be installed. Note that this parameter is ignored if either `pkgs` or `sources` is passed. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the `sources` option.

CLI Example:
```
salt '*' pkg.install <package name>
```

**refresh** force a refresh if set to True. If set to False (default) it depends on zypper if a refresh is executed.

**fromrepo** Specify a package repository to install from.

**downloadonly** Only download the packages, do not install.

**skip_verify** Skip the GPG verification check (e.g., `--no-gpg-checks`)

**version** Can be either a version number, or the combination of a comparison operator (`<`, `>`, `<=`, `>=`, `=`) and a version number (ex. `>1.2.3-4`). This parameter is ignored if `pkgs` or `sources` is passed.

Multiple Package Installation Options:

**pkgs** A list of packages to install from a software repository. Must be passed as a python list. A specific version number can be specified by using a single-element dict representing the package and its version. As with the `version` parameter above, comparison operators can be used to target a specific version of a package.

CLI Examples:
```
salt '*' pkg.install pkgs='["foo", "bar"]'
salt '*' pkg.install pkgs='["foo", {"bar": "1.2.3-4"}]
salt '*' pkg.install pkgs='["foo", {"bar": "<1.2.3-4"}]
```
Salt Documentation, Release 2017.7.8

sources A list of RPM packages to install. Must be passed as a list of dicts, with the keys being package
names, and the values being the source URI or local path to the package.
CLI Example:
salt '*' pkg.install sources='[{"foo": "salt://foo.rpm"},{"bar": "salt://bar.
,→rpm"}]'

ignore_repo_failure Zypper returns error code 106 if one of the repositories are not available for various
reasons. In case to set strict check, this parameter needs to be set to True. Default: False.
Returns a dict containing the new package names and versions:
{'<package>': {'old': '<old-version>',
'new': '<new-version>'}}

salt.modules.zypper.latest_version(*names, **kwargs)
Return the latest version of the named package available for upgrade or installation. If more than one package
name is specified, a dict of name/version pairs is returned.
If the latest version of a given package is already installed, an empty dict will be returned for that package.
refresh force a refresh if set to True (default). If set to False it depends on zypper if a refresh is executed or
not.
CLI example:
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...

salt.modules.zypper.list_downloaded()
New in version 2017.7.0.
List prefetched packages downloaded by Zypper in the local disk.
CLI example:
salt '*' pkg.list_downloaded

salt.modules.zypper.list_installed_patches()
New in version 2017.7.0.
List installed advisory patches on the system.
CLI Examples:
salt '*' pkg.list_installed_patches

salt.modules.zypper.list_installed_patterns()
List installed paerns on the system.
CLI Examples:
salt '*' pkg.list_installed_patterns

salt.modules.zypper.list_locks()
List current package locks.
Return a dict containing the locked package with aributes:
{'<package>': {'case_sensitive': '<case_sensitive>',
'match_type': '<match_type>'
'type': '<type>'}}

19.9. execution modules

2407


CLI Example:

```
salt '*' pkg.list_locks
```

### `salt.modules.zypper.list_patches(refresh=False)`

List all known advisory patches from available repos.

- **refresh** force a refresh if set to True. If set to False (default) it depends on zypper if a refresh is executed.

CLI Examples:

```
salt '*' pkg.list_patches
```

### `salt.modules.zypper.list_patterns(refresh=False)`

List all known patterns from available repos.

- **refresh** force a refresh if set to True. If set to False (default) it depends on zypper if a refresh is executed.

CLI Examples:

```
salt '*' pkg.list_patterns
```

### `salt.modules.zypper.list_pkgs(versions_as_list=False, **kwargs)`

List the packages currently installed as a dict with versions as a comma separated string:

```
{'<package_name>': '<version>[,<version>...]'}
```

- **versions_as_list:** If set to true, the versions are provided as a list
  
  ```
  {'<package_name>': ['<version>', '<version>']}
  ```

- **removed:** not supported
- **purge_desired:** not supported

CLI Example:

```
salt '*' pkg.list_pkgs
```

### `salt.modules.zypper.list_products(all=False, refresh=False)`

List all available or installed SUSE products.

- **all** List all products available or only installed. Default is False.
- **refresh** force a refresh if set to True. If set to False (default) it depends on zypper if a refresh is executed.

Includes handling for OEM products, which read the OEM productline file and overwrite the release value.

CLI Examples:

```
salt '*' pkg.list_products
salt '*' pkg.list_products all=True
```

### `salt.modules.zypper.list_repo_pkgs(**args, **kwargs)`

New in version 2017.7.5, 2018.3.1.

Returns all available packages. Optionally, package names (and name globs) can be passed and the results will be filtered to packages matching those names. This is recommended as it speeds up the function considerably.

This function can be helpful in discovering the version or repo to specify in a `pkg.installed` state.

The return data will be a dictionary mapping package names to a list of version numbers, ordered from newest to oldest. If **repo** is set to True, then the return dictionary will contain repository names at the top level, and each repository will map packages to lists of version numbers. For example:
# With byrepo=False (default)

```bash
{
    'bash': ['4.3-83.3.1',
             '4.3-82.6'],
    'vim': ['7.4.326-12.1']
}
```

```bash
'OSS': {
    'bash': ['4.3-82.6'],
    'vim': ['7.4.326-12.1']
},
'OSS Update': {
    'bash': ['4.3-83.3.1']
}
```

```
fromrepo [None] Only include results from the specified repo(s). Multiple repos can be specified, comma-separated.
```

```
byrepo [False] When True, the return data for each package will be organized by repository.
```

**CLI Examples:**

```
salt '*' pkg.list_repo_pkgs
salt '*' pkg.list_repo_pkgs foo bar baz
salt '*' pkg.list_repo_pkgs 'python2-*' byrepo=True
salt '*' pkg.list_repo_pkgs 'python2-*' fromrepo='OSS Updates'
```

```
salt.modules.zypper.list_repos()
```

Lists all repos.

**CLI Example:**

```
salt '*' pkg.list_repos
```

```
salt.modules.zypper.list_upgrades(refresh=True, **kwargs)
```

List all available package upgrades on this system

**refresh** force a refresh if set to True (default). If set to False it depends on zypper if a refresh is executed.

**CLI Example:**

```
salt '*' pkg.list_upgrades
```

```
salt.modules.zypper.mod_repo(repo, **kwargs)
```

Modify one or more values for a repo. If the repo does not exist, it will be created, so long as the following values are specified:

- **repo or alias** alias by which Zypper refers to the repo
- **url, mirrorlist or baseurl** the URL for Zypper to reference
- **enabled** Enable or disable (True or False) repository, but do not remove if disabled.
- **refresh** Enable or disable (True or False) auto-refresh of the repository.
- **cache** Enable or disable (True or False) RPM files caching.
- **gpgcheck** Enable or disable (True or False) GPG check for this repository.
- **gpgautoimport** [False] If set to True, automatically trust and import public GPG key for the repository. Key/Value pairs may also be removed from a repo's configuration by setting a key to a blank value. Bear in mind that a name cannot be deleted, and a URL can only be deleted if a **mirrorlist** is specified (or vice versa).

**CLI Examples:**
salt 'salt '*' pkg.mod_repo alias alias=new_alias
salt 'salt '*' pkg.mod_repo alias url= mirrorlist=http://host.com/

salt.modules.zypper.modified('packages', '**flags')
List the modified files that belong to a package. Not specifying any packages will return a list of all modified files on the system’s RPM database.

New in version 2015.5.0.
Filtering by flags (True or False):
size Include only files where size changed.
mode Include only files which file's mode has been changed.
checksum Include only files which MD5 checksum has been changed.
device Include only files which major and minor numbers has been changed.
symlink Include only files which are symbolic link contents.
owner Include only files where owner has been changed.
group Include only files where group has been changed.
time Include only files where modification time of the file has been changed.
capabilities Include only files where capabilities differ or not. Note: supported only on newer RPM versions.

CLI Examples:
salt 'salt '*' pkg.modified
salt 'salt '*' pkg.modified httpd
salt 'salt '*' pkg.modified httpd postfix
salt 'salt '*' pkg.modified httpd owner=True group=False

salt.modules.zypper.owner('paths')
Return the name of the package that owns the file. Multiple file paths can be passed. If a single path is passed, a string will be returned, and if multiple paths are passed, a dictionary of file/package name pairs will be returned.

If the file is not owned by a package, or is not present on the minion, then an empty string will be returned for that path.

CLI Examples:
salt 'salt '*' pkg.owner /usr/bin/apachectl
salt 'salt '*' pkg.owner /usr/bin/apachectl /etc/httpd/conf/httpd.conf

salt.modules.zypper.purge(name=None, pkgs=None, **kwargs)
Changed in version 2015.8.12,2016.3.3,2016.11.0: On minions running systemd>=205, systemd-run(1) is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any zypper commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Recursively remove a package and all dependencies which were installed with it, this will call a zypper -n remove -u
name The name of the package to be deleted.

Multiple Package Options:
.pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.
New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'

salt.modules.zypper.refresh_db()

Force a repository refresh by calling zypper refresh --force, return a dict:

```
{'<database name>': Bool}
```

CLI Example:

```
salt '*' pkg.refresh_db
```

salt.modules.zypper.remove(name=None, pkgs=None, **kwargs)

Changed in version 2015.8.12,2016.3.3,2016.11.0: On minions running systemd>=205, systemd-run(1) is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any zypper commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Remove packages with zypper -n remove

name The name of the package to be deleted.
Multiple Package Options:
pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.
New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

salt.modules.zypper.remove_lock(packages, **kwargs)

Remove specified package lock.

CLI Example:

```
salt '*' pkg.remove_lock <package name>
salt '*' pkg.remove_lock <package1>,<package2>,<package3>
salt '*' pkg.remove_lock pkgs='["foo", "bar"]'
```

salt.modules.zypper.search(criteria, refresh=False)

List known packages, available to the system.

refresh force a refresh if set to True. If set to False (default) it depends on zypper if a refresh is executed.

CLI Examples:

```
salt '*' pkg.search <criteria>
```

salt.modules.zypper.upgrade(refresh=True, dryrun=False, dist_upgrade=False, fromrepo=None, novendorchange=False, skip_verify=False, **kwargs)

Changed in version 2015.8.12,2016.3.3,2016.11.0: On minions running systemd>=205, systemd-run(1) is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any zypper commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

CLI Example:

```
salt '*' pkg.upgrade <package name>
salt '*' pkg.upgrade <package1>,<package2>,<package3>
salt '*' pkg.upgrade pkgs='["foo", "bar"]'
```

19.9. execution modules
of `systemd-run(1)` can be suppressed by setting a config option called `systemd.scope`, with a value of `False` (no quotes).

Run a full system upgrade, a zypper upgrade

`refresh` force a refresh if set to True (default). If set to False it depends on zypper if a refresh is executed.

`dryrun` If set to True, it creates a debug solver log file and then perform a dry-run upgrade (no changes are made). Default: False

`dist_upgrade` Perform a system dist-upgrade. Default: False

`fromrepo` Specify a list of package repositories to upgrade from. Default: None

`novendorchange` If set to True, no allow vendor changes. Default: False

`skip_verify` Skip the GPG verification check (e.g., `--no-gpg-checks`)

Returns a dictionary containing the changes:

```
{'<package>': {'old': '<old-version>', 'new': '<new-version>'}}
```

**CLI Example:**

```
salt '* pkg.upgrade
salt '* pkg.upgrade dist-upgrade=True fromrepo=['"MyRepoName"']
salt novendorchange=True
salt '* pkg.upgrade dist-upgrade=True dryrun=True
```

`salt.modules.zypper.upgrade_available(name, **kwargs)`
Check whether or not an upgrade is available for a given package

`refresh` force a refresh if set to True (default). If set to False it depends on zypper if a refresh is executed or not.

**CLI Example:**

```
salt '* pkg.upgrade_available <package name>
```

`salt.modules.zypper.verify('names', **kwargs)`
Runs an rpm -Va on a system, and returns the results in a dict

Files with an attribute of config, doc, ghost, license or readme in the package header can be ignored using the `ignore_types` keyword argument

**CLI Example:**

```
salt '* pkg.verify
salt '* pkg.verify httpd
salt '* pkg.verify 'httpd postfix'
salt '* pkg.verify 'httpd postfix' ignore_types=['config','doc']
```

`salt.modules.zypper.version('names', **kwargs)`
Returns a string representing the package version or an empty dict if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

**CLI Example:**

```
salt '* pkg.version <package name>
salt '* pkg.version <package1> <package2> <package3> ...
```

`salt.modules.zypper.version_cmp(ver1, ver2, ignore_epoch=False)`
New in version 2015.5.4.

Do a cmp-style comparison on two packages. Return -1 if ver1 < ver2, 0 if ver1 == ver2, and 1 if ver1 > ver2. Return None if there was a problem making the comparison.
ignore_epoch  [False] Set to True to ignore the epoch when comparing versions

New in version 2015.8.10,2016.3.2.
CLI Example:

```
salt '*' pkg.version_cmp '0.2-001' '0.2.0.1-002'
```

19.10 netapi modules

19.10.1 rest_cherrypy

A REST API for Salt

New in version 2014.7.0.

depends
- CherryPy Python module. Version 3.2.3 is currently recommended when SSL is enabled, since this version worked the best with SSL in internal testing. Versions 3.2.3 - 4.x can be used if SSL is not enabled. Be aware that there is a known SSL error introduced in version 3.2.5. The issue was reportedly resolved with CherryPy milestone 3.3, but the patch was committed for version 3.6.1.

optdepends
- ws4py Python module for websockets support.

client_libraries
- Java: https://github.com/SUSE/salt-netapi-client
- Python: https://github.com/saltstack/pepper

setup

All steps below are performed on the machine running the Salt Master daemon. Configuration goes into the Master configuration file.

1. Install salt-api. (This step varies between OS and Linux distros. Some package systems have a split package, others include salt-api in the main Salt package. Ensure the salt-api --version output matches the salt --version output.)

2. Install CherryPy. (Read the version caveat in the section above.)

   Using a secure HTTPS connection is strongly recommended since Salt auth authentication credentials will be sent over the wire.

   (a) Install the PyOpenSSL package.

   (b) Generate a self-signed certificate using the create_self_signed_cert() execution function.

```
salt-call --local tls.create_self_signed_cert
```

4. Edit the master config to create at least one external auth user or group following the full external auth instructions.

5. Edit the master config with the following production-ready example to enable the rest_cherrypy module. (Adjust cert paths as needed, or disable SSL (not recommended!)).

```
19.10. netapi modules
```
```yaml
rest_cherrypy:
  port: 8000
  ssl_crt: /etc/pki/tls/certs/localhost.crt
  ssl_key: /etc/pki/tls/certs/localhost.key
```

6. Restart the salt-master daemon.
7. Start the salt-api daemon.

**configuration** All available configuration options are detailed below. These settings configure the CherryPy HTTP server and do not apply when using an external server such as Apache or Nginx.

**port** Required

The port for the webserver to listen on.

**host** [0.0.0.0] The socket interface for the HTTP server to listen on.

**debug** [False] Starts the web server in development mode. It will reload itself when the underlying code is changed and will output more debugging info.

**log_access_file** Path to a file to write HTTP access logs.

New in version 2016.11.0.

**log_error_file** Path to a file to write HTTP error logs.

New in version 2016.11.0.

**ssl_crt** The path to a SSL certificate. (See below)

**ssl_key** The path to the private key for your SSL certificate. (See below)

**ssl_chain** (Optional when using PyOpenSSL) the certificate chain to pass to `Context.load_verify_locations`.

**disable_ssl** A flag to disable SSL. Warning: your Salt authentication credentials will be sent in the clear!

**webhook_disable_auth** [False] The Webhook URL requires authentication by default but external services cannot always be configured to send authentication. See the Webhook documentation for suggestions on securing this interface.

**webhook_url** [/hook] Configure the URL endpoint for the Webhook entry point.

**thread_pool** [100] The number of worker threads to start up in the pool.

**socket_queue_size** [30] Specify the maximum number of HTTP connections to queue.

**expire_responses** [True] Whether to check for and kill HTTP responses that have exceeded the default timeout.

Deprecated since version 2016.11.9; 2017.7.3, Oxygen

The `expire_responses` configuration setting, which corresponds to the `timeout_monitor` setting in CherryPy, is no longer supported in CherryPy versions >= 12.0.0.

**max_request_body_size** [1048576] Maximum size for the HTTP request body.

**collect_stats** [False] Collect and report statistics about the CherryPy server

Reports are available via the Stats URL.

**static** A filesystem path to static HTML/JavaScript/CSS/image assets.

**static_path** [/static] The URL prefix to use when serving static assets out of the directory specified in the static setting.
enable_sessions [True] Enable or disable all endpoints that rely on session cookies. This can be useful to enforce only header-based authentication.

New in version 2017.7.0.

app [index.html] A filesystem path to an HTML file that will be served as a static file. This is useful for bootstrapping a single-page JavaScript app.

Warning! If you set this option to a custom web application, anything that uses cookie-based authentication is vulnerable to XSRF attacks. Send the custom X-Auth-Token header instead and consider disabling the enable_sessions setting.

Changed in version 2017.7.0: Add a proof-of-concept JavaScript single-page app.

app_path [/app] The URL prefix to use for serving the HTML file specified in the app setting. This should be a simple name containing no slashes.

Any path information after the specified path is ignored; this is useful for apps that utilize the HTML5 history API.

root_prefix [/] A URL path to the main entry point for the application. This is useful for serving multiple applications from the same URL.

Authentication

Authentication is performed by passing a session token with each request. Tokens are generated via the Login URL.

The token may be sent in one of two ways: as a custom header or as a session cookie. The latter is far more convenient for clients that support cookies.

- Include a custom header named X-Auth-Token.

For example, using curl:

```
curl -sSk https://localhost:8000/login \
-H 'Accept: application/x-yaml' \
-d username=saltdev \
-d password=saltdev \
-d eauth=auto
```

Copy the token value from the output and include it in subsequent requests:

```
curl -sSk https://localhost:8000 \
-H 'Accept: application/x-yaml' \
-H 'X-Auth-Token: 697adbdc8fe971d09ae4c2a3add7248859c87079'\ 
-d client=local \
-d tgt='*' \
-d fun=test.ping
```

- Sent via a cookie. This option is a convenience for HTTP clients that automatically handle cookie support (such as browsers).

For example, using curl:

```
# Write the cookie file:
curl -sSk https://localhost:8000/login \
-c ~/cookies.txt \
-H 'Accept: application/x-yaml' \
-d username=saltdev \
```
Another example using the **requests** library in Python:

```python
>>> import requests
>>> session = requests.Session()
>>> session.post('http://localhost:8000/login', json={
    'username': 'saltdev',
    'password': 'saltdev',
    'eauth': 'auto',
})
<Response [200]>
>>> resp = session.post('http://localhost:8000', json=[[
    'client': 'local',
    'tgt': '*',
    'fun': 'test.arg',
    'arg': ['foo', 'bar'],
    'kwarg': {'baz': 'Baz!'},
]})
>>> resp.json()
[u'return': [...snip...]]
```

**See also:**

You can bypass the session handling via the **Run URL**.

**Usage**

This interface directly exposes Salt's **Python API**. Everything possible at the CLI is possible through the Python API. Commands are executed on the Salt Master.

The root URL (`/`) is RPC-like in that it accepts instructions in the request body for what Salt functions to execute, and the response contains the result of those function calls.

For example:

```bash
% curl -sSi https://localhost:8000 -H 'Content-type: application/json' -d '[{
    "client": "local",
    "tgt": ",",
    "fun": "test.ping"
}]
HTTP/1.1 200 OK
Content-Type: application/json
[...snip...]
```
The request body must be an array of commands. Use this workflow to build a command:

1. Choose a client interface.
2. Choose a function.
3. Fill out the remaining parameters needed for the chosen client.

The client field is a reference to the main Python classes used in Salt's Python API. Read the full Client APIs documentation, but in short:

- ``local`` uses `LocalClient` which sends commands to Minions. Equivalent to the `salt` CLI command.
- ``runner`` uses `RunnerClient` which invokes runner modules on the Master. Equivalent to the `salt-run` CLI command.
- ``wheel`` uses `WheelClient` which invokes wheel modules on the Master. Wheel modules do not have a direct CLI equivalent but they typically manage Master-side resources such as state files, pillar files, the Salt config files, and the key wheel module exposes similar functionality as the `salt-key` CLI command.

Most clients have variants like synchronous or asynchronous execution as well as others like batch execution. See the full list of client interfaces.

Each client requires different arguments and sometimes has different syntax. For example, `LocalClient` requires the `tgt` argument because it forwards the command to Minions and the other client interfaces do not. `LocalClient` also takes `arg` (array) and `kwarg` (dictionary) arguments because these values are sent to the Minions and used to execute the requested function there. `RunnerClient` and `WheelClient` are executed directly on the Master and thus do not need or accept those arguments.

Read the method signatures in the client documentation linked above, but hopefully an example will help illustrate the concept. This example causes Salt to execute two functions -- the `test.arg` execution function using `LocalClient` and the `test.arg` runner function using `RunnerClient`; note the different structure for each command. The results for both are combined and returned as one response.

```bash
% curl -b ~/cookies.txt -sSi localhost:8000 -H 'Content-type: application/json' -d '{
  {
    "client": "local",
    "tgt": "*",
    "fun": "test.arg",
    "arg": ["positional arg one", "positional arg two"],
    "kwarg": {
      "keyword arg one": "Hello from a minion",
      "keyword arg two": "Hello again from a minion"
    }
  },
  {
    "client": "runner",
    "fun": "test.arg",
    "keyword arg one": "Hello from a master",
    "keyword arg two": "Runners do not support positional args"
  }
}
HTTP/1.1 200 OK
[...snip...]
```
One more example, this time with more commonly used functions:

curl -b /tmp/cookies.txt -ssSi localhost:8000 -H 'Content-type: application/json' -d '[:
    {
      "client": "local",
      "tgt": "+",
      "fun": "state.sls",
      "kwarg": {
        "mods": "apache",
        "pillar": {
          "lookup": {
            "wwwdir": "/srv/httpd/htdocs"
          }
        }
      }
    },
    {
      "client": "runner",
      "fun": "cloud.create",
      "provider": "my-ec2-provider",
      "instances": "my-centos-6",
      "image": "ami-1624987f",
      "delvol_on_destroy", true
    }]
]
HTTP/1.1 200 OK
[...snip...]
"return": [
Content negotiation

This REST interface is flexible in what data formats it will accept as well as what formats it will return (e.g., JSON, YAML, urlencoded).

- Specify the format of data in the request body by including the Content-Type header.
- Specify the desired data format for the response body with the Accept header.

We recommend the JSON format for most HTTP requests. urlencoded data is simple and cannot express complex data structures -- and that is often required for some Salt commands, such as starting a state run that uses Pillar data. Salt's CLI tool can reformat strings passed in at the CLI into complex data structures, and that behavior also works via salt-api, but that can be brittle and since salt-api can accept JSON it is best just to send JSON.

Here is an example of sending urlencoded data:

```bash
curl -sSik https://localhost:8000 \
   -b ~/cookies.txt \
   -d client=runner \
   -d fun='jobs.lookup_jid' \
   -d jid='20150129182456704682'
```

urlencoded data caveats

- Only a single command may be sent per HTTP request.
- Repeating the arg parameter multiple times will cause those parameters to be combined into a single list.

Note, some popular frameworks and languages (notably jQuery, PHP, and Ruby on Rails) will automatically append empty brackets onto repeated query string parameters. E.g., ?foo[]=fooone&foo[]=footwo. This is not supported; send ?foo=fooone&foo=footwo instead, or send JSON or YAML.

A note about curl

The -d flag to curl does not automatically urlencode data which can affect passwords and other data that contains characters that must be encoded. Use the --data-urlencode flag instead. E.g:

```bash
curl -ksi http://localhost:8000/login \
   -H "Accept: application/json" \
   -d username='myapiuser' \
   --data-urlencode password='1234+' \
   -d eauth='pam'
```
Deployment

The rest_cherrypy netapi module is a standard Python WSGI app. It can be deployed one of two ways.

**salt-api using the CherryPy server**

The default configuration is to run this module using **salt-api** to start the Python-based CherryPy server. This server is lightweight, multi-threaded, encrypted with SSL, and should be considered production-ready.

**Using a WSGI-compliant web server**

This module may be deployed on any WSGI-compliant server such as Apache with mod_wsgi or Nginx with FastCGI, to name just two (there are many).

Note, external WSGI servers handle URLs, paths, and SSL certs directly. The rest_cherrypy configuration options are ignored and the salt-api daemon does not need to be running at all. Remember Salt authentication credentials are sent in the clear unless SSL is being enforced!

An example Apache virtual host configuration:

```xml
<VirtualHost *:80>
    ServerName example.com
    ServerAlias *.example.com

    ServerAdmin webmaster@example.com

    LogLevel warn
    ErrorLog /var/www/example.com/logs/error.log
    CustomLog /var/www/example.com/logs/access.log combined

    DocumentRoot /var/www/example.com/htdocs

    WSGIScriptAlias / /path/to/salt/netapi/rest_cherrypy/wsgi.py
</VirtualHost>
```

**REST URI Reference**

- /
- /login
- /logout
- /minions
- /jobs
- /run
- /events
- /hook
- /keys
The primary entry point to Salt's REST API

GET()
An explanation of the API with links of where to go next

GET / Request Headers
- Accept -- the desired response format.

Status Codes
- 200 -- success
- 401 -- authentication required
- 406 -- requested Content-Type not available

Example request:
```
curl -i localhost:8000
```

Example response:
```
HTTP/1.1 200 OK
Content-Type: application/json
```

POST
Mock out specified imports.
This allows autodoc to do its thing without having oodles of req'd installed libs. This doesn't work with import * imports.
This Mock class can be configured to return a specific values at specific names, if required.
http://read-the-docs.readthedocs.org/en/latest/faq.html#i-get-import-errors-on-libraries-that-depend-on-c-modules

/login

class salt.netapi.rest_cherrypy.app.Login(*args, **kwargs)
Log in to receive a session token

Authentication information.

GET()
Present the login interface

GET /login
An explanation of how to log in.

Status Codes
Example request:

curl -i localhost:8000/login

GET /login HTTP/1.1
Host: localhost:8000
Accept: text/html

Example response:

HTTP/1.1 200 OK
Content-Type: text/html

POST(**kwargs)

Authenticate against Salt's eauth system

POST /login

Request Headers
  - X-Auth-Token -- a session token from Login.
  - Accept -- the desired response format.
  - Content-Type -- the format of the request body.

Form Parameters
  - eauth -- the eauth backend configured for the user
  - username -- username
  - password -- password

Status Codes
  - 200 -- success
  - 401 -- authentication required
  - 406 -- requested Content-Type not available

Example request:

curl -si localhost:8000/login \
  -c ~/cookies.txt \
  -H "Accept: application/json" \
  -H "Content-type: application/json" \
  -d '{
      "username": "saltuser",
      "password": "saltuser",
      "eauth": "auto"
  }'

POST / HTTP/1.1
Host: localhost:8000
Content-Length: 42
Content-Type: application/json
Accept: application/json

{"username": "saltuser", "password": "saltuser", "eauth": "auto"}

Example response:
HTTP/1.1 200 OK
Content-Type: application/json
Content-Length: 206
X-Auth-Token: 6d1b722e
Set-Cookie: session_id=6d1b722e; expires=Sat, 17 Nov 2012 03:23:52 GMT; Path=/

{"return": {
    "token": "6d1b722e",
    "start": 1363805943.776223,
    "expire": 1363849143.776224,
    "user": "saltuser",
    "eauth": "pam",
    "perms": [
        "grains.*",
        "status.*",
        "sys.*",
        "test.*"
    ]
}}

/logout

class salt.netapi.rest_cherrypy.app.Logout
Class to remove or invalidate sessions

    POST()
    Destroy the currently active session and expire the session cookie

/minions

class salt.netapi.rest_cherrypy.app.Minions
Convenience URLs for working with minions

    GET(mid=None)
    A convenience URL for getting lists of minions or getting minion details

    GET /minions/(mid)
    Request Headers
    • X-Auth-Token -- a session token from Login.
    • Accept -- the desired response format.
    Status Codes
    • 200 -- success
    • 401 -- authentication required
    • 406 -- requested Content-Type not available

Example request:
curl -i localhost:8000/minions/ms-3

Example response:
POST(**kwargs)
Start an execution command and immediately return the job id

POST /minions
Request Headers
• X-Auth-Token -- a session token from Login.
• Accept -- the desired response format.
• Content-Type -- the format of the request body.

Response Headers
• Content-Type -- the format of the response body; depends on the Accept request header.

Status Codes
• 200 -- success
• 400 -- bad or malformed request
• 401 -- authentication required
• 406 -- requested Content-Type not available

Lowstate data describing Salt commands must be sent in the request body. The client option will be set to local_async().

Example request:

curl -sSi localhost:8000/minions \
  -b ~/cookies.txt \
  -H "Accept: application/x-yaml" \
  -d '[["tgt": ":", "fun": "status.diskusage"]]'

Example response:

HTTP/1.1 202 Accepted
Content-Length: 86
Content-Type: application/x-yaml

return:
- jid: '20130603122505459265'
  minions: [ms-4, ms-3, ms-2, ms-1, ms-0]
  _links:
    jobs:
      - href: /jobs/20130603122505459265
/jobs

class salt.netapi.rest_cherrypy.app.Jobs

GET(jid=None, timeout=``)
A convenience URL for getting lists of previously run jobs or getting the return from a single job

GET /jobs/(jid)
List jobs or show a single job from the job cache.

Request Headers
- X-Auth-Token -- a session token from Login.
- Accept -- the desired response format.

Status Codes
- 200 -- success
- 401 -- authentication required
- 406 -- requested Content-Type not available

Example request:

curl -i localhost:8000/jobs

GET /jobs HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml

Example response:

HTTP/1.1 200 OK
Content-Length: 165
Content-Type: application/x-yaml

return:
- '20121130104633606931':
  Arguments:
  - '3'
  Function: test.fib
  Target: jerry
  Target-type: glob

Example request:

curl -i localhost:8000/jobs/20121130104633606931

GET /jobs/20121130104633606931 HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml

Example response:

HTTP/1.1 200 OK
Content-Length: 73
Content-Type: application/x-yaml

info:
- Arguments:
Function: test.fib
Minions:
- jerry
Target: '*'
Target-type: glob
User: saltdev
jid: '20121130104633606931'
return:
- jerry:
  - 0
  - 1
  - 1
  - 2
  - 6.9141387939453125e-06

class salt.netapi.rest_cherrypy.app.Run
Run commands bypassing the normal session handling

salt-api does not enforce authorization, Salt's eauth system does that. Local/Runner/WheelClient all accept
username/password/eauth or token kwargs that are then checked by the eauth system. The session
mechanism in rest_cherrypy simply pairs a session with a Salt eauth token and then passes the token
kwarg in automatically.

If you already have a Salt eauth token, perhaps generated by the mk_token
function in the Auth Runner
module, then there is no reason to use sessions.
This endpoint accepts either a username, password, eauth trio, or a token kwarg and does not make
use of sessions at all.

POST (**kwargs)
Run commands bypassing the normal session handling Other than that this URL is identical to the root
URL (/).

POST /run
An array of lowstate data describing Salt commands must be sent in the request body.

Status Codes
• 200 -- success
• 400 -- bad or malformed request
• 401 -- authentication required
• 406 -- requested Content-Type not available

Example request:
curl -s$ localhost:8000/run \
-H 'Accept: application/x-yaml' \
-H 'Content-type: application/json' \
-d '[[
  "client": "local",
  "tgt": "*",
  "fun": "test.ping",
  "username": "saltdev",
  "password": "saltdev",}
"eauth": "auto"
}
]

Or using a Salt Eauth token:

curl -sS localhost:8000/run \
   -H 'Accept: application/x-yaml' \
   -H 'Content-type: application/json' \ 
   -d '[[
   "client": "local",
   "tgt": ":*",
   "fun": "test.ping",
   "token": "<salt eauth token here>"
   ]]
   

POST /run HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml
Content-Length: 75
Content-Type: application/json

[["client": "local", "tgt": ":*", "fun": "test.ping", "username": "saltdev", 
  "password": "saltdev", "eauth": "auto"]]

Example response:

HTTP/1.1 200 OK
Content-Length: 73
Content-Type: application/x-yaml

return:
- ms-0: true
- ms-1: true
- ms-2: true
- ms-3: true
- ms-4: true

The /run endpoint can also be used to issue commands using the salt-ssh subsystem.

When using salt-ssh, eauth credentials should not be supplied. Instead, authentication should be handled by the SSH layer itself. The use of the salt-ssh client does not require a salt master to be running. Instead, only a roster file must be present in the salt configuration directory.

All SSH client requests are synchronous.

Example SSH client request:

curl -sS localhost:8000/run \
   -H 'Accept: application/x-yaml' \
   -d client='ssh' \
   -d tgt="*" \
   -d fun='test.ping'

POST /run HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml
Content-Length: 75
Content-Type: application/x-www-form-urlencoded
client=ssh&tgt=*&fun=test.ping

Example SSH response:

```
return:
- silver:
  fun: test.ping
  fun_args: []
  id: silver
  jid: '20141203103525666185'
  retcode: 0
  return: true
  success: true
```

/events

class salt.netapi.rest_cherrypy.app.Events

Expose the Salt event bus

The event bus on the Salt master exposes a large variety of things, notably when executions are started on the master and also when minions ultimately return their results. This URL provides a real-time window into a running Salt infrastructure.

See also:

Events & Reactor

GET (token=None, salt_token=None)

An HTTP stream of the Salt master event bus

This stream is formatted per the Server Sent Events (SSE) spec. Each event is formatted as JSON.

**GET /events**

Status Codes

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

Query Parameters

- **token** -- optional parameter containing the token ordinarily supplied via the X-Auth-Token header in order to allow cross-domain requests in browsers that do not include CORS support in the EventSource API. E.g.,
  ```sh
curl -NsS localhost:8000/events?token=308650d
  ```
- **salt_token** -- optional parameter containing a raw Salt eauth token (not to be confused with the token returned from the /login URL). E.g.,
  ```sh
curl -NsS localhost:8000/events?salt_token=30742765
  ```

Example request:

```sh
curl -NsS localhost:8000/events
```

Example response:
Note, the tag field is not part of the spec. SSE compliant clients should ignore unknown fields. This addition allows non-compliant clients to only watch for certain tags without having to deserialize the JSON object each time.

HTTP/1.1 200 OK
Connection: keep-alive
Cache-Control: no-cache
Content-Type: text/event-stream;charset=utf-8
retry: 400
tag: salt/job/20130802115730568475/new
data: {'tag': 'salt/job/20130802115730568475/new', 'data': {'minions': ['ms-4', 'ms-3', 'ms-2', 'ms-1', 'ms-0']}}
tag: salt/job/20130802115730568475/ret/jerry
data: {'tag': 'salt/job/20130802115730568475/ret/jerry', 'data': {'jid': '20130802115730568475', 'return': True, 'retcode': 0, 'success': True, 'cmd': '_return', 'fun': 'test.ping', 'id': 'ms-1'}}

The event stream can be easily consumed via JavaScript:

```
var source = new EventSource('/events');
source.onopen = function() { console.info('Listening ...') }; 
source.onerror = function(err) { console.error(err) };
source.onmessage = function(message) {
    var saltEvent = JSON.parse(message.data);
    console.log(saltEvent.tag, saltEvent.data);
};
```

Note, the SSE stream is fast and completely asynchronous and Salt is very fast. If a job is created using a regular POST request, it is possible that the job return will be available on the SSE stream before the response for the POST request arrives. It is important to take that asynchrony into account when designing an application. Below are some general guidelines.

- Subscribe to the SSE stream _before_ creating any events.
- Process SSE events directly as they arrive and don’t wait for any other process to ```complete``` first (like an ajax request).
- Keep a buffer of events if the event stream must be used for synchronous lookups.
- Be cautious in writing Salt's event stream directly to the DOM. It is very busy and can quickly overwhelm the memory allocated to a browser tab.

A full, working proof-of-concept JavaScript application is available adjacent to this file. It can be viewed by pointing a browser at the /app endpoint in a running rest_cherrypy instance.

Or using CORS:

```
var source = new EventSource('/events?token=ecd589e4e01912cf3c4835afad73426dbb8db785', {withCredentials: true});
```

It is also possible to consume the stream via the shell.

Records are separated by blank lines; the data: and tag: prefixes will need to be removed manually before attempting to unserialize the JSON.

curl's -N flag turns off input buffering which is required to process the stream incrementally.

Here is a basic example of printing each event as it comes in:

```
curl -NsS localhost:8000/events |\  
   while IFS= read -r line ; do
```
Here is an example of using awk to filter events based on tag:

```
curl -NsS localhost:8000/events |\
    awk 'BEGIN { RS=""; FS="\\n" }\
        $1 ~ /^tag: salt/job/\[0-9]+/new$/ { print $0 }',
```

```
tag: salt/job/20140112010149808995/new
data: {"tag": "salt/job/20140112010149808995/new", "data": {"tgt_type": "glob ~", "jid": "20140112010149808995", "tgt": "jerry", "_stamp": "2014-01-12_01:01:49.809617", "user": "shouse", "arg": [], "fun": "test.ping", "minions":0 ~["jerry"]}}
tag: 20140112010149808995
data: {"tag": "20140112010149808995", "data": {"fun_args": [], "jid": "20140112010149808995", "return": true, "retcode": 0, "success": true, "cmd ~": "_return", "_stamp": "2014-01-12_01:01:49.819316", "fun": "test.ping", ~"id": "jerry"}}
```

Save the output and pipe it to awk to filter events based on tag:

```
echo $line
done
```

/hook

class salt.netapi.rest_cherrypy.app.Webhook
A generic web hook entry point that fires an event on Salt’s event bus.

External services can POST data to this URL to trigger an event in Salt. For example, Amazon SNS, Jenkins-CI or Travis-CI, or GitHub webhooks.

Note: Be mindful of security

Salt’s Reactor can run any code. A Reactor SLS that responds to a hook event is responsible for validating that the event came from a trusted source and contains valid data.

This is a generic interface and securing it is up to you!

This URL requires authentication however not all external services can be configured to authenticate. For this reason authentication can be selectively disabled for this URL. Follow best practices -- always use SSL, pass a secret key, configure the firewall to only allow traffic from a known source, etc.

The event data is taken from the request body. The Content-Type header is respected for the payload.

The event tag is prefixed with salt/netapi/hook and the URL path is appended to the end. For example, a POST request sent to /hook/mycompany/myapp/mydata will produce a Salt event with the tag salt/netapi/hook/mycompany/myapp/mydata.

The following is an example .travis.yml file to send notifications to Salt of successful test runs:

```
language: python
script: python -m unittest tests
after_success: |
    curl -sSk https://saltapi-url.example.com:8000/hook/travis/build/success
    -d branch="${TRAVIS_BRANCH}"
    -d commit="${TRAVIS_COMMIT}"
See also:

Events & Reactor, reactor

**POST**(*args, **kwargs*)

Fire an event in Salt with a custom event tag and data

**POST** /hook

Status Codes

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available
- **413** -- request body is too large

Example request:

```
curl -sS localhost:8000/hook
   -H 'Content-type: application/json'
   -d '{"foo": "Foo!", "bar": "Bar!"}'}
```

**POST** /hook HTTP/1.1
Host: localhost:8000
Content-Length: 16
Content-Type: application/json

{"foo": "Foo!", "bar": "Bar!"}

Example response:

```
HTTP/1.1 200 OK
Content-Length: 14
Content-Type: application/json

{"success": true}
```

As a practical example, an internal continuous-integration build server could send an HTTP POST request to the URL `https://localhost:8000/hook/mycompany/build/success` which contains the result of a build and the SHA of the version that was built as JSON. That would then produce the following event in Salt that could be used to kick off a deployment via Salt’s Reactor:

```
Event fired at Fri Feb 14 17:40:11 2014
*****************************************
Tag: salt/netapi/hook/mycompany/build/success
Data:
{"_stamp": '2014-02-14 17:40:11.440996',
 'headers': {
   'X-My-Secret-Key': 'F0fAgoQjIT@W',
   'Content-Length': '37',
   'Content-Type': 'application/json',
   'Host': 'localhost:8000',
   'Remote-Addr': '127.0.0.1'},
 'post': {'revision': 'aa22a3c4b2e7', 'result': True}}
```

Salt’s Reactor could listen for the event:

```
reactor:
 - salt/netapi/hook/mycompany/build/*/:
   - /srv/reactor/react_ci_builds.sls
```

19.10. netapi modules
And finally deploy the new build:

```python
{% set secret_key = data.get('headers', {}).get('X-My-Secret-Key') %}
{% set build = data.get('post', {}) %}

{% if secret_key == 'F0fAgoQjIT@W' and build.result == True %}
deploy_my_app:
  cmd.state.sls:
    - tgt: 'application*' 
    - arg:
      - myapp.deploy
    - kwarg:
      pillar:
        revision: {{ revision }}
{% endif %}
```

### /keys

class salt.netapi.rest_cherrypy.app.Keys
Convenience URLs for working with minion keys

New in version 2014.7.0.

These URLs wrap the functionality provided by the key wheel module functions.

**GET**(mid=None)
Show the list of minion keys or detail on a specific key

New in version 2014.7.0.

**GET /keys/(mid)**
List all keys or show a specific key

Status Codes
- 200 -- success
- 401 -- authentication required
- 406 -- requested Content-Type not available

**Example request:**

```
curl -i localhost:8000/keys
```

**GET /keys HTTP/1.1**
Host: localhost:8000
Accept: application/x-yaml

**Example response:**

```
HTTP/1.1 200 OK
Content-Length: 165
Content-Type: application/x-yaml

return:
local:
  - master.pem
  - master.pub
minions:
  - jerry
```
Example request:

curl -i localhost:8000/keys/jerry

GET /keys/jerry HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml

Example response:

HTTP/1.1 200 OK
Content-Length: 73
Content-Type: application/x-yaml

return:
minions:

POST(**kwargs)
Easily generate keys for a minion and auto-accept the new key

Accepts all the same parameters as the key.gen_accept.

Note: A note about curl Avoid using the -i flag or HTTP headers will be written and produce an invalid tar file.

Example partial kickstart script to bootstrap a new minion:

```bash
%post
mkdir -p /etc/salt/pki/minion
curl -sSk https://localhost:8000/keys
  -d mid=jerry 
  -d username=kickstart 
  -d password=kickstart 
  -d eauth=pam 
  | tar -C /etc/salt/pki/minion -xf -

mkdir -p /etc/salt/minion.d
printf 'master: 10.0.0.5\nid: jerry' > /etc/salt/minion.d/id.conf
%end
```

POST /keys
Generate a public and private key and return both as a tarball

Authentication credentials must be passed in the request.

Status Codes
- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

Example request:
curl -sSk https://localhost:8000/keys \
-d mid=jerry \
-d username=kickstart \
-d password=kickstart \
-d eauth=pam \
-o jerry-salt-keys.tar

POST /keys HTTP/1.1
Host: localhost:8000

Example response:

HTTP/1.1 200 OK
Content-Length: 10240
Content-Disposition: attachment; filename="saltkeys-jerry.tar"
Content-Type: application/x-tar

jerry.pub000064400000000000000000000007030000000000010730 0ustar 0

/ws

class salt.netapi.rest_cherrypy.app.WebsocketEndpoint

Open a WebSocket connection to Salt’s event bus

The event bus on the Salt master exposes a large variety of things, notably when executions are started on
the master and also when minions ultimately return their results. This URL provides a real-time window into
a running Salt infrastructure. Uses websocket as the transport mechanism.

See also:

Events & Reactor

GET(token=None, **kwargs)

Return a websocket connection of Salt’s event stream

GET /ws/(token)

Query format_events The event stream will undergo server-side formatting if the format_events URL parameter is included in the request. This can be useful to avoid
formatting on the client-side:

curl -NsSk <...snip...> localhost:8000/ws?format_events

Reqheader X-Auth-Token an authentication token from Login.
Status 101 switching to the websockets protocol
Status 401 authentication required
Status 406 requested Content-Type not available

Example request:

curl -NsSk \
-H 'X-Auth-Token: ffedf49d' \
-H 'Host: localhost:8000' \
-H 'Connection: Upgrade' \
-H 'Upgrade: websocket' \
-H 'Origin: https://localhost:8000' \
-H 'Sec-WebSocket-Version: 13' \

GET /ws HTTP/1.1
Connection: Upgrade
Upgrade: websocket
Host: localhost:8000
Origin: https://localhost:8000
Sec-WebSocket-Version: 13
Sec-WebSocket-Key: s65VsgHigh7v/Jcf4nXHnA==
X-Auth-Token: ffedf49d

Example response:

HTTP/1.1 101 Switching Protocols
Upgrade: websocket
Connection: Upgrade
Sec-WebSocket-Accept: mWZjBV9FCglzn1rIKJAxrTFlnJE=
Sec-WebSocket-Version: 13

An authentication token may optionally be passed as part of the URL for browsers that cannot be configured to send the authentication header or cookie:

curl -NsS <...snip...> localhost:8000/ws/ffedf49d

The event stream can be easily consumed via JavaScript:

```javascript
// Note, you must be authenticated!
var source = new WebSocket('ws://localhost:8000/ws/d0ce6c1a');
source.onerror = function(e) { console.debug('error!', e);};
source.onmessage = function(e) { console.debug(e.data); };;

source.send('websocket client ready')
source.close();
```

Or via Python, using the Python module websocket-client for example.

```python
# Note, you must be authenticated!

from websocket import create_connection

ws = create_connection('ws://localhost:8000/ws/d0ce6c1a')
ws.send('websocket client ready')

# Look at https://pypi.python.org/pypi/websocket-client/ for more # examples.
while listening_to_events:
    print ws.recv()
ws.close()
```

Above examples show how to establish a websocket connection to Salt and activating real time updates from Salt's event stream by signaling websocket client ready.
/stats

class salt.netapi.rest_cherrypy.app.Stats
Exposes statistics on the running CherryPy server

GET()
Return a dump of statistics collected from the CherryPy server

GET /stats
Request Headers

- X-Auth-Token -- a session token from Login.
- Accept -- the desired response format.

Response Headers

- Content-Type -- the format of the response body; depends on the Accept request header.

Status Codes

- 200 -- success
- 401 -- authentication required
- 406 -- requested Content-Type not available

19.10.2 rest_tornado

A non-blocking REST API for Salt

depends

- tornado Python module

configuration All authentication is done through Salt's external auth system which requires additional configuration not described here.

In order to run rest_tornado with the salt-master add the following to the Salt master config file:

```
rest_tornado:
  # can be any port
  port: 8000
  # address to bind to (defaults to 0.0.0.0)
  address: 0.0.0.0
  # socket backlog
  backlog: 128
  ssl_crt: /etc/pki/api/certs/server.crt
  # no need to specify ssl_key if cert and key are in one single file
  ssl_key: /etc/pki/api/certs/server.key
  debug: False
  disable_ssl: False
  webhook_disable_auth: False
  cors_origin: null
```

Authentication

Authentication is performed by passing a session token with each request. Tokens are generated via the SaltAuthHandler URL.

The token may be sent in one of two ways:
- Include a custom header named `X-Auth-Token`.
- Sent via a cookie. This option is a convenience for HTTP clients that automatically handle cookie support (such as browsers).

**See also:**
You can bypass the session handling via the `RunSaltAPIHandler` URL.

**CORS**

`rest_tornado` supports Cross-site HTTP requests out of the box. It is by default deactivated and controlled by the `cors_origin` config key.

You can allow all origins by settings `cors_origin` to `*`.

You can allow only one origin with this configuration:

```
rest_tornado:
  cors_origin: http://salt.yourcompany.com
```

You can also be more specific and select only a few allowed origins by using a list. For example:

```
rest_tornado:
  cors_origin:
    - http://salt.yourcompany.com
    - http://salt-preprod.yourcampany.com
```

The format for origin are full URL, with both scheme and port if not standard.

In this case, `rest_tornado` will check if the Origin header is in the allowed list if it's the case allow the origin. Else it will return nothing, effectively preventing the origin to make request.

For reference, CORS is a mechanism used by browser to allow (or disallow) requests made from browser from a different origin than salt-api. It's complementary to Authentication and mandatory only if you plan to use a salt client developed as a Javascript browser application.

**Usage**

Commands are sent to a running Salt master via this module by sending HTTP requests to the URLs detailed below.

**Content negotiation**

This REST interface is flexible in what data formats it will accept as well as what formats it will return (e.g., JSON, YAML, x-www-form-urlencoded).

- Specify the format of data in the request body by including the `Content-Type` header.
- Specify the desired data format for the response body with the `Accept` header.

Data sent in `POST` and `PUT` requests must be in the format of a list of lowstate dictionaries. This allows multiple commands to be executed in a single HTTP request.

**lowstate** A dictionary containing various keys that instruct Salt which command to run, where that command lives, any parameters for that command, any authentication credentials, what returner to use, etc.

Salt uses the lowstate data format internally in many places to pass command data between functions. Salt also uses lowstate for the `LocalClient()` Python API interface.
The following example (in JSON format) causes Salt to execute two commands:

```json
[{
   "client": "local",
   "tgt": "*",
   "fun": "test.fib",
   "arg": ["10"]
},
{
   "client": "runner",
   "fun": "jobs.lookup_jid",
   "jid": "20130603122505459265"
}]
```

Multiple commands in a Salt API request will be executed in serial and makes no guarantees that all commands will run. Meaning that if test.fib (from the example above) had an exception, the API would still execute `jobs.lookup_jid`.

Responses to these lowstates are an in-order list of dicts containing the return data, a yaml response could look like:

```
- ms-1: true
  ms-2: true
- ms-1: foo
  ms-2: bar
```

In the event of an exception while executing a command the return for that lowstate will be a string, for example if no minions matched the first lowstate we would get a return like:

```
- No minions matched the target. No command was sent, no jid was assigned.
- ms-1: true
  ms-2: true
```

**x-www-form-urlencoded**

Sending JSON or YAML in the request body is simple and most flexible, however sending data in urlencoded format is also supported with the caveats below. It is the default format for HTML forms, many JavaScript libraries, and the `curl` command.

For example, the equivalent to running `salt '*' test.ping` is sending `fun=test.ping&arg&client=local&tgt=*` in the HTTP request body.

**Caveats:**

- Only a single command may be sent per HTTP request.
- Repeating the `arg` parameter multiple times will cause those parameters to be combined into a single list.

  Note, some popular frameworks and languages (notably jQuery, PHP, and Ruby on Rails) will automatically append empty brackets onto repeated parameters. E.g., `arg=one, arg=two` will be sent as `arg[]=one, arg[]=two`. This is not supported; send JSON or YAML instead.

**A Websockets add-on to saltnado**

- **depends**
  - tornado Python module
In order to enable saltndo_websockets you must add websockets: True to your saltndo config block.

```python
gerest_tornado:
    # can be any port
    port: 8000
    ssl_crt: /etc/pki/api/certs/server.crt
    # no need to specify ssl_key if cert and key
    # are in one single file
    ssl_key: /etc/pki/api/certs/server.key
    debug: False
    disable_ssl: False
    websockets: True
```

All Events

Exposes all "real-time" events from Salt’s event bus on a websocket connection. It should be noted that "Real-time" here means these events are made available to the server as soon as any salt related action (changes to minions, new jobs etc) happens. Clients are however assumed to be able to tolerate any network transport related latencies. Functionality provided by this endpoint is similar to the /events endpoint.

The event bus on the Salt master exposes a large variety of things, notably when executions are started on the master and also when minions ultimately return their results. This URL provides a real-time window into a running Salt infrastructure. Uses websocket as the transport mechanism.

Exposes GET method to return websocket connections. All requests should include an auth token. A way to obtain authentication tokens is shown below.

```bash
% curl -si localhost:8000/login \
   -H "Accept: application/json" \
   -d username='salt' \
   -d password='salt' \
   -d eauth='pam'
```

Which results in the response

```json
{
    "return": [{
        "perms": [".*", "@runner", "@wheel"],
        "start": 1400556492.277421,
        "token": "d0ce6c1a37e99d0374392f272fe19c0090cca7",
        "expire": 1400599692.277422,
        "user": "salt",
        "eauth": "pam"
    }]
}
```

In this example the token returned is `d0ce6c1a37e99d0374392f272fe19c0090cca7` and can be included in subsequent websocket requests (as part of the URL).

The event stream can be easily consumed via JavaScript:

```javascript
// Note, you must be authenticated!

// Get the Websocket connection to Salt
var source = new WebSocket('wss://localhost:8000/all_events/\n   -d0ce6c1a37e99d0374392f272fe19c0090cca7');
```
// Get Salt's "real time" event stream.
source.onopen = function() { source.send('websocket client ready'); }; 

// Other handlers
source.onerror = function(e) { console.debug('error!', e); }; 

// e.data represents Salt's "real time" event data as serialized JSON.
source.onmessage = function(e) { console.debug(e.data); }; 

// Terminates websocket connection and Salt's "real time" event stream on the server.
source.close();

Or via Python, using the Python module websocket-client for example. Or the tornado client.

```python
# Note, you must be authenticated!

from websocket import create_connection

# Get the Websocket connection to Salt
ws = create_connection('wss://localhost:8000/all_events/
->d0ce6c1a37e99dccc0374392f272fe19c0090cca7')

# Get Salt's "real time" event stream.
ws.send('websocket client ready')

# Simple listener to print results of Salt's "real time" event stream.
# Look at https://pypi.python.org/pypi/websocket-client/ for more examples.
while listening_to_events:
    print ws.recv()  # Salt's "real time" event data as serialized JSON.

# Terminates websocket connection and Salt's "real time" event stream on the server.
ws.close()

# Please refer to https://github.com/liris/websocket-client/issues/81 when using a
-->self signed cert
```

Above examples show how to establish a websocket connection to Salt and activating real time updates from Salt's event stream by signaling websocket client ready.

### Formatted Events

Exposes formatted `"real-time"` events from Salt's event bus on a websocket connection. It should be noted that `"Real-time"` here means these events are made available to the server as soon as any salt related action (changes to minions, new jobs etc) happens. Clients are however assumed to be able to tolerate any network transport related latencies. Functionality provided by this endpoint is similar to the /events end point.

The event bus on the Salt master exposes a large variety of things, notably when executions are started on the master and also when minions ultimately return their results. This URL provides a real-time window into a running Salt infrastructure. Uses websocket as the transport mechanism.

Formatted events parses the raw `"real time"` event stream and maintains a current view of the following:

- minions
- jobs
A change to the minions (such as addition, removal of keys or connection drops) or jobs is processed and clients are updated. Since we use salt's presence events to track minions, please enable `presence_events` and set a small value for the `loop_interval` in the salt master config file.

Exposes GET method to return websocket connections. All requests should include an auth token. A way to obtain authentication tokens is shown below.

```bash
% curl -si localhost:8000/login \
   -H "Accept: application/json" \
   -d username='salt' \
   -d password='salt' \
   -d eauth='pam'
```

Which results in the response

```
{
   "return": [
      {
         "perms": [".*", "@runner", "@wheel"],
         "start": 1400556492.277421,
         "token": "d0ce6c1a37e99dcc0374392f272fe19c0090cca7",
         "expire": 1400599692.277422,
         "user": "salt",
         "eauth": "pam"
      }
   ]
}
```

In this example the token returned is `d0ce6c1a37e99dcc0374392f272fe19c0090cca7` and can be included in subsequent websocket requests (as part of the URL).

The event stream can be easily consumed via JavaScript:

```javascript
// Note, you must be authenticated!

// Get the Websocket connection to Salt
var source = new WebSocket('wss://localhost:8000/formatted_events/'
  + d0ce6c1a37e99dcc0374392f272fe19c0090cca7);

// Get Salt's "real time" event stream.
source.onopen = function() { source.send('websocket client ready'); }; 

// Other handlers
source.onerror = function(e) { console.debug('error!', e); }; 

// e.data represents Salt's "real time" event data as serialized JSON.
source.onmessage = function(e) { console.debug(e.data); }; 

// Terminates websocket connection and Salt's "real time" event stream on the server.
source.close();
```

Or via Python, using the Python module `websocket-client` for example. Or the tornado client.

```python
# Note, you must be authenticated!

from websocket import create_connection

# Get the Websocket connection to Salt
ws = create_connection('wss://localhost:8000/formatted_events/
  + d0ce6c1a37e99dcc0374392f272fe19c0090cca7')
```
# Get Salt's "real time" event stream.
ws.send('websocket client ready')

# Simple listener to print results of Salt's "real time" event stream.
# Look at https://pypi.python.org/pypi/websocket-client/ for more examples.
while listening_to_events:
    print ws.recv()  # Salt's "real time" event data as serialized JSON.

# Terminates websocket connection and Salt's "real time" event stream on the server.
ws.close()

# Please refer to https://github.com/liris/websocket-client/issues/81 when using a self signed cert

Above examples show how to establish a websocket connection to Salt and activating real time updates from Salt's event stream by signaling `websocket client ready`.

Example responses

Minion information is a dictionary keyed by each connected minion's id (mid), grains information for each minion is also included.

Minion information is sent in response to the following minion events:

- connection drops
  - requires running `manage.present` periodically every `loop_interval` seconds
- minion addition
- minion removal

```json
# Not all grains are shown
data: {  
    "minions": {  
        "minion1": {  
            "id": "minion1",  
            "grains": {  
                "kernel": "Darwin",  
                "domain": "local",  
                "zmqversion": "4.0.3",  
                "kernelrelease": "13.2.0"  
            },  
            "kernelrelease": "13.2.0"  
        },  
    }  
}
```

Job information is also tracked and delivered.

Job information is also a dictionary in which each job's information is keyed by salt's jid.

```json
data: {  
    "jobs": {  
        "20140609153646699137": {  
            "tgt_type": "glob",  
            "jid": "20140609153646699137",  
            "tgt": "*",  
```

19.10.3 rest_wsgi

A minimalist REST API for Salt

This `rest_wsgi` module provides a no-frills REST interface for sending commands to the Salt master. There are no dependencies.

Extra care must be taken when deploying this module into production. Please read this documentation in entirety. All authentication is done through Salt's external auth system.

Usage

- All requests must be sent to the root URL (`/`).
- All requests must be sent as a POST request with JSON content in the request body.
- All responses are in JSON.

See also:

`rest_cherrypy`

The `rest_cherrypy` module is more full-featured, production-ready, and has built-in security features.

Deployment

The `rest_wsgi` netapi module is a standard Python WSGI app. It can be deployed one of two ways.
Using a WSGI-compliant web server

This module may be run via any WSGI-compliant production server such as Apache with mod_wsgi or Nginx with FastCGI.

It is strongly recommended that this app be used with a server that supports HTTPS encryption since raw Salt authentication credentials must be sent with every request. Any apps that access Salt through this interface will need to manually manage authentication credentials (either username and password or a Salt token). Tread carefully.

salt-api using a development-only server

If run directly via the salt-api daemon it uses the wsgiref.simple_server() that ships in the Python standard library. This is a single-threaded server that is intended for testing and development. This server does not use encryption; please note that raw Salt authentication credentials must be sent with every HTTP request.

Running this module via salt-api is not recommended!

In order to start this module via the salt-api daemon the following must be put into the Salt master config:

```
rest_wsgi:
  port: 8001
```

Usage examples

**POST /**

Example request for a basic test.ping:

```
% curl -sS -i \
  -H 'Content-Type: application/json' \
  -d '{"eauth":"pam","username":"saltdev","password":"saltdev","client":\n  "local","tgt":"*","fun":"test.ping"}' localhost:8001
```

Example response:

```
HTTP/1.0 200 OK
Content-Length: 89
Content-Type: application/json

{"return": [{"ms--4": true, "ms--3": true, "ms--2": true, "ms--1": true, "ms--0":false}]}  
```

Example request for an asynchronous test.ping:

```
% curl -sS -i \
  -H 'Content-Type: application/json' \
  -d '{"eauth":"pam","username":"saltdev","password":"saltdev","client":\n  "local_async","tgt":"*","fun":"test.ping"}' localhost:8001
```

Example response:

```
HTTP/1.0 200 OK
Content-Length: 103
Content-Type: application/json

{"return": {"jid": "20130412192112593739", "minions": ["ms--4", "ms--3", "ms--2", "ms--1", "ms--0"]}}
```
Example request for looking up a job ID:

```bash
% curl -sS -i -H 'Content-Type: application/json' -d '{"eauth": "pam", "username": "saltdev", "password": "saltdev", "client": "runner", "fun": "jobs.lookup_jid", "jid": "20130412192112593739"}' localhost:8001
```

Example response:

```
HTTP/1.0 200 OK
Content-Length: 89
Content-Type: application/json

{"return": ["ms--4": true, "ms--3": true, "ms--2": true, "ms--1": true, "ms--0": true]}
```

form lowstate  A list of lowstate data appropriate for the client interface you are calling.

status 200  success

status 401  authentication required

### 19.11.1 salt.output.highstate

Outpooter for displaying results of state runs

The return data from the Highstate command is a standard data structure which is parsed by the highstate outpooter to deliver a clean and readable set of information about the HighState run on minions.

Two configurations can be set to modify the highstate outpooter. These values can be set in the master config to change the output of the salt command or set in the minion config to change the output of the salt-call command.
state_verbose: By default state_verbose is set to True, setting this to False will instruct the highstate outputter to omit displaying anything in green, this means that nothing with a result of True and no changes will not be printed.

state_output: The highstate outputter has six output modes, full, terse, mixed, mixed_id, changes and filter.

- The default is set to full, which will display many lines of detailed information for each executed chunk.
- If terse is used, then the output is greatly simplified and shown in only one line.
- If mixed is used, then terse output will be used unless a state failed, in which case full output will be used.
- If mixed_id is used, then the mixed form will be used, but the value for name will be drawn from the state ID. This is useful for cases where the name value might be very long and hard to read.
- If changes is used, then terse output will be used if there was no error and no changes, otherwise full output will be used.
- If filter is used, then either or both of two different filters can be used: exclude or terse.
  - for exclude, state.highstate expects a list of states to be excluded (or None) followed by True for terse output or False for regular output. Because of parsing nuances, if only one of these is used, it must still contain a comma. For instance: exclude=True.
  - for terse, state.highstate expects simply True or False. These can be set as such from the command line, or in the Salt config as state_output_exclude or state_output_terse, respectively.

state_tabular: If state_output uses the terse output, set this to True for an aligned output format. If you wish to use a custom format, this can be set to a string.

Example usage:

If state_output: filter is set in the configuration file:

```bash
salt '*/' state.highstate exclude=however,True
```

means to exclude no states from the highstate and turn on terse output.

```bash
salt twd state.highstate exclude=problemstate1,problemstate2,False
```

means to exclude states problemstate1 and problemstate2 from the highstate, and use regular output.

Example output for the above highstate call when top.sls defines only one other state to apply to minion twd:

```plaintext
twd:
Summary for twd
-----------
Succeeded: 1 (changed=1)
Failed: 0
-----------
Total states run: 1
```

Example output with no special settings in configuration files:

```plaintext
myminion:
----------
   ID: test.ping
       Function: module.run
```

19.11. output modules
Result: True
Comment: Module function test.ping executed
Changes: 

----------
ret:
True

Summary for myminion
----------
Succeeded: 1
Failed: 0
----------
Total: 0

salt.output.highstate.output(data, **kwargs)
The HighState Outpouter is only meant to be used with the state.highstate function, or a function that returns highstate return data.

19.11.2 salt.output.json_out

Display return data in JSON format

configuration The output format can be configured in two ways: Using the --out-indent CLI flag and specifying a positive integer or a negative integer to group JSON from each minion to a single line.

Or setting the output_indent setting in the Master or Minion configuration file with one of the following values:

- Null: put each minion return on a single line.
- pretty: use four-space indents and sort the keys.
- An integer: specify the indentation level.

Salt’s outputters operate on a per-minion basis. Each minion return will be output as a single JSON object once it comes in to the master.

Some JSON parsers can guess when an object ends and a new one begins but many can not. A good way to differentiate between each minion return is to use the single-line output format and to parse each line individually. Example output (truncated):

```json
{"dave": {"en0": {"hwaddr": "02:b0:26:32:4c:69", ...}}}
{"jerry": {"en0": {"hwaddr": "02:26:ab:0d:b9:0d", ...}}}
{"kevin": {"en0": {"hwaddr": "02:6d:7f:ce:9f:ee", ...}}}
{"mike": {"en0": {"hwaddr": "02:48:a2:4b:70:a0", ...}}}
{"phill": {"en0": {"hwaddr": "02:1d:cc:a2:33:55", ...}}}
{"stuart": {"en0": {"hwaddr": "02:9a:e0:ea:9e:3c", ...}}}
```

salt.output.json_out.output(data, **kwargs)

Print the output data in JSON
19.11.3 salt.output.key

Display salt-key output

The `salt-key` command makes use of this outputer to format its output.

```python
salt.output.key.output(data, **kwargs)
```

Read in the dict structure generated by the salt key API methods and print the structure.

19.11.4 salt.output.nested

Recursively display nested data

This is the default outputer for most execution functions.

Example output:

```plaintext
myminion:
   ---------
   foo:
      ---------
         bar:
            baz
      dictionary:
         ---------
            abc:
                123
            def:
                456
      list:
          - Hello
          - World
```

```python
class salt.output.nested.NestDisplay
    Manage the nested display contents

        display(ret, indent, prefix, out)
        Recursively iterate down through data structures to determine output

        ustring(indent, color, msg, prefix='`, suffix=`', endc=None)

salt.output.nested.output(ret, **kwargs)
    Display ret data
```

19.11.5 salt.output.newline_values_only

Display values only, separated by newlines

New in version 2015.5.0.

This outpperter is designed for Salt CLI return data. It will do the following to the return dict:

1. Get just the values (ignoring the minion IDs).
2. Each value, if it is iterable, is split a separate line.
3. Each minion's values are separated by newlines.
This results in a single string of return data containing all the values from the various minions.

**Warning:** As noted above, this outputter will discard the minion ID. If the minion ID is important, then an outputter that returns the full return dictionary in a parsable format (such as `json`, `pprint`, or `yaml`) may be more suitable.

**Example 1**

**Input**

```json
{
    'myminion': ['127.0.0.1', '10.0.0.1'],
    'second-minion': ['127.0.0.1', '10.0.0.2']
}
```

**Output**

```
127.0.0.1
10.0.0.1
127.0.0.1
10.0.0.2
```

**Example 2**

**Input**

```json
{
    'myminion': 8,
    'second-minion': 10
}
```

**Output**

```
8
10
```

```python
callout
salt.output.newline_values_only.output(data, **kwargs)
   Display modified ret data
```

**19.11.6 salt.output.no_out**

**Display no output**

No output is produced when this outputter is selected
salt.output.no_out.output(ret, **kwargs)
    Don’t display data. Used when you only are interested in the return.

19.11.7 salt.output.no_return

Display output for minions that did not return

This outputer is used to display notices about which minions failed to return when a salt function is run with -v or --verbose. It should not be called directly from the CLI.

Example output:

```
virtucentos:
    Minion did not return
```

class salt.output.no_return.NestDisplay
    Create generator for nested output

    display(ret, indent, prefix, out)
        Recursively iterate down through data structures to determine output

salt.output.no_return.output(ret, **kwargs)
    Display ret data

19.11.8 salt.output.overstatestage

Display clean output of an overstate stage

This outputer is used to display Orchestrate Runner stages, and should not be called directly.

salt.output.overstatestage.output(data, **kwargs)
    Format the data for printing stage information from the overstate system

19.11.9 salt.output.pony module

Display Pony output data structure

    depends
        • ponysay CLI program

Display output from a pony. Ponies are better than cows because everybody wants a pony.

Example output:

```
< {'local': True} >
        ----------------
           \
           \
           \ 
           \
           \
```

19.11. output modules
salt.output.pony.output(data, **kwargs)
Mane function

19.11.10 salt.output.pprint_out

Python pretty-print (pprint)

The python pretty-print system was once the default outpuer. It simply passes the return data through to pprint.pformat and prints the results.

Example output:
```python
dict = {'saltmine': {'foo': {'bar': 'baz',
                             'dictionary': {'abc': 123, 'def': 456},
                             'list': ['Hello', 'World']}}
```
salt.output.pprint_out.output(data, **kwargs)
Print out via pretty print

19.11.11 salt.output.progress

Display return data as a progress bar

dict = {'saltmine': {'foo': {'bar': 'baz',
                             'dictionary': {'abc': 123, 'def': 456},
                             'list': ['Hello', 'World']}}
```
salt.output.progress.output(ret, bar, **kwargs)
Update the progress bar
salt.output.progress.progress_iter(progress)
Initialize and return a progress bar iter

19.11.12 salt.output.raw

Display raw output data structure

This outpuer simply displays the output as a python data structure, by printing a string representation of it. It is similar to the pprint outpuer, only the data is not nicely formatted/indented.

This was the original outpuer used by Salt before the outpuer system was developed.

Example output:
salt.output.raw.output(data, **kwargs)
   Rather basic….

19.11.13 salt.output.table_out

Display output in a table format

New in version 2017.7.0.

This outpu\texttt{er} displays a sequence of rows as table.

Example output:

\begin{verbatim}
edge01.bjm01:
   -----------------
   comment:
   -----------------
   out:
   -----------------
   | Active | Interface | Last Move | Mac   | Moves | Static | Vlan |
   | True   | ae1.900   | 0.0       | 40:A6:77:5A:50:01 | 0     | False  | 111  |
   | True   | ae1.111   | 0.0       | 64:16:8D:32:26:58 | 0     | False  | 111  |
   | True   | ae1.111   | 0.0       | 8C:60:4F:73:2D:57 | 0     | False  | 111  |
   | True   | ae1.111   | 0.0       | 8C:60:4F:73:2D:7C | 0     | False  | 111  |
   | True   | ae1.222   | 0.0       | 8C:60:4F:73:2D:57 | 0     | False  | 222  |
   | True   | ae1.222   | 0.0       | F4:0F:18:76:9D:97 | 0     | False  | 222  |
   -----------------------------------------------
result:  
   -----------------
\end{verbatim}

class salt.output.table_out.TableDisplay(has_header=True, row_delimiter='-', delim='|', justify='center', separate_rows=True, prefix='| ', suffix='|', width=50, wrapfunc=None)

Manage the table display content.

display(ret, indent, out, rows_key=None, labels_key=None)
   Display table(s).

display_rows(rows, labels, indent)
   Prepares row content and displays.

prepare_rows(rows, indent, has_header)
   Prepare rows content to be displayed.

ustring(indent, color, msg, prefix='', suffix='', endc=None)
   Build the unicode string to be displayed.

19.11. output modules
**wrap_onspace**(`text`)  
When the text inside the column is longer than the width, will split by space and continue on the next line.

```python
salt.output.table_out.output(ret, "kwargs")
```
Displayed the output as table.

**Parameters**
- `nested_indent(*)` -- integer, specify the left alignment.
- `has_header(*)` -- boolean specifying if header should be displayed. Default: True.
- `row_delimiter(*)` -- character to separate rows. Default: `-`
- `delim(*)` -- character to separate columns. Default: " | ".
- `justify(*)` -- text alignment. Default: center.
- `separate_rows(*)` -- boolean specifying if row separator will be displayed between consecutive rows. Default: True.
- `prefix(*)` -- character at the beginning of the row. Default: " | ".
- `suffix(*)` -- character at the end of the row. Default: " | ".
- `width(*)` -- column max width. Default: 50.
- `rows_key(*)` -- display the rows under a specific key.
- `labels_key(*)` -- use the labels under a certain key. Otherwise will try to use the dictionary keys (if any).
- `title(*)` -- display title when only one table is selected (using the rows_key argument).

### 19.11.14 salt.output.txt

**Simple text outputter**

The txt outputter has been developed to make the output from shell commands on minions appear as they do when the command is executed on the minion.

```python
salt.output.txt.output(data, "kwargs")
```
Output the data in lines, very nice for running commands

### 19.11.15 salt.output.virt_query

**virt.query outputter**

Used to display the output from the *virt.query* runner.

```python
salt.output.virt_query.output(data, "kwargs")
```
Display output for the salt-run virt.query function

### 19.11.16 salt.output.yaml_out

**Display return data in YAML format**

This outputter defaults to printing in YAML block mode for better readability.

Example output:

```
saltmine:
    foo:
        bar: baz
```
```
dictionary:
    abc: 123
    def: 456
list:
    - Hello
    - World
```

```
salt.output.yaml_out.output(data, **kwargs)
    Print out YAML using the block mode
```

## 19.12 pillar modules

<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmd_json</td>
<td>Execute a command and read the output as JSON.</td>
</tr>
<tr>
<td>cmd_yamlex</td>
<td>Execute a command and read the output as YAMLEX.</td>
</tr>
<tr>
<td>cobbler</td>
<td>A module to pull data from Cobbler via its API into the Pillar dictionary</td>
</tr>
<tr>
<td>confidant</td>
<td>An external pillar module for getting credentials from confidant.</td>
</tr>
<tr>
<td>consul_pillar</td>
<td>Use Consul K/V as a Pillar source with values parsed as YAML.</td>
</tr>
<tr>
<td>csvpillar</td>
<td>Store key/value pairs in a CSV file</td>
</tr>
<tr>
<td>digicert</td>
<td>Digicert Pillar Certificates</td>
</tr>
<tr>
<td>django ORM</td>
<td>Generate Pillar data from Django models through the Django ORM.</td>
</tr>
<tr>
<td>ec2_pillar</td>
<td>Retrieve EC2 instance data for minions for ec2_tags and ec2_tags_list</td>
</tr>
<tr>
<td>etcd_pillar</td>
<td>Use etcd data as a Pillar source</td>
</tr>
<tr>
<td>file_tree</td>
<td>The file_tree external pillar allows values from all files in a directory tree to be imported as Pillar data.</td>

#### 19.12.1 salt.pillar.cmd_json

Execute a command and read the output as JSON. The JSON data is then directly overlaid onto the minion's Pillar data.

**salt.pillar.cmd_json.ext_pillar**(minion_id, pillar, command)

Execute a command and read the output as JSON.

#### 19.12.2 salt.pillar.cmd_yaml

Execute a command and read the output as YAML. The YAML data is then directly overlaid onto the minion's Pillar data.

**salt.pillar.cmd_yaml.ext_pillar**(minion_id, pillar, command)

Execute a command and read the output as YAML.

#### 19.12.3 salt.pillar.cmd_yamlex

Execute a command and read the output as YAMLEX. The YAMLEX data is then directly overlaid onto the minion's Pillar data.

**salt.pillar.cmd_yamlex.ext_pillar**(minion_id, pillar, command)

Execute a command and read the output as YAMLEX.

#### 19.12.4 salt.pillar.cobbler

A module to pull data from Cobbler via its API into the Pillar dictionary.
Configuring the Cobbler ext_pillar

The same cobbler.* parameters are used for both the Cobbler tops and Cobbler pillar modules.

```yaml
ext_pillar:
  - cobbler:
      key: cobbler # Nest results within this key. By default, values are not nested.
      only: [parameters] # Add only these keys to pillar.

cobbler.url: https://example.com/cobbler_api #default is http://localhost/cobbler_api
cobbler.user: username # default is no username
cobbler.password: password # default is no password
```

Module Documentation

salt.pillar.cobbler.ext_pillar(minion_id, pillar, key=None, only=())
            Read pillar data from Cobbler via its API.

19.12.5 salt.pillar.confidant

An external pillar module for getting credentials from confidant.

Configuring the Confidant module

The module can be configured via ext_pillar in the minion config:

```yaml
ext_pillar:
  - confidant:
      profile: # The URL of the confidant web service
          url: `https://confidant-production.example.com`
          # The context to use for KMS authentication
          auth_context: from: example-production-iad
to: confidant-production-iad
user_type: service # The KMS master key to use for authentication
auth_key: `alias/authnz`
# Cache file for KMS auth token
token_cache_file: /run/confidant/confidant_token # The duration of the validity of a token, in minutes
token_duration: 60 # key, keyid and region can be defined in the profile, but it's generally
best to use IAM roles or environment variables for AWS
keyid: 98nh9h9h908h09kjjk
key: jhf908gyeghehe0he0g8h9u0j0n09hj09h0
region: us-east-1

depends confidant-common, confidant-client
```

Module Documentation

salt.pillar.confidant.ext_pillar(minion_id, pillar, profile=None)
            Read pillar data from Confidant via its API.

19.12.6 salt.pillar.consul_pillar module

Use Consul K/V as a Pillar source with values parsed as YAML

depends
In order to use an consul server, a profile must be created in the master configuration file:

```yaml
my_consul_config:
  consul.host: 127.0.0.1
  consul.port: 8500
  consul.token: b6376760-a8bb-edd5-fcda-33bc13bf556
  consul.scheme: http
  consul.consistency: default
  consul.dc: dev
  consul.verify: True
```

All parameters are optional.

The `consul.token` requires python-consul >= 0.4.7.

If you have a multi-datacenter Consul cluster you can map your `pillarenv``s to your data centers by providing a dictionary of mappings in `consul.dc` field:

```yaml
my_consul_config:
  consul.dc:
    dev: us-east-1
    prod: us-west-1
```

In the example above we specifying static mapping between Pillar environments and data centers: the data for dev and prod Pillar environments will be fetched from us-east-1 and us-west-1 datacenter respectively.

In fact when `consul.dc` is set to dictionary keys are processed as regular expressions (that can capture named parameters) and values are processed as string templates as per PEP 3101.

```yaml
my_consul_config:
  consul.dc:
    ^dev-.*$: dev-datacenter
    ^(?P<region>.*)-prod$: prod-datacenter-{region}
```

This example maps all Pillar environments starting with dev- to dev-datacenter whereas Pillar environment like eu-prod will be mapped to prod-datacenter-eu.

Before evaluation patterns are sorted by length in descending order.

If Pillar environment names correspond to data center names a single pattern can be used:

```yaml
my_consul_config:
  consul.dc:
    ^(?P<env>.*)$: '{env}'
```

After the profile is created, configure the external pillar system to use it. Optionally, a root may be specified.

```yaml
ext_pillar:
  - consul: my_consul_config

ext_pillar:
  - consul: my_consul_config root=salt
```

Using these configuration profiles, multiple consul sources may also be used:

```yaml
ext_pillar:
  - consul: my_consul_config
  - consul: my_other_consul_config
```
Either the `minion_id`, or the `role`, or the `environment` grain may be used in the root path to expose minion-specific information stored in consul.

```yaml
ext_pillar:
  - consul: my_consul_config root=salt/%(minion_id)s
  - consul: my_consul_config root=salt/%(role)s
  - consul: my_consul_config root=salt/%(environment)s
```

Minion-specific values may override shared values when the minion-specific root appears after the shared root:

```yaml
ext_pillar:
  - consul: my_consul_config root=salt-shared
  - consul: my_other_consul_config root=salt-private/%(minion_id)s
```

If using the `role` or `environment` grain in the consul key path, be sure to define it using `/etc/salt/grains`, or similar:

```yaml
role: my-minion-role
environment: dev
```

It's possible to lock down where the pillar values are shared through minion targeting. Note that double quotes " are required around the target value and cannot be used inside the matching statement. See the section on Compound Matchers for more examples.

```yaml
ext_pillar:
  - consul: my_consul_config root=salt target="L@salt.example.com and G@osarch:x86_64"
```

```python
salt.pillar.consul_pillar.consul_fetch(client, path)
    Query consul for all keys/values within base path
salt.pillar.consul_pillar.ext_pillar(minion_id, pillar, conf)
    Check consul for all data
salt.pillar.consul_pillar.fetch_tree(client, path)
    Grab data from consul, trim base path and remove any keys which are folders. Take the remaining data and send it to be formatted in such a way as to be used as pillar data.
salt.pillar.consul_pillar.get_conn(opts, profile)
    Return a client object for accessing consul
salt.pillar.consul_pillar.pillar_format(ret, keys, value)
    Perform data formatting to be used as pillar data and merge it with the current pillar data
```

### 19.12.7 salt.pillar.csvpillar module

Store key/value pairs in a CSV file

New in version 2016.11.0.

Example configuration:

```yaml
ext_pillar:
  - csv: /path/to/file.csv
# or
ext_pillar:
  - csv:
```

## 19.12. pillar modules
The first column must be minion IDs and the first row must be dictionary keys. E.g.:

<table>
<thead>
<tr>
<th>id</th>
<th>role</th>
<th>env</th>
</tr>
</thead>
<tbody>
<tr>
<td>jerry</td>
<td>web</td>
<td>prod</td>
</tr>
<tr>
<td>stuart</td>
<td>web</td>
<td>stage</td>
</tr>
<tr>
<td>dave</td>
<td>web</td>
<td>qa</td>
</tr>
<tr>
<td>phil</td>
<td>db</td>
<td>prod</td>
</tr>
<tr>
<td>kevin</td>
<td>db</td>
<td>stage</td>
</tr>
<tr>
<td>mike</td>
<td>db</td>
<td>qa</td>
</tr>
</tbody>
</table>

Will produce the following Pillar values for a minion named `jerry`:

```python
{
    'role': 'web',
    'env': 'prod',
}
```

salt.pillar.csvpillar.ext_pillar(*mid*, *pillar*, *path*, *idkey='id'*, *namespace=None*, *fieldnames=None*, *restkey=None*, *restval=None*, *dialect='excel'*)

Read a CSV into Pillar

Parameters

- **path** *(str)* -- Absolute path to a CSV file.
- **idkey** *(str)* -- (Optional) The column name of minion IDs.
- **namespace** *(str)* -- (Optional) A pillar key to namespace the values under.
- **fieldnames** *(list)* -- (Optional) if the first row of the CSV is not column names they may be specified here instead.

19.12.8 salt.pillar.digicert module

Digicert Pillar Certificates

This module will only return pillar data if the digicert runner module has already been used to create certificates.

To configure this module, set **digicert** to `True` in the **ext_pillar** section of your master configuration file:

```yaml
ext_pillar:
    - digicert: True
```

salt.pillar.digicert.ext_pillar(*minion_id*, *pillar*, *conf*)

Return an existing set of certificates

19.12.9 salt.pillar.django_orm

Generate Pillar data from Django models through the Django ORM

- **maintainer** Micah Hausler `<micah.hausler@gmail.com>`
- **maturity** new
Configuring the django_orm ext_pillar

To use this module, your Django project must be on the salt master server with database access. This assumes you are using virtualenv with all the project's requirements installed.

```yaml
ext_pillar:
  - django_orm:
      pillar_name: my_application
      project_path: /path/to/project/
      settings_module: my_application.settings
      env_file: /path/to/env/file.sh
      # Optional: If your project is not using the system python,
      # add your virtualenv path below.
      env: /path/to/virtualenv/

    django_app:
      # Required: the app that is included in INSTALLED_APPS
      my_application.clients:
        # Required: the model name
        Client:
          # Required: model field to use as the key in the rendered
          # Pillar. Must be unique; must also be included in the
          # `fields` list below.
          name: shortname
          # Optional: See Django's QuerySet documentation for how to use .filter()
          filter: {'kw': 'args'}

          # Required: a list of field names
          # List items will be used as arguments to the .values() method.
          # See Django's QuerySet documentation for how to use .values()
          fields:
            - field_1
            - field_2
```

This would return pillar data that would look like

```yaml
my_application:
  my_application.clients:
    Client:
      client_1: data_from_field_1
      field_2: data_from_field_2
      client_2:
        field_1: data_from_field_1
        field_2: data_from_field_2
```

As another example, data from multiple database tables can be fetched using Django's regular lookup syntax. Note, using ManyToManyFields will not currently work since the return from values() changes if a ManyToMany is present.

```yaml
ext_pillar:
  - django_orm:
      pillar_name: djangotutorial
```

19.12. pillar modules
Module Documentation

salt.pillar.django ORM.ext_pillar(minion_id, pillar, pillar_name, project_path, settings_module, django_app, env=None, env_file=None, **kwargs)

Connect to a Django database through the ORM and retrieve model fields

Parameters

- pillar_name (str) -- The name of the pillar to be returned
- project_path (str) -- The full path to your Django project (the directory manage.py is in)
- settings_module (str) -- The settings module for your project. This can be found in your manage.py file
- django_app (str) -- A dictionary containing your apps, models, and fields
- env (str) -- The full path to the virtualenv for your Django project
- env_file (str) -- An optional bash file that sets up your environment. The file is run in a subprocess and the changed variables are then added

19.12.10 salt.pillar.ec2_pillar

Retrieve EC2 instance data for minions for ec2_tags and ec2_tags_list

The minion id must be the AWS instance-id or value in 'tag_match_key'. For example set 'tag_match_key' to 'Name', to have the minion-id matched against the tag 'Name'. The tag contents must be unique. The value of tag_match_value can be 'uqdn' or 'asis'. if 'uqdn' strips any domain before comparison.

The option use_grain can be set to True. This allows the use of an instance-id grain instead of the minion-id. Since this is a potential security risk, the configuration can be further expanded to include a list of minions that are trusted to only allow the alternate id of the instances to specific hosts. There is no glob matching at this time.

The optional 'tag_list_key' indicates which keys should be added to 'ec2_tags_list' and be split by tag_list_sep (default :). If a tag key is included in 'tag_list_key' it is removed from ec2_tags. If a tag does not exist it is still included as an empty list.

Note: restart the salt-master for changes to take effect.
This is a very simple pillar that simply retrieves the instance data from AWS. Currently the only portion implemented are EC2 tags, which returns a list of key/value pairs for all of the EC2 tags assigned to the instance.

```python
salt.pillar.ec2_pillar.ext_pillar(minion_id, pillar, use_grain=False, minion_ids=None,
tag_match_key=None, tag_match_value='asis',
tag_list_key=None, tag_list_sep=';')
```

Execute a command and read the output as YAML.

**19.12.11 salt.pillar.etcd_pillar**

Use etcd data as a Pillar source

New in version 2014.7.0.

```yaml
depends
  • python-etcd
```

In order to use an etcd server, a profile must be created in the master configuration file:

```yaml
my_etcd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001
```

After the profile is created, configure the external pillar system to use it. Optionally, a root may be specified.

```yaml
ext_pillar:
  - etcd: my_etcd_config
ext_pillar:
  - etcd: my_etcd_config root=/salt
```

Using these configuration profiles, multiple etcd sources may also be used:

```yaml
ext_pillar:
  - etcd: my_etcd_config
  - etcd: my_other_etcd_config
```

The minion_id may be used in the root path to expose minion-specific information stored in etcd.

```yaml
ext_pillar:
  - etcd: my_etcd_config root=/salt/%(minion_id)s
```

Minion-specific values may override shared values when the minion-specific root appears after the shared root:

```yaml
ext_pillar:
  - etcd: my_etcd_config root=/salt-shared
  - etcd: my_other_etcd_config root=/salt-private/%(minion_id)s
```

Using the configuration above, the following commands could be used to share a key with all minions but override its value for a specific minion:
```
etchdctl set /salt-shared/mykey my_value
etchdctl set /salt-private/special_minion_id/mykey my_other_value
```

salt.pillar.etcd_pillar.ext_pillar(minion_id, pillar, conf)

Check etcd for all data

### 19.12.12 salt.pillar.file_tree

The `file_tree` external pillar allows values from all files in a directory tree to be imported as Pillar data.

**Note:** This is an external pillar and is subject to the rules and constraints governing external pillars.

New in version 2015.5.0.

In this pillar, data is organized by either Minion ID or Nodegroup name. To setup pillar data for a specific Minion, place it in `<root_dir>/hosts/<minion_id>`. To setup pillar data for an entire Nodegroup, place it in `<root_dir>/nodegroups/<node_group>` where `<node_group>` is the Nodegroup's name.

**Example file_tree Pillar**

**Master Configuration**

```
ext_pillar:
  - file_tree:
      root_dir: /srv/ext_pillar
      follow_dir_links: False
      keep_newline: True

node_groups:
  internal_servers: 'L@bob, stuart, kevin'
```

**Pillar Configuration**

```
(salt-master) # tree /srv/ext_pillar
/srv/ext_pillar/
|-- hosts
| |-- bob
|   |-- apache
|     `-- config.d
|       `-- 00_important.conf
|       |-- 20_bob_extra.conf
|     `-- corporate_app
|         `-- settings
|            `-- bob_settings.cfg
|   `-- kevin
|     |-- apache
|      `-- config.d
|       `-- 00_important.conf
|     `-- corporate_app
|         `-- settings
|            `-- kevin_settings.cfg
```
Verify Pillar Data

```
(salt-master) # salt bob pillar.items
bob:
    --------
    apache:
        --------
        config.d:
            --------
            00_important.conf:
                <important_config important_setting="yes" />
            20_bob_extra.conf:
                <bob_specific_cfg has_freeze_ray="yes" />
    corporate_app:
        --------
        settings:
            --------
            common_settings:
                // This is the main settings file for the corporate
                // internal web app
                main_setting: probably
            bob_settings:
                role: bob
```

**Note:** The leaf data in the example shown is the contents of the pillar files.

```
salt.pillar.file_tree.ext_pillar(minion_id, pillar, root_dir=None, follow_dir_links=False, debug=False, keep_newline=False, render_default=None, renderer_blacklist=None, renderer_whitelist=None, template=False)
```

Compile pillar data from the given root_dir specific to Nodegroup names and Minion IDs.

If a Minion's ID is not found at `<root_dir>/host/<minion_id>` or if it is not included in any Nodegroups named at `<root_dir>/nodegroups/<node_group>`, no pillar data provided by this pillar module will be available for that Minion.

Changed in version 2017.7.0: Templating/rendering has been added. You can now specify a default render pipeline and a black- and whitelist of (dis)allowed renderers.

**template** must be set to True for templating to happen.
Parameters

- **minion_id** -- The ID of the Minion whose pillar data is to be collected
- **pillar** -- Unused by the `file_tree` pillar module
- **root_dir** -- Filesystem directory used as the root for pillar data (e.g. `/srv/ext_pillar`)
- **follow_dir_links** -- Follow symbolic links to directories while collecting pillar files. Defaults to False.

**Warning:** Care should be exercised when enabling this option as it will follow links that point outside of `root_dir`.

**Warning:** Symbolic links that lead to infinite recursion are not filtered.

- **debug** -- Enable debug information at log level `debug`. Defaults to False. This option may be useful to help debug errors when setting up the `file_tree` pillar module.
- **keep_newline** -- Preserve the end-of-file newline in files. Defaults to False. This option may either be a boolean or a list of file globs (as defined by the Python `fnmatch` package) for which end-of-file newlines are to be kept.

`keep_newline` should be turned on if the pillar data is intended to be used to deploy a file using `contents_pillar` with a `file.managed` state.

Changed in version 2015.8.4: The `raw_data` parameter has been renamed to `keep_newline`. In earlier releases, `raw_data` must be used. Also, this parameter can now be a list of globs, allowing for more granular control over which pillar values keep their end-of-file newline. The globs match paths relative to the directories named for Minion IDs and Nodegroup namess underneath the `root_dir`.

```yaml
ext_pillar:
  - file_tree:
    root_dir: /srv/ext_pillar
    keep_newline:
      - apache/config.d/*
      - corporate_app/settings/*
```

**Note:** In earlier releases, this documentation incorrectly stated that binary files would not affected by the `keep_newline`. However, this module does not actually distinguish between binary and text files.

- **render_default** -- Override Salt's **default global renderer** for the `file_tree` pillar.

```yaml
render_default: jinja
```

- **renderer_blacklist** -- Disallow renderers for pillar files.

```yaml
renderer_blacklist:
  - json
```
- **renderer_whitelist** -- Allow renderers for pillar files.

```python
renderer_whitelist:
- yaml
- jinja
```

- **template** -- Enable templating of pillar files. Defaults to False.

### 19.12.13 salt.pillar.foreman

A module to pull data from Foreman via its API into the Pillar dictionary

#### Configuring the Foreman ext_pillar

Set the following Salt config to setup Foreman as external pillar source:

```yaml
ext_pillar:
  - foreman:
      key: foreman # Nest results within this key
      only: ['hostgroup_name', 'parameters'] # Add only these keys to pillar

foreman.url: https://example.com/foreman_api
foreman.user: username # default is admin
foreman.password: password # default is changeme
```

The following options are optional:

```yaml
foreman.api: apiversion # default is 2 (1 is not supported yet)
foreman.verifyssl: False # default is True
foreman.certfile: /etc/ssl/certs/mycert.pem # default is None
foreman.keyfile: /etc/ssl/private/mykey.pem # default is None
foreman.cafile: /etc/ssl/certs/mycert.ca.pem # default is None
foreman.lookup_parameters: True # default is True
```

An alternative would be to use the Foreman modules integrating Salt features in the Smart Proxy and the webinterface.

Further information can be found on GitHub.

#### Module Documentation

**salt.pillar.foreman.**

**ext_pillar**(minion_id, pillar, key=None, only=())

Read pillar data from Foreman via its API.

### 19.12.14 salt.pillar.git_pillar

Use a git repository as a Pillar source

**Note:** This external pillar has been rewritten for the 2015.8.0 release. The old method of configuring this external pillar will be maintained for a couple releases, allowing time for configurations to be updated to reflect the new usage.
This external pillar allows for a Pillar top file and Pillar SLS files to be sourced from a git repository.

However, since git_pillar does not have an equivalent to the `pillar_roots` parameter, configuration is slightly different. A Pillar top file is required to be in the git repository and must still contain the relevant environment, like so:

```
base:
  '*':
    - foo
```

The branch/tag which maps to that environment must then be specified along with the repo's URL. Configuration details can be found below.

**Important:** Each branch/tag used for git_pillar must have its own top file. This is different from how the top file works when configuring *States*. The reason for this is that each git_pillar branch/tag is processed separately from the rest. Therefore, if the qa branch is to be used for git_pillar, it would need to have its own top file, with the qa environment defined within it, like this:

```
qa:
  'dev-*':
    - bar
```

Additionally, while git_pillar allows for the branch/tag to be overridden (see [here](#), or [here](#) for Salt releases before 2015.8.0), keep in mind that the top file must reference the actual environment name. It is common practice to make the environment in a git_pillar top file match the branch/tag name, but when remapping, the environment of course no longer matches the branch/tag, and the top file needs to be adjusted accordingly. When expected Pillar values configured in git_pillar are missing, this is a common misconfiguration that may be to blame, and is a good first step in troubleshooting.

### Configuring git_pillar for Salt releases before 2015.8.0

**Note:** This legacy configuration for git_pillar will no longer be supported as of the Oxygen release of Salt.

For Salt releases earlier than 2015.8.0, GitPython is the only supported provider for git_pillar. Individual repositories can be configured under the `ext_pillar` configuration parameter like so:

```
ext_pillar:
  - git: master https://gitserver/git-pillar.git root=subdirectory
```

The repository is specified in the format `<branch> <repo_url>`, with an optional `root` parameter (added in the 2014.7.0 release) which allows the pillar SLS files to be served up from a subdirectory (similar to `gitfs_root` in gitfs).

To use more than one branch from the same repo, multiple lines must be specified under `ext_pillar`:

```
ext_pillar:
  - git: master https://gitserver/git-pillar.git
  - git: dev https://gitserver/git-pillar.git
```

To remap a specific branch to a specific Pillar environment, use the format `<branch>:<env>`:
ext_pillar:
- git: develop:dev https://gitserver/git-pillar.git
- git: master:prod https://gitserver/git-pillar.git

In this case, the develop branch would need its own top.sls with a dev section in it, like this:

dev:
  '*':
    - bar

The master branch would need its own top.sls with a prod section in it:

prod:
  '*':
    - bar

If __env__ is specified as the branch name, then git_pillar will first look at the minion’s environment option. If unset, it will fall back to using branch specified by the master’s gitfs_base:

ext_pillar:
- git: __env__ https://gitserver/git-pillar.git root=pillar

The corresponding Pillar top file would look like this:

"{{saltenv}}":
  '*':
    - bar

**Note:** This feature was unintentionally omitted when git_pillar was rewritten for the 2015.8.0 release. It was added again in the 2016.3.4 release, but it has changed slightly in that release. On Salt masters running 2015.8.0 through 2016.3.3, this feature can only be accessed using the legacy config described above. For 2016.3.4 and later, refer to explanation of the __env__ parameter in the below section.

Versions 2016.3.0 through 2016.3.4 incorrectly check the master’s environment config option (instead of the minion’s) before falling back to gitfs_base. This has been fixed in the 2016.3.5 and 2016.11.1 releases (2016.11.0 contains the incorrect behavior).

Additionally, in releases before 2016.11.0, both {{env}} and {{saltenv}} could be used as a placeholder for the environment. Starting in 2016.11.0, {{env}} is no longer supported.

### Configuring git_pillar for Salt releases 2015.8.0 and later

**Note:** In version 2015.8.0, the method of configuring git external pillars has changed, and now more closely resembles that of the Git Fileserver Backend. If Salt detects the old configuration schema, it will use the pre-2015.8.0 code to compile the external pillar. A warning will also be logged.

Beginning with Salt version 2015.8.0, pygit2 is now supported in addition to GitPython. The requirements for GitPython and pygit2 are the same as for GitFS, as described here.

**Important:** git_pillar has its own set of global configuration parameters. While it may seem intuitive to use the global gitfs configuration parameters (gitfs_base, etc.) to manage git_pillar, this will not work. The main
difference for this is the fact that the different components which use Salt's git backend code do not all function identically. For instance, in git_pillar it is necessary to specify which branch/tag to be used for git_pillar remotes. This is the reverse behavior from gitfs, where branches/tags make up your environments.

See here for documentation on the git_pillar configuration options and their usage.

Here is an example git_pillar configuration:

```yaml
ext_pillar:
  - git:
    # Use 'prod' instead of the branch name 'production' as the environment
    - production https://gitserver/git-pillar.git:
      - env: prod
    # Use 'dev' instead of the branch name 'develop' as the environment
    - develop https://gitserver/git-pillar.git:
      - env: dev
    # No per-remote config parameters (and no trailing colon), 'qa' will be used as the environment
    - qa https://gitserver/git-pillar.git
    # SSH key authentication
    - master git@other-git-server:pillardata-ssh.git:
      # Pillar SLS files will be read from the 'pillar' subdirectory in this repository
      - root: pillar
      - privkey: /path/to/key
      - pubkey: /path/to/key.pub
      - passphrase: CorrectHorseBatteryStaple
    # HTTPS authentication
    - master https://other-git-server/pillardata-https.git:
      - user: git
      - password: CorrectHorseBatteryStaple
```

The main difference between this and the old way of configuring git_pillar is that multiple remotes can be configured under one git section under ext_pillar. More than one git section can be used, but it is not necessary. Remotes will be evaluated sequentially.

Per-remote configuration parameters are supported (similar to gitfs), and global versions of the git_pillar configuration parameters can also be set. To remap a specific branch to a specific Pillar environment, use the env per-remote parameter:

```yaml
ext_pillar:
  - git:
    - production https://gitserver/git-pillar.git:
      - env: prod
```

If __env__ is specified as the branch name, then git_pillar will decide which branch to use based on the following criteria:

- If the minion has a pillarenv configured, it will use that pillar environment. (2016.11.2 and later)
- Otherwise, if the minion has an environment configured, it will use that environment.
- Otherwise, the master's git_pillar_base will be used.

**Note:** The use of environment to choose the pillar environment dates from a time before the pillarenv parameter was added. In a future release, it will be ignored and either the minion's pillarenv or the master's git_pillar_base will be used.
Here's an example of using __env__ as the git_pillar environment:

```yaml
ext_pillar:
  - git:
    - __env__ https://gitserver/git-pillar.git:
      - root: pillar
```

The corresponding Pillar top file would look like this:

```yaml
{{saltenv}}:
  '{*}':
    - bar
```

**Note:** This feature was unintentionally omitted when git_pillar was rewritten for the 2015.8.0 release. It was added again in the 2016.3.4 release, but it has changed slightly in that release. The fallback value replaced by {{env}} is :conf_master: is `git_pillar_base`, while the legacy config's version of this feature replaces {{env}} with `gitfs_base`.

On Salt masters running 2015.8.0 through 2016.3.3, this feature can only be accessed using the legacy config in the previous section of this page.

The same issue which affected the behavior of the minion's `environment` config value using the legacy configuration syntax (see the documentation in the pre-2015.8.0 section above for the legacy support of this feature) also affects the new-style git_pillar syntax in version 2016.3.4. This has been corrected in version 2016.3.5 and 2016.11.1 (2016.11.0 contains the incorrect behavior).

2016.3.4 incorrectly checks the master's `environment` config option (instead of the minion's) before falling back to the master's `git_pillar_base`.

Additionally, in releases before 2016.11.0, both {{env}} and {{saltenv}} could be used as a placeholder for the environment. Starting in 2016.11.0, {{env}} is no longer supported.

With the addition of pygit2 support, git_pillar can now interact with authenticated remotes. Authentication works just like in gitfs (as outlined in the *Git Fileserver Backend Walkthrough*), only with the global authentication parameter names prefixed with `git_pillar` instead of `gitfs` (e.g. `git_pillar_pubkey`, `git_pillar_privkey`, `git_pillar_passphrase`, etc.).

**Note:** The name parameter can be used to further differentiate between two remotes with the same URL and branch. When using two remotes with the same URL, the name option is required.

### How Multiple Remotes Are Handled

As noted above, multiple remotes can be included in the same `git ext_pillar` configuration. Consider the following:

```yaml
my_etcd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001

ext_pillar:
  - etcd: my_etcd_config
  - git:
    - master https://mydomain.tld/foo.git:
      - root: pillar
    - master https://mydomain.tld/bar.git
```
To understand how pillar data from these repos will be compiled, it’s important to know how Salt will process them. The following points should be kept in mind:

1. Each ext_pillar is called separately from the others. So, in the above example, the etcd ext_pillar will be evaluated first, with the first group of git_pillar remotes evaluated next (and merged into the etcd pillar data). Lastly, the second group of git_pillar remotes will be evaluated, and then merged into the ext_pillar data evaluated before it.

2. Within a single group of git_pillar remotes, each remote will be evaluated in order, with results merged together as each remote is evaluated.

**Note:** Prior to the 2017.7.0 release, remotes would be evaluated in a non-deterministic order.

3. By default, when a repo is evaluated, other remotes’ which share its pillar environment will have their files made available to the remote being processed. The first point should be straightforward enough, but the second and third could use some additional clarification.

First, point #2. In the first group of git_pillar remotes, the top file and pillar SLS files in the foo remote will be evaluated first. The bar remote will be evaluated next, and its results will be merged into the pillar data compiled when the foo remote was evaluated. As the subsequent remotes are evaluated, their data will be merged in the same fashion.

But wait, don’t these repositories belong to more than one pillar environments? Well, yes. The default method of generating pillar data compiles pillar data from all environments. This behavior can be overridden using a pillarenv. Setting a pillarenv in the minion config file will make that minion tell the master to ignore any pillar data from environments which don’t match that pillarenv. A pillarenv can also be specified for a given minion or set of minions when running states, by using the pillarenv argument. The CLI pillarenv will override one set in the minion config file. So, assuming that a pillarenv of base was set for a minion, it would not get any of the pillar variables configured in the qux remote, since that remote is assigned to the dev environment. The only way to get its pillar data would be to specify a pillarenv of dev, which would mean that it would then ignore any items from the base pillarenv. A more detailed explanation of pillar environments can be found here.

Moving on to point #3, and looking at the example ext_pillar configuration, as the foo remote is evaluated, it will also have access to the files from the bar and baz remotes, since all three are assigned to the base pillar environment. So, if an SLS file referenced by the foo remote’s top file does not exist in the foo remote, it will be searched for in the bar remote, followed by the baz remote. When it comes time to evaluate the bar remote, SLS files referenced by the bar remote’s top file will first be looked for in the bar remote, followed by foo, and baz, and when the baz remote is processed, SLS files will be looked for in baz, followed by foo and bar. This “failover” logic is called a directory overlay, and it is also used by file_roots and :conf_minion:pillar_roots. The ordering of which remote is checked for SLS files is determined by the order they are listed. First the remote being processed is checked, then the others that share the same environment are checked. However, before the 2017.7.0 release, since evaluation was unordered, the remote being processed would be checked, followed in no specific order by the other repos which share the same environment.

Beginning with the 2017.7.0 release, this behavior of git_pillar remotes having access to files in other repos which share the same environment can be disabled by setting git_pillar_includes to False. If this is done, then all git_pillar remotes will only have access to their own SLS files. Another way of ensuring that a git_pillar remote will not have access to SLS files from other git_pillar remotes which share the same pillar environment is to put them in a separate git section under ext_pillar. Look again at the example configuration above. In the second
group of git_pillar remotes, the abc remote would not have access to the SLS files from the foo, bar, and baz remotes, and vice-versa.

**Mountpoints**

New in version 2017.7.0.

Assume the following pillar top file:

```yaml
base:
  'web*':
    - common
    - web.server.nginx
    - web.server.appdata
```

Now, assume that you would like to configure the web.server.nginx and web.server.appdata SLS files in separate repos. This could be done using the following ext_pillar configuration (assuming that `git_pillar_includes` has not been set to `False`):

```yaml
ext_pillar:
  - git:
    - master https://mydomain.tld/pillar-common.git
    - master https://mydomain.tld/pillar-nginx.git
    - master https://mydomain.tld/pillar-appdata.git
```

However, in order to get the files in the second and third git_pillar remotes to work, you would need to first create the directory structure underneath it (i.e. place them underneath `web/server/` in the repository). This also makes it tedious to reorganize the configuration, as changing `web.server.nginx` to `web.nginx` in the top file would require you to also move the SLS files in the pillar-nginx up a directory level.

For these reasons, much like gitfs, git_pillar now supports a `mountpoint` feature. Using the following ext_pillar configuration, the SLS files in the second and third git_pillar remotes can be placed in the root of the git repository:

```yaml
ext_pillar:
  - git:
    - master https://mydomain.tld/pillar-common.git
    - master https://mydomain.tld/pillar-nginx.git:
    - mountpoint: web/server/
    - master https://mydomain.tld/pillar-appdata.git:
    - mountpoint: web/server/
```

Now, if the top file changed the SLS target from `web.server.nginx`, instead of reorganizing the git repository, you would just need to adjust the mountpoint to `web/` (and restart the `salt-master` daemon).

**Note:**

- Leading and trailing slashes on the mountpoints are optional.
- Use of the `mountpoint` feature requires that `git_pillar_includes` is not disabled.
- Content from mounted git_pillar repos can only be referenced by a top file in the same pillar environment.

```python
salt.pillar.git_pillar.ext_pillar(minion_id, repo, pillar_dirs)
```

Checkout the ext_pillar sources and compile the resulting pillar SLS.
19.12.15 salt.pillar.gpg module

Decrypt pillar data through the builtin GPG renderer

In most cases, you’ll want to make this the last external pillar used. For example, to pair with the builtin stack pillar you could do something like this:

```
ext_pillar:
  - stack: /path/to/stack.cfg
  - gpg: {}
```

Set gpg_keydir in your config to adjust the homedir the renderer uses.

```
salt.pillar.gpg.ext_pillar(minion_id, pillar, *args, **kwargs)
```

19.12.16 salt.pillar.hg_pillar

Use remote Mercurial repository as a Pillar source.

New in version 2015.8.0.

The module depends on the hglib python module being available. This is the same requirement as for hgfs_ so should not pose any extra hurdles.

This external Pillar source can be configured in the master config file as such:

```
ext_pillar:
  - hg: ssh://hg@example.co/user/repo
```

```
class salt.pillar.hg_pillar.Repo(repo_uri)
    Deal with remote hg (mercurial) repository for Pillar

    close()
       Cleanup mercurial command server

    pull()

    update(branch='default')
       Ensure we are using the latest revision in the hg repository

salt.pillar.hg_pillar.ext_pillar(minion_id, pillar, repo, branch='default', root=None)
    Extract pillar from an hg repository

salt.pillar.hg_pillar.update(repo_uri)
    Execute an hg pull on all the repos
```

19.12.17 salt.pillar.hiera

Use hiera data as a Pillar source

```
salt.pillar.hiera.ext_pillar(minion_id, pillar, conf)
    Execute hiera and return the data
```

19.12.18 salt.pillar.http_json module

A module that adds data to the Pillar structure retrieved by an http request
### Configuring the HTTP_JSON ext_pillar

Set the following Salt config to setup Foreman as external pillar source:

```yaml
ext_pillar:
  - http_json:
      url: http://example.com/api/minion_id
      username: username
      password: password
```

#### Module Documentation

salt.pillar.http_json.ext_pillar(minion_id, pillar, url=None)

Read pillar data from HTTP response.

`:param url String to make request :returns dict with pillar data to add :returns empty if error`

### 19.12.19 salt.pillar.http_yaml module

A module that adds data to the Pillar structure retrieved by an http request

### Configuring the HTTP_YAML ext_pillar

Set the following Salt config to setup an http endpoint as the external pillar source:

```yaml
ext_pillar:
  - http_yaml:
      url: http://example.com/api/minion_id
      username: username
      password: password
```

#### Module Documentation

salt.pillar.http_yaml.ext_pillar(minion_id, pillar, url)

Read pillar data from HTTP response.

`:param url String to make request :returns dict with pillar data to add :returns empty if error`

### 19.12.20 salt.pillar.libvirt

Load up the libvirt keys into Pillar for a given minion if said keys have been generated using the libvirt key runner

```python
depends certtool
```

salt.pillar.libvirt.ext_pillar(minion_id, pillar, command)

Read in the generated libvirt keys

salt.pillar.libvirt.gen_hyper_keys(minion_id, country='US', state='Utah', locality='Salt Lake City', organization='Salted')

Generate the keys to be used by libvirt hypervisors, this routine gens the keys and applies them to the pillar for the hypervisor minions

---

19.12. pillar modules
19.12.21 salt.pillar.makostack module

Simple and flexible YAML ext_pillar which can read pillar from within pillar.

New in version 2016.3.0.

This custom saltstack ext_pillar is a direct ripoff of the `stack` ext_pillar, simply ported to use mako instead of jinja2 for templating.

It supports the following features:

- multiple config files that are mako templates with support for pillar, __grains__, __salt__, __opts__ objects.
- a config file renders as an ordered list of files. Unless absolute, the paths of these files are relative to the current config file - if absolute, they will be treated literally.
- this list of files are read in order as mako templates with support for stack, pillar, __grains__, __salt__, __opts__ objects.
- all these rendered files are then parsed as yaml.
- then all yaml dicts are merged in order, with support for the following, merging strategies: merge-first, merge-last, remove, and overwrite.
- stack config files can be matched based on pillar, grains, or opts values, which make it possible to support kind of self-contained environments.

Configuration in Salt

Like any other external pillar, its configuration takes place through the ext_pillar key in the master config file. However, you can configure MakoStack in 3 different ways:

**Single config file**

This is the simplest option, you just need to set the path to your single MakoStack config file like below:

```yaml
ext_pillar:
  - makostack: /path/to/stack.cfg
```

**List of config files**

You can also provide a list of config files:

```yaml
ext_pillar:
  - makostack:
    - /path/to/stack1.cfg
    - /path/to/stack2.cfg
```

**Select config files through grains|pillar|opts matching**

You can also opt for a much more flexible configuration: MakoStack allows one to select the config files for the current minion based on matching values from either grains, or pillar, or opts objects.

Here is an example of such a configuration, which should speak by itself:
Grafting data from files to arbitrary namespaces

An extended syntax for config files permits defining "graft points" on a per-config-file basis. As an example, if the file foo.cfg would produce the following:

```
foo:
  - bar
  - baz
```

and you specified the cfg file as /path/to/foo.cfg:yummy:fur, the following would actually end up in pillar after all merging was complete:

```
yummy:
  fur:
    foo:
      - bar
      - baz
```

MakoStack configuration files

The config files that are referenced in the above ext_pillar configuration are mako templates which must render as a simple ordered list of yaml files that will then be merged to build pillar data.

Unless an absolute path name is specified, the path of these yaml files is assumed to be relative to the directory containing the MakoStack config file. If a path begins with `/`, however, it will be treated literally and can be anywhere on the filesystem.

The following variables are available in mako templating of makostack configuration files:

- `pillar`: the pillar data (as passed by Salt to our ext_pillar function)
- `minion_id`: the minion id :-)
- `__opts__`: a dictionary of mostly Salt configuration options
- `__grains__`: a dictionary of the grains of the minion making this pillar call
- `__salt__`: a dictionary of Salt module functions, useful so you don’t have to duplicate functions that already exist (note: runs on the master)

So you can use all the power of mako to build your list of yaml files that will be merged in pillar data.

For example, you could have a MakoStack config file which looks like:
And the whole directory structure could look like:

```
$ tree /path/to/stack/
/path/to/stack/
  ├── config.cfg
  │    └── core.yml
  │         └── osarchs/
  │             ├── amd64.yml
  │             │    └── armhf.yml
  │             └── oscodenames/
  │                 ├── wheezy.yml
  │                 │     └── jessie.yml
  │             └── roles/
  │                 ├── web.yml
  │                 │     └── db.yml
  │             └── minions/
  │                 └── test-1-dev.yml
  │                         └── test-2-dev.yml
```

Overall process

In the above MakoStack configuration, given that test-1-dev minion is an amd64 platform running Debian Jessie, and which pillar roles is "db", the following yaml files would be merged in order:

- core.yml
- osarchs/amd64.yml
- oscodenames/jessie.yml
- roles/db.yml
- minions/test-1-dev.yml

Before merging, every files above will be preprocessed as mako templates. The following variables are available in mako templating of yaml files:

- stack: the MakoStack pillar data object that has currently been merged (data from previous yaml files in MakoStack configuration)
- pillar: the pillar data (as passed by Salt to our ext_pillar function)
- minion_id: the minion id ;-)  
- __opts__: a dictionary of mostly Salt configuration options
- __grains__: a dictionary of the grains of the minion making this pillar call
- __salt__: a dictionary of Salt module functions, useful so you don't have to duplicate functions that already exist (note: runs on the master)
So you can use all the power of mako to build your pillar data, and even use other pillar values that has already been merged by MakoStack (from previous yaml files in MakoStack configuration) through the stack variable.

Once a yaml file has been preprocessed by mako, we obtain a Python dict - let’s call it yml_data - then, MakoStack will merge this yml_data dict in the main stack dict (which contains already merged MakoStack pillar data). By default, MakoStack will deeply merge yml_data in stack (similarly to the recurse salt pillar_source_merging_strategy), but 3 merging strategies are currently available for you to choose (see next section).

Once every yaml files have been processed, the stack dict will contain your whole own pillar data, merged in order by MakoStack. So MakoStack ext_pillar returns the stack dict, the contents of which Salt takes care to merge in with all of the other pillars and finally return the whole pillar to the minion.

**Merging strategies**

The way the data from a new yml_data dict is merged with the existing stack data can be controlled by specifying a merging strategy. Right now this strategy can either be merge-last (the default), merge-first, remove, or overwrite.

Note that scalar values like strings, integers, booleans, etc. are always evaluated using the overwrite strategy (other strategies don’t make sense in that case).

The merging strategy can be set by including a dict in the form of:

```
_: <merging_strategy>
```

as the first item of the dict or list. This allows fine grained control over the merging process.

**merge-last (default) strategy**

If the merge-last strategy is selected (the default), then content of dict or list variables is merged recursively with previous definitions of this variable (similarly to the recurse salt pillar_source_merging_strategy). This allows for extending previously defined data.

**merge-first strategy**

If the merge-first strategy is selected, then the content of dict or list variables are swapped between the yml_data and stack objects before being merged recursively with the merge-last previous strategy.

**remove strategy**

If the remove strategy is selected, then content of dict or list variables in stack are removed only if the corresponding item is present in the yml_data dict. This allows for removing items from previously defined data.

**overwrite strategy**

If the overwrite strategy is selected, then the content of dict or list variables in stack is overwritten by the content of yml_data dict. So this allows one to overwrite variables from previous definitions.
Merging examples

Let's go through small examples that should clarify what's going on when a yaml_data dict is merged in the stack dict.

When you don't specify any strategy, the default merge-last strategy is selected:

<table>
<thead>
<tr>
<th>stack</th>
<th>yaml_data</th>
<th>stack (after merge)</th>
</tr>
</thead>
<tbody>
<tr>
<td>users:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>tom:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>uid: 500</td>
<td></td>
<td></td>
</tr>
<tr>
<td>roles:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>- sysadmin</td>
<td></td>
<td></td>
</tr>
<tr>
<td>root:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>uid: 0</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>users:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>tom:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>uid: 1000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>roles:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>- developer</td>
<td></td>
<td></td>
</tr>
<tr>
<td>mat:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>uid: 1001</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Then you can select a custom merging strategy using the `__` key in a dict:
You can also select a custom merging strategy using a `__` object in a list:
salt.pillar.makostack.ext_pillar(minion_id, pillar, *args, **kwargs)

19.12.22 salt.pillar.mongo

Read Pillar data from a mongodb collection

depends pymongo (for salt-master)

This module will load a node-specific pillar dictionary from a mongo collection. It uses the node's id for lookups and can load either the whole document, or just a specific field from that document as the pillar dictionary.

Salt Master Mongo Configuration

The module shares the same base mongo connection variables as salt.returners.mongo_return. These variables go in your master config file.

- mongo.db - The mongo database to connect to. Defaults to 'salt'.
- mongo.host - The mongo host to connect to. Supports replica sets by specifying all hosts in the set, comma-delimited. Defaults to 'salt'.
- mongo.port - The port that the mongo database is running on. Defaults to 27017.
- mongo.user - The username for connecting to mongo. Only required if you are using mongo authentication. Defaults to ''. 
- mongo.password - The password for connecting to mongo. Only required if you are using mongo authentication. Defaults to ''. 

Configuring the Mongo ext_pillar

The Mongo ext_pillar takes advantage of the fact that the Salt Master configuration file is yaml. It uses a sub-dictionary of values to adjust specific features of the pillar. This is the explicit single-line dictionary notation for
yaml. One may be able to get the easier-to-read multi-line dict to work correctly with some experimentation.

```python
ext_pillar:
  - mongo: {collection: vm, id_field: name, re_pattern: \.example\.com, fields: [customer_id, software, apache_vhosts]}
```

In the example above, we've decided to use the `vm` collection in the database to store the data. Minion ids are stored in the `name` field on documents in that collection. And, since minion ids are FQDNs in most cases, we'll need to trim the domain name in order to find the minion by hostname in the collection. When we find a minion, return only the `customer_id`, `software`, and `apache_vhosts` fields, as that will contain the data we want for a given node. They will be available directly inside the `pillar` dict in your SLS templates.

**Module Documentation**

```python
salt.pillar.mongo.ext_pillar(minion_id, pillar, collection='pillar', id_field='_id', re_pattern=None, re_replace='\.', fields=None)
```

Connect to a mongo database and read per-node pillar information.

- **collection**: The mongodb collection to read data from. Defaults to 'pillar'.
- **id_field**: The field in the collection that represents an individual minion id. Defaults to '_id'.
- **re_pattern**: If your naming convention in the collection is shorter than the minion id, you can use this to trim the name. `re_pattern` will be used to match the name, and `re_replace` will be used to replace it. Backrefs are supported as they are in the Python standard library. If `None`, no mangling of the name will be performed - the collection will be searched with the entire minion id. Defaults to `None`.
- **re_replace**: Use as the replacement value in node ids matched with `re_pattern`. Defaults to `. Feel free to use backreferences here.
- **fields**: The specific fields in the document to use for the pillar data. If `None`, will use the entire document. If using the entire document, the `_id` field will be converted to string. Be careful with other fields in the document as they must be string serializable. Defaults to `None`.

### 19.12.23 salt.pillar.mysql

Retrieve Pillar data by doing a MySQL query

MariaDB provides Python support through the MySQL Python package. Therefore, you may use this module with both MySQL or MariaDB.

This module is a concrete implementation of the `sql_base ext_pillar` for MySQL.

```console
maturity new
depends python-mysqldb
platform all
```

**Configuring the mysql ext_pillar**

Use the `mysql` key under `ext_pillar` for configuration of queries.

MySQL configuration of the MySQL returner is being used (mysql.db, mysql.user, mysql.pass, mysql.port, mysql.host) for database connection info.
Required python modules: MySQLdb

Complete example

```python
class salt.pillar.mysql.MySQLExtPillar
    This class receives and processes the database rows from MySQL.
    extract_queries(args, kwargs)
        This function normalizes the config block into a set of queries we can use. The return is a list of consistently laid out dicts.

salt.pillar.mysql.ext_pillar(minion_id, pillar, *args, **kwargs)
    Execute queries against MySQL, merge and return as a dict

19.12.24 salt.pillar.neutron module

Use Openstack Neutron data as a Pillar source. Will list all networks listed inside of Neutron, to all minions.

New in version 2015.5.1.

depends
    • python-neutronclient

A keystone profile must be used for the pillar to work (no generic keystone configuration here). For example:

```
my_openstack_config:
    keystone.user: 'admin'
    keystone.password: 'password'
    keystone.tenant: 'admin'
    keystone.auth_url: 'http://127.0.0.1:5000/v2.0/
    keystone.region_name: 'RegionOne'
    keystone.service_type: 'network'
```

After the profile is created, configure the external pillar system to use it.

```python
ext_pillar:
    - neutron: my_openstack_config
```
Using these configuration profiles, multiple neutron sources may also be used:

```
ext_pillar:
    - neutron: my_openstack_config
    - neutron: my_other_openstack_config
```

By default, these networks will be returned as a pillar item called `networks`. In order to have them returned under a different name, add the name after the Keystone profile name:

```
ext_pillar:
    - neutron: my_openstack_config neutron_networks
```

```
salt.pillar.neutron.ext_pillar(minion_id, pillar, conf)
Check neutron for all data
```

### 19.12.25 salt.pillar.nodegroups

**Nodegroups Pillar**

Introspection: to which nodegroups does my minion belong? Provides a pillar with the default name of `nodegroups` which contains a list of nodegroups which match for a given minion.

New in version 2016.11.0.

**Command Line**

```
salt-call pillar.get nodegroups
local:
    - class_infra
    - colo_sj
    - state_active
    - country_US
    - type_saltmaster
```

**Configuring Nodegroups Pillar**

```
extension_modules: /srv/salt/ext
ext_pillar:
    - nodegroups:
        pillar_name: 'nodegroups'
```

```
salt.pillar.nodegroups.ext_pillar(minion_id, pillar, pillar_name=None)
A salt external pillar which provides the list of nodegroups of which the minion is a member.
Parameters
    • minion_id -- used for compound matching nodegroups
    • pillar -- provided by salt, but not used by nodegroups ext_pillar
    • pillar_name -- optional name to use for the pillar, defaults to `nodegroups`
Returns a dictionary which is included by the salt master in the pillars returned to the minion
```
Pepa

Configuration templating for SaltStack using Hierarchical substitution and Jinja.

### Configuring Pepa

```python
extension_modules: /srv/salt/ext

ext_pillar:
  - pepa:
      resource: host        # Name of resource directory and sub-key in pillars
      sequence:             # Sequence used for hierarchical substitution
        - hostname:       # Name of key
          name: input     # Alias used for template directory
          base_only: True # Only use templates from Base environment, i.e. no

      staging:            # Create a sub-key in pillars, named after the
        - default:
          - environment:
            - location..region:
              name: region
            - location..country:
              name: country
            - location..datacenter:
              name: datacenter
          - roles:
            - osfinger:
              name: os
            - hostname:
              name: override
              base_only: True
              subkey: True # Create a sub-key in pillars, named after the

        resource in this case [host] # Only create a sub-key, and leave the top level
        subkey_only: True            # untouched

    pepa_roots: # Base directory for each environment
      base: /srv/pepa/base # Path for base environment
      dev: /srv/pepa/base  # Associate dev with base
      qa: /srv/pepa/qa
      prod: /srv/pepa/prod

# Use a different delimiter for nested dictionaries, defaults to '..' since some keys
# may use '.' in the name
#pepa_delimiter: ..

# Supply Grains for Pepa, this should **ONLY** be used for testing or validation
#pepa_grains:
#  environment: dev

# Supply Pillar for Pepa, this should **ONLY** be used for testing or validation
#pepa_pillars:
#  saltversion: 0.17.4

# Enable debug for Pepa, and keep Salt on warning
#log_level: debug
```
Pepa can also be used in Master-less SaltStack setup.

**Command line**

```

positional arguments:
  hostname              Hostname

optional arguments:
  -h, --help            show this help message and exit
  -c CONFIG, --config CONFIG
                        Configuration file
  -d, --debug           Print debug info
  -g GRAINS, --grains GRAINS
                        Input Grains as YAML
  -p PILLAR, --pillar PILLAR
                        Input Pillar as YAML
  -n, --no-color        No color output
  -v, --validate        Validate output
```

**Templates**

Templates is configuration for a host or software, that can use information from Grains or Pillars. These can then be used for hierarchically substitution.

**Example File:** host/input/test_example_com.yaml

```yaml
location..region: emea
location..country: nl
location..datacenter: foobar
environment: dev
roles:
  - salt.master
network..gateway: 10.0.0.254
network..interfaces..eth0..hwaddr: 00:20:26:a1:12:12
network..interfaces..eth0..dhcp: False
network..interfaces..eth0..ipv4: 10.0.0.3
network..interfaces..eth0..netmask: 255.255.255.0
network..interfaces..eth0..fqdn: {{ hostname }}
cobbler..profile: fedora-19-x86_64
```

As you see in this example you can use Jinja directly inside the template.

**Example File:** host/region/amer.yaml

```yaml
network..dns..servers:
  - 10.0.0.1
  - 10.0.0.2
```
time.ntp.servers:
- ntp1.amer.example.com
- ntp2.amer.example.com
- ntp3.amer.example.com
time.timezone: America/Chihuahua
yum.mirror: yum.amer.example.com

Each template is named after the value of the key using lowercase and all extended characters are replaced with underscore.

Example:

osfinger: Fedora-19

Would become:

fedora_19.yaml

Nested dictionaries

In order to create nested dictionaries as output you can use double dot ".." as a delimiter. You can change this using `pepa_delimiter` we choose double dot since single dot is already used by key names in some modules, and using ":" requires quoting in the YAML.

Example:

network.dns.servers:
- 10.0.0.1
- 10.0.0.2
network.dns.options:
- timeout:2
- attempts:1
- ndots:1
network.dns.search:
- example.com

Would become:

network:

dns:
  servers:
    - 10.0.0.1
    - 10.0.0.2
  options:
    - timeout:2
    - attempts:1
    - ndots:1
  search:
    - example.com

Operators

Operators can be used to merge/unset a list/hash or set the key as immutable, so it can't be changed.
<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>merge()</td>
<td>Merge list or hash</td>
</tr>
<tr>
<td>unset()</td>
<td>Unset key</td>
</tr>
<tr>
<td>immutable()</td>
<td>Set the key as immutable, so it can’t be changed</td>
</tr>
<tr>
<td>merge()</td>
<td>Set immutable and merge</td>
</tr>
<tr>
<td>unset()</td>
<td>Set immutable and unset</td>
</tr>
</tbody>
</table>

**Example:**

```python
network..dns..search..merge():
    - foobar.com
    - dummy.nl
owner..immutable(): Operations
dns.printers..unset():
```

**Validation**

Since it’s very hard to test Jinja as is, the best approach is to run all the permutations of input and validate the output, i.e. Unit Testing.

To facilitate this in Pepa we use YAML, Jinja and Cerbus [https://github.com/nicolaiarocci/cerbus](https://github.com/nicolaiarocci/cerbus).

**Schema**

So this is a validation schema for network configuration, as you see it can be customized with Jinja just as Pepa templates.

This was designed to be run as a build job in Jenkins or similar tool. You can provide Grains/Pillar input using either the config file or command line arguments.

**File Example: host/validation/network.yaml**

```yaml
network..dns..search:
    type: list
    allowed:
        - example.com

network..dns..options:
    type: list
    allowed: ['timeout:2', 'attempts:1', 'ndots:1']

network..dns..servers:
    type: list
    schema:
        regex: ^([0-9]{1,3}\.){3}[0-9]{1,3}$

network..gateway:
    type: string
    regex: ^([0-9]{1,3}\.){3}[0-9]{1,3}$

{% if network.interfaces is defined %}
{% for interface in network.interfaces %}

network..interfaces..{{{ interface }}}..dhcp:
    type: boolean

network..interfaces..{{{ interface }}}..fqdn:
```

19.12. pillar modules

salt.pillar.pepa.ext_pillar(minion_id, pillar, resource, sequence, subkey=False, subkey_only=False)

Evaluate Pepa templates

salt.pillar.pepa.key_value_to_tree(data)

Convert key/value to tree

salt.pillar.pepa.validate(output, resource)

Validate Pepa templates

19.12.27 salt.pillar.pillar_ldap

Use LDAP data as a Pillar source

This pillar module executes a series of LDAP searches. Data returned by these searches are aggregated, whereby data returned by later searches override data by previous searches with the same key.

The final result is merged with existing pillar data.

The configuration of this external pillar module is done via an external file which provides the actual configuration for the LDAP searches.

Configuring the LDAP ext_pillar

The basic configuration is part of the master configuration.

```
ext_pillar:
  - pillar_ldap: /etc/salt/master.d/pillar_ldap.yaml
```

**Note:** When placing the file in the master.d directory, make sure its name doesn't end in .conf, otherwise the salt-master process will attempt to parse its content.
Warning: Make sure this file has very restrictive permissions, as it will contain possibly sensitive LDAP credentials!

The only required key in the master configuration is `pillar_ldap` pointing to a file containing the actual configuration.

Configuring the LDAP searches

The file is processed using `Salt's Renderers <renderers>` which makes it possible to reference grains within the configuration.

Warning: When using Jinja in this file, make sure to do it in a way which prevents leaking sensitive information. A rogue minion could send arbitrary grains to trick the master into returning secret data. Use only the `id` grain which is verified through the minion's key/cert.

Map Mode

The `it-admins` configuration below returns the Pillar `it-admins` by:

- filtering for: - members of the group `it-admins`, - objects with `objectclass=user`
- returning the data of users, where each user is a dictionary containing the configured string or list attributes.

Configuration

```
salt-users:
  server:  ldap.company.tld
  port:  389
  tls:  true
  dn:  'dc=company,dc=tld'
  binddn:  'cn=salt-pillars,ou=users,dc=company,dc=tld'
  bindpw:  bi7ieBai5Ano
  referrals: false
  anonymous: false
  mode: map
  dn:  'ou=users,dc=company,dc=tld'
  filter:  '(&(memberof=cn=it-admins,ou=groups,dc=company,dc=tld)(objectclass=user))'
  attrs:  
    - cn
    - displayName
    - givenName
    - sn
  lists:  
    - memberOf
  search_order:  
    - salt-users
```
Result

```json
{
  'salt-users': [
    {
      'cn': 'cn=johndoe,ou=users,dc=company,dc=tld',
      'displayName': 'John Doe',
      'givenName': 'John',
      'sn': 'Doe',
      'memberOf': [
        'cn=it-admins,ou=groups,dc=company,dc=tld',
        'cn=team01,ou=groups,dc=company'
      ]
    },
    {
      'cn': 'cn=janedoe,ou=users,dc=company,dc=tld',
      'displayName': 'Jane Doe',
      'givenName': 'Jane',
      'sn': 'Doe',
      'memberOf': [
        'cn=it-admins,ou=groups,dc=company,dc=tld',
        'cn=team02,ou=groups,dc=company'
      ]
    }
  ]
}
```

salt.pillar.pillar_ldap.<code>ext_pillar</code>(minion_id, pillar, config_file)

Execute LDAP searches and return the aggregated data

### 19.12.28 salt.pillar.postgres module

Retrieve Pillar data by doing a postgres query

New in version 2017.7.0.

- **maturity**: new
- **depends**: psycopg2
- **platform**: all

**Complete Example**

```python
group:
    - postgres:
        user: 'salt'
        pass: 'super_secret_password'
        db: 'salt_db'

ext_pillar:
    - postgres:
        fromdb:
            query: 'SELECT col1,col2,col3,col4,col5,col6,col7
                   FROM some_random_table
                   WHERE minion_pattern LIKE %s'
        depth: 5
```
as_list: True
with_lists: [1,3]

class salt.pillar.postgres.POSTGRESExtPillar
This class receives and processes the database rows from POSTGRES.

extract_queries(args, kwargs)
This function normalizes the config block into a set of queries we can use. The return is a list of consistently laid out dicts.

salt.pillar.postgres.ext_pillar(minion_id, pillar, *args, **kwargs)
Execute queries against POSTGRES, merge and return as a dict

19.12.29 salt.pillar.puppet

Execute an unmodified puppet_node_classifier and read the output as YAML. The YAML data is then directly overlaid onto the minion's Pillar data.

salt.pillar.puppet.ext_pillar(minion_id, pillar, command)
Execute an unmodified puppet_node_classifier and read the output as YAML

19.12.30 salt.pillar.reclass_adapter

Use the `reclass` database as a Pillar source

This ext_pillar plugin provides access to the reclass database, such that Pillar data for a specific minion are fetched using reclass.

You can find more information about reclass at http://reclass.pantsfullofunix.net.

To use the plugin, add it to the ext_pillar list in the Salt master config and tell reclass by way of a few options how and where to find the inventory:

```yaml
ext_pillar:
  - reclass:
    storage_type: yaml_fs
    inventory_base_uri: /srv/salt
```

This would cause reclass to read the inventory from YAML files in /srv/salt/nodes and /srv/salt/classes.

If you are also using reclass as master_tops plugin, and you want to avoid having to specify the same information for both, use YAML anchors (take note of the differing data types for ext_pillar and master_tops):

```yaml
reclass: &reclass
  storage_type: yaml_fs
  inventory_base_uri: /srv/salt
  reclass_source_path: ~/code/reclass

ext_pillar:
  - reclass: &reclass

master_tops:
  reclass: &reclass
```

If you want to run reclass from source, rather than installing it, you can either let the master know via the PYTHONPATH environment variable, or by setting the configuration option, like in the example above.
salt.pillar.reclass_adapter.ext_pillar(minion_id, pillar, **kwargs)

Obtain the Pillar data from reclass for the given minion_id.

19.12.31 salt.pillar.redismod

Read pillar data from a Redis backend

New in version 2014.7.0.

depends

- redis Python module (on master)

Salt Master Redis Configuration

The module shares the same base Redis connection variables as salt.returners.redis_return. These variables go in your master config file.

- redis.db - The Redis database to use. Defaults to 0.
- redis.host - The Redis host to connect to. Defaults to 'salt'.
- redis.port - The port that the Redis database is listening on. Defaults to 6379.
- redis.password - The password for authenticating with Redis. Only required if you are using master auth. Defaults to None.

Configuring the Redis ext_pillar

```python
ext_pillar:
  - redis: {function: key_value}
```

salt.pillar.redismod.ext_pillar(minion_id, pillar, function, **kwargs)

Grabs external pillar data based on configured function

salt.pillar.redismod.key_json(minion_id, pillar, pillar_key=None)

Pulls a string from redis and deserializes it from json. Deserialized dictionary data loaded directly into top level if pillar_key is not set.

- pillar_key Pillar key to return data into

salt.pillar.redismod.key_value(minion_id, pillar, pillar_key='redis_pillar')

Looks for key in redis matching minion_id, returns a structure based on the data type of the redis key. String for string type, dict for hash type and lists for lists, sets and sorted sets.

- pillar_key Pillar key to return data into

19.12.32 salt.pillar.s3

Copy pillar data from a bucket in Amazon S3

The S3 pillar can be configured in the master config file with the following options

```python
ext_pillar:
  - s3:
    bucket: my.fancy.pillar.bucket
    keyid: KASKFWAKJASJKDAJKSD
```

```
The `bucket` parameter specifies the target S3 bucket. It is required.

The `keyid` parameter specifies the key id to use when access the S3 bucket. If it is not provided, an attempt to fetch it from EC2 instance meta-data will be made.

The `key` parameter specifies the key to use when access the S3 bucket. If it is not provided, an attempt to fetch it from EC2 instance meta-data will be made.

The `multiple_env` defaults to False. It specifies whether the pillar should interpret top level folders as pillar environments (see mode section below).

The `environment` defaults to `base`. It specifies which environment the bucket represents when in single environments mode (see mode section below). It is ignored if `multiple_env` is True.

The `prefix` defaults to `''`. It specifies a key prefix to use when searching for data in the bucket for the pillar. It works when `multiple_env` is True or False. Essentially it tells `ext_pillar` to look for your pillar data in a 'subdirectory' of your S3 bucket.

The `verify_ssl` parameter defaults to True. It specifies whether to check for valid S3 SSL certificates. NOTE If you use bucket names with periods, this must be set to False else an invalid certificate error will be thrown (issue #12200).

The `service_url` parameter defaults to `s3.amazonaws.com`. It specifies the base url to use for accessing S3.

The `kms_keyid` parameter is optional. It specifies the ID of the Key Management Service (KMS) master key that was used to encrypt the object.

The `s3_cache_expire` parameter defaults to 30s. It specifies expiration time of S3 metadata cache file.

The `s3_sync_on_update` parameter defaults to True. It specifies if cache is synced on update rather than JIT.

The `path_style` parameter defaults to False. It specifies whether to use path style requests or DNS style requests.

The `https_enable` parameter defaults to True. It specifies whether to use HTTPS protocol or HTTP protocol.

This pillar can operate in two modes, single environment per bucket or multiple environments per bucket.

Single environment mode must have this bucket structure:

```
`s3://<bucket name>/<prefix>/<files>`
```

Multiple environment mode must have this bucket structure:

```
`s3://<bucket name>/<prefix>/<environment>/<files>`
```

If you wish to define your pillar data entirely within S3 it's recommended that you use the `prefix=` parameter and specify one entry in `ext_pillar` for each environment rather than specifying `multiple_env`. This is due to issue #22471 (https://github.com/saltstack/salt/issues/22471)
class salt.pillar.s3.S3Credentials(key, keyid, bucket, service_url, verify_ssl=True, kms_keyid=None, location=None, path_style=False, https_enable=True)

salt.pillar.s3.ext_pillar(minion_id, pillar, bucket, key=None, keyid=None, verify_ssl=True, location=None, multiple_env=False, environment='base', prefix='', service_url=None, kms_keyid=None, s3_cache_expire=30, s3_sync_on_update=True, path_style=False, https_enable=True)

Execute a command and read the output as YAML

19.12.33 salt.pillar.sql_base module

Retrieve Pillar data by doing a SQL query

This module is not meant to be used directly as an ext_pillar. It is a place to put code common to PEP 249 compliant SQL database adapters. It exposes a python ABC that can be subclassed for new database providers.

    maturity new
    platform all

Theory of sql_base ext_pillar

Ok, here's the theory for how this works...

- First, any non-keyword args are processed in order.
- Then, remaining keywords are processed.

We do this so that it's backward compatible with older configs. Keyword arguments are sorted before being appended, so that they're predictable, but they will always be applied last so overall it's moot.

For each of those items we process, it depends on the object type:

- Strings are executed as is and the pillar depth is determined by the number of fields returned.
- A list has the first entry used as the query, the second as the pillar depth.
- A mapping uses the keys `"query"` and `"depth"` as the tuple

You can retrieve as many fields as you like, how they get used depends on the exact settings.

Configuring a sql_base ext_pillar

The sql_base ext_pillar cannot be used directly, but shares query configuration with its implementations. These examples use a fake `sql_base' adapter, which should be replaced with the name of the adapter you are using.

A list of queries can be passed in

```yaml
ext_pillar:
  - sql_base:
    - "SELECT pillar,value FROM pillars WHERE minion_id = %s"
    - "SELECT pillar,value FROM more_pillars WHERE minion_id = %s"
```

Or you can pass in a mapping
The query can be provided as a string as we have just shown, but they can be provided as lists:

```yaml
ext_pillar:
  - sql_base:
      main: "SELECT pillar,value FROM pillars WHERE minion_id = %s"
      extras: "SELECT pillar,value FROM more_pillars WHERE minion_id = %s"
```

Or as a mapping:

```yaml
ext_pillar:
  - sql_base:
    - query: "SELECT pillar,value FROM pillars WHERE minion_id = %s"
      depth: 2
```

The depth defines how the dicts are constructed. Essentially if you query for fields a,b,c,d for each row you'll get:

- With depth 1: `{a: {`b`: b, `c`: c, `d`: d}}`
- With depth 2: `{a: {`c`: c, `d`: d}}`
- With depth 3: `{a: {c: d}}`

Depth greater than 3 wouldn't be different from 3 itself. Depth of 0 translates to the largest depth needed, so 3 in this case. (max depth == key count - 1)

Then they are merged in a similar way to plain pillar data, in the order returned by the SQL database.

Thus subsequent results overwrite previous ones when they collide.

The `ignore_null` option can be used to change the overwrite behavior so that only non-NULL values in subsequent results will overwrite. This can be used to selectively overwrite default values.

```yaml
ext_pillar:
  - sql_base:
    - query: "SELECT pillar,value FROM pillars WHERE minion_id = %s"
      depth: 2
      ignore_null: True
```

If you specify `as_list: True` in the mapping expression it will convert collisions to lists.

If you specify `with_lists: `...` ` in the mapping expression it will convert the specified depths to list. The string provided is a sequence numbers that are comma separated. The string `1,3` will result in:

```bash
a,b,c,d,e,1  # field 1 same, field 3 differs
a,b,c,f,g,2  # ^^^^^
a,z,h,y,j,3  # field 1 same, field 3 same
a,z,h,y,k,4  # ^^^^^
^ ^ ^
```

These columns define list grouping
The range for `with_lists` is 1 to `number_of_fields`, inclusive. Numbers outside this range are ignored.

Finally, if you pass the queries in via a mapping, the key will be the first level name where as passing them in as a list will place them in the root. This isolates the query results into their own subtrees. This may be a help or hindrance to your aims and can be used as such.

You can basically use any SELECT query that gets you the information, you could even do joins or subqueries in case your `minion_id` is stored elsewhere. It is capable of handling single rows or multiple rows per minion.

Configuration of the connection depends on the adapter in use.

More complete example for MySQL (to also show configuration)

```yaml
mysql:
  user: 'salt'
  pass: 'super_secret_password'
  db: 'salt_db'

ext_pillar:
  - mysql:
      fromdb:
        query: 'SELECT col1,col2,col3,col4,col5,col6,col7
                 FROM some_random_table
                 WHERE minion_pattern LIKE %s'
        depth: 5
        as_list: True
        with_lists: [1,3]

class salt.pillar.sql_base.SqlBaseExtPillar
  This class receives and processes the database rows in a database agnostic way.
    as_list = False
    depth = 0
    enter_root(root)
      Set self.focus for kwarg queries
    extract_queries(args, kwargs)
      This function normalizes the config block into a set of queries we can use. The return is a list of consistently laid out dicts.
    fetch(minion_id, pillar, *args, **kwargs)
      Execute queries, merge and return as a dict.

  field_names = None
```

2498 Chapter 19. Salt Module Reference
focus = None
ignore_null = False
num_fields = 0

process_fields(field_names, depth)
The primary purpose of this function is to store the sql field list and the depth to which we process.

process_results(rows)
This function takes a list of database results and iterates over, merging them into a dict form.

result = None
with_lists = None

19.12.34 salt.pillar.sqlcipher module

Retrieve Pillar data by running a SQLCipher query

New in version 2016.3.0.

Python SQLCipher support is provided by the pysqlcipher Python package. You need this module installed to query Pillar data from a SQLCipher database.

This module is a concrete implementation of the sql_base ext_pillar for SQLCipher.

- maturity new
- depends pysqlcipher (for py2) or pysqlcipher3 (for py3)
- platform all

Configuring the sqlcipher ext_pillar

Use the `sqlcipher' key under ext_pillar for configuration of queries.

SQLCipher database connection configuration requires the following values configured in the master config:

- sqlcipher.database - The SQLCipher database to connect to. Defaults to '/var/lib/salt/pillar-sqlcipher.db'.
- sqlcipher.pass - The SQLCipher database decryption password.
- sqlcipher.timeout - The connection timeout in seconds.

Example configuration

```yaml
sqlcipher:
  database: /var/lib/salt/pillar-sqlcipher.db
  pass: strong_pass_phrase
  timeout: 5.0
```

Complete Example

```yaml
sqlcipher:
  database: '/var/lib/salt/pillar-sqlcipher.db'
  pass: strong_pass_phrase
  timeout: 5.0
```
class `salt.pillar.sqlcipher.SQLCipherExtPillar`
This class receives and processes the database rows from SQLCipher.

`salt.pillar.sqlcipher.ext_pillar(minion_id, pillar, *args, **kwargs)`
Execute queries against SQLCipher, merge and return as a dict

### 19.12.35 salt.pillar.sqlite3 module

Retrieve Pillar data by doing a SQLite3 query

New in version 2015.8.0.

`sqlite3` is included in the stdlib since Python 2.5.

This module is a concrete implementation of the sql_base ext_pillar for SQLite3.

```
platform  all
```

#### Configuring the sqlite3 ext_pillar

Use the `sqlite3` key under ext_pillar for configuration of queries.

SQLite3 database connection configuration requires the following values configured in the master config:

Note, timeout is in seconds.

```
sqlite3.database: /var/lib/salt/pillar.db
sqlite3.timeout: 5.0
```

#### Complete Example

```
sqlite3:
    database: '/var/lib/salt/pillar.db'
    timeout: 5.0

ext_pillar:
    - sqlite3:
        fromdb:
            query: 'SELECT col1,col2,col3,col4,col5,col6,col7
                FROM some_random_table
                WHERE minion_pattern LIKE ?'
            depth: 5
            as_list: True
            with_lists: [1,3]
```
class `salt.pillar.sqlite3.SQLite3ExtPillar`

This class receives and processes the database rows from SQLite3.

`salt.pillar.sqlite3.ext_pillar(minion_id, pillar, *args, **kwargs)`

Execute queries against SQLite3, merge and return as a dict

### 19.12.36 `salt.pillar.stack`

Simple and flexible YAML `ext_pillar` which can read pillar from within pillar.

New in version 2016.3.0.

PillarStack is a custom saltstack `ext_pillar` which was inspired by `varstack` but is heavily based on Jinja2 for maximum flexibility.

Any issue should be reported to the upstream project at: [https://github.com/bbinet/pillarstack/issues](https://github.com/bbinet/pillarstack/issues)

It supports the following features:

- multiple config files that are jinja2 templates with support for `pillar`, `__grains__`, `__salt__`, `__opts__` objects
- a config file renders as an ordered list of files (paths of these files are relative to the current config file)
- this list of files are read in ordered as jinja2 templates with support for `stack`, `pillar`, `__grains__`, `__salt__`, `__opts__` objects
- all these rendered files are then parsed as yaml
- then all yaml dicts are merged in order with support for the following merging strategies: `merge-first`, `merge-last`, `remove`, and `overwrite`
- stack config files can be matched based on `pillar`, `grains`, or `opts` values, which make it possible to support kind of self-contained environments

### Installation

PillarStack is already bundled with Salt since 2016.3.0 version so there is nothing to install from version 2016.3.0.

If you use an older Salt version or you want to override PillarStack with a more recent one, follow the installation procedure below.

Installing the PillarStack `ext_pillar` is as simple as dropping the `stack.py` file in the `<extension_modules>/pillar` directory (no external python module required), given that `extension_modules` is set in your salt-master configuration, see: [http://docs.saltstack.com/en/latest/ref/configuration/master.html#extension-modules](http://docs.saltstack.com/en/latest/ref/configuration/master.html#extension-modules)

### Configuration in Salt

Like any other external pillar, its configuration takes place through the `ext_pillar` key in the master config file.

However, you can configure PillarStack in 3 different ways:

#### Single config file

This is the simplest option, you just need to set the path to your single PillarStack config file like below:
List of config files

You can also provide a list of config files:

```yaml
ext_pillar:
  - stack: /path/to/stack.cfg
```

Select config files through grains|pillar|opts matching

You can also opt for a much more flexible configuration: PillarStack allows one to select the config files for the current minion based on matching values from either grains, or pillar, or opts objects.

Here is an example of such a configuration, which should speak by itself:

```yaml
ext_pillar:
  - stack:
      pillar:environment:
        dev: /path/to/dev/stack.cfg
        prod: /path/to/prod/stack.cfg
      grains:custom:grain:
        value:
          - /path/to/stack1.cfg
          - /path/to/stack2.cfg
      opts:custom:opt:
        value: /path/to/stack0.cfg
```

PillarStack configuration files

The config files that are referenced in the above `ext_pillar` configuration are jinja2 templates which must render as a simple ordered list of yaml files that will then be merged to build pillar data.

The path of these yaml files must be relative to the directory of the PillarStack config file. These paths support unix style pathname pattern expansion through the Python glob module `<https://docs.python.org/2/library/glob.html>`.

The following variables are available in jinja2 templating of PillarStack configuration files:

- `pillar`: the pillar data (as passed by Salt to our `ext_pillar` function)
- `minion_id`: the minion id ;-)
- `__opts__`: a dictionary of mostly Salt configuration options
- `__grains__`: a dictionary of the grains of the minion making this pillar call
- `__salt__`: a dictionary of Salt module functions, useful so you don't have to duplicate functions that already exist (note: runs on the master)

So you can use all the power of jinja2 to build your list of yaml files that will be merged in pillar data.

For example, you could have a PillarStack config file which looks like:
And the whole directory structure could look like:

```
$ tree /path/to/stack/
/path/to/stack/
  |-- config.cfg
  |-- core.yml
  |   |-- common/
  |   |   |-- xxx.yml
  |   |   |-- yyy.yml
  |   |-- osarchs/
  |   |   |-- amd64.yml
  |   |   |-- armhf.yml
  |   |-- oscodenames/
  |   |   |-- wheezy.yml
  |   |   |-- jessie.yml
  |   |-- roles/
  |   |   |-- web.yml
  |   |   |-- db.yml
  |   |-- minions/
  |   |   |-- test-1-dev.yml
  |   |   |-- test-2-dev.yml
```

**Overall process**

In the above PillarStack configuration, given that test-1-dev minion is an amd64 platform running Debian Jessie, and which pillar roles is ["db"], the following yaml files would be merged in order:

- core.yml
- common/xxx.yml
- common/yyy.yml
- osarchs/amd64.yml
- oscodenames/jessie.yml
- roles/db.yml
- minions/test-1-dev.yml

Before merging, every files above will be preprocessed as Jinja2 templates. The following variables are available in Jinja2 templating of yaml files:

- **stack**: the PillarStack pillar data object that has currently been merged (data from previous yaml files in PillarStack configuration)
- **pillar**: the pillar data (as passed by Salt to our ext_pillar function)
• minion_id: the minion id ;-)  
• __opts__: a dictionary of mostly Salt configuration options  
• __grains__: a dictionary of the grains of the minion making this pillar call  
• __salt__: a dictionary of Salt module functions, useful so you don’t have to duplicate functions that already exist (note: runs on the master)

So you can use all the power of jinja2 to build your pillar data, and even use other pillar values that has already been merged by PillarStack (from previous yaml files in PillarStack configuration) through the stack variable.

Once a yaml file has been preprocessed by Jinja2, we obtain a Python dict - let’s call it yaml_data - then, PillarStack will merge this yaml_data dict in the main stack dict (which contains already merged PillarStack pillar data). By default, PillarStack will deeply merge yaml_data in stack (similarly to the recurse salt pillar_source_merging_strategy), but 3 merging strategies are currently available for you to choose (see next section).

Once every yaml files have been processed, the stack dict will contain your whole own pillar data, merged in order by PillarStack. So PillarStack ext_pillar returns the stack dict, the contents of which Salt takes care to merge in with all of the other pillars and finally return the whole pillar to the minion.

### Merging strategies

The way the data from a new yaml_data dict is merged with the existing stack data can be controlled by specifying a merging strategy. Right now this strategy can either be merge-last (the default), merge-first, remove, or overwrite.

Note that scalar values like strings, integers, booleans, etc. are always evaluated using the overwrite strategy (other strategies don’t make sense in that case).

The merging strategy can be set by including a dict in the form of:

```
__: <merging_strategy>
```

as the first item of the dict or list. This allows fine grained control over the merging process.

**merge-last** (default) strategy

If the merge-last strategy is selected (the default), then content of dict or list variables is merged recursively with previous definitions of this variable (similarly to the recurse salt pillar_source_merging_strategy). This allows for extending previously defined data.

**merge-first strategy**

If the merge-first strategy is selected, then the content of dict or list variables are swapped between the yaml_data and stack objects before being merged recursively with the merge-last previous strategy.

**remove strategy**

If the remove strategy is selected, then content of dict or list variables in stack are removed only if the corresponding item is present in the yaml_data dict. This allows for removing items from previously defined data.
**overwrite strategy**

If the overwrite strategy is selected, then the content of dict or list variables in stack is overwritten by the content of yaml_data dict. So this allows one to overwrite variables from previous definitions.

**Merging examples**

Let's go through small examples that should clarify what's going on when a yaml_data dict is merged in the stack dict.

When you don't specify any strategy, the default merge-last strategy is selected:

<table>
<thead>
<tr>
<th>stack</th>
<th>yaml_data</th>
<th>stack (after merge)</th>
</tr>
</thead>
<tbody>
<tr>
<td>users:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>tom:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>uid: 500</td>
<td></td>
<td></td>
</tr>
<tr>
<td>roles:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>- sysadmin</td>
<td></td>
<td></td>
</tr>
<tr>
<td>root:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>uid: 0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>users:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>tom:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>uid: 1000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>roles:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>- developer</td>
<td></td>
<td></td>
</tr>
<tr>
<td>mat:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>uid: 1001</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Then you can select a custom merging strategy using the __ key in a dict:
<table>
<thead>
<tr>
<th>stack</th>
<th>yaml_data</th>
<th>stack (after merge)</th>
</tr>
</thead>
<tbody>
<tr>
<td>users:</td>
<td>users:</td>
<td>users:</td>
</tr>
<tr>
<td>tom:</td>
<td>users:</td>
<td>users:</td>
</tr>
<tr>
<td>uid: 500</td>
<td>__: merge-last</td>
<td>tom:</td>
</tr>
<tr>
<td>roles:</td>
<td></td>
<td>uid: 1000</td>
</tr>
<tr>
<td>- sysadmin</td>
<td></td>
<td>roles:</td>
</tr>
<tr>
<td>root:</td>
<td></td>
<td>- sysadmin</td>
</tr>
<tr>
<td>uid: 0</td>
<td></td>
<td>- developer</td>
</tr>
<tr>
<td>mat:</td>
<td></td>
<td>uid: 1001</td>
</tr>
<tr>
<td>uid: 1001</td>
<td></td>
<td>root:</td>
</tr>
<tr>
<td>users:</td>
<td>users:</td>
<td>root:</td>
</tr>
<tr>
<td>tom:</td>
<td>__: merge-first</td>
<td>uid: 0</td>
</tr>
<tr>
<td>uid: 500</td>
<td></td>
<td></td>
</tr>
<tr>
<td>roles:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>- sysadmin</td>
<td></td>
<td></td>
</tr>
<tr>
<td>root:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>uid: 0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>users:</td>
<td>users:</td>
<td>users:</td>
</tr>
<tr>
<td>tom:</td>
<td>__: remove</td>
<td>tom:</td>
</tr>
<tr>
<td>uid: 500</td>
<td></td>
<td>uid: 0</td>
</tr>
<tr>
<td>roles:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>- sysadmin</td>
<td></td>
<td></td>
</tr>
<tr>
<td>root:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>uid: 0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>users:</td>
<td>users:</td>
<td>users:</td>
</tr>
<tr>
<td>tom:</td>
<td>__: overwrite</td>
<td>tom:</td>
</tr>
<tr>
<td>uid: 500</td>
<td></td>
<td>uid: 1000</td>
</tr>
<tr>
<td>roles:</td>
<td></td>
<td>roles:</td>
</tr>
<tr>
<td>- sysadmin</td>
<td></td>
<td>- developer</td>
</tr>
<tr>
<td>root:</td>
<td></td>
<td>uid: 1001</td>
</tr>
<tr>
<td>uid: 0</td>
<td></td>
<td>mat:</td>
</tr>
</tbody>
</table>

You can also select a custom merging strategy using a __ object in a list:
**salt.pillar.stack.ext_pillar** *(minion_id, pillar, *args, **kwargs)*

### 19.12.37 salt.pillar.svn_pillar

Clone a remote SVN repository and use the filesystem as a Pillar source

This external Pillar source can be configured in the master config file like so:

```yaml
ext_pillar:
  - svn: trunk svn://svnserver/repo root=subdirectory
```

The `root=` parameter is optional and used to set the subdirectory from where to look for Pillar files (such as `top.sls`).

Changed in version 2014.7.0: The optional `root` parameter will be added.

Note that this is not the same thing as configuring pillar data using the `pillar_roots` parameter. The branch referenced in the `ext_pillar` entry above (master), would evaluate to the `base` environment, so this branch needs to contain a `top.sls` with a `base` section in it, like this:

```yaml
base:
  '*':
    - foo
```

To use other environments from the same SVN repo as `svn_pillar` sources, just add additional lines, like so:

```yaml
ext_pillar:
  - svn: trunk svn://svnserver/repo
  - svn: dev svn://svnserver/repo
```

In this case, the dev branch would need its own `top.sls` with a dev section in it, like this:
Dev:

```
'\*':
  - bar
```

class salt.pillar.svn_pillar.SvnPillar(branch, repo_location, root, opts)
    Deal with the remote SVN repository for Pillar

    **pillar_dir()**
    Returns the directory of the pillars (repo cache + branch + root)

    **update()**

salt.pillar.svn_pillar.ext_pillar(minion_id, pillar, repo_string)
Execute a command and read the output as YAML

### 19.12.38 salt.pillar.varstack_pillar

Use Varstack data as a Pillar source

#### Configuring Varstack

Using varstack in Salt is fairly simple. Just put the following into the config file of your master:

```
ext_pillar:
  - varstack: /etc/varstack.yaml
```

Varstack will then use /etc/varstack.yaml to determine which configuration data to return as pillar information. From there you can take a look at the README of varstack on how this file is evaluated.

salt.pillar.varstack_pillar.ext_pillar(minion_id, pillar, conf)
Parse varstack data and return the result

### 19.12.39 salt.pillar.vault module

Vault Pillar Module

maintainer SaltStack
maturity New
platform all

New in version 2016.11.0.

This module allows pillar data to be stored in Hashicorp Vault.

Base configuration instructions are documented in the execution module docs. Below are noted extra configuration required for the pillar module, but the base configuration must also be completed.

After the base Vault configuration is created, add the configuration below to the ext_pillar section in the Salt master configuration.

```
ext_pillar:
  - vault: path=secret/salt
```

Each key needs to have all the key-value pairs with the names you require. Avoid naming every key `password` as you they will collide:
$ vault write secret/salt auth=my_password master=127.0.0.1

The above will result in two pillars being available, auth and master.

You can then use normal pillar requests to get each key pair directly from pillar root. Example:

$ salt-ssh '*' pillar.get auth

Multiple Vault sources may also be used:

```python
ext_pillar:
    - vault: path=secret/salt
    - vault: path=secret/root
```

```python
salt.pillar.vault.ext_pillar(minion_id, pillar, conf)
    Get pillar data from Vault for the configuration conf.
```

19.12.40 salt.pillar.venafi module

Venafi Pillar Certificates

This module will only return pillar data if the venafi runner module has already been used to create certificates. To configure this module, set venafi to True in the ext_pillar section of your master configuration file:

```python
ext_pillar:
    - venafi: True
```

```python
salt.pillar.venafi.ext_pillar(minion_id, pillar, conf)
    Return an existing set of certificates
```

19.12.41 salt.pillar.virtkey

Accept a key from a hypervisor if the virt runner has already submitted an authorization request

```python
salt.pillar.virtkey.ext_pillar(hyper_id, pillar, name, key)
    Accept the key for the VM on the hyper, if authorized.
```

19.12.42 salt.pillar.vmware_pillar module

Pillar data from vCenter or an ESXi host

New in version 2017.7.0.

```python
depends
```

- pyVmomi

This external pillar can pull attributes from objects in vCenter or an ESXi host and provide those attributes as pillar data to minions. This can allow for pillar based targeting of minions on ESXi hosts. This setup requires only the salt master have access to the vCenter server/ESXi hosts.

The pillar will return an empty dict if the `os' or `virtual' grain are not `VMWare', `ESXi', or `VMWare ESXi'.

19.12. pillar modules
Defaults

- The external pillar will search for Virtual Machines with the VM name matching the minion id.
- Data will be returned into the `vmware` pillar key.
- The external pillar has a default set of properties to return for both VirtualMachine and HostSystem types.

Configuring the VMWare pillar

The required minimal configuration in the salt master ext_pillar setup:

```yaml
ext_pillar:
  - vmware:
      host: <vcenter/esx host>
      username: <user to connect with>
      password: <password>
```

Optionally, the following keyword arguments can be passed to the ext_pillar for customized configuration:

- `pillar_key`  Optionally set the pillar key to return the data into. Default is `vmware`.
- `protocol` Optionally set to alternate protocol if the vCenter server or ESX/ESXi host is not using the default protocol. Default protocol is `https`.
- `port` Optionally set to alternate port if the vCenter server or ESX/ESXi host is not using the default port. Default port is 443.
- `property_name` Property name to match the minion id against. Defaults to `name`.
- `property_types` Optionally specify a list of pyVmomi vim types to search for the minion id in `property_name`. Default is `["VirtualMachine"]`.

For example, to search both vim.VirtualMachine and vim.HostSystem object types:

```yaml
ext_pillar:
  - vmware:
      host: myesx
      username: root
      password: complex_password
      property_types:
        - VirtualMachine
        - HostSystem
```

Additionally, the list of property types can be dicts, the item of the dict being a list specifying the attribute to return for that vim object type.

The pillar will attempt to recurse the attribute and return all child attributes.

To explicitly specify deeper attributes without attempting to recurse an attribute, convert the list item to a dict with the item of the dict being the child attributes to return. Follow this pattern to return attributes as deep within the object as necessary.

**Note:** Be careful when specifying custom attributes! Many attributes have objects as attributes which have the parent object as an attribute and which will cause the pillar to fail due to the attempt to convert all sub-objects recursively (i.e. infinite attribute loops). Specifying only the sub-attributes you would like returned will keep the infinite recursion from occurring.

A maximum recursion exception will occur in this case and the pillar will not return as desired.
ext_pillar:
  - vmware:
    host: myvcenter
    username: my_user
    password: my_pass
    replace_default_attributes: True
    property_types:
      - VirtualMachine:
        - config:
          - bootOptions:
            - bootDelay
            - bootRetryDelay
      - HostSystem:
        - datastore:
          - name

The above ext_pillar example would return a pillar like the following for a VirtualMachine object that's name matched the minion id:

```
vmware:
  config:
    bootOptions:
      bootDelay: 1000
      bootRetryDelay: 1000
```

If you were to retrieve these virtual machine attributes via pyVmomi directly, this would be the same as

```
vmObject.config.bootOptions.bootDelay
vmObject.config.bootOptions.bootRetryDelay
```

The above ext_pillar example would return a pillar like the following for a HostSystem object that's name matched the minion id:

```
vmware:
  datastore:
    - name: Datastore1
    - name: Datastore2
```

The `datastore` property of a HostSystem object is a list of datastores, thus a list is returned.

**replace_default_attributes** If custom attributes are specified by the `property_types` parameter, `replace_default_attributes` determines if those will be added to default attributes (False) or replace the default attributes completely (True). The default setting is `False`.

**Note:** vCenter "Custom Attributes" (i.e. Annotations) will always be returned if it exists on the object as part of the pillar regardless of this setting.

```
salt.pillar.vmware_pillar.ext_pillar(minion_id, pillar, **kwargs)
Check vmware/vcenter for all data
```

## 19.13 proxy modules
chronos
Proxy Minion interface module for managing (practically) any network device with Cisco Network Services Orchestrator (Cisco NSO).

dummy
This is a dummy proxy-minion designed for testing the proxy minion subsystem.

esxi
Proxy Minion interface module for managing VMware ESXi hosts.

fx2
Dell FX2 chassis

junos
Interface with a Junos device via proxy-minion.

marathon
Marathon

napalm
NAPALM: Network Automation and Programmability Abstraction Layer with Multivendor support

nxos
Proxy Minion for Cisco NX OS Switches

philips_hue
Philips HUE lamps module for proxy.

rest_sample
This is a simple proxy-minion designed to connect to and communicate with

ssh_sample
This is a simple proxy-minion designed to connect to and communicate with a server that exposes functionality via SSH.

19.13.1 salt.proxy.chronos module

Chronos

Proxy minion for managing a Chronos cluster.

Dependencies

• chronos execution module (salt.modules.chronos)

Pillar

The chronos proxy configuration requires a `base_url` property that points to the chronos endpoint:

```
proxy:
  proxytype: chronos
  base_url: http://my-chronos-master.mydomain.com:4400
```

New in version 2015.8.2.

salt.proxy.chronos.init(opts)
Perform any needed setup.

salt.proxy.chronos.ping()
Is the chronos api responding?

salt.proxy.chronos.shutdown(opts)
For this proxy shutdown is a no-op
19.13.2 salt.proxy.cisconso

Proxy Minion interface module for managing (practically) any network device with Cisco Network Services Orchestrator (Cisco NSO). Cisco NSO uses a series of remote polling agents, APIs and SSH commands to fetch network configuration and represent it in a data model. PyNSO, the Python module used by this proxy minion does the task of converting native Python dictionaries into NETCONF/YANG syntax that the REST API for Cisco NSO can then use to set the configuration of the target network device.

Supported devices:

- A10 AX Series
- Arista 7150 Series
- Ciena 3000, 5000, ESM
- H3c S5800 Series
- Overture 1400, 2200, 5000, 5100, 6000
- Accedian MetroNID
- Avaya ERS 4000, SR8000, VSP 9000
- Cisco: APIC-DC, ASA, IOS, IOS XE, IOS XR, Me-4600, NX OS, Prime Network Registrar, Quantum, StarOS, UCS ManagWSA
- Huawei: NE40E, quidway series, Enterprise Network Simulation Framework
- PaloAlto PA-2000, PA-3000, Virtualized Firewalls
- Adtran 900 Series
- Brocade ADX, MLX, Netiron, Vyatta
- Dell Force 10 Networking S-Series
- Infinera DTN-X Multi-Terabit Packet Optical Network Platform
- Pulsecom SuperG
- Adva 150CC Series
- CableLabs Converged Cable Access Platform
- Ericsson EFN324 Series, SE family
- Juniper: Contrail, EX, M, MX, QFX, SRX, Virtual SRX
- Quagga Routing Software
- Affirmed Networks
- Citrix Netscaler
- F5 BIG-IP
- NEC iPasolink
- Riverbed Steelhead Series
- Alcatel-Lucent 7XXX, SAM
- Clavister
- Fortinet
- Nominum DCS
This proxy minion enables a consistent interface to fetch, control and maintain the configuration of network devices via a NETCONF-compliant control plane. Cisco Network Services Orchestrator.

More in-depth conceptual reading on Proxy Minions can be found in the Proxy Minion section of Salt’s documentation.

**Dependencies**

- pynso Python module

**PyNSO**

PyNSO can be installed via pip:

```
pip install pynso
```

**Configuration**

To use this integration proxy module, please configure the following:

**Pillar**

Proxy minions get their configuration from Salt’s Pillar. Every proxy must have a stanza in Pillar and a reference in the Pillar top-file that matches the ID. At a minimum for communication with the NSO host, the pillar should look like this:

```
proxy:
  proxytype: cisconso
  host: <ip or dns name of host>
  port: 8080
  use_ssl: false
  username: <username>
  password: password
```

**proxytype**

The proxytype key and value pair is critical, as it tells Salt which interface to load from the proxy directory in Salt’s install hierarchy, or from /srv/salt/_proxy on the Salt Master (if you have created your own proxy module, for example). To use this Cisco NSO Proxy Module, set this to cisconso.
host

The location, or IP/dns, of the Cisco NSO API host. Required.

username

The username used to login to the Cisco NSO host, such as admin. Required.

passwords

The password for the given user. Required.

use_ssl

Whether to use HTTPS messaging to speak to the API.

port

The port that the Cisco NSO API is running on, 8080 by default

Salt Proxy

After your pillar is in place, you can test the proxy. The proxy can run on any machine that has network connectivity to your Salt Master and to the Cisco NSO host in question. SaltStack recommends that the machine running the salt-proxy process also run a regular minion, though it is not strictly necessary.

On the machine that will run the proxy, make sure there is an /etc/salt/proxy file with at least the following in it:

```
master: <ip or hostname of salt-master>
```

You can then start the salt-proxy process with:

```
salt-proxy --proxyid <id you want to give the host>
```

You may want to add -l debug to run the above in the foreground in debug mode just to make sure everything is OK.

Next, accept the key for the proxy on your salt-master, just like you would for a regular minion:

```
salt-key -a <id you gave the cisconso host>
```

You can confirm that the pillar data is in place for the proxy:

```
salt <id> pillar.items
```

And now you should be able to ping the Cisco NSO host to make sure it is responding:

```
salt <id> test.ping
```
```
salt.proxy.cisconso.apply_rollback(datastore, name)
Apply a system rollback
Parameters
  • datastore (DatastoreType (str enum)) -- The datastore, e.g., running, operational. One of the NETCONF store IETF types
  • name (str) -- an ID of the rollback to restore

salt.proxy.cisconso.get_data(datastore, path)
Get the configuration of the device tree at the given path
Parameters
  • datastore (DatastoreType (str enum)) -- The datastore, e.g., running, operational. One of the NETCONF store IETF types
  • path (list of str OR tuple) -- The device path, a list of element names in order, comma separated
Returns
  The network configuration at that tree
Return type
  dict

salt cisco-nso cisconso.get_data devices

salt.proxy.cisconso.get_rollback(name)
Get the backup of stored a configuration rollback
Parameters
  name (str) -- Typically an ID of the backup
Return type
  str
Returns
  the contents of the rollback snapshot

salt.proxy.cisconso.get_rollbacks()
Get a list of stored configuration rollbacks

salt.proxy.cisconso.grains()
Get the grains from the proxy device.

salt.proxy.cisconso.init(opts)

salt.proxy.cisconso.ping()
Check to see if the host is responding. Returns False if the host didn't respond, True otherwise.
CLI Example:
salt cisco-nso test.ping

salt.proxy.cisconso.set_data_value(datastore, path, data)
Get a data entry in a datastore
Parameters
  • datastore (DatastoreType (str enum)) -- The datastore, e.g., running, operational. One of the NETCONF store IETF types
  • path (list of str OR tuple) -- The device path to set the value at, a list of element names in order, comma separated
  • data (dict) -- The new value at the given path
Return type
  bool
Returns
  True if successful, otherwise error.

salt.proxy.cisconso.shutdown()
Shutdown the connection to the proxy device. For this proxy, shutdown is a no-op.

19.13.3 salt.proxy.dummy module
This is a dummy proxy-minion designed for testing the proxy minion subsystem.
```
salt.proxy.dummy.fns()

salt.proxy.dummy.grains()
    Make up some grains

salt.proxy.dummy.grains_refresh()
    Refresh the grains

salt.proxy.dummy.init(opts)

salt.proxy.dummy.initialized()
    Since grains are loaded in many different places and some of those places occur before the proxy can be
    initialized, return whether our init() function has been called

salt.proxy.dummy.package_install(name, **kwargs)
    Install a "package" on the REST server

salt.proxy.dummy.package_list()
    List "packages" installed on the REST server

salt.proxy.dummy.package_remove(name)
    Remove a "package" on the REST server

salt.proxy.dummy.package_status(name)
    Check the installation status of a package on the REST server

salt.proxy.dummy.ping()
    Degenerate ping

salt.proxy.dummy.service_list()
    List "services" on the REST server

salt.proxy.dummy.service_restart(name)
    Restart a "service" on the REST server

salt.proxy.dummy.service_start(name)
    Start a "service" on the dummy server

salt.proxy.dummy.service_status(name)
    Check if a service is running on the REST server

salt.proxy.dummy.service_stop(name)
    Stop a "service" on the dummy server

salt.proxy.dummy.shutdown(opts)
    For this proxy shutdown is a no-op

salt.proxy.dummy.test_from_state()
    Test function so we have something to call from a state :return:

salt.proxy.dummy.upgrade()
    "Upgrade" packages

salt.proxy.dummy.uptodate()
    Call the REST endpoint to see if the packages on the "server" are up to date.

19.13.4 salt.proxy.esxi

Proxy Minion interface module for managing VMware ESXi hosts.

New in version 2015.8.4.
Special Note: SaltStack thanks Adobe Corporation for their support in creating this Proxy Minion integration.

This proxy minion enables VMware ESXi (hereafter referred to as simply `ESXi`) hosts to be treated individually like a Salt Minion.

Since the ESXi host may not necessarily run on an OS capable of hosting a Python stack, the ESXi host can't run a Salt Minion directly. Salt's `Proxy Minion` functionality enables you to designate another machine to host a minion process that ``proxies`` communication from the Salt Master. The master does not know nor care that the target is not a ``real`` Salt Minion.

More in-depth conceptual reading on Proxy Minions can be found in the Proxy Minion section of Salt's documentation.

Dependencies

- pyVmomi Python Module
- ESXCLI

**pyVmomi**

PyVmomi can be installed via pip:

```
pip install pyVmomi
```

**Note:** Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, Python 2.6, Python 2.7.9, or newer must be present. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the following:

```
pip install pyVmomi==5.5.0.2014.1.1
```

The 5.5.0.2014.1.1 is a known stable version that this original ESXi State Module was developed against.

**ESXCLI**

Currently, about a third of the functions used in the vSphere Execution Module require the ESXCLI package be installed on the machine running the Proxy Minion process.

The ESXCLI package is also referred to as the VMware vSphere CLI, or vCLI. VMware provides vCLI package installation instructions for vSphere 5.5 and vSphere 6.0.

Once all of the required dependencies are in place and the vCLI package is installed, you can check to see if you can connect to your ESXi host or vCenter server by running the following command:

```
esxcli -s <host-location> -u <username> -p <password> system syslog config get
```

If the connection was successful, ESXCLI was successfully installed on your system. You should see output related to the ESXi host's syslog configuration.
Configuration

To use this integration proxy module, please configure the following:

Pillar

Proxy minions get their configuration from Salt’s Pillar. Every proxy must have a stanza in Pillar and a reference in the Pillar top-file that matches the ID. At a minimum for communication with the ESXi host, the pillar should look like this:

```yaml
proxy:
    proxytype: esxi
    host: <ip or dns name of esxi host>
    username: <ESXi username>
    passwords:
        - first_password
        - second_password
        - third_password
    credstore: <path to credential store>
```

**proxytype**

The `proxytype` key and value pair is critical, as it tells Salt which interface to load from the `proxy` directory in Salt’s install hierarchy, or from `/srv/salt/_proxy` on the Salt Master (if you have created your own proxy module, for example). To use this ESXi Proxy Module, set this to `esxi`.

**host**

The location, or ip/dns, of the ESXi host. Required.

**username**

The username used to login to the ESXi host, such as `root`. Required.

**passwords**

A list of passwords to be used to try and login to the ESXi host. At least one password in this list is required.

The proxy integration will try the passwords listed in order. It is configured this way so you can have a regular password and the password you may be updating for an ESXi host either via the `vsphere.update_host_password` execution module function or via the `esxi.password_present` state function. This way, after the password is changed, you should not need to restart the proxy minion—it should just pick up the the new password provided in the list. You can then change pillar at will to move that password to the front and retire the unused ones.

This also allows you to use any number of potential fallback passwords.

**Note:** When a password is changed on the host to one in the list of possible passwords, the further down on the list the password is, the longer individual commands will take to return. This is due to the nature of pyVmomi’s login system. We have to wait for the first attempt to fail before trying the next password on the list.
This scenario is especially true, and even slower, when the proxy minion first starts. If the correct password is not the first password on the list, it may take up to a minute for `test.ping` to respond with a `True` result. Once the initial authorization is complete, the responses for commands will be a little faster.

To avoid these longer waiting periods, SaltStack recommends moving the correct password to the top of the list and restarting the proxy minion at your earliest convenience.

### protocol

If the ESXi host is not using the default protocol, set this value to an alternate protocol. Default is `https`.

### port

If the ESXi host is not using the default port, set this value to an alternate port. Default is `443`.

### credstore

If the ESXi host is using an untrusted SSL certificate, set this value to the file path where the credential store is located. This file is passed to `esxcli`. Default is `<HOME>/vmware/credstore/vicredentials.xml` on Linux and `<APPDATA>/VMware/credstore/vicredentials.xml` on Windows.

**Note:** HOME variable is sometimes not set for processes running as system services. If you want to rely on the default credential store location, make sure HOME is set for the proxy process.

### Salt Proxy

After your pillar is in place, you can test the proxy. The proxy can run on any machine that has network connectivity to your Salt Master and to the ESXi host in question. SaltStack recommends that the machine running the salt-proxy process also run a regular minion, though it is not strictly necessary.

On the machine that will run the proxy, make sure there is an `/etc/salt/proxy` file with at least the following in it:

```yaml
master: <ip or hostname of salt-master>
```

You can then start the salt-proxy process with:

```
salt-proxy --proxyid <id you want to give the host>
```

You may want to add `-l debug` to run the above in the foreground in debug mode just to make sure everything is OK.

Next, accept the key for the proxy on your salt-master, just like you would for a regular minion:

```
salt-key -a <id you gave the esxi host>
```

You can confirm that the pillar data is in place for the proxy:

```
salt <id> pillar.items
```
And now you should be able to ping the ESXi host to make sure it is responding:

```
salt <id> test.ping
```

At this point you can execute one-off commands against the host. For example, you can get the ESXi host’s system information:

```
salt <id> esxi.cmd system_info
```

Note that you don’t need to provide credentials or an ip/hostname. Salt knows to use the credentials you stored in Pillar.

It’s important to understand how this particular proxy works. `Salt.modules.vsphere` is a standard Salt execution module. If you pull up the docs for it you’ll see that almost every function in the module takes credentials and a target host. When credentials and a host aren’t passed, Salt runs commands through `pyVmomi` against the local machine. If you wanted, you could run functions from this module on any host where an appropriate version of `pyVmomi` is installed, and that host would reach out over the network and communicate with the ESXi host.

`esxi.cmd` acts as a `shim` between the execution module and the proxy. Its first parameter is always the function from `salt.modules.vsphere`. If the function takes more positional or keyword arguments you can append them to the call. It’s this shim that speaks to the ESXi host through the proxy, arranging for the credentials and hostname to be pulled from the Pillar section for this Proxy Minion.

Because of the presence of the shim, to lookup documentation for what functions you can use to interface with the ESXi host, you’ll want to look in `salt.modules.vsphere` instead of `salt.modules.esxi`.

**States**

Associated states are thoroughly documented in `salt.states.esxi`. Look there to find an example structure for Pillar as well as an example `.sls` file for standing up an ESXi host from scratch.

```
salt.proxy.esxi.ch_config(cmd, *args, **kwargs)
```

This function is called by the `salt.modules.esxi.cmd` shim. It then calls whatever is passed in `cmd` inside the `salt.modules.vsphere` module. Passes the return through from the vsphere module.

- `cmd` The command to call inside `salt.modules.vsphere`
- `args` Arguments that need to be passed to that command.
- `kwargs` Keyword arguments that need to be passed to that command.

```
salt.proxy.esxi.find_credentials(host)
```

Cycle through all the possible credentials and return the first one that works.

```
salt.proxy.esxi.grains()
```

Get the grains from the proxy device.

```
salt.proxy.esxi.grains_refresh()
```

Refresh the grains from the proxy device.

```
salt.proxy.esxi.init(opts)
```

This function gets called when the proxy starts up. For ESXi devices, the host, login credentials, and, if configured, the protocol and port are cached.

```
salt.proxy.esxi.ping()
```

Check to see if the host is responding. Returns False if the host didn’t respond, True otherwise.

**CLI Example:**

```
salt esxi-host test.ping
```
salt.proxy.esxi.shutdown()
	Shutdown the connection to the proxy device. For this proxy, shutdown is a no-op.

19.13.5 salt.proxy.fx2

Dell FX2 chassis

New in version 2015.8.2.

Proxy minion interface module for managing Dell FX2 chassis (Dell Chassis Management Controller version 1.2 and above, iDRAC8 version 2.00 and above)

Dependencies

- iDRAC Remote execution module (salt.modules.dracr)
- Chassis command shim (salt.modules.chassis)
- Dell Chassis States (salt.states.dellchassis)
- Dell's racadm command line interface to CMC and iDRAC devices.

Special Note: SaltStack thanks Adobe Corporation for their support in creating this proxy minion integration.

This proxy minion enables Dell FX2 and FX2s (hereafter referred to as simply `chassis`, `CMC`, or `FX2`) chassis to be treated individually like a salt-minion.

Since the CMC embedded in the chassis does not run an OS capable of hosting a Python stack, the chassis can't run a minion directly. Salt's "Proxy Minion" functionality enables you to designate another machine to host a minion process that "proxies" communication from the salt-master. The master does not know nor care that the target is not a real minion.

More in-depth conceptual reading on Proxy Minions can be found in the Proxy Minion section of Salt's documentation.

To configure this integration, follow these steps:

Pillar

Proxy minions get their configuration from Salt's Pillar. Every proxy must have a stanza in Pillar, and a reference in the Pillar topfile that matches the ID. At a minimum for communication with the chassis the pillar should look like this:

```yaml
proxy:
  host: <ip or dns name of chassis controller>
  admin_username: <iDRAC username for the CMC, usually 'root'>
  fallback_admin_username: <username to try if the first fails>
  passwords:
    - first_password
    - second_password
    - third_password
  proxytype: fx2
```
The `proxytype` line above is critical, it tells Salt which interface to load from the `proxy` directory in Salt's install hierarchy, or from `/srv/salt/_proxy` on the salt-master (if you have created your own proxy module, for example).

The proxy integration will try the passwords listed in order. It is configured this way so you can have a regular password, a potential fallback password, and the third password can be the one you intend to change the chassis to use. This way, after it is changed, you should not need to restart the proxy minion—it should just pick up the third password in the list. You can then change pillar at will to move that password to the front and retire the unused ones.

Beware, many Dell CMC and iDRAC units are configured to lockout IP addresses or users after too many failed password attempts. This can generate user panic in the form of ``I no longer know what the password is‼''. To mitigate panic try the web interface from a different IP, or setup a emergency administrator user in the CMC before doing a wholesale password rotation.

The automatic lockout can be disabled via Salt with the following:

```bash
salt <cmc> chassis.cmd set_general cfgRacTuning cfgRacTuneIpBlkEnable 0
```

and then verified with

```bash
salt <cmc> chassis.cmd get_general cfgRacTuning cfgRacTuneIpBlkEnable
```

**salt-proxy**

After your pillar is in place, you can test the proxy. The proxy can run on any machine that has network connectivity to your salt-master and to the chassis in question. SaltStack recommends that this machine also run a regular minion, though it is not strictly necessary.

On the machine that will run the proxy, make sure there is an `/etc/salt/proxy` file with at least the following in it:

```bash
master: <ip or hostname of salt-master>
```

You can start the proxy with

```bash
salt-proxy --proxyid <id you want to give the chassis>
```

You may want to add `-l debug` to run the above in the foreground in debug mode just to make sure everything is OK.

Next, accept the key for the proxy on your salt-master, just like you would for a regular minion:

```bash
salt-key -a <id you want to give the chassis>
```

You can confirm that the pillar data is in place for the proxy:

```bash
salt <id> pillar.items
```

And now you should be able to ping the chassis to make sure it is responding:

```bash
salt <id> test.ping
```

At this point you can execute one-off commands against the chassis. For example, you can get the chassis inventory:

```bash
salt <id> chassis.cmd inventory
```

19.13. proxy modules
Note that you don't need to provide credentials or an ip/hostname. Salt knows to use the credentials you stored in Pillar.

It's important to understand how this particular proxy works. `Salt.modules.dracr` is a standard Salt execution module. If you pull up the docs for it you'll see that almost every function in the module takes credentials and a target host. When credentials and a host aren't passed, Salt runs `racadm` against the local machine. If you wanted you could run functions from this module on any host where an appropriate version of `racadm` is installed, and that host would reach out over the network and communicate with the chassis.

Chassis.cmd acts as a ``shim`` between the execution module and the proxy. It's first parameter is always the function from `salt.modules.dracr` to execute. If the function takes more positional or keyword arguments you can append them to the call. It's this shim that speaks to the chassis through the proxy, arranging for the credentials and hostname to be pulled from the pillar section for this proxy minion.

Because of the presence of the shim, to lookup documentation for what functions you can use to interface with the chassis, you'll want to look in `salt.modules.dracr` instead of `salt.modules.chassis`.

**States**

Associated states are thoroughly documented in `salt.states.dellchassis`. Look there to find an example structure for pillar as well as an example .sls file for standing up a Dell Chassis from scratch.

```python
salt.proxy.fx2.admin_password()
    Return the admin_password in the DETAILS dictionary, or `calvin` (the Dell default) if there is none present

salt.proxy.fx2.admin_username()
    Return the admin_username in the DETAILS dictionary, or root if there is none present

salt.proxy.fx2.chconfig(cmd, *args, **kwargs)
    This function is called by the `salt.modules.chassis.cmd` shim. It then calls whatever is passed in cmd inside the `salt.modules.dracr` module.

    Parameters
    • cmd -- The command to call inside salt.modules.dracr
    • args -- Arguments that need to be passed to that command
    • kwargs -- Keyword arguments that need to be passed to that command

    Returns Passthrough the return from the drac module.

salt.proxy.fx2.find_credentials()
    Cycle through all the possible credentials and return the first one that works

salt.proxy.fx2.grains()
    Get the grains from the proxied device

salt.proxy.fx2.grains_refresh()
    Refresh the grains from the proxied device

salt.proxy.fx2.host()

salt.proxy.fx2.init(opts)
    This function gets called when the proxy starts up. We check opts to see if a fallback user and password are supplied. If they are present, and the primary credentials don't work, then we try the backup before failing.

    Whichever set of credentials works is placed in the persistent DETAILS dictionary and will be used for further communication with the chassis.

salt.proxy.fx2.ping()
    Is the chassis responding?

    Returns Returns False if the chassis didn't respond, True otherwise.
**salt.proxy.fx2.shutdown**(opts)

Shutdown the connection to the proxied device. For this proxy shutdown is a no-op.

### 19.13.6 salt.proxy.junos

Interface with a Junos device via proxy-minion. To connect to a junos device via junos proxy, specify the host information in the pillar in `/srv/pillar/details.sls`

```yaml
proxy:
  proxytype: junos
  host: <ip or dns name of host>
  username: <username>
  port: 830
  password: <secret>
```

In `/srv/pillar/top.sls` map the device details with the proxy name.

```yaml
base:
  'vmx':
    - details
```

After storing the device information in the pillar, configure the proxy in `/etc/salt/proxy`

```yaml
master: <ip or hostname of salt-master>
```

Run the salt proxy via the following command:

```bash
salt-proxy --proxyid=vmx
```

**salt.proxy.junos.conn()**

**salt.proxy.junos.get_serialized_facts()**

**salt.proxy.junos.init(opts)**

Open the connection to the Junos device, login, and bind to the Resource class

**salt.proxy.junos.initialized()**

**salt.proxy.junos.ping()**

Ping? Pong!

**salt.proxy.junos.proxytype()**

Returns the name of this proxy

**salt.proxy.junos.shutdown(opts)**

This is called when the proxy-minion is exiting to make sure the connection to the device is closed cleanly.

### 19.13.7 salt.proxy.marathon module

Marathon

Proxy minion for managing a Marathon cluster.

**Dependencies**

- *marathon execution module (salt.modules.marathon)*
Pillar

The marathon proxy configuration requires a `base_url` property that points to the marathon endpoint:

```yaml
proxy:
  proxypredtype: marathon
  base_url: http://my-marathon-master.mydomain.com:8080
```

New in version 2015.8.2.

```python
salt.proxy.marathon.init(opts)

Perform any needed setup.
```

```python
salt.proxy.marathon.ping()

Is the marathon api responding?
```

```python
salt.proxy.marathon.shutdown(opts)

For this proxy shutdown is a no-op
```

19.13.8 salt.proxy.napalm

NAPALM: Network Automation and Programmability Abstraction Layer with Multivendor support

Proxy minion for managing network devices via NAPALM library.

- **codeauthor** Mircea Ulinic <mircea@cloudflare.com> & Jerome Fleury <jf@cloudflare.com>
- **maturity** new
- **depends** napalm
- **platform** unix

**Dependencies**

The napalm proxy module requires NAPALM library to be installed: `pip install napalm` Please check Installation for complete details.

**Note:** Beginning with Salt release 2017.7.3, it is recommended to use napalm >= 2.0.0. The library has been unified into a monolithic package, as in opposite to separate packages per driver. For more details you can check this document. While it will still work with the old packages, bear in mind that the NAPALM core team will maintain only the main napalm package.

Moreover, for additional capabilities, the users can always define a library that extends NAPALM's base capabilities and configure the provider option (see below).

Pillar

The napalm proxy configuration requires the following parameters in order to connect to the network device:

- **driver** Specifies the network device operating system. For a complete list of the supported operating systems please refer to the NAPALM Read the Docs page.
- **host** The IP Address or FQDN to use when connecting to the device. Alternatively, the following field names can be used instead: hostname, fqdn, ip.
username The username to be used when connecting to the device.

passwd The password needed to establish the connection.

**Note:** This field may not be mandatory when working with SSH-based drivers, and the username has a SSH key properly configured on the device targeted to be managed.

**optional_args** Dictionary with the optional arguments. Check the complete list of supported optional arguments.

**always alive:** **True** In certain less dynamic environments, maintaining the remote connection permanently open with the network device is not always beneficial. In that case, the user can select to initialize the connection only when needed, by specifying this field to `false`. Default: `true` (maintains the connection with the remote network device).

New in version 2017.7.0.

**provider:** **napalm_base** The library that provides the `get_network_device` function. This option is useful when the user has more specific needs and requires to extend the NAPALM capabilities using a private library implementation. The only constraint is that the alternative library needs to have the `get_network_device` function available.

New in version 2017.7.1.

**multiprocessing:** **False** Overrides the `multiprocessing` option, per proxy minion. The `multiprocessing` option must be turned off for SSH-based proxies. However, some NAPALM drivers (e.g. Arista, NX-OS) are not SSH-based. As multiple proxy minions may share the same configuration file, this option permits the configuration of the `multiprocessing` option more specifically, for some proxy minions.

New in version 2017.7.2.

Proxy pillar file example:

```
proxy:
    proxitype: napalm
    driver: junos
    host: core05.nrt02
    username: my_username
    passwd: my_password
    optional_args:
        port: 12201
```

Example using a user-specific library, extending NAPALM's capabilities, e.g. `custom_napalm_base`:

```
proxy:
    proxitype: napalm
    driver: ios
    fqdn: cr1.th2.par.as1234.net
    username: salt
    password: 
    provider: custom_napalm_base
```

See also:

- **NAPALM grains**: select network devices based on their characteristics
- **NET module**: network basic features
- **Network config state**: Manage the configuration using arbitrary templates
- **NAPALM YANG state**: Manage the configuration according to the YANG models (OpenConfig/IETF)
• Network ACL module: Generate and load ACL (firewall) configuration
• Network ACL state: Manage the firewall configuration
• NTP operational and configuration management module
• BGP operational and configuration management module
• Routes details
• SNMP configuration module
• Users configuration management

New in version 2016.11.0.

```
salt.proxy.napalm.alive(*opts)
    Return the connection status with the remote device.
```

New in version 2017.7.0.

```
salt.proxy.napalm.call(*method, **args, **kwargs)
    Calls a specific method from the network driver instance. Please check the readthedocs page for the updated list of getters.
    Parameters
        • method -- specifies the name of the method to be called
        • params -- contains the mapping between the name and the values of the parameters needed to call the method
    Returns
        A dictionary with three keys:
        • result (True/False): if the operation succeeded
        • out (object): returns the object as-is from the call
        • comment (string): provides more details in case the call failed
        • traceback (string): complete traceback in case of exception. Please submit an issue including this traceback on the correct driver repo and make sure to read the FAQ
    Example:
```

```
    __proxy__[napalm.call](*cli'
        **{
            'commands': [
                'show version',
                'show chassis fan'
            ]
        })
```

```
salt.proxy.napalm.fns()
    Method called by NAPALM grains module.
```

```
salt.proxy.napalm.get_device()
    Returns the network device object.
```

```
salt.proxy.napalm.get_grains()
    Retrieve facts from the network device.
```

```
salt.proxy.napalm.grains_refresh()
    Refresh the grains.
```

```
salt.proxy.napalm.init(*opts)
    Opens the connection with the network device.
```

```
salt.proxy.napalm.initialized()
    Connection finished initializing?
```
salt.proxy.napalm.ping()
  Connection open successfully?
salt.proxy.napalm.shutdown(opts)
  Closes connection with the device.

19.13.9 salt.proxy.nxos module

Proxy Minion for Cisco NX OS Switches
The Cisco NX OS Proxy Minion uses the built in SSHConnection module in salt.utils.vt_helper
To configure the proxy minion:

```
proxy:
  proxytype: nxos
  host: 192.168.187.100
  username: admin
  password: admin
  prompt_name: switch
  ssh_args: '-o PubkeyAuthentication=no'
  key_accept: True
```

proxytype (REQUIRED) Use this proxy minion nxos
host (REQUIRED) ip address or hostname to connect to
username (REQUIRED) username to login with
password (REQUIRED) password to use to login with
prompt_name (REQUIRED) The name in the prompt on the switch. By default, use your devices hostname.
ssh_args Any extra args to use to connect to the switch.
key_accept Whether or not to accept a the host key of the switch on initial login. Defaults to False.
The functions from the proxy minion can be run from the salt commandline using the salt.modules.nxos execution module.
salt.proxy.nxos.add_config(lines)
  Add one or more config lines to the switch running config
  ```
  salt '*' nxos.cmd add_config 'snmp-server community TESTSTRINGHERE group network-operator'
  ```

Note: For more than one config added per command, lines should be a list.

salt.proxy.nxos.check_password(username, password, encrypted=False)
  Check if passed password is the one assigned to user
salt.proxy.nxos.check_role(username, role)
  Check if user is assigned a specific role on switch
  ```
  salt '*' nxos.cmd check_role username=admin role=network-admin
  ```
salt.proxy.nxos.delete_config(lines)
  Delete one or more config lines to the switch running config
Note: For more than one config deleted per command, lines should be a list.

```
salt '*' nxos.cmd delete_config 'snmp-server community TESTSTRINGHERE group*network-operator'
```

**Note:** For more than one config deleted per command, lines should be a list.

```
salt.proxy.nxos.find(pattern)
    Find all instances where the pattern is in the running command
```

```
salt '*' nxos.cmd find '^snmp-server.*$'
```

**Note:** This uses the `re.MULTILINE` regex format for python, and runs the regex against the whole `show_run` output.

```
salt.proxy.nxos.get_roles(username)
    Get roles that the username is assigned from switch
```

```
salt.proxy.nxos.get_user(username)
    Get username line from switch
```

```
salt.proxy.nxos.grains()
    Get grains for proxy minion
```

```
salt.proxy.nxos.grains_refresh()
    Refresh the grains from the proxy device.
```

```
salt.proxy.nxos.init(opts=None)
    Required. Can be used to initialize the server connection.
```

```
salt.proxy.nxos.initialized()
```

```
salt.proxy.nxos.ping()
    Ping the device on the other end of the connection
```

```
salt.proxy.nxos.remove_user(username)
    Remove user from switch
```

```
salt '*' nxos.cmd remove_user username=daniel
```

```
salt.proxy.nxos.replace(old_value, new_value, full_match=False)
    Replace string or full line matches in switch's running config
    If full_match is set to True, then the whole line will need to be matched as part of the old value.
```

```
salt '*' nxos.cmd replace 'TESTSTRINGHERE' 'NEWTESTSTRINGHERE'
```

```
salt.proxy.nxos.sendline(command)
    Run command through switch's cli
```

```
salt.proxy.nxos.set_password(username, password, encrypted=False, role=None, crypt_salt=None, algorithm='sha256')
    Set users password on switch
```

```
salt '*' nxos.cmd set_password admin TestPass
salt '*' nxos.cmd set_password admin \
    password='$5$2fWwO2vK$s7.Hr3YltMNHywQQ3nfOo.dgAPHgs3S0BYyGT3E.A' \  
    encrypted=True
```
salt.proxy.nxos.set_role(username, role)
Assign role to username
```
salt '*' nxos.cmd set_role username=daniel role=vdc-admin
```

salt.proxy.nxos.show_run()
Shortcut to run show run on switch
```
salt '*' nxos.cmd show_run
```

salt.proxy.nxos.show_ver()
Shortcut to run show ver on switch
```
salt '*' nxos.cmd show_ver
```

salt.proxy.nxos.shutdown(opts)
Disconnect

salt.proxy.nxos.system_info()
Return system information for grains of the NX OS proxy minion
```
salt '*' nxos.system_info
```

salt.proxy.nxos.unset_role(username, role)
Remove role from username
```
salt '*' nxos.cmd unset_role username=daniel role=vdc-admin
```

19.13.10 salt.proxy.philips_hue module
Philips HUE lamps module for proxy.
New in version 2015.8.3.

class salt.proxy.philips_hue.Const
Constants for the lamp operations.
```
COLOR_BLUE = {'hue': 46920, 'sat': 254}
COLOR_DAYLIGHT = {'xy': [0.3806, 0.3576]}
COLOR_GREEN = {'hue': 25500, 'sat': 254}
COLOR_ORANGE = {'hue': 12000, 'sat': 254}
COLOR_PINK = {'xy': [0.3688, 0.2095]}
COLOR_PURPLE = {'xy': [0.3787, 0.1724]}
COLOR_RED = {'hue': 0, 'sat': 254}
COLOR_WHITE = {'xy': [0.3227, 0.329]}
COLOR_YELLOW = {'xy': [0.4432, 0.5154]}
LAMP_OFF = {'transitiontime': 0, 'on': False}
LAMP_ON = {'transitiontime': 0, 'on': True}
```
salt.proxy.philips_hue.call_alert(*args, **kwargs)
Lamp alert
Options:
- **id**: Specifies a device ID. Can be a comma-separated values. All, if omitted.
- **on**: Turns on or off an alert. Default is True.
CLI Example:
salt '*' hue.alert
salt '*' hue.alert id=1
salt '*' hue.alert id=1,2,3 on=false

salt.proxy.philips_hue.call_blink(*args, **kwargs)
Blink a lamp. If lamp is ON, then blink ON-OFF-ON, otherwise OFF-ON-OFF.
Options:
- **id**: Specifies a device ID. Can be a comma-separated values. All, if omitted.
- **pause**: Time in seconds. Can be less than 1, i.e. 0.7, 0.5 sec.
CLI Example:
salt '*' hue.blink id=1
salt '*' hue.blink id=1,2,3

salt.proxy.philips_hue.call_brightness(*args, **kwargs)
Set an effect to the lamp.
Arguments:
- **value**: 0–255 brightness of the lamp.
Options:
- **id**: Specifies a device ID. Can be a comma-separated values. All, if omitted.
- **transition**: Transition 0–200. Default 0.
CLI Example:
salt '*' hue.brightness value=100
salt '*' hue.brightness id=1 value=150
salt '*' hue.brightness id=1,2,3 value=255

salt.proxy.philips_hue.call_color(*args, **kwargs)
Set a color to the lamp.
Options:
- **id**: Specifies a device ID. Can be a comma-separated values. All, if omitted.
- **color**: Fixed color. Values are: red, green, blue, orange, pink, white, yellow, daylight, purple. Default white.
- **transition**: Transition 0–200.
Advanced:
- **gamut**: XY coordinates. Use gamut according to the Philips HUE devices documentation. More: http://www.developers.meethue.com/documentation/hue-xy-values
CLI Example:
salt '*' hue.color
salt '*' hue.color id=1
salt '*' hue.color id=1,2,3 color=red transition=30
salt '*' hue.color id=1 gamut=0.3,0.5

salt.proxy.philips_hue.call_effect(*args, **kwargs)
Set an effect to the lamp.
Options:

- **id**: Specifies a device ID. Can be a comma-separated values. All, if omitted.
- **type**: Type of the effect. Possible values are `none` or `colorloop`. Default `none`.

**CLI Example:**

```plaintext
salt '*' hue.effect
salt '*' hue.effect id=1
salt '*' hue.effect id=1,2,3 type=colorloop
```

### `salt.proxy.philips_hue.call_lights(**args, **kwargs)`

Get info about all available lamps.

**Options:**

- **id**: Specifies a device ID. Can be a comma-separated values. All, if omitted.

**CLI Example:**

```plaintext
salt '*' hue.lights
salt '*' hue.lights id=1
salt '*' hue.lights id=1,2,3
```

### `salt.proxy.philips_hue.call_ping(**args, **kwargs)`

Ping the lamps by issuing a short inversion blink to all available devices.

**CLI Example:**

```plaintext
salt '*' hue.ping
```

### `salt.proxy.philips_hue.call_rename(**args, **kwargs)`

Rename a device.

**Options:**

- **id**: Specifies a device ID. Only one device at a time.
- **title**: Title of the device.

**CLI Example:**

```plaintext
salt '*' hue.rename id=1 title='WC for cats'
```

### `salt.proxy.philips_hue.call_status(**args, **kwargs)`

Return the status of the lamps.

**Options:**

- **id**: Specifies a device ID. Can be a comma-separated values. All, if omitted.

**CLI Example:**

```plaintext
salt '*' hue.status
salt '*' hue.status id=1
salt '*' hue.status id=1,2,3
```

### `salt.proxy.philips_hue.call_switch(**args, **kwargs)`

Switch lamp ON/OFF.

If no particular state is passed, then lamp will be switched to the opposite state.

**Options:**

- **id**: Specifies a device ID. Can be a comma-separated values. All, if omitted.
- **on**: True or False. Inverted current, if omitted

**CLI Example:**
salt '*

```shell
salt '*' hue.switch
salt '*' hue.switch id=1
salt '*' hue.switch id=1,2,3 on=True
```

```python
salt.proxy.philips_hue.call_temperature(*args, **kwargs)
```

Set the mired color temperature. More: http://en.wikipedia.org/wiki/Mired

Arguments:
- **value**: 150–500.

Options:
- **id**: Specifies a device ID. Can be a comma-separated values. All, if omitted.

CLI Example:
```shell
salt '*' hue.temperature value=150
salt '*' hue.temperature value=150 id=1
salt '*' hue.temperature value=150 id=1,2,3
```

```python
salt.proxy.philips_hue.init(cnf)
```

Initialize the module.

```python
salt.proxy.philips_hue.ping(*args, **kw)
```

Ping the lamps.

```python
salt.proxy.philips_hue.shutdown(opts, *args, **kw)
```

Shuts down the service.

### 19.13.11 salt.proxy.rest_sample

This is a simple proxy-minion designed to connect to and communicate with the botle-based web service contained in https://github.com/saltstack/salt-contrib/tree/master/proxyminion_rest_example

```python
salt.proxy.rest_sample.alive(opts)
salt.proxy.rest_sample.fix_outage()
salt.proxy.rest_sample.fns()
salt.proxy.rest_sample.grains()
```

Get the grains from the proxied device

```python
salt.proxy.rest_sample.grains_refresh()
```

Refresh the grains from the proxied device

```python
salt.proxy.rest_sample.id(opts)
```

Return a unique ID for this proxy minion. This ID MUST NOT CHANGE. If it changes while the proxy is running, the salt-master will get really confused and may stop talking to this minor

```python
salt.proxy.rest_sample.init(opts)
```

```python
salt.proxy.rest_sample.initialized()
```

Since grains are loaded in many different places and some of those places occur before the proxy can be initialized, return whether our init() function has been called.

```python
salt.proxy.rest_sample.package_install(name, **kwargs)
```

Install a `package` on the REST server

```python
salt.proxy.rest_sample.package_list()
```

List `packages` installed on the REST server
salt.proxy.rest_sample.package_remove(name)
    Remove a ``package`` on the REST server

salt.proxy.rest_sample.package_status(name)
    Check the installation status of a package on the REST server

salt.proxy.rest_sample.ping()
    Is the REST server up?

salt.proxy.rest_sample.service_list()
    List ``services`` on the REST server

salt.proxy.rest_sample.service_restart(name)
    Restart a ``service`` on the REST server

salt.proxy.rest_sample.service_start(name)
    Start a ``service`` on the REST server

salt.proxy.rest_sample.service_status(name)
    Check if a service is running on the REST server

salt.proxy.rest_sample.service_stop(name)
    Stop a ``service`` on the REST server

salt.proxy.rest_sample.shutdown(opts)
    For this proxy shutdown is a no-op

salt.proxy.rest_sample.test_from_state()
    Test function so we have something to call from a state :return:

salt.proxy.rest_sample.uptodate(name)
    Call the REST endpoint to see if the packages on the ``server`` are up to date.

---

19.13.12 salt.proxy.ssh_sample

This is a simple proxy-minion designed to connect to and communicate with a server that exposes functionality via SSH. This can be used as an option when the device does not provide an api over HTTP and doesn't have the python stack to run a minion.

salt.proxy.ssh_sample.fns()

salt.proxy.ssh_sample.grains()
    Get the grains from the proxied device

salt.proxy.ssh_sample.grains_refresh()
    Refresh the grains from the proxied device

salt.proxy.ssh_sample.init(opts)
    Required. Can be used to initialize the server connection.

salt.proxy.ssh_sample.initialized()
    Since grains are loaded in many different places and some of those places occur before the proxy can be initialized, return whether our init() function has been called

salt.proxy.ssh_sample.package_install(name, **kwargs)
    Install a ``package`` on the ssh server

salt.proxy.ssh_sample.package_list()
    List ``packages`` by executing a command via ssh This function is called in response to the salt command
    ..code-block::bash  salt target_minion pkg.list_pkgs
salt.proxy.ssh_sample.package_remove(name)
    Remove a "package" on the ssh server

salt.proxy.ssh_sample.parse(out)
    Extract json from out.
    Parameter out: Type string. The data returned by the ssh command.

salt.proxy.ssh_sample.ping()
    Required. Ping the device on the other end of the connection

salt.proxy.ssh_sample.service_list()
    Start a "service" on the ssh server
    New in version 2015.8.2.

salt.proxy.ssh_sample.service_restart(name)
    Restart a "service" on the ssh server
    New in version 2015.8.2.

salt.proxy.ssh_sample.service_start(name)
    Start a "service" on the ssh server
    New in version 2015.8.2.

salt.proxy.ssh_sample.service_stop(name)
    Stop a "service" on the ssh server
    New in version 2015.8.2.

salt.proxy.ssh_sample.shutdown(opts)
    Disconnect

19.14 queue modules

<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pgjsonb_queue</td>
<td>New in version 2016.3.0.</td>
</tr>
<tr>
<td>sqlite_queue</td>
<td>New in version 2014.7.0.</td>
</tr>
</tbody>
</table>

19.14.1 salt.queues.pgjsonb_queue module

New in version 2016.3.0.

This is a queue with postgres as the backend. It uses the jsonb store to store information for queues.

    depends  python-psycopg2

To enable this queue, the following needs to be configured in your master config. These are the defaults:

```
queue.pgjsonb.host: 'salt'
queue.pgjsonb.user: 'salt'
queue.pgjsonb.pass: 'salt'
queue.pgjsonb.db: 'salt'
queue.pgjsonb.port: 5432
```

Use the following Pg database schema:
CREATE DATABASE salt WITH ENCODING 'utf-8';

-- Table structure for table `salt`
--
DROP TABLE IF EXISTS salt;
CREATE OR REPLACE TABLE salt(
    id SERIAL PRIMARY KEY,
    data jsonb NOT NULL
);

salt-run queue.insert test '{"name": "redis", "host": "172.16.0.8", "port": 6379}';
backend=pgjsonb
salt-run queue.process_queue test all backend=pgjsonb

salt.queues.pgjsonb_queue.delete(queue, items)
    Delete an item or items from a queue
salt.queues.pgjsonb_queue.handle_queue_creation(queue)
salt.queues.pgjsonb_queue.insert(queue, items)
    Add an item or items to a queue
salt.queues.pgjsonb_queue.list_items(queue)
    List contents of a queue
salt.queues.pgjsonb_queue.list_length(queue)
    Provide the number of items in a queue
salt.queues.pgjsonb_queue.list_queues()
    Return a list of Salt Queues on the Salt Master
salt.queues.pgjsonb_queue.pop(queue, quantity=1)
    Pop one or more or all items from the queue return them.

19.14.2 salt.queues.sqlite_queue module

New in version 2014.7.0.

This is the default local master event queue built on sqlite. By default, an sqlite3 database file is created in the sqlite_queue_dir which is found at:

/var/cache/salt/master/queues

It's possible to store the sqlite3 database files by setting sqlite_queue_dir to another location:

sqlite_queue_dir: /home/myuser/salt/master/queues

salt.queues.sqlite_queue.delete(queue, items)
    Delete an item or items from a queue
salt.queues.sqlite_queue.insert(queue, items)
    Add an item or items to a queue
salt.queues.sqlite_queue.list_items(queue)
    List contents of a queue
salt.queues.sqlite_queue.list_length(queue)
    Provide the number of items in a queue
salt.queues.sqlite_queue.list_queues()
    Return a list of Salt Queues on the Salt Master

salt.queues.sqlite_queue.pop(queue, quantity=1)
    Pop one or more or all items from the queue return them.

## 19.15 roster modules

<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ansible</td>
<td>Read in an Ansible inventory file or script</td>
</tr>
<tr>
<td>cache</td>
<td>The cache roster provides a flexible interface to the Salt Masters’ minion cache to access regular minions over salt-ssh.</td>
</tr>
<tr>
<td>cloud</td>
<td>Use the cloud cache on the master to derive IPv4 addresses based on minion ID.</td>
</tr>
<tr>
<td>clustershell</td>
<td>This roster resolves hostname in a pdsh/clustershell style.</td>
</tr>
<tr>
<td>flat</td>
<td>Read in the roster from a flat file using the renderer system</td>
</tr>
<tr>
<td>range</td>
<td>This roster resolves targets from a range server.</td>
</tr>
<tr>
<td>scan</td>
<td>Scan a netmask or ipaddr for open ssh ports</td>
</tr>
</tbody>
</table>

### 19.15.1 salt.roster.ansible

Read in an Ansible inventory file or script

Flat inventory files should be in the regular ansible inventory format.

```plaintext
[servers]
salt.gtmanfred.com ansible_ssh_user=gtmanfred ansible_ssh_host=127.0.0.1 ansible_ssh_port=22 ansible_ssh_pass='password'

[desktop]
home ansible_ssh_user=gtmanfred ansible_ssh_host=12.34.56.78 ansible_ssh_port=23 ansible_ssh_pass='password'

[computers:children]
desktop
servers

[names:vars]
http_port=80
```

Then salt-ssh can be used to hit any of them

```bash
[-]# salt-ssh all test.ping
salt.gtmanfred.com: True
home: True
[-]# salt-ssh desktop test.ping
home: True
[-]# salt-ssh computers test.ping
salt.gtmanfred.com: True
```

---

2538 Chapter 19. Salt Module Reference
There is also the option of specifying a dynamic inventory, and generating it on the fly

```
#!/bin/bash
echo '{
    "servers": [
        "salt.gtmanfred.com"
    ],
    "desktop": [
        "home"
    ],
    "computers": {
        "hosts": [],
        "children": [
            "desktop",
            "servers"
        ]
    },
    "_meta": {
        "hostvars": {
            "salt.gtmanfred.com": {
                "ansible_ssh_user": "gtmanfred",
                "ansible_ssh_host": "127.0.0.1",
                "ansible_sudo_pass": "password",
                "ansible_ssh_port": 22
            },
            "home": {
                "ansible_ssh_user": "gtmanfred",
                "ansible_ssh_host": "12.34.56.78",
                "ansible_sudo_pass": "password",
                "ansible_ssh_port": 23
            }
        }
    }
}'
```

This is the format that an inventory script needs to output to work with ansible, and thus here.

```
[~]# salt-ssh --roster-file /etc/salt/hosts salt.gtmanfred.com test.ping
salt.gtmanfred.com: True
```

Any of the [groups] or direct hostnames will return. The `all' is special, and returns everything.

```python
class salt.roster.ansible.Inventory(tgt, tgt_type='glob', inventory_file='./etc/salt/roster')
Matcher for static inventory files

class salt.roster.ansible.Script(tgt, tgt_type='glob', inventory_file='./etc/salt/roster')
Matcher for Inventory scripts

class salt.roster.ansible.Target

    get_glob()
```

19.15. roster modules
Return minions that match via glob

\texttt{targets()}

Execute the correct tgt\_type routine and return

\texttt{salt.roster.ansible.targets(tgt, tgt\_type='glob', **kwargs)}

Return the targets from the ansible inventory\_file Default: /etc/salt/roster

\section*{19.15.2 \texttt{salt.roster.cache}}

The \texttt{cache} roster provides a flexible interface to the Salt Masters' minion cache to access regular minions over \texttt{salt-ssh}.

New in version 2017.7.0: grains, pillar, mine data matching SDB URLs IPv6 support roster\_order per config key default order changed to industry-wide best practices CIDR range selection

\subsection*{Targeting}

This roster supports all matching and targeting of the Salt Master. The matching will be done using only the Salt Master's cache.

\subsection*{The Roster Order}

The roster's composition can be configured using \texttt{roster\_order}. In the \texttt{roster\_order} you can define any roster key and fill it with a parameter overriding the one in \texttt{roster\_defaults}:

- \texttt{roster\_order: host: id} # use the minion id as hostname

You can define lists of parameters as well, the first result from the list will become the value.

\subsection*{Selecting a host}

\begin{verbatim}
# default
roster_order: host:
  - ipv6-private # IPv6 addresses in private ranges
  - ipv6-global # IPv6 addresses in global ranges
  - ipv4-private # IPv4 addresses in private ranges
  - ipv4-public # IPv4 addresses in public ranges
  - ipv4-local # loopback addresses
\end{verbatim}

This is the default \texttt{roster\_order}. It prefers IPv6 over IPv4 addresses and private addresses over public ones. The relevant data will be fetched from the cache in-order, and the first match will fill the \texttt{host} key.

Other address selection parameters are also possible:

\begin{verbatim}
roster_order: host:
  - global|public|private|local # Both IPv6 and IPv4 addresses in that range
  - 2000::/3 # CIDR networks, both IPv4 and IPv6 are supported
\end{verbatim}
Using cached data

Several cached libraries can be selected using the `library:` prefix, followed by the library key. This can be referenced using the same `:` syntax as e.g. `pillar.get`. Lists of references are also supported during the lookup, as are Salt SDB URLs.

This should be especially useful for the other roster keys:

```
roster_order:
  host:
    - grain: fqdn_ip4  # Lookup this grain
    - mine: network.ip_addrs  # Mine data lookup works the same
  password: sdb://vault/ssh_pass  # Salt SDB URLs are also supported
  user:
    - pillar: ssh:auth:user  # Lookup this pillar key
    - sdb://osenv/USER  # Lookup this env var through sdb
  priv:
    - pillar:  # Lists are also supported
      - salt:ssh:private_key
      - ssh:auth:private_key
```

```
salt.roster.cache.targets(tgt, tgt_type='glob'; **kwargs)
```

Return the targets from the Salt Masters’ minion cache. All targets and matchers are supported.

The resulting roster can be configured using `roster_order` and `roster_default`.

### 19.15.3 salt.roster.cloud

Use the cloud cache on the master to derive IPv4 addresses based on minion ID.

This roster requires that the minion in question was created using at least the 2015.5.0 version of Salt Cloud. Starting with the 2015.5.0 release, Salt Cloud maintains an index of minions that it creates and deletes. This index tracks the provider and profile configuration used to provision the minion, including authentication information. So long as this configuration remains current, it can be used by Salt SSH to log into any minion in the index.

To connect as a user other than root, modify the cloud configuration file usually located at `/etc/salt/cloud`. For example, add the following:

```
ssh_username: my_user
sudo: True
```

```
salt.roster.cloud.extract_ipv4(roster_order, ipv4)
```

Extract the preferred IP address from the ipv4 grain

```
salt.roster.cloud.targets(tgt, tgt_type='glob'; **kwargs)
```

Return the targets from the flat yaml file, checks opts for location but defaults to `/etc/salt/roster`

### 19.15.4 salt.roster.clustershell

This roster resolves hostname in a pdsh/clustershell style.

```
depends clustershell, https://github.com/cea-hpc/clustershell
```

When you want to use host globs for target matching, use `--roster clustershell`. For example:
salt-ssh --roster clustershell 'server_[1-10,21-30],test_server[5,7,9]' test.ping

salt.roster.clustershell.targets(tgt, tgt_type='glob', **kwargs)

Return the targets

19.15.5 salt.roster.flat

Read in the roster from a flat file using the renderer system

class salt.roster.flat.RosterMatcher(raw, tgt, tgt_type, ipv='ipv4')
    Matcher for the roster data structure

    get_data(minion)
        Return the configured ip

    ret_glob_minions()
        Return minions that match via glob

    ret_list_minions()
        Return minions that match via list

    ret_nodetnodegroup_minions()
        Return minions which match the special list-only groups defined by ssh_list_nodegroups

    ret_pcre_minions()
        Return minions that match via pcre

    ret_range_minions()
        Return minions that are returned by a range query

    targets()
        Execute the correct tgt_type routine and return

salt.roster.flat.targets(tgt, tgt_type='glob', **kwargs)

Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster

19.15.6 salt.roster.range module

This roster resolves targets from a range server.

depends seco.range, https://github.com/ytoolshed/range

When you want to use a range query for target matching, use --roster range. For example:

salt-ssh --roster range '%example.range.cluster' test.ping

salt.roster.range.target_glob(tgt, hosts)

salt.roster.range.target_range(tgt, hosts)

salt.roster.range.targets(tgt, tgt_type='range', **kwargs)

Return the targets from a range query

19.15.7 salt.roster.scan

Scan a netmask or ipaddr for open ssh ports
class salt.roster.scan.RosterMatcher(tgt, tgt_type)
    Matcher for the roster data structure

    targets()
    Return ip addrs based on netmask, sitting in the `glob` spot because it is the default

salt.roster.scan.targets(tgt, tgt_type='glob', **kwargs)
    Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster

19.16 runner modules

<table>

### 19.16.1 salt.runners.asam

**Novell ASAM Runner**

New in version Beryllium.

Runner to interact with Novell ASAM Fan-Out Driver

*codeauthor* Nitin Madhok &lt;nmadhok@clemson.edu&gt;

To use this runner, set up the Novell Fan-Out Driver URL, username and password in the master configuration at `/etc/salt/master` or `/etc/salt/master.d/asam.conf`:

```yaml
asam:
    prov1.domain.com
    username: "testuser"
    password: "verybadpass"
    prov2.domain.com
    username: "testuser"
    password: "verybadpass"
```

**Note:** Optionally, `protocol` and `port` can be specified if the Fan-Out Driver server is not using the defaults. Default is `protocol: https` and `port: 3451`.

**salt.runners.asam.add_platform(name, platform_set, server_url)**

To add an ASAM platform using the specified ASAM platform set on the Novell Fan-Out Driver

**CLI Example:**

```
salt-run asam.add_platform my-test-vm test-platform-set prov1.domain.com
```
salt.runners.asam.list_platform_sets(server_url)
To list all ASAM platform sets present on the Novell Fan-Out Driver

CLI Example:
salt-run asam.list_platform_sets prov1.domain.com

salt.runners.asam.list_platforms(server_url)
To list all ASAM platforms present on the Novell Fan-Out Driver

CLI Example:
salt-run asam.list_platforms prov1.domain.com

salt.runners.asam.remove_platform(name, server_url)
To remove specified ASAM platform from the Novell Fan-Out Driver

CLI Example:
salt-run asam.remove_platform my-test-vm prov1.domain.com

19.16.2  salt.runners.auth

Authentication runner for creating, deleting, and managing eauth tokens.
New in version 2016.11.0.

salt.runners.auth.del_token(token)
Delete an eauth token by name

CLI Example:
salt-run auth.del_token 6556760736e4077daa601baec2b67c24

salt.runners.auth.mk_token(**load)
Create an eauth token using provided credentials
Non-root users may specify an expiration date -- if allowed via the token_expire_user_override setting -- by passing an additional token_expire param. This overrides the token_expire setting of the same name in the Master config and is how long a token should live in seconds.

CLI Example:
salt-run auth.mk_token username=saltdev password=saltdev eauth=auto

# Create a token valid for three years.
salt-run auth.mk_token username=saltdev password=saltdev eauth=auto \
   token_expire=94670856

# Calculate the number of seconds using expr.
salt-run auth.mk_token username=saltdev password=saltdev eauth=auto \
   token_expire=$(expr \((365 \* 24 \* 60 \* 60) \* 3)"

19.16.3  salt.runners.bgp

BGP Finder
New in version 2017.7.0.
Runner to search BGP neighbors details.

**Configuration**

- Minion (proxy) config

  The `bgp.neighbors` function must be appended in the list of `mine_functions`:

  ```yaml
  mine_functions:
    bgp.neighbors: []
  ```

  Which instructs Salt to cache the data returned by the `neighbors` function from the `NAPALM BGP module`.

  How often the mines are refreshed, can be specified using:

  ```yaml
  mine_interval: <X minutes>
  ```

- Master config

  By default the following options can be configured on the master. They are not mandatory, but available in case the user has different requirements.

  `tgt`: * From what minions will collect the mine data. Default: * (collect mine data from all minions)

  `return_fields` What fields to return in the output. It can display all the fields from the `neighbors` function from the `NAPALM BGP module`.

    Some fields cannot be removed:
    - `as_number`: the AS number of the neighbor
    - `device`: the minion ID
    - `neighbor_address`: the neighbor remote IP address

    By default, the following extra fields are returned (displayed):
    - `connection_stats`: connection stats, as described below
    - `import_policy`: the name of the import policy
    - `export_policy`: the name of the export policy

    Special fields:
    - `vrf`: return the name of the VRF.
    - `connection_stats`: returning an output of the form `<State> <Active>/<Received>/<Accepted>/<Damped>`, e.g. `Established 398/399/399/0` similar to the usual output from network devices.
    - `interface_description`: matches the neighbor details with the corresponding interface and returns its description. This will reuse functionality from the `net runner`, so the user needs to enable the mines as specified in the documentation.
    - `interface_name`: matches the neighbor details with the corresponding interface and returns the name. Similar to `interface_description`, this will reuse functionality from the `net runner`, so the user needs to enable the mines as specified in the documentation.
display: True Display on the screen or return structured object? Default: True (return on the CLI).

outputter: table Specify the outputter name when displaying on the CLI. Default: table.

Configuration example:

```yaml
runners:
bgp:
tgt: 'edge*
tgt_type: 'glob'
return_fields:
- up
- connection_state
- previous_connection_state
- suppress_4byte_as
- holdtime
- flap_count
outputter: yaml
```

salt.runners.bgp.neighbors(*asns, **kwargs)
Search for BGP neighbors details in the mines of the bgp.neighbors function.

Arguments:
asns A list of AS numbers to search for. The runner will return only the neighbors of these AS numbers.
device Filter by device name (minion ID).
ip Search BGP neighbor using the IP address. In multi-VRF environments, the same IP address could be used by more than one neighbors, in different routing tables.
network Search neighbors within a certain IP network.
title Custom title.
display: True Display on the screen or return structured object? Default: True (return on the CLI).
outputter: table Specify the outputter name when displaying on the CLI. Default: table.

In addition, any field from the output of the neighbors function from the NAPALM BGP module can be used as a filter.

CLI Example:

```bash
salt-run bgp.neighbors 13335 15169
salt-run bgp.neighbors 13335 ip=172.17.19.1
salt-run bgp.neighbors multipath=True
salt-run bgp.neighbors up=False export_policy=my-export-policy multihop=False
salt-run bgp.neighbors network=192.168.0.0/16
```

Output example:

```
<table>
<thead>
<tr>
<th>Device</th>
<th>AS Number</th>
<th>Neighbor Address</th>
<th>State</th>
<th>Active/Received/Accepted/Damped</th>
<th>Policy IN</th>
<th>Policy OUT</th>
</tr>
</thead>
<tbody>
<tr>
<td>edge01.bjm01</td>
<td>13335</td>
<td>172.17.109.11</td>
<td>Established 0/398/398/0</td>
<td>import-policy</td>
<td>export-policy</td>
<td></td>
</tr>
<tr>
<td>edge01.bjm01</td>
<td>13335</td>
<td>172.17.109.12</td>
<td>Established 0/397/398/398/0</td>
<td>import-policy</td>
<td>export-policy</td>
<td></td>
</tr>
</tbody>
</table>
```

19.16. runner modules
19.16.4 salt.runners.cache

Return cached data from minions

salt.runners.cache.clear_all(tgt=None, tgt_type='glob', expr_form=None)

Changed in version 2017.7.0: The expr_form argument has been renamed to tgt_type, earlier releases must use expr_form.

Clear the cached pillar, grains, and mine data of the targeted minions

CLI Example:

```
salt-run cache.clear_all
```

salt.runners.cache.clear_git_lock(role, remote=None, **kwargs)

New in version 2015.8.2.

Remove the update locks for Salt components (gitfs, git_pillar, winrepo) which use gitfs backend code from salt.utils.gitfs.

**Note:** Running cache.clear_all will not include this function as it does for pillar, grains, and mine.

Additionally, executing this function with a role of gitfs is equivalent to running salt-run file-server.clear_lock backend=git.

**role** Which type of lock to remove (gitfs, git_pillar, or winrepo)

**remote** If specified, then any remotes which contain the passed string will have their lock cleared. For example, a remote value of github will remove the lock from all github.com remotes.

**type** [update,checkout] The types of lock to clear. Can be update, checkout, or both of them (either comma-separated or as a Python list).

CLI Example:
salt-run cache.clear_git_lock git_pillar

```
salt.runners.cache.clear_grains(tgt=None, tgt_type='glob', expr_form=None)
```

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Clear the cached grains data of the targeted minions

CLI Example:
```
salt-run cache.clear_grains
```

```
salt.runners.cache.clear_mine(tgt=None, tgt_type='glob', expr_form=None)
```

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Clear the cached mine data of the targeted minions

CLI Example:
```
salt-run cache.clear_mine
```

```
salt.runners.cache.clear_mine_func(tgt=None, tgt_type='glob', clear_mine_func_flag=None, expr_form=None)
```

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Clear the cached mine function data of the targeted minions

CLI Example:
```
salt-run cache.clear_mine_func tgt='x' clear_mine_func_flag='network.interfaces'
```

```
salt.runners.cache.clear_pillar(tgt=None, tgt_type='glob', expr_form=None)
```

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Clear the cached pillar data of the targeted minions

CLI Example:
```
salt-run cache.clear_pillar
```

```
salt.runners.cache.cloud(tgt, provider=None)
```

Return cloud cache data for target.

**Note:** Only works with glob matching

```
tgt  Glob Target to match minion ids
provider  Cloud Provider
```

CLI Example:
```
salt-run cache.cloud 'salt*'
salt-run cache.cloud glance.example.org provider=openstack
```

```
salt.runners.cache.fetch(bank, key, cachedir=None)
```

Fetch data from a salt.cache bank.
CLI Example:
```
salt-run cache.fetch cloud/active/ec2/myec2 myminion cachedir=/var/cache/salt/
```

`salt.runners.cache.flush(bank, key=None, cachedir=None)`
Remove the key from the cache bank with all the key content. If no key is specified remove the entire bank with all keys and sub-banks inside.

CLI Examples:
```
salt-run cache.flush cloud/active/ec2/myec2 cachedir=/var/cache/salt/
salt-run cache.flush cloud/active/ec2/myec2 myminion cachedir=/var/cache/salt/
```

`salt.runners.cache.grains(tgt=None, tgt_type='glob', **kwargs)`
Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Return cached grains of the targeted minions.

**tgt** Target to match minion ids.

Changed in version 2017.7.5,2018.3.0: The `tgt` argument is now required to display cached grains. If not used, the function will not return grains. This optional argument will become mandatory in the Salt Sodium release.

**tgt_type** The type of targeting to use for matching, such as `glob`, `list`, etc.

CLI Example:
```
salt-run cache.grains '*'
```

`salt.runners.cache.list_(bank, cachedir=None)`
Lists entries stored in the specified bank.

CLI Example:
```
salt-run cache.list cloud/active/ec2/myec2 cachedir=/var/cache/salt/
```

`salt.runners.cache.mine(tgt=None, tgt_type='glob', **kwargs)`
Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Return cached mine data of the targeted minions.

CLI Example:
```
salt-run cache.mine
```

`salt.runners.cache.pillar(tgt=None, tgt_type='glob', **kwargs)`
Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Return cached pillars of the targeted minions.

CLI Example:
```
salt-run cache.pillar
```

`salt.runners.cache.store(bank, key, data, cachedir=None)`
Lists entries stored in the specified bank.

CLI Example:
19.16.5 salt.runners.cloud

The Salt Cloud Runner

This runner wraps the functionality of salt cloud making salt cloud routines available to all internal apis via the runner system

salt.runners.cloud.action(func=None, cloudmap=None, instances=None, provider=None, instance=None, **kwargs)

Execute a single action on the given map/provider/instance

CLI Example:
salt-run cloud.action start my-salt-vm

salt.runners.cloud.create(provider, instances, opts=None, **kwargs)

Create an instance using Salt Cloud

CLI Example:
salt-run cloud.create my-ec2-config myinstance

salt.runners.cloud.destroy(instances)

Destroy the named vm(s)

salt.runners.cloud.full_query(query_type='list_nodes_full')

List all available cloud provider data

salt.runners.cloud.list_images(provider='all')

List cloud provider images for the given providers

salt.runners.cloud.list_locations(provider='all')

List cloud provider sizes for the given providers

salt.runners.cloud.list_sizes(provider='all')

List cloud provider sizes for the given providers

salt.runners.cloud.map_run(path=None, **kwargs)

Execute a salt cloud map file

salt.runners.cloud.profile(prof=None, instances=None, opts=None, **kwargs)

Create a cloud vm with the given profile and instances, instances can be a list or comma-delimited string

CLI Example:
salt-run cloud.profile prof=my-ec2 instances=node1,node2,node3

salt.runners.cloud.query(query_type='list_nodes')

List cloud provider data for all providers

salt.runners.cloud.select_query(query_type='list_nodes_select')

List selected nodes
## 19.16.6 salt.runners.ddns

### Dynamic DNS Runner

New in version Beryllium.

Runner to interact with DNS server and create/delete/update DNS records

**codeauthor** Nitin Madhok <nmadhok@clemson.edu>

#### add_host

salt.runners.ddns.add_host(zone, name, ttl, ip, keyname, keyfile, nameserver, timeout, port=53, keyalgorithm='hmac-md5')

Create both A and PTR (reverse) records for a host.

**CLI Example:**

```sh
salt-run ddns.add_host domain.com my-test-vm 3600 10.20.30.40 my-tsig-key /etc/salt/tsig.keyring 10.0.0.1 5
```

#### create

salt.runners.ddns.create(zone, name, ttl, rdtype, data, keyname, keyfile, nameserver, timeout, port=53, keyalgorithm='hmac-md5')

Create a DNS record. The nameserver must be an IP address and the master running this runner must have create privileges on that server.

**CLI Example:**

```sh
salt-run ddns.create domain.com my-test-vm 3600 A 10.20.30.40 my-tsig-key /etc/salt/tsig.keyring 10.0.0.1 5
```

#### delete

salt.runners.ddns.delete(zone, name, keyname, keyfile, nameserver, timeout, rdtype=None, data=None, port=53, keyalgorithm='hmac-md5')

Delete a DNS record.

**CLI Example:**

```sh
salt-run ddns.delete domain.com my-test-vm my-tsig-key /etc/salt/tsig.keyring 10.0.0.1 5 A
```

#### delete_host

salt.runners.ddns.delete_host(zone, name, keyname, keyfile, nameserver, timeout, port=53, keyalgorithm='hmac-md5')

Delete both forward (A) and reverse (PTR) records for a host only if the forward (A) record exists.

**CLI Example:**

```sh
salt-run ddns.delete_host domain.com my-test-vm my-tsig-key /etc/salt/tsig.keyring 10.0.0.1 5
```

#### update

salt.runners.ddns.update(zone, name, ttl, rdtype, data, keyname, keyfile, nameserver, timeout, replace=False, port=53, keyalgorithm='hmac-md5')

Replace, or update a DNS record. The nameserver must be an IP address and the master running this runner must have update privileges on that server.

**Note:** If replace is set to True, all records for this name and type will first be deleted and then recreated. Default is replace=False.

**CLI Example:**

```sh
dev:run ddns.update domain.com my-test-vm 3600 A 10.20.30.40 my-tsig-key /etc/salt/tsig.keyring 10.0.0.1 5
```
19.16.7 salt.runners.digicertapi

Support for Digicert. Heavily based on the Venafi runner by Joseph Hall (jphall@saltstack.com).

Before using this module you need to register an account with Digicert's CertCentral.

Login to CertCentral, ensure you have a payment method configured and/or there are adequate funds attached to your account. Click the Account item in the left sidebar, and select Account Access. The right hand pane should show "Account Access" and a link to create an API key. Create a new API key and assign it to the user that should be attached to requests coming from Salt.

NOTE CertCentral will not show the API key again after revealing it the first time. Make sure you copy it right away or you will have to revoke it and generate a new one.

Now open /etc/salt/master and add the API key as shown below.

```yaml
digicert:
  api_key: 
    ABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABC
```

Restart your Salt Master.

You can also include default values of the following variables to help with creating CSRs:

```yaml
digicert:
  api_key: 
    ABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZABC
  shatype: sha256
```

This API currently only supports RSA key types. Support for other key types will be added if interest warrants.

salt.runners.digicertapi.del_cached_domain(domains)
Delete cached domains from the master

CLI Example:
```
salt-run digicert.del_cached_domain domain1.example.com,domain2.example.com
```

salt.runners.digicertapi.gen_csr(minion_id, dns_name=None, organization_id, ou_name=None, key_len=2048, shatype='sha256', password=None)

CLI Example:
```
salt-run digicert.gen_csr <minion_id> <dns_name>
```

salt.runners.digicertapi.gen_key(minion_id, dns_name=None, password=None, key_len=2048)
Generate and return a private_key. If a dns_name is passed in, the private_key will be cached under that name.

CLI Example:
```
salt-run digicert.gen_key <minion_id> [dns_name] [password]
```

salt.runners.digicertapi.get_certificate(order_id=None, certificate_id=None, minion_id=None, cert_format='pem_all', filename=None)
Retrieve a certificate by order_id or certificate_id and write it to stdout or a filename.
A list of permissible cert Formats is here: https://www.digicert.com/services/v2/documentation/appx-certificate-formats

CLI Example:

salt-run digicert.get_certificate order_id=48929454 cert_format=apache

Including a `filename` will write the certificate to the desired file. Note that some cert formats are zipped files, and some are binary.

If the certificate has not been issued, this function will return the order details inside of which will be a status (one of pending, rejected, processing, issued, revoked, canceled, needs_csr, and needs_approval)

If for some reason you want to pipe the output of this command to a file or other command you will want to leave off the `filename` argument and make sure to include `--no-color` so there will be no terminal ANSI escape sequences.

salt.runners.digicertapi.get_org_details(organization_id)

Return the details for an organization

CLI Example:

salt-run digicert.get_org_details 34

Returns a dictionary with the org details, or with `error` and `status` keys.

salt.runners.digicertapi.list_domain_cache()

List domains that have been cached

CLI Example:

salt-run digicert.list_domain_cache

salt.runners.digicertapi.list_domains(container_id=None)

List domains that CertCentral knows about. You can filter by container_id (also known as `Division`) by passing a container_id.

CLI Example:

salt-run digicert.list_domains

salt.runners.digicertapi.list_orders(status=None)

List certificate orders made to CertCentral.

CLI Example:

salt-run digicert.list_orders

salt.runners.digicertapi.list_organizations(container_id=None, include_validation=True)

List organizations that CertCentral knows about. You can filter by container_id (also known as `Division`) by passing a container_id. This function returns validation information by default; pass `include_validation=False` to turn it off.

CLI Example:

salt-run digicert.list_organizations

salt.runners.digicertapi.list_requests(status=None)

List certificate requests made to CertCentral. You can filter by status: pending, approved, rejected

CLI Example:
salt-run digicert.list_requests pending

salt.runners.digicertapi.order_certificate(minion_id, common_name, organization_id, validity_years, cert_key_passphrase=None, signature_hash=None, key_len=2048, dns_names=None, organization_units=None, server_platform=None, custom_expiration_date=None, comments=None, disable_renewal_notifications=False, renewal_of_order_id=None)

Order a certificate. Requires that an Organization has been created inside Digicert's CertCentral.
See here for API documentation: https://www.digicert.com/services/v2/documentation/order/order-ssl-determinator

CLI Example:

```
salt-run digicert.order_certificate my_minionid my.domain.com 10 !
  signature_hash=sha256
dns_names=['this.domain.com', 'that.domain.com', 'thatother.domain.com']
organization_units='My Domain Org Unit'
  comments='Comment goes here for the approver'
```

This runner can also be used to renew a certificate by passing renewal_of_order_id. Previous order details can be retrieved with digicertapi.list_orders.

salt.runners.digicertapi.show_csrs()
Show certificate requests for this API key

CLI Example:

```
salt-run digicert.show_csrs
```

salt.runners.digicertapi.show_organization(domain)
Show organization information, especially the company id

CLI Example:

```
salt-run digicert.show_company example.com
```

salt.runners.digicertapi.show_rsa(minion_id, dns_name)
Show a private RSA key

CLI Example:

```
salt-run digicert.show_rsa myminion domain.example.com
```

19.16.8 salt.runners.doc

A runner module to collect and display the inline documentation from the various module types

salt.runners.doc.execution()
Collect all the sys.doc output from each minion and return the aggregate

CLI Example:

```
salt-run doc.execution
```
salt.runners.doc.runner()
Return all inline documentation for runner modules

CLI Example:
salt-run doc.runner

salt.runners.doc.wheel()
Return all inline documentation for wheel modules

CLI Example:
salt-run doc.wheel

19.16.9 salt.runners.drac
Manage Dell DRAC from the Master
The login credentials need to be configured in the Salt master configuration file.
salt.runners.drac.poweroff(hostname, timeout=20, username=None, password=None)
Power server off

CLI Example:
salt-run drac.poweroff example.com

salt.runners.drac.poweron(hostname, timeout=20, username=None, password=None)
Power server on

CLI Example:
salt-run drac.poweron example.com

salt.runners.drac.pxe(hostname, timeout=20, username=None, password=None)
Connect to the Dell DRAC and have the boot order set to PXE and power cycle the system to PXE boot

CLI Example:
salt-run drac.pxe example.com

salt.runners.drac.reboot(hostname, timeout=20, username=None, password=None)
Reboot a server using the Dell DRAC

CLI Example:
salt-run drac.reboot example.com

salt.runners.drac.version(hostname, timeout=20, username=None, password=None)
Display the version of DRAC

CLI Example:
salt-run drac.version example.com
19.16.10  salt.runners.error

Error generator to enable integration testing of salt runner error handling

```python
salt.runners.error.error(name=None, message='``

If name is None Then return empty dict

Otherwise raise an exception with __name__ from name, message from message

CLI Example:

salt-run error
salt-run error.error name="Exception" message="This is an error."
```

19.16.11  salt.runners.event

Module for sending events using the runner system.

New in version 2016.11.0.

```python
salt.runners.event.send(tag, data=None)
```

Send an event with the given tag and data.

This is useful for sending events directly to the master from the shell with salt-run. It is also quite useful for sending events in orchestration states where the fire_event requisite isn't sufficient because it does not support sending custom data with the event.

Note that event tags will not be namespaced like events sent with the fire_event requisite! Whereas events produced from fire_event are prefixed with 

salt/state_result/<jid>/<minion_id>/<name>, events sent using this runner module will have no such prefix. Make sure your reactors don't expect a prefix!

Parameters

- **tag** -- the tag to send with the event
- **data** -- an optional dictionary of data to send with the event

CLI Example:

```
salt-run event.send my/custom/event '{"foo": "bar"}'
```

Orchestration Example:

```
# orch/command.sls

run_a_command:
    salt.function:
        - name: cmd.run
        - tgt: my_minion
        - arg:
            - exit {{ pillar['exit_code'] }}

send_success_event:
    salt.runner:
        - name: event.send
        - tag: my_event/success
        - data:
            foo: bar
        - require:
            - salt: run_a_command
```

19.16. runner modules
send_failure_event:
salt.runner:
  - name: event.send
  - tag: my_event/failure
  - data:
    - baz: qux
  - onfail:
    - salt: run_a_command

```
salt-run state.orchestrate orch.command pillar='"exit_code": 0'
salt-run state.orchestrate orch.command pillar='"exit_code": 1'
```

## 19.16.12 salt.runners.f5

Runner to provide F5 Load Balancer functionality

depends
- pycontrol Python module

configuration In order to connect to a F5 Load Balancer, you must specify in the Salt master configuration the currently available load balancers

```python
load_balancers:
  bigip1.example.com
    username: admin
    password: secret
  bigip2.example.com:
    username: admin
    password: secret
```

class salt.runners.f5.F5Mgmt(lb, username, password)

```
add_pool_member(name, port, pool_name)
  Add a node to a pool
check_member_pool(member, pool_name)
  Check a pool member exists in a specific pool
check_pool(name)
  Check to see if a pool exists
check_virtualserver(name)
  Check to see if a virtual server exists
create_pool(name, method='ROUND_ROBIN')
  Create a pool on the F5 load balancer
create_vs(name, ip, port, protocol, profile, pool_name)
  Create a virtual server
lbmethods()
  List all the load balancer methods
```

salt.runners.f5.add_pool_member(lb, name, port, pool_name)
  Add a node to a pool

CLI Examples:
salt-run f5.add_pool_member load_balancer 10.0.0.1 80 my_pool

salt.runners.f5.check_member_pool(lb, member, pool_name)
Check a pool member exists in a specific pool

CLI Examples:
salt-run f5.check_member_pool load_balancer 10.0.0.1 my_pool

salt.runners.f5.check_pool(lb, name)
Check to see if a pool exists

CLI Examples:
salt-run f5.check_pool load_balancer pool_name

salt.runners.f5.check_virtualserver(lb, name)
Check to see if a virtual server exists

CLI Examples:
salt-run f5.check_virtualserver load_balancer virtual_server

salt.runners.f5.create_pool(lb, name, method='ROUND_ROBIN')
Create a pool on the F5 load balancer

CLI Examples:
salt-run f5.create_pool load_balancer pool_name loadbalance_method
salt-run f5.create_pool load_balancer my_pool ROUND_ROBIN

salt.runners.f5.create_vs(lb, name, ip, port, protocol, profile, pool_name)
Create a virtual server

CLI Examples:
salt-run f5.create_vs lbalancer vs_name 10.0.0.1 80 tcp http poolname

19.16.13 salt.runners.fileserver

Directly manage the Salt fileserver plugins

salt.runners.fileserver.clear_cache(backend=None)
New in version 2015.5.0.

Clear the fileserver cache from VCS fileserver backends (git, hg, svn). Executing this runner with no arguments will clear the cache for all enabled VCS fileserver backends, but this can be narrowed using the backend argument.

backend Only clear the update lock for the specified backend(s). If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.

CLI Example:
salt-run fileserver.clear_cache
salt-run fileserver.clear_cache backend=git,hg
salt-run fileserver.clear_cache hg
salt-run fileserver.clear_cache -roots
salt.runners.fileserver.clear_file_list_cache(saltenv=None, backend=None)

New in version 2016.11.0.

The Salt fileserver caches the files/directories/symlinks for each fileserver backend and environment as they are requested. This is done to help the fileserver scale better. Without this caching, when hundreds/thousands of minions simultaneously ask the master what files are available, this would cause the master's CPU load to spike as it obtains the same information separately for each minion.

**saltenv** By default, this runner will clear the file list caches for all environments. This argument allows for a list of environments to be passed, to clear more selectively. This list can be passed either as a comma-separated string, or a Python list.

**backend** Similar to the **saltenv** parameter, this argument will restrict the cache clearing to specific fileserver backends (the default behavior is to clear from all enabled fileserver backends). This list can be passed either as a comma-separated string, or a Python list.

Since the ability to clear these caches is often required by users writing custom runners which add/remove files, this runner can easily be called from within a custom runner using any of the following examples:

```
# Clear all file list caches
__salt__['fileserver.clear_file_list_cache']()
# Clear just the 'base' saltenv file list caches
__salt__['fileserver.clear_file_list_cache'](saltenv='base')
# Clear just the 'base' saltenv file list caches from just the 'roots' fileserver backend
__salt__['fileserver.clear_file_list_cache'](saltenv='base', backend='roots')
# Clear all file list caches from the 'roots' fileserver backend
__salt__['fileserver.clear_file_list_cache'](backend='roots')
```

**Note:** In runners, the **__salt__** dictionary will likely be renamed to **__runner__** in a future Salt release to distinguish runner functions from remote execution functions. See this GitHub issue for discussion/updates on this.

If using Salt's Python API (not a runner), the following examples are equivalent to the ones above:

```
import salt.config
import salt.runner

opts = salt.config.master_config('/etc/salt/master')
opts['fun'] = 'fileserver.clear_file_list_cache'

# Clear all file list caches
opts['arg'] = [] # No arguments
runner = salt.runner.Runner(opts)
cleared = runner.run()

# Clear just the 'base' saltenv file list caches
opts['arg'] = ['base', None]
runner = salt.runner.Runner(opts)
cleared = runner.run()

# Clear just the 'base' saltenv file list caches from just the 'roots' fileserver backend
opts['arg'] = ['base', 'roots']
runner = salt.runner.Runner(opts)
cleared = runner.run()
```
Salt Documentation, Release 2017.7.8

```python
# Clear all file list caches from the 'roots' fileserver backend
opts['arg'] = ['None', 'roots']
runner = salt.runner.Runner(opts)
cleared = runner.run()
```

This function will return a dictionary showing a list of environments which were cleared for each backend. An empty return dictionary means that no changes were made.

CLI Examples:

```bash
# Clear all file list caches
salt-run fileserver.clear_file_list_cache
# Clear just the 'base' saltenv file list caches
salt-run fileserver.clear_file_list_cache saltenv=base
# Clear just the 'base' saltenv file list caches from just the 'roots'
# fileserver backend
salt-run fileserver.clear_file_list_cache saltenv=base backend=roots
# Clear all file list caches from the 'roots' fileserver backend
salt-run fileserver.clear_file_list_cache backend=roots
```

salt.runners.fileserver.clear_lock(backend=None, remote=None)

New in version 2015.5.0.

Clear the fileserver update lock from VCS fileserver backends (git, hg, svn). This should only need to be done if a fileserver update was interrupted and a remote is not updating (generating a warning in the Master's log file). Executing this runner with no arguments will remove all update locks from all enabled VCS fileserver backends, but this can be narrowed by using the following arguments:

- **backend** Only clear the update lock for the specified backend(s).
- **remote** If specified, then any remotes which contain the passed string will have their lock cleared. For example, a remote value of github will remove the lock from all github.com remotes.

CLI Example:

```bash
salt-run fileserver.clear_lock
salt-run fileserver.clear_lock backend=git,hg
salt-run fileserver.clear_lock backend=git remote=github
salt-run fileserver.clear_lock remote=bitbucket
```

salt.runners.fileserver.dir_list(saltenv='base', backend=None)

Return a list of directories in the given environment

- **saltenv** [base] The salt fileserver environment to be listed
- **backend** Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.

New in version 2015.5.0.

CLI Example:

```bash
salt-run fileserver.dir_list
salt-run fileserver.dir_list saltenv=prod
salt-run fileserver.dir_list saltenv=dev backend=git
salt-run fileserver.dir_list base hg,roots
salt-run fileserver.dir_list -git
```

salt.runners.fileserver.empty_dir_list(saltenv='base', backend=None)

Return a list of empty directories in the given environment

New in version 2015.5.0.
saltenv  [base] The salt fileserver environment to be listed
backend  Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.

**Note:** Some backends (such as git and hg) do not support empty directories. So, passing backend=git or backend=hg will result in an empty list being returned.

CLI Example:

```
salt-run fileserver.empty_dir_list
salt-run fileserver.empty_dir_list saltenv=prod
salt-run fileserver.empty_dir_list backend=roots
```

salt.runners.fileserver.envs(backend=None, sources=False)
Return the available fileserver environments. If no backend is provided, then the environments for all configured backends will be returned.

backend  Narrow fileserver backends to a subset of the enabled ones.

Changed in version 2015.5.0: If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.

Additionally, fileserver backends can now be passed as a comma-separated list. In earlier versions, they needed to be passed as a python list (ex: backend=["roots","git"])

CLI Example:

```
salt-run fileserver.envs
salt-run fileserver.envs backend=roots,git
salt-run fileserver.envs git
```

salt.runners.fileserver.file_list(saltenv='base', backend=None)
Return a list of files from the salt fileserver

saltenv  [base] The salt fileserver environment to be listed
backend  Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.

New in version 2015.5.0.

CLI Examples:

```
salt-run fileserver.file_list
salt-run fileserver.file_list saltenv=prod
salt-run fileserver.file_list saltenv=dev backend=git
salt-run fileserver.file_list base hg,roots
salt-run fileserver.file_list -git
```

salt.runners.fileserver.lock(backend=None, remote=None)
New in version 2015.5.0.

Set a fileserver update lock for VCS fileserver backends (git, hg, svn).

**Note:** This will only operate on enabled backends (those configured in fileserver_backend).
**backend** Only set the update lock for the specified backend(s).
**remote** If not None, then any remotes which contain the passed string will have their lock cleared. For example, a remote value of `*github.com*` will remove the lock from all github.com remotes.

**CLI Example:**
```
salt-run fileserver.lock
salt-run fileserver.lock backend=git hg
salt-run fileserver.lock backend=git remote=*github.com*
salt-run fileserver.lock remote=bitbucket
```

salt.runners.fileserver.symlink_list(saltenv='base', backend=None)
Return a list of symlinked files and dirs
**saltenv** [base] The salt fileserver environment to be listed
**backend** Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (`-`), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: `backend=-roots,git`) then the ones starting with a minus sign will be disregarded.

New in version 2015.5.0.
**CLI Example:**
```
salt-run fileserver.symlink_list
salt-run fileserver.symlink_list saltenv=prod
salt-run fileserver.symlink_list saltenv=dev backend=git
salt-run fileserver.symlink_list base hg,roots
salt-run fileserver.symlink_list -git
```

salt.runners.fileserver.update(backend=None)
Update the fileserver cache. If no backend is provided, then the cache for all configured backends will be updated.
**backend** Narrow fileserver backends to a subset of the enabled ones.

Changed in version 2015.5.0: If all passed backends start with a minus sign (`-`), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: `backend=-roots,git`) then the ones starting with a minus sign will be disregarded.

Additionally, fileserver backends can now be passed as a comma-separated list. In earlier versions, they needed to be passed as a python list (ex: `backend="['roots','git']"`).

**CLI Example:**
```
salt-run fileserver.update
salt-run fileserver.update backend=roots,git
```

19.16.14 salt.runners.git_pillar

Runner module to directly manage the git external pillar

salt.runners.git_pillar.update(branch=None, repo=None)
New in version 2014.1.0.

Changed in version 2015.8.4: This runner function now supports the new git_pillar configuration schema introduced in 2015.8.0. Additionally, the branch and repo can now be omitted to update all git_pillar remotes. The return data has also changed. For releases 2015.8.3 and earlier, there is no value returned. Starting with 2015.8.4, the return data is a dictionary. If using the old git_pillar configuration schema, then the dictionary values will be True if the update completed without error, and False if an error occurred. If using the new new...
git_pillar configuration schema, the values will be True only if new commits were fetched, and False if there were errors or no new commits were fetched.

Fetch one or all configured git_pillar remotes.

Note: This will not fast-forward the git_pillar cachedir on the master. All it does is perform a git fetch. If this runner is executed with -l debug, you may see a log message that says that the repo is up-to-date. Keep in mind that Salt automatically fetches git_pillar repos roughly every 60 seconds (or whatever loop_interval is set to). So, it is possible that the repo was fetched automatically in the time between when changes were pushed to the repo, and when this runner was executed. When in doubt, simply refresh pillar data using saltutil.refresh_pillar and then use pillar.item to check if the pillar data has changed as expected.

CLI Example:

```
# Update specific branch and repo
salt-run git_pillar.update branch='branch' repo='https://foo.com/bar.git'
# Update all repos (2015.8.4 and later)
salt-run git_pillar.update
# Run with debug logging
salt-run git_pillar.update -l debug
```

19.16.15 salt.runners.http

Module for making various web calls. Primarily designed for webhooks and the like, but also useful for basic http testing.

New in version 2015.5.0.

salt.runners.http.query(url, output=True, **kwargs)

Query a resource, and decode the return data

New in version 2015.5.0.

CLI Example:

```
salt-run http.query http://somelink.com/
salt-run http.query http://somelink.com/ method=POST params='key1=val1&key2=val2'
salt-run http.query http://somelink.com/ method=POST data='<xml>
  <somecontent/></xml>'
```

salt.runners.http.update_ca_bundle(target=None, source=None, merge_files=None)

Update the local CA bundle file from a URL

New in version 2015.5.0.

CLI Example:

```
salt-run http.update_ca_bundle
tsalt-run http.update_ca_bundle target=/path/to/cacerts.pem
tsalt-run http.update_ca_bundle source=https://example.com/cacerts.pem
```

If the target is not specified, it will be pulled from the ca_cert configuration variable available to the master. If it cannot be found there, it will be placed at <<FILE_ROOTS>>/cacerts.pem.
If the source is not specified, it will be pulled from the ca_cert_url configuration variable available to the master. If it cannot be found, it will be downloaded from the cURL website, using an http (not https) URL. USING THE DEFAULT URL SHOULD BE AVOIDED!

merge_files may also be specified, which includes a string or list of strings representing a file or files to be appended to the end of the CA bundle, once it is downloaded.

CLI Example:

```
salt-run http.update_ca_bundle merge_files=/path/to/mycert.pem
```

19.16.16 salt.runners.jobs

A convenience system to manage jobs, both active and already run

salt.runners.jobs.active(display_progress=False)

Return a report on all actively running jobs from a job id centric perspective

CLI Example:

```
salt-run jobs.active
```

salt.runners.jobs.exit_success(jid, ext_source=None)

Check if a job has been executed and exit successfully

jid The jid to look up.

ext_source The external job cache to use. Default: None.

CLI Example:

```
salt-run jobs.exit_success 20160520145827701627
```

salt.runners.jobs.last_run(ext_source=None, outputter=None, metadata=None, function=None, target=None, display_progress=False)

New in version 2015.8.0.

List all detectable jobs and associated functions

CLI Example:

```
salt-run jobs.last_run
salt-run jobs.last_run target=nodename
salt-run jobs.last_run function='cmd.run'
salt-run jobs.last_run metadata="{'foo': 'bar'}"
```

salt.runners.jobs.list_job(jid, ext_source=None, display_progress=False)

List a specific job given by its jid

ext_source If provided, specifies which external job cache to use.

display_progress [False] If True, fire progress events.

CLI Example:

```
salt-run jobs.list_job 20130916125524463507
salt-run jobs.list_job 20130916125524463507 --out=pprint
```

salt.runners.jobs.list_jobs(ext_source=None, outputter=None, search_metadata=None, search_function=None, search_target=None, start_time=None, end_time=None, display_progress=False)

List all detectable jobs and associated functions
ext_source  If provided, specifies which external job cache to use.

FILTER OPTIONS

Note: If more than one of the below options are used, only jobs which match all of the filters will be returned.

search_metadata  Specify a dictionary to match to the job's metadata. If any of the key-value pairs in this dictionary match, the job will be returned. Example:

```bash
classic-run jobs.list_jobs search_metadata='{"foo": "bar", "baz": "qux"}'
```

search_function  Can be passed as a string or a list. Returns jobs which match the specified function. Globbing is allowed. Example:

```bash
classic-run jobs.list_jobs search_function='test.*'
classic-run jobs.list_jobs search_function='["test.*", "pkg.install"]'
```

Changed in version 2015.8.8: Multiple targets can now also be passed as a comma-separated list. For example:

```bash
classic-run jobs.list_jobs search_function='test.*,pkg.install'
```

search_target  Can be passed as a string or a list. Returns jobs which match the specified minion name. Globbing is allowed. Example:

```bash
classic-run jobs.list_jobs search_target='*.mydomain.tld'
classic-run jobs.list_jobs search_target='["db", "myminion"]'
```

Changed in version 2015.8.8: Multiple targets can now also be passed as a comma-separated list. For example:

```bash
classic-run jobs.list_jobs search_target='db*,myminion'
```

start_time  Accepts any timestamp supported by the dateutil Python module (if this module is not installed, this argument will be ignored). Returns jobs which started after this timestamp.

dateutil  Accepts any timestamp supported by the dateutil Python module (if this module is not installed, this argument will be ignored). Returns jobs which started before this timestamp.

CLI Example:

```bash
classic-run jobs.list_jobs
classic-run jobs.list_jobs search_function='test.*' search_target='localhost' search_metadata='{"bar": "foo"}'
classic-run jobs.list_jobs start_time='2015, Mar 16 19:00' end_time='2015, Mar 18 22:00'
```

salt.runners.jobs.list_jobs_filter(count, filter_find_job=True, ext_source=None, outputter=None, display_progress=False)

List all detectable jobs and associated functions

ext_source  The external job cache to use. Default: None.

CLI Example:

```bash
classic-run jobs.list_jobs_filter 50
classic-run jobs.list_jobs_filter 100 filter_find_job=False
```

salt.runners.jobs.lookup_jid(jid, ext_source=None, returned=True, missing=False, display_progress=False)

Return the printout from a previously executed job

jid  The jid to look up.
ext_source  The external job cache to use. Default: None.

returned  [True] If True, include the minions that did return from the command.

   New in version 2015.8.0.

missing  [False] If True, include the minions that did not return from the command.

display_progress  [False] If True, fire progress events.

   New in version 2015.5.0.

CLI Example:

```bash
salt-run jobs.lookup_jid 20130916125524463507
salt-run jobs.lookup_jid 20130916125524463507 --out=highstate
```

```
salt.runners.jobs.print_job(jid, ext_source=None)
   Print a specific job's detail given by it's jid, including the return data.

   CLI Example:

   ```bash
   salt-run jobs.print_job 20130916125524463507
   ```
```

19.16.17  `salt.runners.launchd`

Manage launchd plist files

```python
salt.runners.launchd.write_launchd_plist(program)
   Write a launchd plist for managing salt-master or salt-minion

   CLI Example:

   ```bash
   salt-run launchd.write_launchd_plist salt-master
   ```
```

19.16.18  `salt.runners.lxc`

Control Linux Containers via Salt

```python
salt.runners.lxc.cloud_init(names, host=None, quiet=False, **kwargs)
   Wrapper for using lxc.init in saltcloud compatibility mode

   names  Name of the containers, supports a single name or a comma delimited list of names.
   host  Minion to start the container on. Required.
   path  path to the container parent default: /var/lib/lxc (system default)

   New in version 2015.8.0.

   saltcloud_mode  init the container with the saltcloud opts format instead
```

```python
salt.runners.lxc.find_guest(name, quiet=False, path=None)
   Returns the host for a container.

   path  path to the container parent default: /var/lib/lxc (system default)

   New in version 2015.8.0.

   ```bash
   salt-run lxc.find_guest name
   ```
```

```python
salt.runners.lxc.find_guests(names, path=None)
   Return a dict of hosts and named guests
```

19.16.  runner modules
**path**  path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

`salt.runners.lxc.freeze`(*name*, *quiet=False, path=None*)

Freeze the named container

**path**  path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```
salt-run lxc.freeze name
```

`salt.runners.lxc.info`(*name*, *quiet=False, path=None*)

Returns information about a container.

**path**  path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```
salt-run lxc.info name
```

`salt.runners.lxc.init`(*names*, *host=None, saltcloud_mode=False, quiet=False, **kwargs*)

Initialize a new container

```
salt-run lxc.init name host=minion_id [cpuset=cgroups_cpuset]\[
    [cpushare=cgroups_cpushares] [memory=cgroups_memory]\[
    [template=lxc_template_name] [clone=original_name]\[
    [profile=lxc_profile] [network_profile=network_profile]\[
    [nic=network_profile] [nic_opts=nic_opts]\[
    [start=(true|false)] [seed=(true|false)]]\[
    [install=(true|false)] [config=minion_config]\[
    [snapshot=(true|false)]
```

**names**  Name of the containers, supports a single name or a comma delimited list of names.

**host**  Minion on which to initialize the container *(required)*

**path**  path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

**saltcloud_mode**  init the container with the saltcloud opts format instead See lxc.init_interface module documentation

**cpuset**  cgroups cpuset.

**cpushare**  cgroups cpu shares.

**memory**  cgroups memory limit, in MB

  Changed in version 2015.5.0: If no value is passed, no limit is set. In earlier Salt versions, not passing this value causes a 1024MB memory limit to be set, and it was necessary to pass `memory=0` to set no limit.

**template**  Name of LXC template on which to base this container

**clone**  Clone this container from an existing container

**profile**  A LXC profile (defined in config or pillar).

**network_profile**  Network profile to use for the container

New in version 2015.5.2.

**nic**  Deprecated since version 2015.5.0: Use `network_profile` instead

**nic_opts**  Extra options for network interfaces. E.g.

```
{"eth0": {"mac": "aa:bb:cc:dd:ee:ff","ipv4": "10.1.1.1","ipv6": "2001:db8::ff00:42:8329"}}
```

**start**  Start the newly created container.

**seed**  Seed the container with the minion config and autosign its key. Default: true
install If salt-minion is not already installed, install it. Default: true
config Optional config parameters. By default, the id is set to the name of the container.

salt.runners.lxc.list_(host=None, quiet=False, path=None)
List defined containers (running, stopped, and frozen) for the named (or all) host(s).
path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```
salt-run lxc.list [host=minion_id]
```

salt.runners.lxc.purge(name, delete_key=True, quiet=False, path=None)
Purge the named container and delete its minion key if present. WARNING: Destroys all data associated with the container.
path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```
salt-run lxc.purge name
```

salt.runners.lxc.start(name, quiet=False, path=None)
Start the named container.
path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```
salt-run lxc.start name
```

salt.runners.lxc.stop(name, quiet=False, path=None)
Stop the named container.
path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```
salt-run lxc.stop name
```

salt.runners.lxc.unfreeze(name, quiet=False, path=None)
Unfreeze the named container
path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```
salt-run lxc.unfreeze name
```

19.16.19 salt.runners.manage

General management functions for salt, tools like seeing what hosts are up and what hosts are down

salt.runners.manage.alived(subset=None, show_ipv4=False)
Print a list of all minions that are up according to Salt's presence detection (no commands will be sent to minions)
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.

CLI Example:
salt-run manage.alived

salt.runners.manage.allowed(subset=None, show_ipv4=False)
   New in version 2015.8.0.
   Print a list of all minions that are up according to Salt's presence detection (no commands will be sent to minions)
   subset [None] Pass in a CIDR range to filter minions by IP address.
   show_ipv4 [False] Also show the IP address each minion is connecting from.
   CLI Example:
   salt-run manage.allowed

salt.runners.manage.bootstrap(version='develop', script=None, hosts='', root_user=False, script_args='', roster='flat', ssh_user=None, ssh_password=None, ssh_priv_key=None, tmp_dir='/tmp/.bootstrap', http_backend='tornado')

Bootstrap minions with salt-bootstrap
   version [develop] Git tag of version to install
   script [https://bootstrap.saltstack.com] URL containing the script to execute
   hosts Comma-separated hosts [example: hosts='host1.local,host2.local']. These hosts need to exist in the specified roster.
   root_user [False] Prepend root@ to each host. Default changed in Salt 2016.11.0 from True to False.
      Changed in version 2016.11.0.
      Deprecated since version Oxygen.
   script_args Any additional arguments that you want to pass to the script.
      New in version 2016.11.0.
   roster [flat] The roster to use for Salt SSH. More information about roster files can be found in Salt's Roster Documentation.
      A full list of roster types, see the builtin roster modules documentation.
      New in version 2016.11.0.
   ssh_user If user isn't found in the roster, a default SSH user can be set here. Keep in mind that ssh_user will not override the roster user value if it is already defined.
      New in version 2016.11.0.
   ssh_password If passwd isn't found in the roster, a default SSH password can be set here. Keep in mind that ssh_password will not override the roster passwd value if it is already defined.
      New in version 2016.11.0.
   ssh_privkey If priv isn't found in the roster, a default SSH private key can be set here. Keep in mind that ssh_password will not override the roster passwd value if it is already defined.
      New in version 2016.11.0.
   tmp_dir [/tmp/.bootstrap] The temporary directory to download the bootstrap script in. This directory will have ~<uuid4> appended to it. For example: /tmp/.bootstrap-a19a728e-d40a-4801-aba9-d0655c143a7/
      New in version 2016.11.0.
   http_backend [tornado] The backend library to use to download the script. If you need to use a file:/// URL, then you should set this to urllib2.
      New in version 2016.11.0.
   CLI Example:
salt.runners.manage.bootstrap_psexec(\nhosts=’, master=None, version=None, arch=’win32’, installer_url=None, username=None, password=None)\n
Bootstrap Windows minions via PsExec.\nhosts Comma separated list of hosts to deploy the Windows Salt minion.\nmaster Address of the Salt master passed as an argument to the installer.\nversion Point release of installer to download. Defaults to the most recent.\narch Architecture of installer to download. Defaults to win32.\ninstaller_url URL of minion installer executable. Defaults to the latest version from https://repo.saltstack.com/windows/\nusername Optional user name for login on remote computer.\npASSWORD Password for optional username. If omitted, PsExec will prompt for one to be entered for each host.\n
CLI Example:

salt-run manage.bootstrap_psexec hosts='host1,host2'\nsalt-run manage.bootstrap_psexec hosts='host1,host2' version='0.17' username='DOMAIN\Administrator'\nsalt-run manage.bootstrap_psexec installer_url='http://exampledomain/salt-installer.exe'\n
salt.runners.manage.down(\nremovekeys=False, tgt=None, tgt_type=’glob’, expr_form=None)\n
Print a list of all the down or unresponsive salt minions Optionally remove keys of down minions\n
CLI Example:

salt-run manage.down\nsalt-run manage.down removekeys=True\nsalt-run manage.down tgt=’web servers’ tgt_type=’node group’\n
salt.runners.manage.get_stats(\nestate=None, stack=’road’)\n
Print the stack stats\nestate [None] The name of the target estate. Master stats would be requested by default\nstack [‘road’] Show stats on either road or lane stack Allowed values are ‘road’ or ‘lane’.\n
CLI Example:

salt-run manage.get_stats [estate=alpha_minion] [stack=lane]\n
salt.runners.manage.joined(subset=None, show_ipv4=False)\n
New in version 2015.8.0.\nPrint a list of all minions that are up according to Salt’s presence detection (no commands will be sent to minions)\nsubset [None] Pass in a CIDR range to filter minions by IP address.\nshow_ipv4 [False] Also show the IP address each minion is connecting from.\n
CLI Example:
salt-run manage.joined

salt.runners.manage.key_regen()
This routine is used to regenerate all keys in an environment. This is invasive! ALL KEYS IN THE SALT ENVIRONMENT WILL BE REGENERATED!!

The key_regen routine sends a command out to minions to revoke the master key and remove all minion keys, it then removes all keys from the master and prompts the user to restart the master. The minions will all reconnect and keys will be placed in pending.

After the master is restarted and minion keys are in the pending directory execute a salt-key -A command to accept the regenerated minion keys.

The master must be restarted within 60 seconds of running this command or the minions will think there is something wrong with the keys and abort.

Only Execute this runner after upgrading minions and master to 0.15.1 or higher!

CLI Example:

```
salt-run manage.key_regen
```

salt.runners.manage.lane_stats(estate=None)
Print the estate manor lane stack stats

```
estate [None] The name of the target estate. Master stats would be requested by default
```

CLI Example:

```
salt-run manage.lane_stats [estate=alpha_minion]
```

salt.runners.manage.list_not_state(subset=None, show_ipv4=False, state=None)
New in version 2015.8.0.
Print a list of all minions that are NOT up according to Salt's presence detection (no commands will be sent to minions)

```
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.
state ['available'] Show minions being in specific state that is one of 'available', 'joined', 'allowed', 'alived' or 'reaped'.
```

CLI Example:

```
salt-run manage.list_not_state
```

salt.runners.manage.list_state(subset=None, show_ipv4=False, state=None)
New in version 2015.8.0.
Print a list of all minions that are up according to Salt's presence detection (no commands will be sent to minions)

```
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.
state ['available'] Show minions being in specific state that is one of 'available', 'joined', 'allowed', 'alived' or 'reaped'.
```

CLI Example:

```
salt-run manage.list_state
```

salt.runners.manage.not_alived(subset=None, show_ipv4=False)
New in version 2015.8.0.
Print a list of all minions that are NOT up according to Salt's presence detection (no commands will be sent)
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.

CLI Example:
salt-run manage.not_alived

salt.runners.manage.not_allowed(subset=None, show_ipv4=False)
New in version 2015.8.0.
Print a list of all minions that are NOT up according to Salt’s presence detection (no commands will be sent)
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.

CLI Example:
salt-run manage.not_allowed

salt.runners.manage.not_joined(subset=None, show_ipv4=False)
New in version 2015.8.0.
Print a list of all minions that are NOT up according to Salt’s presence detection (no commands will be sent)
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.

CLI Example:
salt-run manage.not_joined

salt.runners.manage.not_present(subset=None, show_ipv4=False)
New in version 2015.5.0.
Print a list of all minions that are NOT up according to Salt’s presence detection (no commands will be sent)
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.

CLI Example:
salt-run manage.not_present

salt.runners.manage.not_reaped(subset=None, show_ipv4=False)
New in version 2015.8.0.
Print a list of all minions that are NOT up according to Salt’s presence detection (no commands will be sent)
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.

CLI Example:
salt-run manage.not_reaped

salt.runners.manage.present(subset=None, show_ipv4=False)
Print a list of all minions that are up according to Salt’s presence detection (no commands will be sent to minions)
subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.

CLI Example:
salt-run manage.present

salt.runners.manage.reaped(subset=None, show_ipv4=False)
New in version 2015.8.0.
Print a list of all minions that are up according to Salt's presence detection (no commands will be sent to minions)

**subset** [None] Pass in a CIDR range to filter minions by IP address.

**show_ipv4** [False] Also show the IP address each minion is connecting from.

CLI Example:

```
salt-run manage.reaped
```

**salt.runners.manage.road_stats**(estate=None)

Print the estate road stack stats

**estate** [None] The name of the target estate. Master stats would be requested by default

CLI Example:

```
salt-run manage.road_stats [estate=alpha_minion]
```

**salt.runners.manage.safe_accept**(target, tgt_type='glob', expr_form=None)

Changed in version 2017.7.0: The **expr_form** argument has been renamed to **tgt_type**, earlier releases must use **expr_form**.

Accept a minion's public key after checking the fingerprint over salt-ssh

CLI Example:

```
salt-run manage.safe_accept my_minion
salt-run manage.safe_accept minion1,minion2 tgt_type=list
```

**salt.runners.manage.status**(output=True, tgt='*', tgt_type='glob', expr_form=None, timeout=None, gather_job_timeout=None)

Changed in version 2017.7.0: The **expr_form** argument has been renamed to **tgt_type**, earlier releases must use **expr_form**.

Print the status of all known salt minions

CLI Example:

```
salt-run manage.status
salt-run manage.status tgt="webservers" tgt_type="nodegroup"
salt-run manage.status timeout=5 gather_job_timeout=10
```

**salt.runners.manage.up**(tgt='*', tgt_type='glob', expr_form=None, timeout=None, gather_job_timeout=None)

Changed in version 2017.7.0: The **expr_form** argument has been renamed to **tgt_type**, earlier releases must use **expr_form**.

Print a list of all of the minions that are up

CLI Example:

```
salt-run manage.up
salt-run manage.up tgt="webservers" tgt_type="nodegroup"
salt-run manage.up timeout=5 gather_job_timeout=10
```

**salt.runners.manage.versions()**

Check the version of active minions

CLI Example:

```
salt-run manage.versions
```
19.16.20  salt.runners.mattermost

Note for 2017.7 releases!

Due to the salt.runners.config module not being available in this release series, importing the salt.runners.config module from the develop branch is required to make this module work.

Ref: Mattermost runner failing to retrieve config values due to unavailable config runner #43479

Module for sending messages to Mattermost
New in version 2017.7.0.

configuration This module can be used by either passing an api_url and hook directly or by specifying both in a configuration profile in the salt master/minion config. For example:

```
mattermost:
  hook: peWcBiMOS9Hzg15peWcBiMOS9Hzg15
  api_url: https://example.com
```

salt.runners.mattermost.post_event(event, channel=None, username=None, api_url=None, hook=None)

Send an event to a Mattermost channel.

:param channel: The channel name, either will work.
:param username: The username of the poster.
:param event: The event to send to the Mattermost channel.
:param api_url: The Mattermost api url, if not specified in the configuration.
:param hook: The Mattermost hook, if not specified in the configuration.
:return: Boolean if message was sent successfully.

salt.runners.mattermost.post_message(message, channel=None, username=None, api_url=None, hook=None)

Send a message to a Mattermost channel.

:param channel: The channel name, either will work.
:param username: The username of the poster.
:param message: The message to send to the Mattermost channel.
:param api_url: The Mattermost api url, if not specified in the configuration.
:param hook: The Mattermost hook, if not specified in the configuration.
:return: Boolean if message was sent successfully.

CLI Example:

```
salt-run mattermost.post_message message='Build is done'
```

19.16.21  salt.runners.mine

A runner to access data from the salt mine

salt.runners.mine.get(tgt, fun, tgt_type='glob')

Gathers the data from the specified minions' mine, pass in the target, function to look up and the target type

CLI Example:

```
salt-run mine.get '*' network.interfaces
```

salt.runners.mine.update(tgt, tgt_type='glob', clear=|False, mine_functions=None)

New in version 2017.7.0.

Update the mine data on a certain group of minions.

tgt Which minions to target for the execution.

tgt_type: glob The type of tgt.

clear: False Boolean flag specifying whether updating will clear the existing mines, or will update. Default: False (update).

mine_functions Update the mine data on certain functions only. This feature can be used when updating the mine for functions that require refresh at different intervals than the rest of the functions specified under mine_functions in the minion/master config or pillar.
**CLI Example:**

```
salt-run mine.update '*'
salt-run mine.update 'juniper-edges' tgt_type='nodegroup'
```

---

**19.16.22 salt.runners.nacl**

This runner helps create encrypted passwords that can be included in pillars.

`depends libnacl, https://github.com/saltstack/libnacl`

This is often useful if you wish to store your pillars in source control or share your pillar data with others that you trust. I don't advise making your pillars public regardless if they are encrypted or not.

The following configurations can be defined in the master config so your users can create encrypted passwords using the runner nacl:

```
cat /etc/salt/master.d/nacl.conf
nacl.config:
    key: 'cKEzd4kXsbeCE7/nLTIqXwnUiD1ulg4NoeeYcCFpd9k='
    keyfile: /root/.nacl
```

Now with the config in the master you can use the runner nacl like:

```
salt-run nacl.enc 'data'
```

**salt.runners.nacl.dec**(data, **kwargs)

Takes a key generated from nacl.keygen and decrypt some data.

CLI Examples:

```
salt-run nacl.dec pEXHQM6cuaF7A=
salt-run nacl.dec data='pEXHQM6cuaF7A=' keyfile=/root/.nacl
salt-run nacl.dec data='pEXHQM6cuaF7A=' key='cKEzd4kXsbeCE7/nLTIqXwnUiD1ulg4NoeeYcCFpd9k='
```

**salt.runners.nacl.enc**(data, **kwargs)

Takes a key generated from nacl.keygen and encrypt some data.

CLI Examples:

```
salt-run nacl.enc datatoenc
salt-run nacl.enc datatoenc keyfile=/root/.nacl
salt-run nacl.enc datatoenc key='cKEzd4kXsbeCE7/nLTIqXwnUiD1ulg4NoeeYcCFpd9k='
```

**salt.runners.nacl.keygen**(keyfile=None)

Use libnacl to generate a private key

CLI Examples:

```
salt-run nacl.keygen
salt-run nacl.keygen keyfile=/root/.nacl
salt-run --out=newline_values_only nacl.keygen > /root/.nacl
```
19.16.23 salt.runners.net

NET Finder

New in version 2017.7.0.
A runner to find network details easily and fast. It's smart enough to know what you are looking for.

Configuration

- Minion (proxy) config

To have the complete features, one needs to add the following mine configuration in the minion (proxy) config file:

```python
mine_functions:
    net.ipaddrs: []
    net.lldp: []
    net.mac: []
    net.arp: []
    net.interfaces: []
```

Which instructs Salt to cache the data returned by the NAPALM-functions. While they are not mandatory, the less functions configured, the less details will be found by the runner.

How often the mines are refreshed, can be specified using:

```python
mine_interval: <X minutes>
```

- Master config

By default the following options can be configured on the master. They are not necessary, but available in case the user has different requirements.

target: * From what minions will collect the mine data. Default: * (collect from all minions).
ignore_interfaces A list of interfaces name to ignore. By default will consider all interfaces.
display: True Display on the screen or return structured object? Default: True (return on the CLI).
outputter: table Specify the outputter name when displaying on the CLI. Default: table.

Configuration example:

```python
runners:
    net.find:
        target: 'edge*'
        expr_form: 'glob'
        ignore_interfaces:
            - lo0
            - em1
            - jsrv
            - fxp0
        outputter: yaml
```
salt.runners.net.find\( (addr, best=True, display=True) \)

Search in all possible entities (Interfaces, MAC tables, ARP tables, LLDP neighbors), using the following mine functions:

- net.mac
- net.arp
- net.lldp
- net.ipaddrs
- net.interfaces

This function has the advantage that it knows where to look, but the output might become quite long as it returns all possible matches.

Optional arguments:

**best**: `True` Return only the best match with the interfaces IP networks when the searching pattern is a valid IP Address or Network.

**display**: `True` Display on the screen or return structured object? Default: `True` (return on the CLI).

CLI Example:

```sh
$ sudo salt-run net.find 10.10.10.7
```

Output Example:

```
Details for all interfaces that include network 10.10.10.7/32 - only best match

<table>
<thead>
<tr>
<th>Device</th>
<th>Interface</th>
<th>Interface Description</th>
<th>UP</th>
<th>Enabled</th>
<th>Speed  [Mbps]</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>irb</td>
<td></td>
<td>True</td>
<td>True</td>
<td>-1</td>
</tr>
<tr>
<td></td>
<td>5C:5E:AB:AC:52:B4</td>
<td>10.10.10.1/22</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

ARP Entries for IP 10.10.10.7

```
<table>
<thead>
<tr>
<th>Device</th>
<th>Interface</th>
<th>MAC</th>
<th>IP</th>
<th>Age</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>irb.349 [ae0.349]</td>

<td>10.10.10.7</td>
<td>832.0</td>
</tr>
</tbody>
</table>
```

salt.runners.net.findarp\( (device=None, interface=None, mac=None, ip=None, display=True) \)

Search for entries in the ARP tables using the following mine functions:

- net.arp

Optional arguments:

**device** Return interface data from a certain device only.

**interface** Return data selecting by interface name.

**mac** Search using a specific MAC Address.

**ip** Search using a specific IP Address.

**display**: `True` Display on the screen or return structured object? Default: `True`, will return on the CLI.

CLI Example:

```sh
$ sudo salt-run net.findarp mac=8C:60:0F:78:EC:41
```

Output Example:
ARP Entries for MAC 8C:60:0F:78:EC:41

<table>
<thead>
<tr>
<th>Device</th>
<th>Interface</th>
<th>MAC</th>
<th>IP</th>
<th>Age</th>
</tr>
</thead>
<tbody>
<tr>
<td>edge01.bjm01</td>
<td>irb.171 [ae0.171]</td>
<td>8C:60:0F:78:EC:41</td>
<td>172.172.17.19</td>
<td>956.0</td>
</tr>
</tbody>
</table>

salt.runners.net.findmac

Search in the MAC Address tables, using the following mine functions:

- net.mac

Optional arguments:
- device: Return interface data from a certain device only.
- interface: Return data selecting by interface name.
- mac: Search using a specific MAC Address.
- vlan: Search using a VLAN ID.
- display: True Display on the screen or return structured object? Default: True, will return on the CLI.

CLI Example:

```bash
$ sudo salt-run net.findmac mac=8C:60:0F:78:EC:41
```

Output Example:

MAC Address(es)

<table>
<thead>
<tr>
<th>Device</th>
<th>Interface</th>
<th>MAC</th>
<th>VLAN</th>
<th>Static</th>
<th>Active</th>
<th>Moves</th>
<th>Last move</th>
</tr>
</thead>
<tbody>
<tr>
<td>edge01.bjm01</td>
<td>ae0.171</td>
<td>8C:60:0F:78:EC:41</td>
<td>171</td>
<td>False</td>
<td>True</td>
<td>0</td>
<td>0.0</td>
</tr>
</tbody>
</table>

salt.runners.net.interfaces

Search for interfaces details in the following mine functions:

- net.interfaces
- net.ipaddr

Optional arguments:
- device: Return interface data from a certain device only.
- interface: Return data selecting by interface name.
- pattern: Return interfaces that contain a certain pattern in their description.
- ipnet: Return interfaces whose IP networks associated include this IP network.
- best: True When ipnet is specified, this argument says if the runner should return only the best match (the output will contain at most one row). Default: True (return only the best match).
- display: True Display on the screen or return structured object? Default: True (return on the CLI).
- title: Display a custom title for the table.

CLI Example:

```bash
$ sudo salt-run net.interfaces interface=vt-0/0/10
```

Output Example:

Details for interface xe-0/0/0

---

19.16. runner modules
<table>

</table>

salt.runners.net.lldp(device=None, interface=None, title=None, pattern=None, chassis=None, display=True)

Search in the LLDP neighbors, using the following mine functions:
- net.lldp

Optional arguments:
- device Return interface data from a certain device only.
- interface Return data selecting by interface name.
- pattern Return LLDP neighbors that have contain this pattern in one of the following fields:
  - Remote Port ID
  - Remote Port Description
  - Remote System Name
  - Remote System Description
- chassis Search using a specific Chassis ID.
- display: True Display on the screen or return structured object? Default: True (return on the CLI).
- display: True Display on the screen or return structured object? Default: True (return on the CLI).
- title Display a custom title for the table.

CLI Example:
```
$ sudo salt-run net.lldp pattern=Ethernet1/48
```

Output Example:
```
Pattern "Ethernet1/48" found in one of the following LLDP details

| Device    | Interface | Parent Interface | Remote Chassis ID | Remote Port ID
|-----------|-----------|------------------|-------------------|-----------------|
| edge01.bjm01 | xe-2/3/4 | ae0 | 8C:60:4F:3B:52:19 | Ethernet1/48
| | | | edge05.bjm01.dummy.net | Cisco NX-OS(tm) n6000,|
| | | | | Software (n6000-uk9), |
| | | | | Version 7.3(0)N7(5), RELEASE
| | | | | SOFTWARE Copyright |
```
salt.runners.net.multi_find("patterns," "kwargs")

Execute multiple search tasks. This function is based on the find function. Depending on the search items, some information might overlap.

Optional arguments:
best: True Return only the best match with the interfaces IP networks when the searching pattern is a valid IP Address or Network.
display: True Display on the screen or return structured object? Default: True (return on the CLI).

CLI Example:

```
$ sudo salt-run net.multi_find Ethernet1/49 xe-0/1/2
```

Output Example:

```
Pattern "Ethernet1/49" found in one of the following LLDP details
```
<table>
<thead>
<tr>
<th>Device</th>
<th>Interface</th>
<th>Parent Interface</th>
<th>Remote Chassis ID</th>
<th>Remote Port Description</th>
<th>Remote Port ID</th>
<th>Remote System Description</th>

19.16.24 salt.runners.network

Network tools to run from the Master

salt.runners.network.wol(mac, bcast='255.255.255.255', destport=9)

Send a "Magic Packet" to wake up a Minion

CLI Example:

salt-run network.wol 08-00-27-13-69-77
salt-run network.wol 080027136977 255.255.255.255 7
salt-run network.wol 08:00:27:13:69:77 255.255.255.255 7
salt.runners.network.wolist *(maclist, bcast='255.255.255.255', destport=9)*

Send a "Magic Packet" to wake up a list of Minions. This list must contain one MAC hardware address per line.

**CLI Example:**

```bash
salt-run network.wolist '/path/to/malist'
salt-run network.wolist '/path/to/malist' 255.255.255.255 7
salt-run network.wolist '/path/to/malist' 255.255.255.255 7
```

### 19.16.25 salt.runners.pagerduty

**Runner Module for Firing Events via PagerDuty**

New in version 2014.1.0.

**configuration** This module can be used by specifying the name of a configuration profile in the master config.

For example:

```yaml
my-pagerduty-account:
    pagerduty.api_key: F3Rbyjvbe43rfFwF2214
    pagerduty.subdomain: mysubdomain
```

**salt.runners.pagerduty.create_event**(service_key=None, description=None, details=None, incident_key=None, profile=None)

Create an event in PagerDuty. Designed for use in states.

**CLI Example:**

```bash
salt-run pagerduty.create_event <service_key> <description> <details> profile=my-pagerduty-account
```

The following parameters are required:

- **service_key** This key can be found by using pagerduty.list_services.
- **description** This is a short description of the event.
- **details** This can be a more detailed description of the event.
- **profile** This refers to the configuration profile to use to connect to the PagerDuty service.

**salt.runners.pagerduty.list_escalation_policies**(profile=None, api_key=None)

This function is an alias of list_policies.

List escalation policies belonging to this account

**CLI Example:**

```bash
salt-run pagerduty.list_policies my-pagerduty-account
salt-run pagerduty.list_escalation_policies my-pagerduty-account
```

**salt.runners.pagerduty.list_incidents**(profile=None, api_key=None)

List incidents belonging to this account

**CLI Example:**

```bash
salt-run pagerduty.list_incidents my-pagerduty-account
```

**salt.runners.pagerduty.list_maintenance_windows**(profile=None, api_key=None)

This function is an alias of list_windows.

List maintenance windows belonging to this account

**CLI Example:**

```bash
```
salt-run pagerduty.list_windows my-pagerduty-account  
salt-run pagerduty.list_maintenance_windows my-pagerduty-account

salt.runners.pagerduty.list_policies(profile=None, api_key=None)
List escalation policies belonging to this account

CLI Example:
salt-run pagerduty.list_policies my-pagerduty-account  
salt-run pagerduty.list_escalation_policies my-pagerduty-account

salt.runners.pagerduty.list_schedules(profile=None, api_key=None)
List schedules belonging to this account

CLI Example:
salt-run pagerduty.list_schedules my-pagerduty-account

salt.runners.pagerduty.list_services(profile=None, api_key=None)
List services belonging to this account

CLI Example:
salt-run pagerduty.list_services my-pagerduty-account

salt.runners.pagerduty.list_users(profile=None, api_key=None)
List users belonging to this account

CLI Example:
salt-run pagerduty.list_users my-pagerduty-account

salt.runners.pagerduty.list_windows(profile=None, api_key=None)
List maintenance windows belonging to this account

CLI Example:
salt-run pagerduty.list_windows my-pagerduty-account  
salt-run pagerduty.list_maintenance_windows my-pagerduty-account

19.16.26 salt.runners.pillar

Functions to interact with the pillar compiler on the master

salt.runners.pillar.show_pillar(minion='', **kwargs)
Returns the compiled pillar either of a specific minion or just the global available pillars. This function assumes
that no minion has the id *_. Function also accepts pillarenv as attribute in order to limit to a specific pillar
branch of git

CLI Example:
shows minion specific pillar:
salt-run pillar.show_pillar 'www.example.com'

shows global pillar:
salt-run pillar.show_pillar

shows global pillar for `dev` pillar environment: (note that not specifying pillarenv will merge all pillar envi-
ronments using the master config option pillar_source_merging_strategy.)
salt-run pillar.show_pillar 'pillarenv=dev'

shows global pillar for `dev` pillar environment and specific pillarenv = dev:
salt-run pillar.show_pillar 'saltenv=dev' 'pillarenv=dev'

API Example:

```python
import salt.config
import salt.runner
opts = salt.config.master_config('/etc/salt/master')
runner = salt.runner.RunnerClient(opts)
pillar = runner.cmd('pillar.show_pillar', [])
print(pillar)
```

```python
salt.runners.pillar.show_top(minion=None, saltenv='base')
```

Returns the compiled top data for pillar for a specific minion. If no minion is specified, we use the first minion we find.

CLI Example:

```
salt-run pillar.show_top
```

### 19.16.27 salt.runners.pkg

Package helper functions using `salt.modules.pkg`

New in version 2015.8.0.

```python
salt.runners.pkg.list_upgrades(jid, style='group', output='nested', ext_source=None)
```

Show list of available pkg upgrades using a specified format style

CLI Example:

```
salt-run pkg.list_upgrades jid=20141120114141719 style=group
```

### 19.16.28 salt.runners.queue

General management and processing of queues.

This runner facilitates interacting with various queue backends such as the included sqlite3 queue or the planned AWS SQS and Redis queues.

The queue functions such as `insert`, `delete`, and `pop` can be used for typical management of the queue.

The `process_queue` function pops the requested number of items from the queue and creates a Salt Event that can then be processed by a Reactor. The `process_queue` function can be called manually, or can be configured to run on a schedule with the Salt Scheduler or regular system cron. It is also possible to use the peer system to allow a minion to call the runner.

This runner, as well as the Queues system, is not api stable at this time.

There are many things that could potentially be done with queues within Salt. For the time being the focus will be on queueing infrastructure actions on specific minions. The queues generally will be populated with minion IDs. When the `process_queue` runner function is called events are created on the Salt Event bus that indicate the queue and a list of one or more minion IDs. The reactor is set up to match on event tags for a specific queue and then take infrastructure actions on those minion IDs. These actions might be to delete the minion’s key from the master, use `salt-cloud` to destroy the vm, or some other custom action.
Queued runners

Using the Salt Queues, references to the command line arguments of other runners can be saved to be processed later. The queue runners require a queue backend that can store JSON data (default: `pgjsonb`).

Once the queue is set up, the `runner_queue` will need to be configured.

```
runner_queue:
  queue: runners
  backend: pgjsonb
```

**Note:** only the queue is required, this defaults to using `pgjsonb`

Once this is set, then the following can be added to the scheduler on the master and it will run the specified amount of commands per time period.

```
schedule:
  runner_queue:
    schedule:
      function: queue.process_runner
      minutes: 1
      kwargs:
        quantity: 2
```

The above configuration will pop 2 runner jobs off the runner queue, and then run them. And it will do this every minute, unless there are any jobs that are still running from the last time the `process_runner` task was executed.

- `salt.runners.queue.delete(queue, items, backend='sqlite')`  
  Delete an item or items from a queue
  
  **CLI Example:**
  ```
salt-run queue.delete myqueue myitem
salt-run queue.delete myqueue myitem backend=sqite
salt-run queue.delete myqueue "['item1', 'item2', 'item3']"
```

- `salt.runners.queue.insert(queue, items, backend='sqlite')`  
  Add an item or items to a queue
  
  **CLI Example:**
  ```
salt-run queue.insert myqueue myitem
salt-run queue.insert myqueue "['item1', 'item2', 'item3']"
salt-run queue.insert myqueue myitem backend=sqite
salt-run queue.insert myqueue "['item1', 'item2', 'item3']" backend=sqite
```

- `salt.runners.queue.insert_runner(fun, args=None, kwargs=None, queue=None, backend=None)`  
  Insert a reference to a runner into the queue so that it can be run later.
  
  **fun** The runner function that is going to be run
  **args** list or comma-separated string of args to send to fun
  **kwargs** dictionary of keyword arguments to send to fun
  **queue** queue to insert the runner reference into
  **backend** backend that to use for the queue
  
  **CLI Example:**
  ```
salt-run queue.insert_runner test.stdout_print
salt-run queue.insert_runner event.send test_insert_runner kwargs='{"data": {"foo": "bar"}}}''
```
salt.runners.queue.list_items(queue, backend='sqlite')
    List contents of a queue
    CLI Example:
    
    ```
    salt-run queue.list_items myqueue
    salt-run queue.list_items myqueue backend=sqlite
    ```

salt.runners.queue.list_length(queue, backend='sqlite')
    Provide the number of items in a queue
    CLI Example:
    
    ```
    salt-run queue.list_length myqueue
    salt-run queue.list_length myqueue backend=sqlite
    ```

salt.runners.queue.list_queues(backend='sqlite')
    Return a list of Salt Queues on the backend
    CLI Example:
    
    ```
    salt-run queue.list_queues
    salt-run queue.list_queues backend=sqlite
    ```

salt.runners.queue.pop(queue, quantity=1, backend='sqlite')
    Pop one or more or all items from a queue
    CLI Example:
    
    ```
    salt-run queue.pop myqueue
    salt-run queue.pop myqueue 6
    salt-run queue.pop myqueue all
    salt-run queue.pop myqueue 6 backend=sqlite
    salt-run queue.pop myqueue all backend=sqlite
    ```

salt.runners.queue.process_queue(queue, quantity=1, backend='sqlite')
    Pop items off a queue and create an event on the Salt event bus to be processed by a Reactor.
    CLI Example:
    
    ```
    salt-run queue.process_queue myqueue
    salt-run queue.process_queue myqueue 6
    salt-run queue.process_queue myqueue all backend=sqlite
    ```

salt.runners.queue.process_runner(quantity=1, queue=None, backend=None)
    Process queued runners
    quantity  number of runners to process
    queue    queue to insert the runner reference into
    backend  backend that to use for the queue
    CLI Example:
    
    ```
    salt-run queue.process_runner
    salt-run queue.process_runner 5
    ```
19.16.29 salt.runners.reactor

A convenience system to manage reactors

Beginning in the 2017.7 release, the reactor runner requires that the reactor system is running. This is accomplished one of two ways, either by having reactors configured or by including `reactor` in the engine configuration for the Salt master.

```
engines:
  - reactor
```

call `salt-run reactor.add` event, reactors, saltenv='base', test=None

Add a new reactor

CLI Example:

```
salt-run reactor.add 'salt/cloud/*/destroyed' reactors='/srv/reactor/destroy/*.sls'
```

call `salt-run reactor.delete` event, saltenv='base', test=None

Delete a reactor

CLI Example:

```
salt-run reactor.delete 'salt/cloud/*/destroyed'
```

call `salt-run reactor.list` saltenv='base', test=None

List currently configured reactors

CLI Example:

```
salt-run reactor.list
```

19.16.30 salt.runners.salt

This runner makes Salt's execution modules available on the salt master.

New in version 2016.11.0. Salt's execution modules are normally available on the salt minion. Use this runner to call execution modules on the salt master. Salt execution modules are the functions called by the `salt` command.

Execution modules can be called with `salt-run`:

```
salt-run salt.cmd test.ping
  # call functions with arguments and keyword arguments
salt-run salt.cmd test.arg 1 2 3 key=value a=1
```

Execution modules are also available to salt runners:

```
__salt__['salt.cmd'](fun=fun, args=args, kwargs=kwargs)
```

call `salt.runners.salt.cmd` fun, `args`, `kwargs`

Execute fun with the given args and kwargs. Parameter fun should be the string `name` of the execution module to call.

Note that execution modules will be loaded every time this function is called.

CLI example:
salt-run salt.cmd test.ping
# call functions with arguments and keyword arguments
salt-run salt.cmd test.arg 1 2 3 a=1

salt.runners.salt.execute(tgt, fun=(), timeout=None, tgt_type='glob', ret='`, jid='`, kwarg=None, **kwargs)

New in version 2017.7.0.

Execute fun on all minions matched by tgt and tgt_type. Parameter fun is the name of execution module function to call.

This function should mainly be used as a helper for runner modules, in order to avoid redundant code. For example, when inside a runner one needs to execute a certain function on arbitrary groups of minions, only has to:

ret1 = __salt__['salt.execute']('*', 'mod.fun')
ret2 = __salt__['salt.execute']('my_nodegroup', 'mod2.fun2', tgt_type='nodegroup')

It can also be used to schedule jobs directly on the master, for example:

```
schedule:
  collect_bgp_stats:
    function: salt.execute
    args:
      - edge-routers
      - bgp.neighbors
    kwarg:
      tgt_type: nodegroup
    days: 1
    returner: redis
```

### 19.16.31 salt.runners.saltutil

Sync custom types to the Master

New in version 2016.3.0.

salt.runners.saltutil.sync_all(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)

Sync all custom types

saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

extmod_whitelist [None] dictionary of modules to sync based on type

extmod_blacklist [None] dictionary of modules to blacklist based on type

CLI Example:

```
salt-run saltutil.sync_all
salt-run saltutil.sync_all extmod_whitelist=['runners': ['custom_runner'], 'grains ←': []]
```

salt.runners.saltutil.sync_cache(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)

New in version 2017.7.0.

Sync utils modules from salt://_cache to the master

saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.

extmod_whitelist [None] comma-separated list of modules to sync
extmod_blacklist [None] comma-separated list of modules to blacklist based on type
CLI Example:
salt-run saltutil.sync_cache

salt.runners.saltutil.sync_clouds(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
New in version 2017.7.0.
Sync utils modules from salt://_clouds to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
extmod_whitelist [None] comma-separated list of modules to sync
extmod_blacklist [None] comma-separated list of modules to blacklist based on type
CLI Example:
salt-run saltutil.sync_clouds

salt.runners.saltutil.sync_engines(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
Sync engines from salt://_engines to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
extmod_whitelist [None] comma-separated list of modules to sync
extmod_blacklist [None] comma-separated list of modules to blacklist based on type
CLI Example:
salt-run saltutil.sync_engines

salt.runners.saltutil.sync_grains(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
Sync grains modules from salt://_grains to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
extmod_whitelist [None] comma-separated list of modules to sync
extmod_blacklist [None] comma-separated list of modules to blacklist based on type
CLI Example:
salt-run saltutil.sync_grains

salt.runners.saltutil.sync_modules(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
Sync execution modules from salt://_modules to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
extmod_whitelist [None] comma-separated list of modules to sync
extmod_blacklist [None] comma-separated list of modules to blacklist based on type
CLI Example:
salt-run saltutil.sync_modules

salt.runners.saltutil.sync_output(salentv='base', extmod_whitelist=None, extmod_blacklist=None)
Sync output modules from salt://_output to the master
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
extmod_whitelist [None] comma-separated list of modules to sync
extmod_blacklist [None] comma-separated list of modules to blacklist based on type

CLI Example:

```
salt-run saltutil.sync_output
```

```
salt.runners.saltutil.sync_pillar(saltenv='base',
                                extmod_whitelist=None,
                                extmod_blacklist=None)
```

Sync pillar modules from salt:///_pillar to the master

```
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
```

```
extmod_whitelist [None] comma-separated list of modules to sync
```

```
extmod_blacklist [None] comma-separated list of modules to blacklist based on type
```

CLI Example:

```
salt-run saltutil.sync_pillar
```

```
salt.runners.saltutil.sync_proxymodules(saltenv='base',
                                        extmod_whitelist=None,
                                        extmod_blacklist=None)
```

Sync proxy modules from salt:///_proxy to the master

```
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
```

```
extmod_whitelist [None] comma-separated list of modules to sync
```

```
extmod_blacklist [None] comma-separated list of modules to blacklist based on type
```

CLI Example:

```
salt-run saltutil.sync_proxy
```

```
salt.runners.saltutil.sync_queues(saltenv='base',
                                  extmod_whitelist=None,
                                  extmod_blacklist=None)
```

Sync queue modules from salt:///_queues to the master

```
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
```

```
extmod_whitelist [None] comma-separated list of modules to sync
```

```
extmod_blacklist [None] comma-separated list of modules to blacklist based on type
```

CLI Example:

```
salt-run saltutil.sync_queues
```

```
salt.runners.saltutil.sync_renderers(saltenv='base',
                                      extmod_whitelist=None,
                                      extmod_blacklist=None)
```

Sync renderer modules from salt:///_renderers to the master

```
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
```

```
extmod_whitelist [None] comma-separated list of modules to sync
```

```
extmod_blacklist [None] comma-separated list of modules to blacklist based on type
```

CLI Example:

```
salt-run saltutil.sync_renderers
```

```
salt.runners.saltutil.sync_returners(saltenv='base',
                                      extmod_whitelist=None,
                                      extmod_blacklist=None)
```

Sync returner modules from salt:///_returners to the master

```
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
```

```
extmod_whitelist [None] comma-separated list of modules to sync
```

```
extmod_blacklist [None] comma-separated list of modules to blacklist based on type
```

CLI Example:
CLI Example:
```
salt-run saltutil.sync_returners
```

```
salt.runners.saltutil.sync_roster(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
```
New in version 2017.7.0.
Sync utils modules from `salt://_roster` to the master

```
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
```

```
exitmod_whitelist [None] comma-separated list of modules to sync
```

```
exitmod_blacklist [None] comma-separated list of modules to blacklist based on type
```
CLI Example:
```
salt-run saltutil.sync_roster
```

```
salt.runners.saltutil.sync_runners(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
```
Sync runners from `salt://_runners` to the master

```
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
```

```
exitmod_whitelist [None] comma-separated list of modules to sync
```

```
exitmod_blacklist [None] comma-separated list of modules to blacklist based on type
```
CLI Example:
```
salt-run saltutil.sync_runners
```

```
salt.runners.saltutil.sync_sdb(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
```
New in version 2017.7.0.
Sync utils modules from `salt://_sdb` to the master

```
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
```

```
exitmod_whitelist [None] comma-separated list of modules to sync
```

```
exitmod_blacklist [None] comma-separated list of modules to blacklist based on type
```
CLI Example:
```
salt-run saltutil.sync_sdb
```

```
salt.runners.saltutil.sync_states(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
```
Sync state modules from `salt://_states` to the master

```
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
```

```
exitmod_whitelist [None] comma-separated list of modules to sync
```

```
exitmod_blacklist [None] comma-separated list of modules to blacklist based on type
```
CLI Example:
```
salt-run saltutil.sync_states
```

```
salt.runners.saltutil.sync_tops(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
```
New in version 2016.3.7,2016.11.4,2017.7.0.
Sync master_tops modules from `salt://_tops` to the master

```
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
```

```
exitmod_whitelist [None] comma-separated list of modules to sync
```

```
exitmod_blacklist [None] comma-separated list of modules to blacklist based on type
```
CLI Example:
```
salt-run saltutil.sync_tops
```
CLI Example:

```
salt-run saltutil.sync_tops
```

```
salt.runners.saltutil.sync_utils(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
```

New in version 2016.11.0.
Sync utils modules from salt://_utils to the master

```
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
```
```
extmod_whitelist [None] comma-separated list of modules to sync
```
```
extmod_blacklist [None] comma-separated list of modules to blacklist based on type
```

CLI Example:

```
salt-run saltutil.sync_utils
```

```
salt.runners.saltutil.sync_wheel(saltenv='base', extmod_whitelist=None, extmod_blacklist=None)
```

Sync wheel modules from salt://_wheel to the master

```
saltenv [base] The fileserver environment from which to sync. To sync from more than one environment, pass a comma-separated list.
```
```
extmod_whitelist [None] comma-separated list of modules to sync
```
```
extmod_blacklist [None] comma-separated list of modules to blacklist based on type
```

CLI Example:

```
salt-run saltutil.sync_wheel
```

19.16.32 salt.runners.sdb

Runner for setting and querying data via the sdb API on the master

```
salt.runners.sdb.delete(uri)
```
Delete a value from a db, using a uri in the form of sdb://<profile>/<key>. If the uri provided does not start with sdb:// or the value is not successfully deleted, return False.

CLI Example:

```
salt '*' sdb.delete sdb://mymemcached/foo
```

```
salt.runners.sdb.get(uri)
```
Get a value from a db, using a uri in the form of sdb://<profile>/<key>. If the uri provided does not start with sdb://, then it will be returned as-is.

CLI Example:

```
salt '*' sdb.get sdb://mymemcached/foo
```

```
salt.runners.sdb.get_or_set_hash(uri, length=8, chars='abcdefghijklmnopqrstuvwxyz0123456789%@#$%^&*(-_=+)
```
Perform a one-time generation of a hash and write it to sdb. If that value has already been set return the value instead.

This is useful for generating passwords or keys that are specific to multiple minions that need to be stored somewhere centrally.

CLI Example:
salt-run sdb.get_or_set_hash 'SECRET_KEY' 50

**Warning:** This function could return strings which may contain characters which are reserved as directives by the YAML parser, such as strings beginning with `%`. To avoid issues when using the output of this function in an SLS file containing YAML+Jinja, surround the call with single quotes.

salt.runners.sdb.set(uri, value)
Set a value in a db, using a uri in the form of sdb://<profile>/<key>. If the uri provided does not start with sdb:// or the value is not successfully set, return False.

CLI Example:
salt '*' sdb.set sdb://mymemcached/foo bar

### 19.16.33 salt.runners.smartos_vmadm

Runner for SmartOS minions control vmadm

salt.runners.smartos_vmadm.get(search, one=True)
Return information for vms
search [string] filter vms, see the execution module.
one [boolean] return only one vm

**Note:** If the search parameter does not contain an equal (=) symbol it will be assumed it will be tried as uuid, hostname, and alias.

CLI Example:
salt-run vmadm.get 91244bba-1146-e4ec-c07e-e825e0223aa9
salt-run vmadm.get search='alias=saskia'

salt.runners.smartos_vmadm.is_running(search)
Return true if vm is running
search [string] filter vms, see the execution module.

**Note:** If the search parameter does not contain an equal (=) symbol it will be assumed it will be tried as uuid, hostname, and alias.

**Note:** If multiple vms are matched, the result will be true of ALL vms are running

CLI Example:
salt-run vmadm.is_running 91244bba-1146-e4ec-c07e-e825e0223aa9
salt-run vmadm.is_running search='alias=julia'

salt.runners.smartos_vmadm.list_vms(search=None, verbose=False)
List all vms
search [string] filter vms, see the execution module
verbose [boolean] print additional information about the vm
CLI Example:

```
salt-run vmadm.list
salt-run vmadm.list search='type=KVM'
salt-run vmadm.list verbose=True
```

```
salt.runners.smartos_vmadm.nodes(verbos=False)
List all compute nodes
verbose [boolean] print additional information about the node e.g. platform version, hvm capable, ...
```

CLI Example:

```
salt-run vmadm.nodes
salt-run vmadm.nodes verbose=True
```

```
salt.runners.smartos_vmadm.reboot(search, one=True, force=False)
Reboot one or more vms
search [string] filter vms, see the execution module.
one [boolean] reboot only one vm
force [boolean] force reboot, faster but no graceful shutdown
```

Note: If the search parameter does not contain an equal (=) symbol it will be assumed it will be tried as uuid, hostname, and alias.

CLI Example:

```
salt-run vmadm.reboot 91244bba-1146-e4ec-c07e-e825e0223aa9
salt-run vmadm.reboot search='alias=marije'
salt-run vmadm.reboot search='type=KVM' one=False
```

```
salt.runners.smartos_vmadm.start(search, one=True)
Start one or more vms
search [string] filter vms, see the execution module.
one [boolean] start only one vm
```

Note: If the search parameter does not contain an equal (=) symbol it will be assumed it will be tried as uuid, hostname, and alias.

CLI Example:

```
salt-run vmadm.start 91244bba-1146-e4ec-c07e-e825e0223aa9
salt-run vmadm.start search='alias=jiska'
salt-run vmadm.start search='type=KVM' one=False
```

```
salt.runners.smartos_vmadm.stop(search, one=True)
Stop one or more vms
search [string] filter vms, see the execution module.
one [boolean] stop only one vm
```

Note: If the search parameter does not contain an equal (=) symbol it will be assumed it will be tried as uuid, hostname, and alias.

CLI Example:
19.16.34 salt.runners.search

Runner frontend to search system

salt.runners.search.query(term)
Query the search system

CLI Example:

```
salt-run search.query foo
```

19.16.35 salt.runners.spacewalk

Spacewalk Runner

New in version 2016.3.0.
Runner to interact with Spacewalk using Spacewalk API

codeauthor Nitin Madhok <nmadhok@clemson.edu>, Joachim Werner <joe@suse.com>, Benedikt Werner <1benediktwerner@gmail.com>
maintainer Benedikt Werner <1benediktwerner@gmail.com>

To use this runner, set up the Spacewalk URL, username and password in the master configuration at /etc/salt/master or /etc/salt/master.d/spacewalk.conf:

```
spacewalk:
spacewalk01.domain.com:  
  username: 'testuser'  
  password: 'verybadpass'
spacewalk02.domain.com:  
  username: 'testuser'  
  password: 'verybadpass'
```

Note: Optionally, protocol can be specified if the spacewalk server is not using the defaults. Default is protocol: https.

salt.runners.spacewalk.addGroupsToKey(server, activation_key, groups)
Add server groups to a activation key

CLI Example:

```
salt-run spacewalk.addGroupsToKey spacewalk01.domain.com 1-my-key '[group1,'  
  'group2]'  
```

salt.runners.spacewalk.api(server, command, *args, **kwargs)
Call the Spacewalk xmlrpc api.

CLI Example:
salt-run spacewalk.api spacewalk01.domain.com systemgroup.create MyGroup
    # Description
salt-run spacewalk.api spacewalk01.domain.com systemgroup.create arguments='[
    # "MyGroup", "Description"]'

State Example:

```python
create_group:
salt.runner:
    - name: spacewalk.api
    - server: spacewalk01.domain.com
    - command: systemgroup.create
      - arguments:
        # MyGroup
        - Description
```

salt.runners.spacewalk.deleteAllActivationKeys(server)
Delete all activation keys from Spacewalk
CLI Example:

```
salt-run spacewalk.deleteAllActivationKeys spacewalk01.domain.com
```

salt.runners.spacewalk.deleteAllGroups(server)
Delete all server groups from Spacewalk

salt.runners.spacewalk.deleteAllSystems(server)
Delete all systems from Spacewalk
CLI Example:

```
salt-run spacewalk.deleteAllSystems spacewalk01.domain.com
```

salt.runners.spacewalk.unregister(name, server_url)
Unregister specified server from Spacewalk
CLI Example:

```
salt-run spacewalk.unregister my-test-vm spacewalk01.domain.com
```

19.16.36 salt.runners.ssh

A Runner module interface on top of the salt-ssh Python API.
This allows for programmatic use from salt-api, the Reactor, Orchestrate, etc.
salt.runners.ssh.cmd(tgt, fun, arg=(), timeout=None, tgt_type='glob', kwarg=None, expr_form=None)
New in version 2015.5.0.
Changed in version 2017.7.0: The expr_form argument has been renamed to tgt_type, earlier releases must use expr_form.
Execute a single command via the salt-ssh subsystem and return all routines at once
A wrapper around the SSHClient.cmd method.
19.16.37 salt.runners.state

Execute orchestration functions

```
salt.runners.state.event(tagmatch='*', count=-1, quiet=False, sock_dir=None, pretty=False, node='master')
```

Watch Salt's event bus and block until the given tag is matched

New in version 2014.7.0.

This is useful for utilizing Salt's event bus from shell scripts or for taking simple actions directly from the CLI.

Enable debug logging to see ignored events.

**Parameters**

- **tagmatch** -- the event is written to stdout for each tag that matches this pattern; uses the same matching semantics as Salt's Reactor.
- **count** -- this number is decremented for each event that matches the tagmatch parameter; pass -1 to listen forever.
- **quiet** -- do not print to stdout; just block
- **sock_dir** -- path to the Salt master's event socket file.
- **pretty** -- Output the JSON all on a single line if False (useful for shell tools); pretty-print the JSON output if True.
- **node** -- Watch the minion-side or master-side event bus. .. versionadded:: 2016.3.0

**CLI Examples:**

```
# Reboot a minion and run highstate when it comes back online
salt 'jerry' system.reboot && \
    salt-run state.event 'salt/minion/jerry/start' count=1 quiet=True && \
    salt 'jerry' state.highstate

# Reboot multiple minions and run highstate when all are back online
salt -L 'kevin,stewart,dave' system.reboot && \
    salt-run state.event 'salt/minion/*/start' count=3 quiet=True && \
    salt -L 'kevin,stewart,dave' state.highstate

# Watch the event bus forever in a shell while-loop.
salt-run state.event | while read -r tag data; do
    echo $tag
    echo $data | jq --color-output .
done
```

**See also:**

See https://github.com/saltstack/salt/blob/develop/tests/eventlisten.sh for an example of usage within a shell script.

```
salt.runners.state.orchestrate(mods, saltenv='base', test=None, exclude=None, pillar=None, pillarenv=None, pillar_enc=None, orchestration_jid=None)
```

New in version 0.17.0.

Execute a state run from the master, used as a powerful orchestration system.

**See also:**

More Orchestrate documentation

- Full Orchestrate Tutorial
- Docs for the master-side state module

**CLI Examples:**
**salt-run state.orchestrate webserver**

Changed in version 2014.1.1: Runner renamed from `state.sls` to `state.orchestrate`

Changed in version 2014.7.0: Runner uses the pillar variable

Changed in version develop: Runner uses the pillar_enc variable that allows renderers to render the pillar. This is usable when supplying the contents of a file as pillar, and the file contains gpg-encrypted entries.

**See also:**

GPG renderer documentation

**CLI Examples:**

```bash
salt-run state.orchestrate webserver saltenv=dev test=True
salt-run state.orchestrate webserver saltenv=dev pillarenv=aws
```

```
salt-run state.orchestrate webserver pillar_enc=gpg pillar="$(cat somefile.json)"
```

**salt.runners.state.orchestrate_high**

Execute a single state orchestration routine

New in version 2015.5.0.

**CLI Example:**

```bash
salt-run state.orchestrate_high '{
  stage_one:
    {salt.state: [{tgt: "db*"}, {sls: postgres_setup}]},
  stage_two:
    {salt.state: [{tgt: "web*"}, {sls: apache_setup}, {
      require: [{salt: stage_one}],
    }]},
}'
```

**salt.runners.state.orchestrate_single**

Execute a single state orchestration routine

New in version 2015.5.0.

**CLI Example:**

```bash
salt-run state.orchestrate_single fun=salt.wheel name=key.list_all
```

### 19.16.38 salt.runners.survey

A general map/reduce style salt runner for aggregating results returned by several different minions.

New in version 2014.7.0.

Aggregated results are sorted by the size of the minion pools which returned matching results.

Useful for playing the game: "some of these things are not like the others..." when identifying discrepancies in a large infrastructure managed by salt.

**salt.runners.survey.diff**

Return the DIFFERENCE of the result sets returned by each matching minion pool

New in version 2014.7.0.
These pools are determined from the aggregated and sorted results of a salt command. This command displays the ``diffs'' as a series of 2-way differences -- namely the difference between the FIRST displayed minion pool (according to sort order) and EACH SUBSEQUENT minion pool result set. Differences are displayed according to the Python difflib.unified_diff() as in the case of the salt execution module file.get_diff.

This command is submitted via a salt runner using the general form:

```
salt-run survey.diff [survey_sort=up/down] <target> <salt-execution-module> <salt-execution-module parameters>
```

Optionally accept a survey_sort= parameter. Default: survey_sort=down

CLI Example #1: (Example to display the ``differences of files")
```
salt-run survey.diff survey_sort=up "*" cp.get_file_str file:///etc/hosts
```

salt.runners.survey.hash('args,'**kwargs')
Return the MATCHING minion pools from the aggregated and sorted results of a salt command

New in version 2014.7.0.

This command is submitted via a salt runner using the general form:

```
salt-run survey.hash [survey_sort=up/down] <target> <salt-execution-module> <salt-execution-module parameters>
```

Optionally accept a survey_sort= parameter. Default: survey_sort=down

CLI Example #1: (functionally equivalent to salt-run manage.up)
```
salt-run survey.hash "*" test.ping
```

CLI Example #2: (find an ``outlier'' minion config file)
```
salt-run survey.hash "*" file.get_hash /etc/salt/minion survey_sort=up
```

19.16.39 salt.runners.test

This runner is used only for test purposes and servers no production purpose

salt.runners.test.arg('args,'**kwargs)
Output the given args and kwargs
Kwargs will be filtered for `private' keynames.

salt.runners.test.metasyntactic(locality='us')
Return common metasyntactic variables for the given locality

salt.runners.test.raw_arg('args,'**kwargs)
Output the given args and kwargs

salt.runners.test.sleep(s_time=10)
Sleep t seconds, then return True

salt.runners.test.stdout_print()
Print 'foo' and return 'bar'
19.16.40 salt.runners.thin

The thin runner is used to manage the salt thin systems.

Salt Thin is a transport-less version of Salt that can be used to run routines in a standalone way. This runner has tools which generate the standalone salt system for easy consumption.

```python
salt.runners.thin.generate(extra_mods='`, overwrite=False, so_mods='`, python2_bin='python2';
              python3_bin='python3', absonly=True, compress='gzip')
```

Generate the salt-thin tarball and print the location of the tarball Optional additional mods to include (e.g. mako) can be supplied as a comma delimited string. Permits forcing an overwrite of the output file as well.

CLI Example:
```
salt-run thin.generate
salt-run thin.generate mako
salt-run thin.generate mako,wempy 1
salt-run thin.generate overwrite=1
```

```python
salt.runners.thin.generate_min(extra_mods='`, overwrite=False, so_mods='`,
              python2_bin='python2', python3_bin='python3')
```

Generate the salt-thin tarball and print the location of the tarball Optional additional mods to include (e.g. mako) can be supplied as a comma delimited string. Permits forcing an overwrite of the output file as well.

CLI Example:
```
salt-run thin.generate_min
```

19.16.41 salt.runners.vault

- maintainer SaltStack
- maturity new
- platform all

Runner functions supporting the Vault modules. Configuration instructions are documented in the execution module docs.

```python
salt.runners.vault.generate_token(minion_id, signature, impersonated_by_master=False)
```

Generate a Vault token for minion minion_id

- **minion_id** The id of the minion that requests a token
- **signature** Cryptographic signature which validates that the request is indeed sent by the minion (or the master, see impersonated_by_master).
- **impersonated_by_master** If the master needs to create a token on behalf of the minion, this is True. This happens when the master generates minion pillars.

```python
salt.runners.vault.show_policies(minion_id)
```

Show the Vault policies that are applied to tokens for the given minion

- **minion_id** The minions id

CLI Example:
```
salt-run vault.show_policies myminion
```
19.16.42 salt.runners.venafiapi

Support for Venafi

Before using this module you need to register an account with Venafi, and configure it in your master configuration file.

First, you need to add a placeholder to the master file. This is because the module will not load unless it finds an api_key setting, valid or not. Open up /etc/salt/master and add:

```yaml
venafi:
    api_key: None
```

Then register your email address with Venafi using the following command:

```shell
salt-run venafi.register <youremail@yourdomain.com>
```

This command will not return an api_key to you; that will be sent to you via email from Venafi. Once you have received that key, open up your master file and set the api_key to it:

```yaml
venafi:
    api_key: abcdef01-2345-6789-abcd-ef0123456789
```

salt.runners.venafiapi.del_cached_domain(domains)

Delete cached domains from the master

CLI Example:

```shell
salt-run venafi.del_cached_domain domain1.example.com,domain2.example.com
```

salt.runners.venafiapi.gen_csr(minion_id, dns_name=None, zone='default', country=None, state=None, loc=None, org=None, org_unit=None, password=None)

Generate a csr using the host's private_key. Analogous to:

```bash
```

CLI Example:

```shell
salt-run venafi.gen_csr <minion_id> <dns_name>
```

salt.runners.venafiapi.gen_key(minion_id, dns_name=None, zone='default', password=None)

Generate and return an private_key. If a dns_name is passed in, the private_key will be cached under that name. The type of key and the parameters used to generate the key are based on the default certificate use policy associated with the specified zone.

CLI Example:

```shell
salt-run venafi.gen_key <minion_id> [dns_name] [zone] [password]
```

salt.runners.venafiapi.get_zone_id(zone_name)

Get the zone ID for the given zone name

CLI Example:

```shell
salt-run venafi.get_zone_id default
```

salt.runners.venafiapi.list_domain_cache()

List domains that have been cached
CLI Example:

```
salt-run venafi.list_domain_cache
```

```
salt.runners.venafiapi.pickup(id_)
Show certificate requests for this API key
```

CLI Example:

```
salt-run venafi.show_cert 01234567-89ab-cdef-0123-456789abcde
```

```
salt.runners.venafiapi.register(email)
Register a new user account
```

CLI Example:

```
salt-run venafi.register email@example.com
```

```
salt.runners.venafiapi.request(minion_id, dns_name=None, zone='default', request_id=None, country='US', state='California', loc='Palo Alto', org='Beta Organization', org_unit='Beta Group', password=None, zone_id=None)

Request a new certificate

Uses the following command:

```
VCert enroll -z <zone> -k <api key> -cn <domain name>
```

CLI Example:

```
salt-run venafi.request <minion_id> <dns_name>
```

```
salt.runners.venafiapi.show_cert(id_)
Show certificate requests for this API key
```

CLI Example:

```
salt-run venafi.show_cert 01234567-89ab-cdef-0123-456789abcde
```

```
salt.runners.venafiapi.show_company(domain)
Show company information, especially the company id
```

CLI Example:

```
salt-run venafi.show_company example.com
```

```
salt.runners.venafiapi.show_csrs()
Show certificate requests for this API key
```
CLI Example:

```
salt-run venafi.show_csrs
```

`salt.runners.venafiapi.show_policies()`
Show zone details for the API key owner's company

CLI Example:

```
salt-run venafi.show_policies
```

`salt.runners.venafiapi.show_rsa(minion_id, dns_name)`
Show a private RSA key

CLI Example:

```
salt-run venafi.show_rsa myminion domain.example.com
```

`salt.runners.venafiapi.show_zones()`
Show zone details for the API key owner's company

CLI Example:

```
salt-run venafi.show_zones
```

---

### 19.16.43 `salt.runners.virt`

Control virtual machines via Salt

`salt.runners.virt.force_off(name)`
Force power down the named virtual machine

`salt.runners.virt.host_info(host=None)`
Return information about the host connected to this master

`salt.runners.virt.init(name, cpu, mem, image, hypervisor='kvm', host=None, seed=True, nic='default', install=True, start=True, disk='default', saltenv='base', enable_vnc=False, seed_cmd='seed.apply', enable_qcow=False)`
This routine is used to create a new virtual machine. This routine takes a number of options to determine what the newly created virtual machine will look like.

- `name` The mandatory name of the new virtual machine. The name option is also the minion id, all minions must have an id.
- `cpu` The number of cpus to allocate to this new virtual machine.
- `mem` The amount of memory to allocate to this virtual machine. The number is interpreted in megabytes.
- `image` The network location of the virtual machine image, commonly a location on the salt fileserver, but http, https and ftp can also be used.
- `hypervisor` The hypervisor to use for the new virtual machine. Default is `kvm`.
- `host` The host to use for the new virtual machine, if this is omitted Salt will automatically detect what host to use.
- `seed` Set to `False` to prevent Salt from seeding the new virtual machine.
- `nic` The nic profile to use, defaults to the `default` nic profile which assumes a single network interface per VM associated with the `br0` bridge on the master.
- `install` Set to `False` to prevent Salt from installing a minion on the new VM before it spins up.
- `disk` The disk profile to use
- `saltenv` The Salt environment to use
- `enable_vnc` Whether a VNC screen is attached to resulting VM. Default is `False`.
- `seed_cmd` If seed is `True`, use this execution module function to seed new VM. Default is `seed.apply`. 
enable_qcow  Clone disk image as a copy-on-write qcow2 image, using downloaded image as backing file.

salt.runners.virt.list(host=None, quiet=False, hyper=None)

List the virtual machines on each host, this is a simplified query, showing only the virtual machine names belonging to each host. A single host can be passed in to specify an individual host to list.

salt.runners.virt.migrate(name, target='')

Migrate a VM from one host to another. This routine will just start the migration and display information on how to look up the progress.

salt.runners.virt.next_host()

Return the host to use for the next autodeployed VM. This queries the available host and executes some math the determine the most "available" next host.

salt.runners.virt.pause(name)

Pause the named VM

salt.runners.virt.purge(name, delete_key=True)

Destroy the named VM

salt.runners.virt.query(host=None, quiet=False)

Query the virtual machines. When called without options all hosts are detected and a full query is returned. A single host can be passed in to specify an individual host to query.

salt.runners.virt.reset(name)

Force power down and restart an existing VM

salt.runners.virt.resume(name)

Resume a paused VM

salt.runners.virt.start(name)

Start a named virtual machine

salt.runners.virt.vm_info(name, quiet=False)

Return the information on the named VM

19.16.44 salt.runners.vistara

Vistara Runner

Runner to interact with the Vistara (http://www.vistarait.com/) REST API

codeauthor Brad Thurber <brad.thurber@gmail.com>

To use this runner, the Vistara client_id and Vistara oauth2 client_key and client_secret must be set in the master config.

For example /etc/salt/master.d/_vistara.conf:

```
vistara:
  client_id: client_012345
  client_key: N0tReallyaR3alKeyButShouldB12345
  client_secret: ThisI5AreallyLongsecretKeyIwonderwhyTheyMakethemSoBigTheseDays00
```

salt.runners.vistara.delete_device(name, safety_on=True)

Deletes a device from Vistara based on DNS name or partial name. By default, delete_device will only perform the delete if a single host is returned. Set safety_on=False to delete all matches (up to default API search page size)

CLI Example:
19.16.45 salt.runners.winrepo

Runner to manage Windows software repo

```
salt-run winrepo.genrepo (opts=None, fire_event=True)
```
Generate winrepo_cachefile based on sls files in the winrepo_dir

**opts** Specify an alternate opts dict. Should not be used unless this function is imported into an execution module.

**fire_event** [True] Fire an event on failure. Only supported on the master.

CLI Example:

```
salt-run winrepo.genrepo
```

```
salt-run winrepo.update_git_repos (opts=None, clean=False, masterless=False)
```
Checkout git repos containing Windows Software Package Definitions

**opts** Specify an alternate opts dict. Should not be used unless this function is imported into an execution module.

**clean** [False] Clean repo cachedirs which are not configured under winrepo_remotes.

**Warning:** This argument should not be set to True if a mix of git and non-git repo definitions are being used, as it will result in the non-git repo definitions being removed.

New in version 2015.8.0.

CLI Examples:

```
salt-run winrepo.update_git_repos
salt-run winrepo.update_git_repos clean=True
```

19.17 sdb modules

</table>
19.17.1 salt.sdb.cache module

cache Module

maintainer SaltStack

maturity New

platform all

New in version 2017.7.0.

This module provides access to Salt's cache subsystem.

Like all sdb modules, the cache module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```
mastercloudcache:
  driver: cache
  bank: cloud/active/ec2/my-ec2-conf/saltmaster
  cachedir: /var/cache/salt
```

The driver refers to the cache module, bank refers to the cache bank that contains the data and cachedir (optional), if used, points to an alternate directory for cache data storage.

```
master_ip: sdb://mastercloudcache/public_ips
```

It is also possible to override both the bank and cachedir options inside the SDB URI:

```
```

For this reason, both the bank and the cachedir options can be omitted from the SDB profile. However, if the bank option is omitted, it must be specified in the URI:

```
```

salt.sdb.cache.delete(key, service=None, profile=None)

Get a value from the cache service

salt.sdb.cache.get(key, service=None, profile=None)

Get a value from the cache service

salt.sdb.cache.set_(key, value, service=None, profile=None)

Set a key/value pair in the cache service

19.17.2 salt.sdb.confidant

An SDB module for getting credentials from confidant.

Configuring the Confidant module

The module can be configured via sdb in the minion config:

```
confidant:
  driver: confidant
  # The URL of the confidant web service
  url: 'https://confidant-production.example.com'
```
# The context to use for KMS authentication
auth_context:
  from: example-production-iad
  to: confidant-production-iad
  user_type: service
# The KMS master key to use for authentication
auth_key: "alias/authnz"
# Cache file for KMS auth token
token_cache_file: /run/confidant/confidant_token
# The duration of the validity of a token, in minutes
token_duration: 60

depends  confidant-common, confidant-client

## Module Documentation

class sdb.confidant.get:
  Read pillar data from Confidant via its API.

  CLI Example:
  salt myminion sdb.get `sdb://confidant/credentials'

  Valid keys are: credentials, credentials_metadata, result. credentials returns a dict of joined credential_pairs, credentials_metadata returns a dict of metadata relevant to the credentials mapped to the confidant service, and result returns a bool that can be used to determine if the sdb call succeeded or failed to fetch credentials from confidant (or from local cache). If result is false, the data in credentials or credentials_metadata can't be trusted.

### 19.17.3 sdb.consul module

This module allows access to Consul using an sdb:// URI

Like all sdb modules, the Consul module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. For example:

myconsul:
  driver: consul
  host: 127.0.0.1
  port: 8500
  token: b6376760-a8bb-edd5-fcda-33bc13bfc556
  scheme: http
  consistency: default
  dc: dev
  verify: True
The driver refers to the Consul module, all other options are optional. For option details see: https://python-consul.readthedocs.io/en/latest/#consul

```python
salt.sdb.consul.get(key, profile=None)
```

```python
salt.sdb.consul.get_conn(profile)
```

Return a client object for accessing consul

```python
salt.sdb.consul.set_(key, value, profile=None)
```

### 19.17.4 salt.sdb.couchdb

CouchDB sdb Module

- **maintainer** SaltStack
- **maturity** New
- **depends** python2-couchdb
- **platform** all

This allow interaction between Salt and a CouchDB [couchdb.apache.org] database. It uses salt's sdb system to allow for inserts and retrievals using the sdb:// prefix in salt configuration files.

To use the couchbase sdb module, it must first be configured in the salt master or minion config. The following arguments are required:

```python
couchdb_sdb:
    driver: couchdb
    host: localhost
    port: 5984
    database: salt_sdb
```

One could then query the CouchDB instance via an sdb:// URI such as the following:

```python
password: sdb://couchdb_sdb/mykey
```

To use this interface, you must track IDs on your own or have another source to do the map-reduce logic necessary to calculate the ID you wish to fetch.

Additional contributions to build true map-reduce functionality into this module would be welcome.

```python
salt.sdb.couchdb.get(key, profile=None)
```

Get a value from couchdb by id

```python
salt.sdb.couchdb.set_(key, value, profile=None)
```

Set a key/value pair in couchdb

### 19.17.5 salt.sdb.env module

Environment sdb Module

- **maintainer** SaltStack
- **maturity** New
- **depends** None
- **platform** all
This module allows access to environment variables using an `sdb://` URI.

Example configuration for this module:

```yaml
osenv:
  driver: env
```

**WARNING:**

OS environment variables will be available to read via SDB. Please make sure you don’t have any sensitive data in your environment variables‼

Example usage of sdb env module:

```yaml
set some env var:
  cmd.run:
    - name: echo {{ salt['sdb.set']('sdb://osenv/foo', 'bar') }}
    - order: 1

{% if salt['sdb.get']('sdb://osenv/foo') == 'bar' %}
  always-changes-and-succeeds:
    test.succeed_with_changes:
      - name: foo
{% else %}
  always-changes-and-fails:
    test.fail_with_changes:
      - name: foo
{% endif %}
```

The above example will return success.

The `env` sdb module can also be used with salt cloud. Assuming you have exported the environment variable named `compute` (and have `osenv` defined). The example below will look for the salt cloud config key `compute_name` in the environment:

```yaml
my-openstack-config:
  compute_name: sdb://osenv/compute
  ..snip

salt.sdb.env.get(key, profile=None)
  Get a value

salt.sdb.env.set_(key, value, profile=None)
  Set a key/value pair
```

### 19.17.6 salt.sdb.etcd_db

`etcd` Database Module

- **maintainer**: SaltStack
- **maturity**: New
- **depends**: python-etcd
- **platform**: all
New in version 2015.5.0.

This module allows access to the etcd database using an `sdb://` URI. This package is located at

Like all sdb modules, the etcd module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```yaml
myetcd:
  driver: etcd
  etcd.host: 127.0.0.1
  etcd.port: 4001
```

The driver refers to the etcd module, etcd.host refers to the host that is hosting the etcd database and etcd.port refers to the port on that host.

```yaml
password: sdb://myetcd/mypassword
```

```python
salt.sdb.etcd_db.delete(key, service=None, profile=None)
    Get a value from the etcd service

salt.sdb.etcd_db.get(key, service=None, profile=None)
    Get a value from the etcd service

salt.sdb.etcd_db.set_(key, value, service=None, profile=None)
    Set a key/value pair in the etcd service
```

**19.17.7 salt.sdb.keyring_db**

Keyring Database Module

```yaml
maintainer SaltStack
maturity New
depends keyring
platform all
```

This module allows access to the keyring package using an `sdb://` URI. This package is located at

Care must be taken when using keyring. Not all keyend backends are supported on all operating systems. Also, many backends require an agent to be running in order to work. For instance, the "Secret Service" backend requires a compatible agent such as gnome-keyring-daemon or kwallet to be running. The keyczar backend does not seem to enjoy the benefits of an agent, and so using it will require either that the password is typed in manually (which is unreasonable for the salt-minion and salt-master daemons, especially in production) or an agent is written for it.

Like all sdb modules, the keyring module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```yaml
mykeyring:
  driver: keyring
  service: system
```

The driver refers to the keyring module, service refers to the service that will be used inside of keyring (which may be likened unto a database table) and mykeyring refers to the name that will appear in the URI:
password: sdb://mykeyring/mypassword

The underlying backend configuration must be configured via keyring itself. For examples and documentation, see keyring:

https://pypi.python.org/pypi/keyring

New in version 2014.1.4.

salt.sdb.keyring_db.get(key, service=None, profile=None)
Get a value from a keyring service

salt.sdb.keyring_db.set_(key, value, service=None, profile=None)
Set a key/value pair in a keyring service

19.17.8 salt.sdb.memcached

Memcached sdb Module

    maintainer SaltStack
    maturity New
    depends python-memcached
    platform all

This module allows access to memcached using an sdb:// URI. This package is located at https://pypi.python.org/pypi/python-memcached.

Like all sdb modules, the memcached module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

mymemcache:
    driver: memcached
    host: localhost
    port: 11211

The driver refers to the memcached module, host and port the memcached server to connect to (defaults to localhost and 11211, and mymemcached refers to the name that will appear in the URI:

password: sdb://mymemcached/mykey

salt.sdb.memcached.get(key, profile=None)
Get a value from memcached

salt.sdb.memcached.set_(key, value, profile=None)
Set a key/value pair in memcached

19.17.9 salt.sdb.rest module

Generic REST API SDB Module

    maintainer SaltStack
    maturity New
    platform all
New in version 2015.8.0.

This module allows access to a REST interface using an sdb:// URI.

Like all REST modules, the REST module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```
my-rest-api:
  driver: rest
  urls:
    url: https://api.github.com/
  keys:
    url: https://api.github.com/users/{{user}}/keys
    backend: requests
```

The `driver` refers to the REST module, and must be set to `rest` in order to use this driver. Each of the other items inside this block refers to a separate set of HTTP items, including a URL and any options associated with it. The options used here should match the options available in `salt.utils.http.query()`.

In order to call the `urls` item in the example, the following reference can be made inside a configuration file:

```
github_urls: sdb://my-rest-api/urls
```

Key/Value pairs may also be used with this driver, and merged into the URL using the configured renderer (`jinja`, by default). For instance, in order to use the `keys` item in the example, the following reference can be made:

```
github_urls: sdb://my-rest-api/keys?user=myuser
```

This will cause the following URL to actually be called:

```
https://api.github.com/users/myuser/keys
```

Key/Value pairs will NOT be passed through as GET data. If GET data needs to be sent to the URL, then it should be configured in the SDB configuration block. For instance:

```
another-rest-api:
  driver: rest
  user_data:
    url: https://api.example.com/users/
    params:
      user: myuser
```

`salt.sdb.rest.get(key, service=None, profile=None)`
Get a value from the REST interface

`salt.sdb.rest.query(key, value=None, service=None, profile=None)`
Get a value from the REST interface

`salt.sdb.rest.set(key, value, service=None, profile=None)`
Set a key/value pair in the REST interface

### 19.17.10 salt.sdb.sqlite3

SQLite sdb Module

- **Maintainer**: SaltStack
- **Maturity**: New
platform all

This module allows access to sqlite3 using an sdb:// URI

Like all sdb modules, the sqlite3 module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. For example:

```yaml
mysqlite:
  driver: sqlite3
  database: /tmp/sdb.sqlite
  table: sdb
  create_table: True
```

The `driver` refers to the sqlite3 module, `database` refers to the sqlite3 database file. `table` is the table within the db that will hold keys and values (defaults to sdb). The database and table will be created if they do not exist.

**Advanced Usage:**

Instead of a table name, it is possible to provide custom SQL statements to create the table(s) and get and set values.

```python
salt.sdb.sqlite3.get(key, profile=None)
Get a value from sqlite3
salt.sdb.sqlite3.set_(key, value, profile=None)
Set a key/value pair in sqlite3
```

### 19.17.11 salt.sdb.tism module

**tISM - the Immutalbe Secrets Manager SDB Module**

- maintainer tISM
- maturity New
- platform all

New in version 2017.7.0.

This module will decrypt PGP encrypted secrets against a tISM server.

```
sdb://<profile>://<encrypted secret>
sdb://tism/
  hQEMAzJ+GfdAB3KqAQf9E3cyvrPEWR1sf1tMvH0nrJ0b2a9kDFLPxvtwAOqlRiNp0F7IpiVRF+h+sW5Mb4ff31TEiMzQ+/
  G5tpd6Cjm6BsuGeajWmvLEi41C6/
  9vlrYyjileOCCcN4DIAhFnuNo3rB8akTDvSANpVgHtRTQdltt5UEHsyYXM8RaeCrBw50r1vC9Ctxt2saVb3xmALQvhzkU/
  H30L/r50+CBkuI/u4M2pXDcMYsvvt4ajCbjn91qaQ7BDI=
```

A profile must be setup in the minion configuration or pillar. If you want to use sdb in a runner or pillar you must also place a profile in the master configuration.

```yaml
tism:
  driver: tism
  url: https://my.tismd:8080/decrypt
token: eyJhbGciOiJIUzI1NiIsInR5cCI6IkpXVCJ9.
  eyJhZG1pbiI6MSwiZXhwIjoxNTg1MTExNDYwLCJqGkiOiI3NnA5cWNiMwtdmwy4Iiwia2V5cyI6WyJEw1k1JkE0.
  RtAhG6Uorf5xnSf4Ya_GwJnoHkCsql4r1_hi0eDSLzo
```
salt.sdb.tism.get(key, service=None, profile=None)
Get a decrypted secret from the tISMd API

19.17.12 salt.sdb.vault module

Vault SDB Module

maintainer SaltStack
maturity New
platform all
New in version 2016.11.0.

This module allows access to Hashicorp Vault using an sdb:// URI.

Base configuration instructions are documented in the execution module docs. Below are noted extra configuration required for the sdb module, but the base configuration must also be completed.

Like all sdb modules, the vault module requires a configuration profile to be configured in either the minion configuration file or a pillar. This profile requires only setting the driver parameter to vault:

```
myvault:
    driver: vault
```

Once configured you can access data using a URL such as:

```
password: sdb://myvault/secret/passwords?mypassword
```

In this URL, myvault refers to the configuration profile, secret/passwords is the path where the data resides, and mypassword is the key of the data to return.

The above URI is analogous to running the following vault command:

```
$ vault read -field=mypassword secret/passwords
```

salt.sdb.vault.get(key, profile=None)
Get a value from the vault service

salt.sdb.vault.set_(key, value, profile=None)
Set a key/value pair in the vault service

19.17.13 salt.sdb.yaml module

Pull sdb values from a YAML file

maintainer SaltStack
maturity New
platform all
New in version 2017.7.0.

Configuration:

```
my-yaml-file:
    driver: yaml
    files:
```

19.17. sdb modules
The files are merged together and the result is searched using the same mechanism Salt uses for searching Grains and Pillar data structures.

Optional configuration:

```yaml
my-yaml-file:
  driver: yaml
  files:
    - /path/to/foo.yaml
    - /path/to/bar.yaml
  merge:
    strategy: smart
    merge_list: false
```

```python
salt.sdb.yaml.get(key, profile=None)
    Get a value from the REST interface

salt.sdb.yaml.set_(*args, **kwargs)
    Setting a value is not supported; edit the YAML files directly
```

## 19.18 serializer modules

<table>
<thead>
<tr>
<th>Module</th>
<th>Module Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>configparser</td>
<td>salt.serializers.configparser</td>
</tr>
<tr>
<td>json</td>
<td>salt.serializers.json</td>
</tr>
<tr>
<td>msgpack</td>
<td>salt.serializers.msgpack</td>
</tr>
<tr>
<td>python</td>
<td>salt.serializers.python</td>
</tr>
<tr>
<td>yaml</td>
<td>salt.serializers.yaml</td>
</tr>
<tr>
<td>yamlex</td>
<td>salt.serializers.yamlex</td>
</tr>
</tbody>
</table>

### 19.18.1 salt.serializers.configparser module

```python
salt.serializers.configparser
```

New in version 2016.3.0.

Implements a configparser serializer.

```python
salt.serializers.configparser.deserialize(stream_or_string, **options)
    Deserialize any string or stream like object into a Python data structure.
    Parameters
    • stream_or_string -- stream or string to deserialize.
    • options -- options given to lower configparser module.
```

```python
salt.serializers.configparser.serialize(obj, **options)
    Serialize Python data to a configparser formatted string or file.
    Parameters
    • obj -- the data structure to serialize
    • options -- options given to lower configparser module.
```
19.18.2 salt.serializers.json

salt.serializers.json

Implements JSON serializer.
It's just a wrapper around json (or simplejson if available).

salt.serializers.json.deserialze(stream_or_string, **options)
Deserialze any string or stream like object into a Python data structure.

Parameters
- `stream_or_string` -- stream or string to deserialze.
- `options` -- options given to lower json/simplejson module.

salt.serializers.json.serialize(obj, **options)
Serialize Python data to JSON.

Parameters
- `obj` -- the data structure to serialize
- `options` -- options given to lower json/simplejson module.

19.18.3 salt.serializers.msgpack

salt.serializers.msgpack

Implements MsgPack serializer.

salt.serializers.msgpack.deserialze(stream_or_string, **options)
Deserialze any string of stream like object into a Python data structure.

Parameters
- `stream_or_string` -- stream or string to deserialze.
- `options` -- options given to lower msgpack module.

salt.serializers.msgpack.serialize(obj, **options)
Serialize Python data to MsgPack.

Parameters
- `obj` -- the data structure to serialize
- `options` -- options given to lower msgpack module.

19.18.4 salt.serializers.python module

salt.serializers.python

New in version 2016.3.0.
Implements a Python serializer (via pprint.format)

salt.serializers.python.serialize(obj, **options)
Serialize Python data to a Python string representation (via pprint.format)

Parameters
- `obj` -- the data structure to serialize
- `options` -- options given to pprint.format
19.18.5  salt.serializers.yaml

salt.serializers.yaml

Implements YAML serializer.
Underneath, it is based on pyyaml and use the safe dumper and loader. It also use C bindings if they are available.

salt.serializers.yaml.deserializer(stream_or_string, *options)
Deserilaze any string of stream like object into a Python data structure.

Parameters
- stream_or_string -- stream or string to deserialize.
- options -- options given to lower yaml module.

salt.serializers.yaml.serialize(obj, *options)
Serialize Python data to YAML.

Parameters
- obj -- the data structure to serialize
- options -- options given to lower yaml module.

19.18.6  salt.serializers.yamlex

salt.serializers.yamlex

YAMLEX is a format that allows for things like sls files to be more intuitive.
It's an extension of YAML that implements all the salt magic: - it implies omap for any dict like. - it implies that string like data are str, not unicode - ...

For example, the file states.sls has this contents:

    foo:
       bar: 42
       baz: [1, 2, 3]

The file can be parsed into Python like this

    from salt.serializers import yamlex
    with open('state.sls', 'r') as stream:
        obj = yamlex.deserialize(stream)

Check that obj is an OrderedDict

    from salt.utils.odict import OrderedDict
    assert isinstance(obj, dict)
    assert isinstance(obj, OrderedDict)

yamlex __repr__ and __str__ objects' methods render YAML understandable string. It means that they are template friendly.

    print '{0}'.format(obj)

returns:
and they are still valid YAML:

```python
from salt.serializers import yaml
yml_obj = yaml.deserialize(str(obj))
assert yml_obj == obj
```

yamlex implements also custom tags:

```
!aggregate
  this tag allows structures aggregation.

For example:

  placeholder: !aggregate foo
  placeholder: !aggregate bar
  placeholder: !aggregate baz

is rendered as

  placeholder: [foo, bar, baz]
```

```
!reset
  this tag flushes the computing value.

 placeholder: {!aggregate foo: {foo: 42}}
 placeholder: {!aggregate foo: {bar: null}}
 !reset placeholder: {!aggregate foo: {baz: inga}}

is roughly equivalent to

  placeholder: {!aggregate foo: {baz: inga}}
```

Document is defacto an aggregate mapping.

```python
salt.serializers.yamlx.deserialize(stream_or_string, **options)
Deserialize any string of stream like object into a Python data structure.
Parameters
  - stream_or_string -- stream or string to deserialize.
  - options -- options given to lower yaml module.
```

```python
salt.serializers.yamlx.serialize(obj, **options)
Serialize Python data to YAML.
Parameters
  - obj -- the data structure to serialize
  - options -- options given to lower yaml module.
```

## 19.19 state modules

<table>
<thead>

19.19.1 salt.states.acme module

ACME / Let’s Encrypt certificate management state

See also the module documentation

```python
reload-gitlab:
    cmd.run:
        - name: gitlab-ctl hup

develop.example.com:
    acme.cert:
        - aliases:
        - gitlab.example.com
        - email: acmemaster@example.com
        - webroot: /opt/gitlab/embedded/service/gitlab-rails/public
        - renew: 14
        - fire_event: acme/dev.example.com
        - onchanges_in:
            - cmd: reload-gitlab
```

```python
salt.states.acme.cert(name=None, aliases=None, email=None, webroot=None, test_cert=False, renew=None, keysize=None, server=None, owner='root', group='root', mode='0640', certname=None)
```

Obtain/renew a certificate from an ACME CA, probably Let’s Encrypt.

**Parameters**

- **name** -- Common Name of the certificate (DNS name of certificate)
- **aliases** -- subjectAltNames (Additional DNS names on certificate)
- **email** -- e-mail address for interaction with ACME provider
- **webroot** -- True or a full path to webroot. Otherwise use standalone mode
- **test_cert** -- Request a certificate from the Happy Hacker Fake CA (mutually exclusive with `server`)
- **renew** -- True/`force` to force a renewal, or a window of renewal before expiry in days
- **keysize** -- RSA key bits
- **server** -- API endpoint to talk to
- **owner** -- owner of the private key file
- **group** -- group of the private key file
- **mode** -- mode of the private key file
- **certname** -- Name of the certificate to save
19.19.2 salt.states.alias

Configuration of email aliases

The mail aliases file can be managed to contain definitions for specific email aliases:

```yaml
username:
  alias.present:
    - target: user@example.com

thomas:
  alias.present:
    - target: thomas@example.com
```

The default alias file is set to `/etc/aliases`, as defined in Salt's `config execution module`. To change the alias file from the default location, set the following in your minion config:

```yaml
aliases.file: /my/alias/file
```

**salt.states.alias.absent(**name**)**

Ensure that the named alias is absent

- **name**: The alias to remove

**salt.states.alias.present(**name**, **target**)**

Ensures that the named alias is present with the given target or list of targets. If the alias exists but the target differs from the previous entry, the target(s) will be overwritten. If the alias does not exist, the alias will be created.

- **name**: The local user/address to assign an alias to
- **target**: The forwarding address

19.19.3 salt.states.alternatives

Configuration of the alternatives system

Control the alternatives system

```yaml
{% set my_hadoop_conf = '/opt/hadoop/conf' %}

{{{ my_hadoop_conf }}):
  file.directory

hadoop-0.20-conf:
  alternatives.install:
    - name: hadoop-0.20-conf
    - link: /etc/hadoop-0.20/conf
    - path: {{{ my_hadoop_conf }}}
    - priority: 30
    - require:
      - file: {{{ my_hadoop_conf }}}

hadoop-0.20-conf:
  alternatives.remove:
    - name: hadoop-0.20-conf
    - path: {{{ my_hadoop_conf }}}

salt.states.alternatives.auto(**name**)

New in version 0.17.0.
Instruct alternatives to use the highest priority path for `<name>`

```python
salt.states.alternatives.install(name, link, path, priority)
```

- **name** is the master name for this link group (e.g. pager)
- **link** is the symlink pointing to `/etc/alternatives/<name>` (e.g. `/usr/bin/pager`)
- **path** is the location of the new alternative target. NB: This file / directory must already exist. (e.g. `/usr/bin/less`)
- **priority** is an integer; options with higher numbers have higher priority in automatic mode.

```python
salt.states.alternatives.remove(name, path)
```

- **name** is the master name for this link group (e.g. pager)
- **path** is the location of one of the alternative target files. (e.g. `/usr/bin/less`)

```python
salt.states.alternatives.set_(name, path)
```

- **name** is the master name for this link group (e.g. pager)
- **path** is the location of one of the alternative target files. (e.g. `/usr/bin/less`)

```yaml
foo:
  alternatives.set:
    - path: /usr/bin/foo-2.0
```

### 19.19.4 salt.states.apache

Apache state

New in version 2014.7.0.

Allows for inputting a yaml dictionary into a file for apache configuration files.

The variable `this` is special and signifies what should be included with the above word between angle brackets (`<>`).

```yaml
/etc/httpd/conf.d/website.com.conf:
  apache.configfile:
    - config:
      - VirtualHost:
        - this: '*:80'
          ServerName:
            - website.com
          ServerAlias:
            - www.website.com
            - dev.website.com
        ErrorLog: logs/website.com-error_log
        CustomLog: logs/website.com-access_log combined
        DocumentRoot: /var/www/vhosts/website.com
        Directory:
          - this: /var/www/vhosts/website.com
          - Order: Deny,Allow
            Deny from: all
            Allow from:
              - 127.0.0.1
```

2628 Chapter 19. Salt Module Reference
- 192.168.100.0/24
  Options:
  - Indexes
  - FollowSymlinks
  AllowOverride: All

salt.states.apache.configfile(name, config)

19.19.5 salt.states.apache_conf module

Manage Apache Confs
New in version 2016.3.0.
Enable and disable apache confs.

Enable security conf:
  apache_conf.enabled:
    - name: security

Disable security conf:
  apache_conf.disabled:
    - name: security

salt.states.apache_conf.disabled(name)
  Ensure an Apache conf is disabled.
  name  Name of the Apache conf

salt.states.apache_conf.enabled(name)
  Ensure an Apache conf is enabled.
  name  Name of the Apache conf

19.19.6 salt.states.apache_module

Manage Apache Modules
New in version 2014.7.0.
Enable and disable apache modules.

Enable cgi module:
  apache_module.enabled:
    - name: cgi

Disable cgi module:
  apache_module.disabled:
    - name: cgi

salt.states.apache_module.disabled(name)
  Ensure an Apache module is disabled.
  New in version 2016.3.0.
  name  Name of the Apache module

salt.states.apache_module.enabled(name)
  Ensure an Apache module is enabled.
  New in version 2016.3.0.
name  Name of the Apache module

19.19.7  salt.states.apache_site module

Manage Apache Sites
New in version 2016.3.0.
Enable and disable apache sites.

Enable default site:
   apache_site.enabled:
     - name: default

Disable default site:
   apache_site.disabled:
     - name: default

salt.states.apache_site.disabled(name)
   Ensure an Apache site is disabled.
   name  Name of the Apache site

salt.states.apache_site.enabled(name)
   Ensure an Apache site is enabled.
   name  Name of the Apache site

19.19.8  salt.states.aptpkg

Package management operations specific to APT- and DEB-based systems

salt.states.aptpkg.held(name)
   Set package in 'hold' state, meaning it will not be upgraded.
   name  The name of the package, e.g., 'tmux'

19.19.9  salt.states.archive

Extract an archive
New in version 2014.1.0.

salt.states.archive.extracted(name, source, source_hash=None, source_hash_name=None, source_hash_update=False, skip_verify=False, password=None, options=None, list_options=None, force=False, overwrite=False, clean=False, user=None, group=None, if_missing=None, trim_output=False, use_cmd_unzip=None, extract_perms=True, enforce_toplevel=True, enforce_ownership_on=None, archive_format=None, **kwargs)

New in version 2014.1.0.

Changed in version 2016.11.0: This state has been rewritten. Some arguments are new to this release and will not be available in the 2016.3 release cycle (and earlier). Additionally, the ZIP Archive Handling section below applies specifically to the 2016.11.0 release (and newer).

Ensure that an archive is extracted to a specific directory.
Important: Changes for 2016.11.0

In earlier releases, this state would rely on the if_missing argument to determine whether or not the archive needed to be extracted. When this argument was not passed, then the state would just assume if_missing is the same as the name argument (i.e. the parent directory into which the archive would be extracted).

This caused a number of annoyances. One such annoyance was the need to know beforehand a path that would result from the extraction of the archive, and setting if_missing to that directory, like so:

```
extract_myapp:
  archive.extracted:
    - name: /var/www
    - source: salt://apps/src/myapp-16.2.4.tar.gz
    - user: www
    - group: www
    - if_missing: /var/www/myapp-16.2.4
```

If /var/www already existed, this would effectively make if_missing a required argument, just to get Salt to extract the archive.

Some users worked around this by adding the top-level directory of the archive to the end of the name argument, and then used --strip or --strip-components to remove that top-level dir when extracting:

```
extract_myapp:
  archive.extracted:
    - name: /var/www/myapp-16.2.4
    - source: salt://apps/src/myapp-16.2.4.tar.gz
    - user: www
    - group: www
    - tar_options: --strip-components=1
```

With the rewrite for 2016.11.0, these workarounds are no longer necessary. if_missing is still a supported argument, but it is no longer required. The equivalent SLS in 2016.11.0 would be:

```
extract_myapp:
  archive.extracted:
    - name: /var/www
    - source: salt://apps/src/myapp-16.2.4.tar.gz
    - user: www
    - group: www
```

Salt now uses a function called archive.list to get a list of files/directories in the archive. Using this information, the state can now check the minion to see if any paths are missing, and know whether or not the archive needs to be extracted. This makes the if_missing argument unnecessary in most use cases.

Important: ZIP Archive Handling

Note: this information applies to 2016.11.0 and later.

Salt has two different functions for extracting ZIP archives:

1. `archive.unzip`, which uses Python's zipfile module to extract ZIP files.
2. `archive.cmd_unzip`, which uses the unzip CLI command to extract ZIP files.

Salt will prefer the use of `archive.cmd_unzip` when CLI options are specified (via the options argument), and will otherwise prefer the `archive.unzip` function. Use of `archive.cmd_unzip` can be
forced however by setting the `use_cmd_unzip` argument to `True`. By contrast, setting this argument to `False` will force usage of `archive.unzip`. For example:

```
/var/www:
  archive.extracted:
    - source: salt://foo/bar/myapp.zip
    - use_cmd_unzip: True
```

When `use_cmd_unzip` is omitted, Salt will choose which extraction function to use based on the source archive and the arguments passed to the state. When in doubt, simply do not set this argument; it is provided as a means of overriding the logic Salt uses to decide which function to use.

There are differences in the features available in both extraction functions. These are detailed below.

- **Command-line options** (only supported by `archive.cmd_unzip`) - When the `options` argument is used, `archive.cmd_unzip` is the only function that can be used to extract the archive. Therefore, if `use_cmd_unzip` is specified and set to `False`, and `options` is also set, the state will not proceed.

- **Permissions** - Due to an upstream bug in Python, permissions are not preserved when the `zipfile` module is used to extract an archive. As of the 2016.11.0 release, `archive.unzip` (as well as this state) has an `extract_perms` argument which, when set to `True` (the default), will attempt to match the permissions of the extracted files/directories to those defined within the archive. To disable this functionality and have the state not attempt to preserve the permissions from the ZIP archive, set `extract_perms` to `False`:

```
/var/www:
  archive.extracted:
    - source: salt://foo/bar/myapp.zip
    - extract_perms: False
```

- **name** Directory into which the archive should be extracted
- **source** Archive to be extracted

**Note:** This argument uses the same syntax as its counterpart in the `file.managed` state.

- **source_hash** Hash of source file, or file with list of hash-to-file mappings

**Note:** This argument uses the same syntax as its counterpart in the `file.managed` state.

Changed in version 2016.11.0: If this argument specifies the hash itself, instead of a URI to a file containing hashes, the hash type can now be omitted and Salt will determine the hash type based on the length of the hash. For example, both of the below states are now valid, while before only the second one would be:

```
foo_app:
  archive.extracted:
    - name: /var/www
    - source: https://mydomain.tld/foo.tar.gz
    - source_hash: 3360db35e682f1c5f9c58aa307de16d41361618c

bar_app:
  archive.extracted:
    - name: /var/www
    - source: https://mydomain.tld/bar.tar.gz
    - source_hash: sha1=5edb7d584b82dcbf76e311601f5d4442974aaa5
```
source_hash_name  When source_hash refers to a hash file, Salt will try to find the correct hash by matching the filename part of the source URI. When managing a file with a source of salt://files/foo.tar.gz, then the following line in a hash file would match:

```
acbd18db4cc2f85cedef654fccc4a4d8   foo.tar.gz
```

This line would also match:

```
acbd18db4cc2f85cedef654fccc4a4d8   ./dir1/foo.tar.gz
```

However, sometimes a hash file will include multiple similar paths:

```
37b51d194a7513e45b56f6524f2d51f2   ./dir1/foo.txt
acbd18db4cc2f85cedef654fccc4a4d8   ./dir2/foo.txt
73feffa4b7f6bb68e44cf984c85f6e88   ./dir3/foo.txt
```

In cases like this, Salt may match the incorrect hash. This argument can be used to tell Salt which filename to match, to ensure that the correct hash is identified. For example:

```
/var/www:
  archive.extracted:
    - source: https://mydomain.tld/dir2/foo.tar.gz
    - source_hash: https://mydomain.tld/haes
    - source_hash_name: ./dir2/foo.tar.gz
```

Note:  This argument must contain the full filename entry from the checksum file, as this argument is meant to disambiguate matches for multiple files that have the same basename. So, in the example above, simply using foo.txt would not match.

New in version 2016.11.0.

source_hash_update  [False] Set this to True if archive should be extracted if source_hash has changed. This would extract regardless of the if_missing parameter.

New in version 2016.3.0.

skip_verify  [False] If True, hash verification of remote file sources (http://, https://, ftp://) will be skipped, and the source_hash argument will be ignored.

New in version 2016.3.4.

keep_source  [True] For source archives not local to the minion (i.e. from the Salt fileserver or a remote source such as http(s) or ftp), Salt will need to download the archive to the minion cache before they can be extracted. To remove the downloaded archive after extraction, set this argument to False.

New in version 2017.7.3.

keep  [True] Same as keep_source, kept for backward-compatibility.

Note:  If both keep_source and keep are used, keep will be ignored.

password  For ZIP archives only.  Password used for extraction.

New in version 2016.3.0.

Changed in version 2016.11.0:  The newly-added archive.is_encrypted function will be used to determine if the archive is password-protected. If it is, then the password argument will be required for the state to proceed.

options  For tar and zip archives only.  This option can be used to specify a string of additional arguments to pass to the tar/zip command.
If this argument is not used, then the minion will attempt to use Python's native `tarfile/zipfile` support to extract it. For zip archives, this argument is mostly used to overwrite existing files with `o`.

Using this argument means that the `tar` or `unzip` command will be used, which is less platform-independent, so keep this in mind when using this option; the CLI options must be valid options for the `tar/unzip` implementation on the minion's OS.

New in version 2016.11.0: The `tar_options` and `zip_options` parameters have been deprecated in favor of a single argument name.

Changed in version 2015.8.11,2016.3.2: XZ-compressed tar archives no longer require J to manually be set in the options, they are now detected automatically and decompressed using the `xz` CLI command and extracted using `tar xvf`. This is a more platform-independent solution, as not all tar implementations support the `J` argument for extracting archives.

**Note:** For tar archives, main operators like `-x`, `--extract`, `--get`, `-c` and `--file` should not be used here.

**tar_options** Deprecated since version 2016.11.0: Use `options` instead.

**zip_options** New in version 2016.3.1.

Deprecated since version 2016.11.0: Use `options` instead.

**list_options** For tar archives only. This state uses `archive.list` to discover the contents of the source archive so that it knows which file paths should exist on the minion if the archive has already been extracted. For the vast majority of tar archives, `archive.list` "just works". Archives compressed using gzip, bzip2, and xz/lzma (with the help of the `xz` CLI command) are supported automatically. However, for archives compressed using other compression types, CLI options must be passed to `archive.list`.

This argument will be passed through to `archive.list` as its `options` argument, to allow it to successfully list the archive's contents. For the vast majority of archives, this argument should not need to be used, it should only be needed in cases where the state fails with an error stating that the archive's contents could not be listed.

New in version 2016.11.0.

**force** [False] If a path that should be occupied by a file in the extracted result is instead a directory (or vice-versa), the state will fail. Set this argument to `True` to force these paths to be removed in order to allow the archive to be extracted.

**Warning:** Use this option very carefully.

New in version 2016.11.0.

**overwrite** [False] Set this to `True` to force the archive to be extracted. This is useful for cases where the filenames/directories have not changed, but the content of the files have.

New in version 2016.11.1.

**clean** [False] Set this to `True` to remove any top-level files and recursively remove any top-level directory paths before extracting.

**Note:** Files will only be cleaned first if extracting the archive is deemed necessary, either by paths missing on the minion, or if `overwrite` is set to `True`.

New in version 2016.11.1.

**user** The user to own each extracted file. Not available on Windows.
New in version 2015.8.0.

Changed in version 2016.3.0: When used in combination with if_missing, ownership will only be enforced if if_missing is a directory.

Changed in version 2016.11.0: Ownership will be enforced only on the file/directory paths found by running `archive.list` on the source archive. An alternative root directory on which to enforce ownership can be specified using the `enforce_ownership_on` argument.

**group** The group to own each extracted file. Not available on Windows.

New in version 2015.8.0.

Changed in version 2016.3.0: When used in combination with if_missing, ownership will only be enforced if if_missing is a directory.

Changed in version 2016.11.0: Ownership will be enforced only on the file/directory paths found by running `archive.list` on the source archive. An alternative root directory on which to enforce ownership can be specified using the `enforce_ownership_on` argument.

**if_missing** If specified, this path will be checked, and if it exists then the archive will not be extracted. This path can be either a directory or a file, so this option can also be used to check for a semaphore file and conditionally skip extraction.

Changed in version 2016.3.0: When used in combination with either user or group, ownership will only be enforced when if_missing is a directory.

Changed in version 2016.11.0: Ownership enforcement is no longer tied to this argument, it is simply checked for existence and extraction will be skipped if if is present.

**trim_output** [False] Useful for archives with many files in them. This can either be set to True (in which case only the first 100 files extracted will be in the state results), or it can be set to an integer for more exact control over the max number of files to include in the state results.

New in version 2016.3.0.

**use_cmd_unzip** [False] Set to True for zip files to force usage of the `archive.cmd_unzip` function to extract.

New in version 2016.11.0.

**extract_perms** [True] For ZIP archives only. When using `archive.unzip` to extract ZIP archives, Salt works around an upstream bug in Python to set the permissions on extracted files/directories to match those encoded into the ZIP archive. Set this argument to False to skip this workaround.

New in version 2016.11.0.

**enforce_toplevel** [True] This option will enforce a single directory at the top level of the source archive, to prevent extracting a 'tar-bomb'. Set this argument to False to allow archives with files (or multiple directories) at the top level to be extracted.

New in version 2016.11.0.

**enforce_ownership_on** When user or group is specified, Salt will default to enforcing permissions on the file/directory paths detected by running `archive.list` on the source archive. Use this argument to specify an alternate directory on which ownership should be enforced.

---

**Note:** This path must be within the path specified by the `name` argument.

New in version 2016.11.0.

**archive_format** One of tar, zip, or rar.

Changed in version 2016.11.0: If omitted, the archive format will be guessed based on the value of the `source` argument. If the minion is running a release older than 2016.11.0, this option is required.

**Examples**
1. **tar with lmza (i.e. xz) compression**:

```yaml
graylog2-server:
  archive.extracted:
    - name: /opt/
    - source: https://github.com/downloads/Graylog2/graylog2-server/graylog2-server-0.9.6p1.tar.lzma
    - source_hash: md5=499ae16dcae71eeb7c3a30c75ea7a1a6
```

2. **tar archive with flag for verbose output, and enforcement of user/group ownership**:

```yaml
graylog2-server:
  archive.extracted:
    - name: /opt/
    - source: https://github.com/downloads/Graylog2/graylog2-server/graylog2-server-0.9.6p1.tar.gz
    - source_hash: md5=499ae16dcae71eeb7c3a30c75ea7a1a6
    - options: v
    - user: foo
    - group: foo
```

3. **tar archive, with source_hash_update set to True to prevent state from attempting extraction unless the source_hash differs from the previous time the archive was extracted**:

```yaml
graylog2-server:
  archive.extracted:
    - name: /opt/
    - source: https://github.com/downloads/Graylog2/graylog2-server/graylog2-server-0.9.6p1.tar.lzma
    - source_hash: md5=499ae16dcae71eeb7c3a30c75ea7a1a6
    - source_hash_update: True
```

### 19.19.10 salt.states.artifactory

This state downloads artifacts from artifactory.

**salt.states.artifactory.downloaded** *(name, artifact, target_dir='/tmp', target_file=None)*

Ensures that the artifact from artifactory exists at given location. If it doesn’t exist, then it will be downloaded. If it already exists then the checksum of existing file is checked against checksum in artifactory. If it is different then the step will fail.

**artifact** Details of the artifact to be downloaded from artifactory. Various options are:

- **artifact_url**: URL of the artifactory instance
- **repository**: Repository in artifactory
- **artifact_id**: Artifact ID
- **group_id**: Group ID
- **packaging**: Packaging
- **classifier**: Classifier .. versionadded:: 2015.8.0
- **version**: Version One of the following: - Version to download - latest - Download the latest release of this artifact - latest_snapshot - Download the latest snapshot for this artifact
- **username**: Artifactory username .. versionadded:: 2015.8.0
- **password**: Artifactory password .. versionadded:: 2015.8.0

**target_dir** Directory where the artifact should be downloaded. By default it is downloaded to /tmp directory.

**target_file** Target file to download artifact to. By default file name is resolved by artifactory.

An example to download an artifact to a specific file:
19.19.11  salt.states.at

Configuration disposable regularly scheduled tasks for at.

The at state can be add disposable regularly scheduled tasks for your system.

salt.states.at.absent(name, jobid=None, **kwargs)

Changed in version 2017.7.0.

Remove a job from queue

jobid: string|int  Specific jobid to remove
tag  [string]  Job's tag
runas  [string]  Runs user-specified jobs
kwargs  Addition kwargs can be provided to filter jobs. See output of at.jobcheck for more.

example1:

at.absent:

**Warning:** this will remove all jobs!

example2:

at.absent:
  - year: 13

example3:

at.absent:
  - tag: rose
example4:
  at.absent:
   - tag: rose
   - day: 13
   - hour: 16

example5:
  at.absent:
   - jobid: 4

salt.states.at.mod_watch(name, **kwargs)
The at watcher, called to invoke the watch command.

**Note:** This state exists to support special handling of the watch *requisite*. It should not be called directly.

Parameters for this function should be set by the state being triggered.

name The name of the atjob

salt.states.at.present(name, timespec, tag=None, user=None, job=None, unique_tag=False)
Changed in version 2017.7.0.

Add a job to queue.

job [string] Command to run.

timespec [string] The `timespec` follows the format documented in the at(1) manpage.

tag [string] Make a tag for the job.

user [string] The user to run the at job .. versionadded:: 2014.1.4

unique_tag [boolean] If set to True job will not be added if a job with the tag exists. .. versionadded:: 2017.7.0

rose:
  at.present:
   - job: 'echo "I love saltstack" > love'
   - timespec: '9:09 11/09/13'
   - tag: love
   - user: jam

salt.states.at.watch(name, timespec, tag=None, user=None, job=None, unique_tag=False)
New in version 2017.7.0.

Add an at job if trigger by watch

job [string] Command to run.

timespec [string] The `timespec` follows the format documented in the at(1) manpage.

tag [string] Make a tag for the job.

user [string] The user to run the at job .. versionadded:: 2014.1.4

unique_tag [boolean] If set to True job will not be added if a job with the tag exists. .. versionadded:: 2017.7.0

minion_restart:
  at.watch:
   - job: 'salt-call --local service.restart salt-minion'
   - timespec: 'now +1 min'
   - tag: minion_restart
   - unique_tag: trye
   - watch:
     - file: /etc/salt/minion
19.19.12 salt.states.augeas

Configuration management using Augeas
New in version 0.17.0.
This state requires the augeas Python module.

Augeas can be used to manage configuration files.

**Warning:** Minimal installations of Debian and Ubuntu have been seen to have packaging bugs with python-augeas, causing the augeas module to fail to import. If the minion has the augeas module installed, and the state fails with a comment saying that the state is unavailable, first restart the salt-minion service. If the problem persists past that, the following command can be run from the master to determine what is causing the import to fail:

```
salt minion-id cmd.run 'python -c "from augeas import Augeas"'
```

For affected Debian/Ubuntu hosts, installing libpython2.7 has been known to resolve the issue.

```
salt.states.augeas.change(name, context=None, changes=None, lens=None, load_path=None, **kwargs)
```

New in version 2014.7.0.
This state replaces setvalue().

Issue changes to Augeas, optionally for a specific context, with a specific lens.

- **name** State name
- **context** A file path, prefixed by /files. Should resolve to an actual file (not an arbitrary augeas path).
  This is used to avoid duplicating the file name for each item in the changes list (for example, set bind 0.0.0.0 in the example below operates on the file specified by context). If context is not specified, a file path prefixed by /files should be included with the set command.
  The file path is examined to determine if the specified changes are already present.

```
redis-conf:
  augeas.change:
  - context: /files/etc/redis/redis.conf
  - changes:
    - set bind 0.0.0.0
    - set maxmemory 1G
```

- **changes** List of changes that are issued to Augeas. Available commands are set, setm, mv/move, ins/insert, and rm/remove.
- **lens** The lens to use, needs to be suffixed with .lns, e.g.: Nginx.lns. See the list of stock lenses shipped with Augeas.
New in version 2016.3.0.
- **load_path** A list of directories that modules should be searched in. This is in addition to the standard load path and the directories in AUGEAS_LENS_LIB.

Usage examples:

Set the bind parameter in /etc/redis/redis.conf:

```
redis-conf:
  augeas.change:
  - changes:
    - set /files/etc/redis/redis.conf/bind 0.0.0.0
```
**Note:** Use the `context` parameter to specify the file you want to manipulate. This way you don't have to include this in the changes every time:

```yaml
redis-conf:
augeas.change:
  - context: /files/etc/redis/redis.conf
  - changes:
    - set bind 0.0.0.0
    - set databases 4
    - set maxmemory 1G
```

Augeas is aware of a lot of common configuration files and their syntax. It knows the difference between for example ini and yaml files, but also files with very specific syntax, like the hosts file. This is done with *lenses*, which provide mappings between the Augeas tree and the file.

There are many *preconfigured lenses* that come with Augeas by default, and they specify the common locations for configuration files. So most of the time Augeas will know how to manipulate a file. In the event that you need to manipulate a file that Augeas doesn't know about, you can specify the lens to use like this:

```yaml
redis-conf:
augeas.change:
  - lens: redis
    - context: /files/etc/redis/redis.conf
    - changes:
      - set bind 0.0.0.0
```

**Note:** Even though Augeas knows that `/etc/redis/redis.conf` is a Redis configuration file and knows how to parse it, it is recommended to specify the lens anyway. This is because by default, Augeas loads all known lenses and their associated file paths. All these files are parsed when Augeas is loaded, which can take some time. When specifying a lens, Augeas is loaded with only that lens, which speeds things up quite a bit.

A more complex example, this adds an entry to the services file for Zabbix, and removes an obsolete service:

```yaml
zabbix-service:
augeas.change:
  - lens: services
    - context: /files/etc/services
    - changes:
      - ins service-name after service-name[last()]
      - set service-name[last()]/zabbix-agent
      - set service-name[. = 'zabbix-agent']/#comment "Zabbix Agent service"
      - set service-name[. = 'zabbix-agent']/port 10050
      - set service-name[. = 'zabbix-agent']/protocol tcp
      - rm service-name[. = 'im-obsolete']
      - unless: grep "zabbix-agent" /etc/services
```

**Warning:** Don't forget the `unless` here, otherwise a new entry will be added every time this state is run.
19.19.13  salt.states.aws_sqs

Manage SQS Queues

Create and destroy SQS queues. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses the awscli tool provided by Amazon. This can be downloaded from pip. Also check the documentation for awscli for configuration information.

```yaml
myqueue:
  aws_sqs.exists:
    - region: eu-west-1

salt.states.aws_sqs.absent(name, region, user=None, opts=False)
Remove the named SQS queue if it exists.
  name  Name of the SQS queue.
  region Region to remove the queue from
  user  Name of the user performing the SQS operations
  opts  Include additional arguments and options to the aws command line

salt.states.aws_sqs.exists(name, region, user=None, opts=False)
Ensure the SQS queue exists.
  name  Name of the SQS queue.
  region Region to create the queue
  user  Name of the user performing the SQS operations
  opts  Include additional arguments and options to the aws command line
```

19.19.14  salt.states.beacon

Management of the Salt beacons

New in version 2015.8.0.

```yaml
ps:
  beacon.present:
    - enable: False
    - salt-master: running
    - apache2: stopped

sh:
  beacon.present:

load:
  beacon.present:
    - 1m:
      - 0.0
      - 2.0
    - 5m:
      - 0.0
      - 1.5
    - 15m:
      - 0.1
      - 1.0

salt.states.beacon.absent(name, **kwargs)
Ensure beacon is absent.
  name  The name of the beacon ensured absent.
```
salt.states.beacon.disabled(name, **kwargs)
    Disable a beacon.
    name  The name of the beacon to disable.

salt.states.beacon.enabled(name, **kwargs)
    Enable a beacon.
    name  The name of the beacon to enable.

salt.states.beacon.present(name, **kwargs)
    Ensure beacon is configured with the included beacon data.
    name  The name of the beacon ensure is configured.

19.19.15 salt.states.bigip

A state module designed to enforce load-balancing configurations for F5 Big-IP entities.

    maturity  develop
    platform  f5_bigip_11.6

salt.states.bigip.add_pool_member(hostname, username, password, name, member)
    A function to connect to a bigip device and add a new member to an existing pool.
    hostname  The host/address of the bigip device
    username  The iControl REST username
    password  The iControl REST password
    name      The name of the pool to modify
    member    The member to add to the pool

salt.states.bigip.create_monitor(hostname, username, password, monitor_type, name, **kwargs)
    A function to connect to a bigip device and create a monitor.
    hostname  The host/address of the bigip device
    username  The iControl REST username
    password  The iControl REST password
    monitor_type  The type of monitor to create
    name      The name of the monitor to create
    kwargs    [ arg=val ] ...

    Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

salt.states.bigip.create_node(hostname, username, password, name, address)
    Create a new node if it does not already exist.
    hostname  The host/address of the bigip device
    username  The iControl REST username
    password  The iControl REST password
    name      The name of the node to create
    address   The address of the node
salt.states.bigip.create_pool( hostname, username, password, name, members=None, allow_nat=None, allow_snat=None, description=None, gateway_failsafe_device=None, ignore_persisted_weight=None, ip_tos_to_client=None, ip_tos_to_server=None, link_qos_to_client=None, link_qos_to_server=None, load_balancing_mode=None, min_active_members=None, min_up_members=None, min_up_members_action=None, min_up_members_checking=None, monitor=None, profiles=None, queue_depth_limit=None, queue_on_connection_limit=None, queue_time_limit=None, reselect_tries=None, service_down_action=None, slow_ramp_time=None)

Create a new node if it does not already exist.

hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the pool to create
members List of members to be added to the pool
allow_nat [yes | no]
allow_snat [yes | no]
description [string]
gateway_failsafe_device [string]
ignore_persisted_weight [enabled | disabled]
ip_tos_to_client [pass-through | [integer]]
ip_tos_to_server [pass-through | [integer]]

reselect_tries [integer]
service_down_action [drop | none | reselect | reset]
slow_ramp_time [integer]

salt.states.bigip.create_profile( hostname, username, password, profile_type, name, **kwargs)

A function to connect to a bigip device and create a profile.

hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
profile_type The type of profile to create
name The name of the profile to create
kwargs [ arg=val ] ...

Consult F5 BIGIP user guide for specific options for each profile type. Typically, tmsh arg names are used.
Special Characters |, , and : must be escaped using \ when used within strings.

```
salt.states.bigip.create_virtual(hostname, username, password, name, destination, pool=None, address_status=None, auto_lasthop=None, bwc_policy=None, cmp_enabled=None, connection_limit=None, dhcp_relay=None, description=None, fallback_persistence=None, flow_eviction_policy=None, gtm_score=None, ip_forward=None, ip_protocol=None, internal=None, twelve_forward=None, last_hop_pool=None, mask=None, mirror=None, nat64=None, persist=None, profiles=None, policies=None, rate_class=None, rate_limit=None, rate_limit_mode=None, rate_limit_dst=None, rate_limit_src=None, rules=None, related_rules=None, reject=None, source=None, source_address_translation=None, source_port=None, virtual_state=None, traffic_classes=None, translate_address=None, translate_port=None, vlans=None)
```

A function to connect to a bigip device and create a virtual server if it does not already exists.

- **hostname**  The host/address of the bigip device
- **username**  The iControl REST username
- **password**  The iControl REST password
- **name**  The name of the virtual to create

           vlan_ids [ list]
          enabled  [ true | false ]

salt.states.bigip.delete_monitor(hostname, username, password, monitor_type, name)
Modify an existing monitor. If it does exists, only the parameters specified will be enforced.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
monitor_type The type of monitor to create
name The name of the monitor to create
kwargs [ arg=val ] ...
Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

salt.states.bigip.delete_node(hostname, username, password, name)
Delete an existing node.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the node which will be deleted.

salt.states.bigip.delete_pool(hostname, username, password, name)
Delete an existing pool.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the pool which will be deleted

salt.states.bigip.delete_pool_member(hostname, username, password, name, member)
Delete an existing pool member.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the pool to be modified
member The name of the member to delete from the pool

salt.states.bigip.delete_profile(hostname, username, password, profile_type, name)
Modify an existing profile. If it does exists, only the parameters specified will be enforced.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
profile_type The type of profile to create
name The name of the profile to create
kwargs [ arg=val ] ...
Consult F5 BIGIP user guide for specific options for each profile type. Typically, tmsh arg names are used.

salt.states.bigip.delete_virtual(hostname, username, password, name)
Delete an existing virtual.
hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
name  The name of the virtual which will be deleted

salt.states.bigip.list_monitor(hostname, username, password, monitor_type, name)
A function to list an existing monitor.
hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
monitor_type  The type of monitor to list
name  The name of the monitor to list

salt.states.bigip.list_node(hostname, username, password, name)
A function to connect to a bigip device and list a specific node.
hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
name  The name of the node to list.

salt.states.bigip.list_pool(hostname, username, password, name)
A function to connect to a bigip device and list a specific pool.
hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
name  The name of the pool to list.

salt.states.bigip.list_profile(hostname, username, password, profile_type, name)
A function to list an existing profile.
hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
profile_type  The type of profile to list
name  The name of the profile to list

salt.states.bigip.list_virtual(hostname, username, password, name)
A function to list a specific virtual.
hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
name  The name of the virtual to list

salt.states.bigip.manage_monitor(hostname, username, password, monitor_type, name, **kwargs)
Create a new monitor if a monitor of this type and name does not already exists. If it does exists, only the parameters specified will be enforced.
hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
monitor_type  The type of monitor to create
name  The name of the monitor to create
kwargs [ arg=val ] ...

Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.
salt.states.bigip.manage_node(hostname, username, password, name, address, connection_limit=None, description=None, dynamic_ratio=None, logging=None, monitor=None, rate_limit=None, ratio=None, session=None, node_state=None)

Manages a node of a given bigip device. If the node does not exist it will be created, otherwise, only the properties which are different than the existing will be updated.

**hostname** The host/address of the bigip device

**username** The iControl REST username

**password** The iControl REST password

**name** The name of the node to manage

**address** The address of the node

**connection_limit** [integer]

**description** [string]

**dynamic_ratio** [integer]

**logging** [enabled | disabled]

**monitor** [[name] | none | default]

**rate_limit** [integer]

**ratio** [integer]

**session** [user-enabled | user-disabled]

**node_state** (state) [user-down | user-up]

salt.states.bigip.manage_pool(hostname, username, password, name, allow_nat=None, allow_snat=None, description=None, gateway_failsafe_device=None, ignore_persisted_weight=None, ip_tos_to_client=None, ip_tos_to_server=None, link_qos_to_client=None, link_qos_to_server=None, load_balancing_mode=None, min_active_members=None, min_up_members=None, min_up_members_action=None, min_up_members_checking=None, monitor=None, profiles=None, queue_depth_limit=None, queue_on_connection_limit=None, queue_time_limit=None, reselect_tries=None, service_down_action=None, slow_ramp_time=None)

Create a new pool if it does not already exist. Pool members are managed separately. Only the parameters specified are enforced.

**hostname** The host/address of the bigip device

**username** The iControl REST username

**password** The iControl REST password

**name** The name of the pool to create

**allow_nat** [yes | no]

**allow_snat** [yes | no]

**description** [string]

**gateway_failsafe_device** [string]

**ignore_persisted_weight** [enabled | disabled]

**ip_tos_to_client** [pass-through | [integer]]

**ip_tos_to_server** [pass-through | [integer]]

**link_qos_to_client** [pass-through | [integer]]

**link_qos_to_server** [pass-through | [integer]]

**load_balancing_mode** [dynamic-ratio-member | dynamic-ratio-node | fastest-app-response | fastest-node | least-connections-members | least-connections-node | least-sessions | observed-member | observed-node | predictive-member | predictive-node | ratio-least-connections-member | ratio-least-connections-node | ratio-member | ratio-node | ratio-session | round-robin | weighted-least-connections-member | weighted-least-connections-node]

**min_active_members** [integer]

**min_up_members** [integer]

**min_up_members_action** [failover | reboot | restart-all]
min_up_members_checking  [enabled | disabled]
monitor [name]
profiles  [none | profile_name]
queue_depth_limit  [integer]
queue_on_connection_limit  [enabled | disabled]
queue_time_limit  [integer]
reselect_tries  [integer]
service_down_action  [drop | none | reselect | reset]
slow_ramp_time  [integer]

salt.states.bigip.manage_pool_members( hostname, username, password, name, members)
Manage the members of an existing pool. This function replaces all current pool members. Only the parameters specified are enforced.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the pool to modify
members list of pool members to manage.

salt.states.bigip.manage_profile( hostname, username, password, profile_type, name, **kwargs)
Create a new profile if a monitor of this type and name does not already exists. If it does exists, only the parameters specified will be enforced.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
profile_type The type of profile to create
name The name of the profile to create
kwargs [ arg=val ] ...
Consult F5 BIGIP user guide for specific options for each profile type. Typically, tmsh arg names are used.

salt.states.bigip.manage_virtual( hostname, username, password, name, destination, pool=None, address_status=None, auto_lasthop=None, bwc_policy=None, cmp_enabled=None, connection_limit=None, dhcp_relay=None, description=None, fallback_persistence=None, flow_eviction_policy=None, gtm_score=None, ip_forward=None, ip_protocol=None, internal=None, twelve_forward=None, last_hop_pool=None, mask=None, mirror=None, nat64=None, persist=None, profiles=None, policies=None, rate_class=None, rate_limit=None, rate_limit_mode=None, rate_limit_dst=None, rate_limit_src=None, rules=None, related_rules=None, reject=None, source=None, source_address_translation=None, source_port=None, virtual_state=None, traffic_classes=None, translate_address=None, translate_port=None, vlans=None)
Manage a virtual server. If a virtual does not exists it will be created, otherwise only the parameters specified will be enforced.
hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the virtual to create
destination  [ [virtual_address_name:port] | [ipv4:port] | [ipv6:port] ]
pool  [ [pool_name] | none ]

```python
salt.states.bigip.modify_monitor( hostname, username, password, monitor_type, name, **kwargs)
```

Modify an existing monitor. If it does exists, only the parameters specified will be enforced.

- **hostname** The host/address of the bigip device
- **username** The iControl REST username
- **password** The iControl REST password
- **monitor_type** The type of monitor to create
- **name** The name of the monitor to create
- **kwargs** [ arg=val ] ...

Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

salt.states.bigip.modify_pool_member( hostname, username, password, name, member, 
  connection_limit=None, description=None, dynamic_ratio=None, inherit_profile=None, 
  logging=None, monitor=None, priority_group=None, profiles=None, 
  rate_limit=None, ratio=None, session=None, member_state=None )

A function to connect to a bigip device and modify a member of an existing pool.

hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the pool to modify
member The member modify
collection_limit [integer]
description [string]
dynamic_ratio [integer]
inherit_profile [enabled | disabled]
logging [enabled | disabled]
monitor [name]
priority_group [integer]
profiles [none | profile_name]
rate_limit [integer]
ratio [integer]
session [user-enabled | user-disabled]
member_state (state) [ user-up | user-down ]

salt.states.bigip.modify_profile( hostname, username, password, profile_type, name, **kwargs )

Modify an existing profile. If it does exists, only the parameters specified will be enforced.

hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
profile_type The type of profile to create
name The name of the profile to create
kwarg [ arg=val ] ...

Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.
salt.states.bigip.modify_virtual(hostname, username, password, name, destination, pool=None, address_status=None, auto_lasthop=None, bwc_policy=None, cmp_enabled=None, connection_limit=None, dhcp_relay=None, description=None, fallback_persistence=None, flow_eviction_policy=None, gtm_score=None, ip_forward=None, ip_protocol=None, internal=None, twelve_forward=None, last_hop_pool=None, mask=None, mirror=None, nat64=None, persist=None, profiles=None, policies=None, rate_class=None, rate_limit=None, rate_limit_mode=None, rate_limit_dst=None, rate_limit_src=None, rules=None, related_rules=None, reject=None, source=None, source_address_translation=None, source_port=None, virtual_state=None, traffic_classes=None, translate_address=None, translate_port=None, vlans=None)

Modify an virtual server. modify an existing virtual. Only parameters specified will be enforced.

hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
name  The name of the virtual to create
destination  [ [virtual_address_name:port] | [ipv4:port] | [ipv6:port] ]

19.19.16 salt.states.blockdev

Management of Block Devices

A state module to manage blockdevices

```
/dev/sda:
    blockdev.tuned:
        - read-only: True

master-data:
    blockdev.tuned:
        - name: /dev/vg/master-data
        - read-only: True
        - read-ahead: 1024
```

New in version 2014.7.0.

salt.states.blockdev.formatted(name, fs_type='ext4', force=False, **kwargs)

Manage filesystems of partitions.

name: The name of the block device
fs_type: The filesystem it should be formatted as
force: Force mkfs to create a filesystem, even if the specified device is not a partition on a block special device. This option is only enabled for ext and xfs filesystems

This option is dangerous, use it with caution.

New in version 2016.11.0.

salt.states.blockdev.tuned(name, **kwargs)

Manage options of block device

name: The name of the block device

opts:
    • read-ahead: Read-ahead buffer size
    • filesystem-read-ahead: Filesystem Read-ahead buffer size
    • read-only: Set Read-Only
    • read-write: Set Read-Write

19.19.17 salt.states.boto3_elasticache module

Manage Elasticache with boto3

New in version 2017.7.0.

Create, destroy and update Elasticache clusters. Be aware that this interacts with Amazon's services, and so may incur charges.
This module uses boto3 behind the scenes - as a result it inherits any limitations it boto3's implementation of the AWS API. It is also designed to as directly as possible leverage boto3's parameter naming and semantics. This allows one to use http://boto3.readthedocs.io/en/latest/reference/services/elasticache.html as an excellent source for details too involved to reiterate here.

Note: This module is designed to be transparent ("intentionally ignorant" is the phrase I used to describe it to my boss) to new AWS / boto options - since all AWS API params are passed directly through both the state and executions modules, any new args to existing functions which become available after this documentation is written should work immediately.

Brand new API calls, of course, would still require new functions to be added :)

This module accepts explicit elasticache credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information is available here.

If IAM roles are not used you need not to specify them either in a pillar file or in the minion's config file:

```
elasticache.keyid: GKTADJGHEIQSXMKKRBJ08H
elasticache.key: askdjghsdfjkgHwupUjasdfklkdfkljgsdfjajkgghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgHwupUjasdfklkdfkljgsdfjajkgghs
  region: us-east-1
```

Ensure myelasticache exists:

```
boto3_elasticache.present:
  - name: myelasticache
    - engine: redis
    - cache_node_type: cache.t1.micro
    - num_cache_nodes: 1
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkgHwupUjasdfklkdfkljgsdfjajkgghs
```

# Using a profile from pillars
Ensure myelasticache exists:

```
boto3_elasticache.present:
  - name: myelasticache
    - engine: redis
    - cache_node_type: cache.t1.micro
    - num_cache_nodes: 1
    - region: us-east-1
    - profile: myprofile
```

# Passing in a profile
Ensure myelasticache exists:

```
boto3_elasticache.present:
  - name: myelasticache
    - engine: redis
    - cache_node_type: cache.t1.micro
    - num_cache_nodes: 1
```
- region: us-east-1
- profile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgHupUjasdflkdfklgjsdfjajkghs

salt.states.boto3_elasticache.cache_cluster_absent(name, wait=600, region=None, key=None, keyid=None, profile=None, **args)

Ensure a given cache cluster is deleted.

name Name of the cache cluster.

wait Integer describing how long, in seconds, to wait for confirmation from AWS that the resource is in the desired state. Zero meaning to return success or failure immediately of course. Note that waiting for the cluster to become available is generally the better course, as failure to do so will often lead to subsequent failures when managing dependent resources.

CacheClusterId The node group (shard) identifier. Note: In general this parameter is not needed, as `name` is used if it’s not provided.

FinalSnapshotIdentifier The user-supplied name of a final cache cluster snapshot. This is the unique name that identifies the snapshot. ElastiCache creates the snapshot, and then deletes the cache cluster immediately afterward.

region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto3_elasticache.cache_cluster_present(name, wait=900, security_groups=None, region=None, key=None, keyid=None, profile=None, **args)

Ensure a given cache cluster exists.

name Name of the cache cluster (cache cluster id).

wait Integer describing how long, in seconds, to wait for confirmation from AWS that the resource is in the desired state. Zero meaning to return success or failure immediately of course. Note that waiting for the cluster to become available is generally the better course, as failure to do so will often lead to subsequent failures when managing dependent resources.

security_groups One or more VPC security groups (names and/or IDs) associated with the cache cluster.

Note: This is additive with any sec groups provided via the SecurityGroupIds parameter below. Use this parameter ONLY when you are creating a cluster in a VPC.

CacheClusterId The node group (shard) identifier. This parameter is stored as a lowercase string.

Constraints:
- A name must contain from 1 to 20 alphanumeric characters or hyphens.
- The first character must be a letter.
- A name cannot end with a hyphen or contain two consecutive hyphens.

Note: In general this parameter is not needed, as `name` is used if it’s not provided.

ReplicationGroupId The ID of the replication group to which this cache cluster should belong. If this parameter is specified, the cache cluster is added to the specified replication group as a read replica; otherwise, the cache cluster is a standalone primary that is not part of any replication group. If the specified replication group is Multi-AZ enabled and the Availability Zone is not specified, the cache cluster is created...
in Availability Zones that provide the best spread of read replicas across Availability Zones.

**AZMode**  Specifies whether the nodes in this Memcached cluster are created in a single Availability Zone or created across multiple Availability Zones in the cluster's region. If the AZMode and PreferredAvailabilityZones are not specified, ElastiCache assumes single-az mode.

**Note:** This parameter is ONLY supported for Memcached cache clusters.

**PreferredAvailabilityZone**  The EC2 Availability Zone in which the cache cluster is created. All nodes belonging to this Memcached cache cluster are placed in the preferred Availability Zone. If you want to create your nodes across multiple Availability Zones, use PreferredAvailabilityZones.

Default: System chosen Availability Zone.

**PreferredAvailabilityZones**  A list of the Availability Zones in which cache nodes are created. The order of the zones in the list is not important. The number of Availability Zones listed must equal the value of NumCacheNodes. If you want all the nodes in the same Availability Zone, use PreferredAvailabilityZone instead, or repeat the Availability Zone multiple times in the list.

Default: System chosen Availability Zones.

**Note:** This option is ONLY supported on Memcached.

If you are creating your cache cluster in an Amazon VPC (recommended) you can only locate nodes in Availability Zones that are associated with the subnets in the selected subnet group.

**NumCacheNodes**  The initial (integer) number of cache nodes that the cache cluster has.

**Note:** For clusters running Redis, this value must be 1. For clusters running Memcached, this value must be between 1 and 20.

**CacheNodeType**  The compute and memory capacity of the nodes in the node group (shard). Valid node types (and pricing for them) are exhaustively described at https://aws.amazon.com/elasticache/pricing/

**Note:**
All T2 instances must be created in a VPC
Redis backup/restore is not supported for Redis (cluster mode disabled) T1 and T2 instances. Backup/restore is supported on Redis (cluster mode enabled) T2 instances.
Redis Append-only files (AOF) functionality is not supported for T1 or T2 instances.

**Engine**  The name of the cache engine to be used for this cache cluster. Valid values for this parameter are: memcached | redis

**EngineVersion**  The version number of the cache engine to be used for this cache cluster. To view the supported cache engine versions, use the DescribeCacheEngineVersions operation.

**Note:** You can upgrade to a newer engine version but you cannot downgrade to an earlier engine version. If you want to use an earlier engine version, you must delete the existing cache cluster or replication group and create it anew with the earlier engine version.

**CacheParameterGroupName**  The name of the parameter group to associate with this cache cluster. If this argument is omitted, the default parameter group for the specified engine is used. You cannot use any parameter group which has cluster-enabled='yes' when creating a cluster.

**CacheSubnetGroupName**  The name of the Cache Subnet Group to be used for the cache cluster. Use this parameter ONLY when you are creating a cache cluster within a VPC.
**Note:** If you’re going to launch your cluster in an Amazon VPC, you need to create a subnet group before you start creating a cluster.

**CacheSecurityGroupNames** A list of Cache Security Group names to associate with this cache cluster. Use this parameter ONLY when you are creating a cache cluster outside of a VPC.

**SecurityGroupIds** One or more VPC security groups associated with the cache cluster. Use this parameter ONLY when you are creating a cache cluster within a VPC.

**Tags** A list of tags to be added to this resource. Note that due to shortcomings in the AWS API for ElastiCache, these can only be set during resource creation - later modification is not (currently) supported.

**SnapshotArns** A single-element string list containing an Amazon Resource Name (ARN) that uniquely identifies a Redis RDB snapshot file stored in Amazon S3. The snapshot file is used to populate the node group (shard). The Amazon S3 object name in the ARN cannot contain any commas.

**Note:** This parameter is ONLY valid if the Engine parameter is redis.

**SnapshotName** The name of a Redis snapshot from which to restore data into the new node group (shard). The snapshot status changes to restoring while the new node group (shard) is being created.

**Note:** This parameter is ONLY valid if the Engine parameter is redis.

**PreferredMaintenanceWindow** Specifies the weekly time range during which maintenance on the cache cluster is permitted. It is specified as a range in the format ddd:hh24:mi-ddd:hh24:mi (24H Clock UTC). The minimum maintenance window is a 60 minute period. Valid values for ddd are: sun, mon, tue, wed, thu, fri, sat

Example: sun:23:00-mon:01:30

**Port** The port number on which each of the cache nodes accepts connections.

Default: 6379

**NotificationTopicArn** The Amazon Resource Name (ARN) of the Amazon Simple Notification Service (SNS) topic to which notifications are sent.

**Note:** The Amazon SNS topic owner must be the same as the cache cluster owner.

**AutoMinorVersionUpgrade** This (boolean) parameter is currently disabled.

**SnapshotRetentionLimit** The number of days for which ElastiCache retains automatic snapshots before deleting them.

Default: 0 (i.e., automatic backups are disabled for this cache cluster).

**Note:** This parameter is ONLY valid if the Engine parameter is redis.

**SnapshotWindow** The daily time range (in UTC) during which ElastiCache begins taking a daily snapshot of your node group (shard). If you do not specify this parameter, ElastiCache automatically chooses an appropriate time range.

Example: 05:00-09:00

**Note:** This parameter is ONLY valid if the Engine parameter is redis.

**AuthToken** The password used to access a password protected server.

Password constraints:
- Must be only printable ASCII characters.
- Must be at least 16 characters and no more than 128 characters in length.
- Cannot contain any of the following characters: `/`, `''`, or `@`.

**CacheNodeIdsToRemove** A list of cache node IDs to be removed. A node ID is a numeric identifier (0001, 0002, etc.). This parameter is only valid when NumCacheNodes is less than the existing number of cache nodes. The number of cache node IDs supplied in this parameter must match the difference between the existing number of cache nodes in the cluster or pending cache nodes, whichever is greater, and the value of NumCacheNodes in the request.

**NewAvailabilityZones** The list of Availability Zones where the new Memcached cache nodes are created. This parameter is only valid when NumCacheNodes in the request is greater than the sum of the number of active cache nodes and the number of cache nodes pending creation (which may be zero). The number of Availability Zones supplied in this list must match the cache nodes being added in this request. Note: This option is only supported on Memcached clusters.

**NotificationTopicStatus** The status of the SNS notification topic. Notifications are sent only if the status is active.

- Valid values: active | inactive
- region Region to connect to.
- key Secret key to be used.
- keyid Access key to be used.
- profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
cache_subnet_group_absent(name, region=None, key=None, keyid=None, profile=None, **args)
```

Ensure a given cache subnet group is deleted.
- name Name of the cache subnet group.
- CacheSubnetGroupName A name for the cache subnet group. Note: In general this parameter is not needed, as `name` is used if it's not provided.
- region Region to connect to.
- key Secret key to be used.
- keyid Access key to be used.
- profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
ensure_subnet_group_present(name, subnets=None, region=None, key=None, keyid=None, profile=None, **args)
```

Ensure cache subnet group exists.
- name A name for the cache subnet group. This value is stored as a lowercase string. Constraints: Must contain no more than 255 alphanumeric characters or hyphens.
- subnets A list of VPC subnets (IDs, Names, or a mix) for the cache subnet group.
- CacheSubnetGroupName A name for the cache subnet group. This value is stored as a lowercase string. Constraints: Must contain no more than 255 alphanumeric characters or hyphens. Note: In general this parameter is not needed, as `name` is used if it's not provided.
- CacheSubnetGroupDescription A description for the cache subnet group.
- SubnetIds A list of VPC subnet IDs for the cache subnet group. This is ADDITIVE with `subnets` above.
- region Region to connect to.
- key Secret key to be used.
- keyid Access key to be used.
- profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto3_elasticache.replication_group_absent(name, wait=600, region=None, key=None, keyid=None, profile=None, **args)

Ensure a given replication group is deleted.

name Name of the replication group.
wait Integer describing how long, in seconds, to wait for confirmation from AWS that the resource is in the desired state. Zero meaning to return success or failure immediately of course. Note that waiting for the cluster to become available is generally the better course, as failure to do so will often lead to subsequent failures when managing dependent resources.

ReplicationGroupId The replication group identifier. Note: In general this parameter is not needed, as `name' is used if it's not provided.

RetainPrimaryCluster If set to true, all of the read replicas are deleted, but the primary node is retained.

FinalSnapshotIdentifier The name of a final node group (shard) snapshot. ElastiCache creates the snapshot from the primary node in the cluster, rather than one of the replicas; this is to ensure that it captures the freshest data. After the final snapshot is taken, the replication group is immediately deleted.

region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto3_elasticache.replication_group_present(name, wait=900, security_groups=None, region=None, key=None, keyid=None, profile=None, **args)

Ensure a replication group exists and is in the given state.

name Name of replication group
wait Integer describing how long, in seconds, to wait for confirmation from AWS that the resource is in the desired state. Zero meaning to return success or failure immediately of course. Note that waiting for the cluster to become available is generally the better course, as failure to do so will often lead to subsequent failures when managing dependent resources.

security_groups One or more VPC security groups (names and/or IDs) associated with the cache cluster.

Note: This is additive with any sec groups provided via the SecurityGroupIds parameter below. Use this parameter ONLY when you are creating a cluster in a VPC.

ReplicationGroupId The replication group identifier. This parameter is stored as a lowercase string.

Constraints:
- A name must contain from 1 to 20 alphanumeric characters or hyphens.
- The first character must be a letter.
- A name cannot end with a hyphen or contain two consecutive hyphens.

Note: In general this parameter is not needed, as `name' is used if it's not provided.

ReplicationGroupDescription A user-created description for the replication group.

PrimaryClusterId The identifier of the cache cluster that serves as the primary for this replication group. This cache cluster must already exist and have a status of available. This parameter is not required if NumCacheClusters, NumNodeGroups, or ReplicasPerNodeGroup is specified.

AutomaticFailoverEnabled Specifies whether a read-only replica is automatically promoted to read/write primary if the existing primary fails. If true, Multi-AZ is enabled for this replication group. If false, Multi-AZ is disabled for this replication group.
Default: False

**Note:** AutomaticFailoverEnabled must be enabled for Redis (cluster mode enabled) replication groups.

ElastiCache Multi-AZ replication groups is not supported on:
- Redis versions earlier than 2.8.6.
- Redis (cluster mode disabled): T1 and T2 node types.
- Redis (cluster mode enabled): T2 node types.

**NumCacheClusters** The number of clusters this replication group initially has. This parameter is not used if there is more than one node group (shard). You should use ReplicasPerNodeGroup instead. If Multi-AZ is enabled, the value of this parameter must be at least 2. The maximum permitted value for NumCacheClusters is 6 (primary plus 5 replicas).

**PreferredCacheClusterAZs** A list of EC2 Availability Zones in which the replication group's cache clusters are created. The order of the Availability Zones in the list is the order in which clusters are allocated. The primary cluster is created in the first AZ in the list. This parameter is not used if there is more than one node group (shard). You should use NodeGroupConfiguration instead. The number of Availability Zones listed must equal the value of NumCacheClusters.

Default: System chosen Availability Zones.

**Note:** If you are creating your replication group in an Amazon VPC (recommended), you can only locate cache clusters in Availability Zones associated with the subnets in the selected subnet group.

**NumNodeGroups** An optional parameter that specifies the number of node groups (shards) for this Redis (cluster mode enabled) replication group. For Redis (cluster mode disabled) either omit this parameter or set it to 1.

Default: 1

**ReplicasPerNodeGroup** An optional parameter that specifies the number of replica nodes in each node group (shard). Valid values are: 0 to 5

**NodeGroupConfiguration** A list of node group (shard) configuration options. Each node group (shard) configuration has the following: Slots, PrimaryAvailabilityZone, ReplicaAvailabilityZones, ReplicaCount. If you're creating a Redis (cluster mode disabled) or a Redis (cluster mode enabled) replication group, you can use this parameter to configure one node group (shard) or you can omit this parameter. For fiddly details of the expected data layout of this param, see [http://boto3.readthedocs.io/en/latest/reference/services/elasticache.html#ElastiCache.Client.create_replication_group](http://boto3.readthedocs.io/en/latest/reference/services/elasticache.html#ElastiCache.Client.create_replication_group)

**CacheNodeType** The compute and memory capacity of the nodes in the node group (shard). See [https://aws.amazon.com/elasticache/pricing/](https://aws.amazon.com/elasticache/pricing/) for current sizing, prices, and constraints.

**Engine** The name of the cache engine to be used for the cache clusters in this replication group.

**EngineVersion** The version number of the cache engine to be used for the cache clusters in this replication group.

To view the supported cache engine versions, use the DescribeCacheEngineVersions operation.

**Note:** You can upgrade to a newer engine version but you cannot downgrade to an earlier engine version. If you want to use an earlier engine version, you must delete the existing cache cluster or replication group and create it anew with the earlier engine version.

**CacheParameterGroupName** The name of the parameter group to associate with this replication group. If this argument is omitted, the default cache parameter group for the specified engine is used.

**Note:** If you are running Redis version 3.2.4 or later, only one node group (shard), and want to use a default parameter group, we recommend that you specify the parameter group by name.

To create a Redis (cluster mode disabled) replication group, use CacheParameterGroup-
Name=default.redis3.2

To create a Redis (cluster mode enabled) replication group, use CacheParameterGroup-
Name=default.redis3.2.cluster.on

CacheSubnetGroupName  The name of the cache subnet group to be used for the replication group.

**Note:** If you’re going to launch your cluster in an Amazon VPC, you need to create a s group before
you start creating a cluster. For more information, see Subnets and Subnet Groups.

CacheSecurityGroupNames  A list of cache security group names to associate with this replication group.
SecurityGroupIds  One or more Amazon VPC security groups associated with this replication group. Use this
parameter only when you are creating a replication group in an VPC.
Tags  A list of tags to be added to this resource. Note that due to shortcomings in the AWS API for Elasticache,
these can only be set during resource creation - later modification is not (currently) supported.
SnapshotArns  A list of ARNs that uniquely identify the Redis RDB snapshot files stored in Amazon S3. These
snapshot files are used to populate the replication group. The Amazon S3 object name in the ARN cannot
contain any commas. The list must match the number of node groups (shards) in the replication group,
which means you cannot repartition.

**Note:** This parameter is only valid if the Engine parameter is redis.

SnapshotName  The name of a snapshot from which to restore data into the new replication group. The
snapshot status changes to restoring while the new replication group is being created. Note: This
parameter is only valid if the Engine parameter is redis.

PreferredMaintenanceWindow  Specifies the weekly time range during which maintenance on the cluster
is performed. It is specified as a range in the format ddd:hh24:mi-ddd:hh24:mi (24H Clock UTC). The
minimum maintenance window is a 60 minute period. Valid values for ddd are: sun, mon, tue, wed,
thu, fri, sat

Example: sun:23:00-mon:01:30

Port  The port number on which each member of the replication group accepts connections.
NotificationTopicArn  The ARN of an SNS topic to which notifications are sent.

**Note:** The SNS topic owner must be the same as the cache cluster owner.

AutoMinorVersionUpgrade  This parameter is currently disabled.
SnapshotRetentionLimit  The number of days for which ElastiCache will retain automatic snapshots before
deleting them.

Default: 0 (that is, automatic backups are disabled for this cache cluster).

**Note:** This parameter is only valid if the Engine parameter is redis.

SnapshotWindow  The daily time range (in UTC) during which ElastiCache begins taking a daily snapshot
of your node group (shard). If you do not specify this parameter, ElastiCache automatically chooses an
appropriate time range.

Example: 05:00-09:00

**Note:** This parameter is only valid if the Engine parameter is redis.

AuthToken  The password used to access a password protected server. Password constraints:
• Must be only printable ASCII characters.
• Must be at least 16 characters and no more than 128 characters in length.
• Cannot contain any of the following characters: `/', `''', or ``@``.

**SnapshottingClusterId** The cache cluster ID that is used as the daily snapshot source for the replication group.

**NotificationTopicStatus** The status of the SNS notification topic. Notifications are sent only if the status is active. Valid values: active | inactive

- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 19.19.18 salt.states.boto3_route53 module

Manage Route53 records with Boto 3

New in version 2017.7.0.

Create and delete Route53 records. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto3, which can be installed via package, or pip.

This module accepts explicit route53 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
route53.keyid: GKTADJGHEIQSXMKKRBJ08H
route53.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
    region: us-east-1
```

An exciting new AWS Route 53 Hosted Zone:

```
boto_route53.hosted_zone_present:
    - Name: example.com.
    - PrivateZone: true
    - VPCs:
        - VPCName: MyLittleVPC
          VPCRegion: us-east-1
        - VPCId: vpc-12345678
          region: us-east-1
        - keyid: GKTADJGHEIQSXMKKRBJ08H
        - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

```
mycnamerecord:
    boto_route53.rr_present:
        - Name: test.example.com.
        - ResourceRecords:
            - my-elb.us-east-1.elb.amazonaws.com.
```
- DomainName: example.com.
- TTL: 60
- Type: CNAME
- region: us-east-1
- keyid: GKTADJGHEIQSXMKKRBJ08H
- key: askdjghsdfjkgHwupUjasdfsflkdfklgjsdfjajkghs

salt.states.boto3_route53.hosted_zone_absent(name, Name=None, PrivateZone=False, region=None, key=None, keyid=None, profile=None)

Ensure the Route53 Hostes Zone described is absent
name The name of the state definition.
Name The name of the domain. This should be a fully-specified domain, and should terminate with a period.
If not provided, the value of name will be used.
PrivateZone Set True if deleting a private hosted zone.

salt.states.boto3_route53.hosted_zone_present(name, Name=None, PrivateZone=False, CallerReference=None, Comment=None, VPCs=None, region=None, key=None, keyid=None, profile=None)

Ensure a hosted zone exists with the given attributes.
name The name of the state definition. This will be used as the `CallerReference' param when creating the
hosted zone to help ensure idempotency.
Name The name of the domain. This should be a fully-specified domain, and should terminate with a period.
This is the name you have registered with your DNS registrar. It is also the name you will delegate from
your registrar to the Amazon Route 53 delegation servers returned in response to this request. If not
provided, the value of name will be used.
PrivateZone Set True if creating a private hosted zone. If true, then `VPCs' is also required.
Comment Any comments you want to include about the hosted zone.
CallerReference A unique string that identifies the request and that allows create_hosted_zone() calls to
be retried without the risk of executing the operation twice. This helps ensure idempotency across
state calls, but can cause issues if a zone is deleted and then an attempt is made to recreate it with
the same CallerReference. If not provided, a unique UUID will be generated at each state run, which
can potentially lead to duplicate zones being created if the state is run again while the previous zone
creation is still in PENDING status (which can occasionally take several minutes to clear). Maximum
length of 128.
VPCs A list of dicts, each dict composed of a VPCRegion, and either a VPCId or a VPCName. Note that this
param is ONLY used if PrivateZone == True
VPCId When creating a private hosted zone, either the VPC ID or VPC Name to associate with is
required. Exclusive with VPCName.
VPCName When creating a private hosted zone, either the VPC ID or VPC Name to associate with is
required. Exclusive with VPCId.
VPCRegion When creating a private hosted zone, the region of the associated VPC is required. If not
provided, an effort will be made to determine it from VPCId or VPCName, if possible. This will
fail if a given VPCName exists in multiple regions visible to the bound account, in which case
you'll need to provide an explicit value for VPCRegion.

salt.states.boto3_route53.rr_absent(name, HostedZoneId=None, DomainName=None, PrivateZone=False, Name=None, Type=None, SetIdentifier=None, region=None, key=None, keyid=None, profile=None)

Ensure the Route53 record is deleted.
name The name of the state definition. This will be used for Name if the latter is not provided.
HostedZoneId The ID of the zone to delete the record from. Exclusive with DomainName.
DomainName The domain name of the zone to delete the record from. Exclusive with HostedZoneId.
PrivateZone Set to True if the RR to be removed is in a private zone, False if public.
Name  Name of the resource record.
Type  The record type (A, NS, MX, TXT, etc.)
SetIdentifier Valid for Weighted, Latency, Geolocation, and Failover resource record sets only. An identifier that differentiates among multiple resource record sets that have the same combination of DNS name and type. The value of SetIdentifier must be unique for each resource record set that has the same combination of DNS name and type. Omit SetIdentifier for any other types of record sets.
region  The region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  Dict, or pillar key pointing to a dict, containing AWS region/key/keyid.

salt.states.boto3_route53.rr_present(name, HostedZoneId=None, DomainName=None, PrivateZone=False, Name=None, Type=None, SetIdentifier=None, Weight=None, Region=None, GeoLocation=None, Failover=None, TTL=None, ResourceRecords=None, AliasTarget=None, HealthCheckId=None, TrafficPolicyInstanceId=None, region=None, key=None, keyid=None, profile=None)

Ensure the Route53 record is present.
name  The name of the state definition. This will be used for Name if the latter is not provided.
HostedZoneId  The ID of a zone to create the record in. Exclusive with DomainName.
DomainName  The domain name of a zone to create the record in. Exclusive with HostedZoneId.
PrivateZone  Set to True if the resource record should be in a private zone, False if public.
Name  Name of the Route 53 resource record being managed.
Type  The record type (A, NS, MX, TXT, etc.)
SetIdentifier Valid for Weighted, Latency, Geolocation, and Failover resource record sets only. An identifier that differentiates among multiple resource record sets that have the same combination of DNS name and type. The value of SetIdentifier must be unique for each resource record set that has the same combination of DNS name and type. Omit SetIdentifier for any other types of record sets.
Weight  Valid for Weighted resource record sets only. Among resource record sets that have the same combination of DNS name and type, a value that determines the proportion of DNS queries that Amazon Route 53 responds to using the current resource record set. Amazon Route 53 calculates the sum of the weights for the resource record sets that have the same combination of DNS name and type. Amazon Route 53 then responds to queries based on the ratio of a resource's weight to the total.

Note the following:
• You must specify a value for the Weight element for every weighted resource record set.
• You can only specify one ResourceRecord per weighted resource record set.
• You can't create latency, failover, or geolocation resource record sets that have the same values for the Name and Type elements as weighted resource record sets.
• You can create a maximum of 100 weighted resource record sets that have the same values for the Name and Type elements.
• For weighted (but not weighted alias) resource record sets, if you set Weight to 0 for a resource record set, Amazon Route 53 never responds to queries with the applicable value for that resource record set. However, if you set Weight to 0 for all resource record sets that have the same combination of DNS name and type, traffic is routed to all resources with equal probability. The effect of setting Weight to 0 is different when you associate health checks with weighted resource record sets. For more information, see Options for Configuring Amazon Route 53 Active-Active and Active-Passive Failover in the Amazon Route 53 Developer Guide.
Region  Valid for Latency-based resource record sets only. The Amazon EC2 Region where the resource that is specified in this resource record set resides. The resource typically is an AWS resource, such as an EC2 instance or an ELB load balancer, and is referred to by an IP address or a DNS domain name, depending on the record type.
GeoLocation  Geo location resource record sets only. A dict that lets you control how Route 53 responds to DNS queries based on the geographic origin of the query. For example, if you want all queries from
Africa to be routed to a web server with an IP address of 192.0.2.111, create a resource record set with a Type of A and a ContinentCode of AF.

<table>
<thead>
<tr>
<th>ContinentCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>The two-letter code for the continent.</td>
</tr>
<tr>
<td>Valid values: AF</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>CountryCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>The two-letter code for the country.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>SubdivisionCode</th>
</tr>
</thead>
<tbody>
<tr>
<td>The code for the subdivision, for example, a state in the United States or a province in Canada.</td>
</tr>
</tbody>
</table>

Notes

- Creating geolocation and geolocation alias resource record sets in private hosted zones is not supported.
- If you create separate resource record sets for overlapping geographic regions (for example, one resource record set for a continent and one for a country on the same continent), priority goes to the smallest geographic region. This allows you to route most queries for a continent to one resource and to route queries for a country on that continent to a different resource.
- You can't create two geolocation resource record sets that specify the same geographic location.
- The value * in the CountryCode element matches all geographic locations that aren't specified in other geolocation resource record sets that have the same values for the Name and Type elements.
- Geolocation works by mapping IP addresses to locations. However, some IP addresses aren't mapped to geographic locations, so even if you create geolocation resource record sets that cover all seven continents, Amazon Route 53 will receive some DNS queries from locations that it can't identify. We recommend that you create a resource record set for which the value of CountryCode is *, which handles both queries that come from locations for which you haven't created geolocation resource record sets and queries from IP addresses that aren't mapped to a location. If you don't create a * resource record set, Amazon Route 53 returns a "no answer" response for queries from those locations.
- You can't create non-geolocation resource record sets that have the same values for the Name and Type elements as geolocation resource record sets.

TTL The resource record cache time to live (TTL), in seconds. Note the following:

- If you're creating an alias resource record set, omit TTL. Amazon Route 53 uses the value of TTL for the alias target.
- If you're associating this resource record set with a health check (if you're adding a HealthCheckId element), we recommend that you specify a TTL of 60 seconds or less so clients respond quickly to changes in health status.
- All of the resource record sets in a group of weighted, latency, geolocation, or failover resource record sets must have the same value for TTL.
- If a group of weighted resource record sets includes one or more weighted alias resource record sets for which the alias target is an ELB load balancer, we recommend that you specify a TTL of 60 seconds for all of the non-alias weighted resource record sets that have the same name and type. Values other than 60 seconds (the TTL for load balancers) will change the effect of the values that you specify for Weight.

ResourceRecords A list, containing one or more values for the resource record. No single value can exceed 4,000 characters. For details on how to format values for different record types, see Supported DNS Resource Record Types in the Amazon Route 53 Developer Guide.

Note: You can specify more than one value for all record types except CNAME and SOA.

It is also possible to pass "magic" strings as resource record values. This functionality can easily be...
extended, but for the moment supports the following:

```
magic:ec2_instance_tag:some_tag_name:some_string:some_instance_attr'
```

This tells Salt to lookup an EC2 instance with a tag `some_tag_name` which has the value `some_string` and substitute the `some_instance_attr` attribute of that instance as the resource record value being evaluated.

This should work generally for any EC2 instance tags, as long as the instance attribute being fetched is available to `getattr(instance, 'attribute')` as seen in the code below. Anything else will most likely require this function to be extended to handle it.

The canonical use-case for this (at least at our site) is to query the Name tag (which we always populate with the host’s FQDN) to lookup the public or private IPs bound to the instance, so we can then automagically create Route 53 records for them.

**AliasTarget** The rules governing how to define an AliasTarget for the various supported use-cases are obtuse beyond reason and attempting to paraphrase them (or even worse, cut-and-paste them in their entirety) would be silly and counterproductive. If you need this feature, then Read The Fine Materials at the Boto 3 Route 53 page and/or the AWS Route 53 docs and suss them for yourself - I sure won’t claim to understand them particularly well.

- **region** The region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** Dict, or pillar key pointing to a dict, containing AWS region/key/keyid.

### 19.19.19 salt.states.boto_apigateway module

**Manage Apigateway Rest APIs**

New in version 2016.11.0.

Create and destroy rest apis depending on a swagger version 2 definition file. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto3, which can be installed via package, or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:

```yaml
vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure Apigateway API exists:

```yaml
boto_apigateway.present:
  - name: myfunction
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```
salt.states.boto_apigateway.absent(name, api_name, stage_name, nuke_api=False, region=None, key=None, keyid=None, profile=None)

Ensure the stage_name associated with the given api_name deployed by boto_apigateway's present state is removed. If the currently associated deployment to the given stage_name has no other stages associated with it, the deployment will also be removed.

- **name** Name of the swagger file in YAML format
- **api_name** Name of the rest api on AWS ApiGateway to ensure is absent.
- **stage_name** Name of the stage to be removed irrespective of the swagger file content. If the current deployment associated with the stage_name has no other stages associated with it, the deployment will also be removed.
- **nuke_api** If True, removes the API itself only if there are no other stages associated with any other deployments once the given stage_name is removed.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_apigateway.present(name, api_name, swagger_file, stage_name, api_key_required, lambda_integration_role, lambda_region=None, stage_variables=None, region=None, key=None, keyid=None, profile=None, lambda_funcname_format='{stage}_{api}_{resource}_{method}', authorization_type='NONE', error_response_template=None, response_template=None)

Ensure the specified api_name with the corresponding swaggerfile is deployed to the given stage_name in AWS ApiGateway.

This state currently only supports ApiGateway integration with AWS Lambda, and CORS support is handled through a Mock integration.

There may be multiple deployments for the API object, each deployment is tagged with a description (i.e. unique label) in pretty printed json format consisting of the following key/values.

```json
{
    "api_name": api_name,
    "swagger_file": basename_of_swagger_file,
    "swagger_file_md5sum": md5sum_of_swagger_file,
    "swagger_info_object": info_object_content_in_swagger_file
}
```

Please note that the name of the lambda function to be integrated will be derived via the provided lambda_funcname_format parameters:

- the default lambda_funcname_format is a string with the following substitutable keys: ```{stage}_{api}_{resource}_{method}```. The user can choose to reorder the known keys.
- the stage key corresponds to the stage_name passed in.
- the api key corresponds to the api_name passed in.
- the resource corresponds to the resource path defined in the passed swagger file.
- the method corresponds to the method for a resource path defined in the passed swagger file.

For the default lambda_funcname_format, given the following input:

```python
api_name = 'Test Service'
stage_name = 'alpha'
basePath = '/api'
path = '/a/{b}/c'
method = 'POST'
```
We will end up with the following Lambda Function Name that will be looked up: `test_service_alpha_a_b_c_post`

The canonicalization of these input parameters is done in the following order:

1. lambda_funcname_format is formatted with the input parameters as passed,
2. resulting string is stripped for leading/trailing spaces,
3. path parameter's curly braces are removed from the resource path,
4. consecutive spaces and forward slashes in the paths are replaced with `_`
5. consecutive `_` are replaced with `_`

Please note that for error response handling, the swagger file must have an error response model with the following schema. The lambda functions should throw exceptions for any non-successful responses. An optional pattern field can be specified in error_message field to aid the response mapping from Lambda to the proper error return status codes.

```
Error:
  type: object
  properties:
    stackTrace:
      type: array
      items:
        type: array
        items:
          type: string
          description: call stack
    errorType:
      type: string
      description: error type
    errorMessage:
      type: string
      description: Error message, will be matched based on pattern. If no pattern is specified, the default pattern used for response mapping will be `+*`.
```

**name**  The name of the state definition

**api_name**  The name of the rest api that we want to ensure exists in AWS API Gateway

**swagger_file**  Name of the location of the swagger rest api definition file in YAML format.

**stage_name**  Name of the stage we want to be associated with the given api_name and swagger_file definition

**api_key_required**  True or False - whether the API Key is required to call API methods

**lambda_integration_role**  The name or ARN of the IAM role that the AWS ApiGateway assumes when it executes your lambda function to handle incoming requests

**lambda_region**  The region where we expect to find the lambda functions. This is used to determine the region where we should look for the Lambda Function for integration purposes. The region determination is based on the following priority:

1. lambda_region as passed in (is not None)
2. if lambda_region is None, use the region as if a boto_lambda function were executed without explicitly specifying lambda region.
3. if region determined in (2) is different than the region used by boto_apigateway functions, a final lookup will be attempted using the boto_apigateway region.

**stage_variables**  A dict with variables and their values, or a pillar key (string) that contains a dict with variables and their values. key and values in the dict must be strings. `{"string": "string"}`

**region**  Region to connect to.

**key**  Secret key to be used.

**keyid**  Access key to be used.

**profile**  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
lambda_funcname_format  Please review the earlier example for the usage. The only substitutable keys in the funcname format are {stage}, {api}, {resource}, {method}. Any other keys or positional substitution parameters will be flagged as an invalid input.

authorization_type This field can be either `NONE', or `AWS_IAM'. This will be applied to all methods in the given swagger spec file. Default is set to `NONE'

error_response_template String value that defines the response template mapping that should be applied in cases error occurs. Refer to AWS documentation for details: http://docs.aws.amazon.com/apigateway/latest/developerguide/api-gateway-mapping-template-reference.html

If set to None, the following default value is used:

```
'#{set($inputRoot = $input.path($'))\n
'{
'  "errorMessage" : "$inputRoot.errorMessage",
'  "errorType" : "$inputRoot.errorType",
'  "stackTrace" : "\n
"foreach($stackTrace in $inputRoot.stackTrace)\n
  [\n
  "foreach($elem in $stackTrace)\n
    "$elem"

  ]\n
  "if($foreach.hasNext),#end\n
'  ]\n
'  "if($foreach.hasNext),#end\n
'  ]\n
'
```

New in version 2017.7.0.

response_template String value that defines the response template mapping applied in case of success (including OPTIONS method) If set to None, empty ([]) template is assumed, which will transfer response from the lambda function as is.

New in version 2017.7.0.

salt.states.boto_apigateway.usage_plan_absent(name, plan_name, region=None, key=None, keyid=None, profile=None)

Ensures usage plan identified by name is no longer present

New in version 2017.7.0.

name  name of the state

plan_name  name of the plan to remove

```
usage plan absent:
  boto_apigateway.usage_plan_absent:
    - plan_name: my_usage_plan
    - profile: my_profile
```

salt.states.boto_apigateway.usage_plan_association_absent(name, plan_name, api_stages, region=None, key=None, keyid=None, profile=None)

Ensures usage plan identified by name is removed from provided api_stages If a plan is associated to stages not listed in api_stages parameter, those associations remain intact.

New in version 2017.7.0.

name  name of the state

plan_name  name of the plan to use

api_stages  list of dictionaries, where each dictionary consists of the following keys:
apiId apid of the api to detach usage plan from
stage stage name of the api to detach usage plan from

UsagePlanAssociationAbsent:
boto_apigateway.usage_plan_association_absent:
  - plan_name: my_plan
  - api_stages:
    - apiId: 9kb0404ec0
      stage: my_stage
    - apiId: l9v7o2aj90
      stage: my_stage
  - profile: my_profile

salt.states.boto_apigateway.usage_plan_association_present(name, plan_name, api_stages, region=None, key=None, keyid=None, profile=None)

Ensures usage plan identified by name is added to provided api_stages

New in version 2017.7.0.
name name of the state
plan_name name of the plan to use
api_stages list of dictionaries, where each dictionary consists of the following keys:
  apiId apiId of the api to attach usage plan to
  stage stage name of the api to attach usage plan to

UsagePlanAssociationPresent:
boto_apigateway.usage_plan_association_present:
  - plan_name: my_plan
  - api_stages:
    - apiId: 9kb0404ec0
      stage: my_stage
    - apiId: l9v7o2aj90
      stage: my_stage
  - profile: my_profile

salt.states.boto_apigateway.usage_plan_present(name, plan_name, description=None, throttle=None, quota=None, region=None, key=None, keyid=None, profile=None)

Ensure the specified usage plan with the corresponding metrics is deployed

New in version 2017.7.0.
name name of the state
plan_name [Required] name of the usage plan
throttle [Optional] throttling parameters expressed as a dictionary. If provided, at least one of the throttling parameters must be present
rateLimit rate per second at which capacity bucket is populated
burstLimit maximum rate allowed
quota [Optional] quota on the number of api calls permitted by the plan. If provided, limit and period must be present
limit [Required] number of calls permitted per quota period
offset [Optional] number of calls to be subtracted from the limit at the beginning of the period
period [Required] period to which quota applies. Must be DAY, WEEK or MONTH
UsagePlanPresent:
  boto_apigateway.usage_plan_present:
    - plan_name: my_usage_plan
    - throttle:
      - rateLimit: 70
      - burstLimit: 100
    - quota:
      - limit: 1000
      - offset: 0
      - period: DAY
    - profile: my_profile

19.19.20 salt.states.boto_asg

Manage Autoscale Groups

New in version 2014.7.0.

Create and destroy autoscale groups. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit autoscale credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

    asg.keyid: GKTADJGHEIQSXMKKRBJ08H
    asg.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

    myprofile:
      keyid: GKTADJGHEIQSXMKKRBJ08H
      key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
      region: us-east-1

Ensure myasg exists:
    boto_asg.present:
      - name: myasg
        - launch_config_name: mylc
        - availability_zones:
          - us-east-1a
          - us-east-1b
        - min_size: 1
        - max_size: 1
        - desired_capacity: 1
        - load_balancers:
          - myelb
        - suspended_processes:
          - AddToLoadBalancer
          - AlarmNotification

19.19. state modules
- scaling_policies
  - adjustment_type: ChangeInCapacity
  - as_name: api-production-iad
  - cooldown: 1800
  - min_adjustment_step: None
  - name: ScaleDown
  - scaling_adjustment: -1
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkgHwupUjasdflkdfklgjsdfjajkghs

# Using a profile from pillars.
Ensure myasg exists:
  boto_asg.present:
    - name: myasg
    - launch_config_name: mylc
    - availability_zones:
      - us-east-1a
      - us-east-1b
    - min_size: 1
    - max_size: 1
    - desired_capacity: 1
    - load_balancers:
      - myelb
    - profile: myprofile

# Passing in a profile.
Ensure myasg exists:
  boto_asg.present:
    - name: myasg
    - launch_config_name: mylc
    - availability_zones:
      - us-east-1a
      - us-east-1b
    - min_size: 1
    - max_size: 1
    - desired_capacity: 1
    - load_balancers:
      - myelb
    - profile:
      keyid: GKTADJGHEIQSXMKKRBJ08H
      key: askdjghsdfjkgHwupUjasdflkdfklgjsdfjajkghs
      region: us-east-1

# Deleting an autoscale group with running instances.
Ensure myasg is deleted:
  boto_asg.absent:
    - name: myasg

    # If instances exist, we must force the deletion of the asg.
    - force: True

It's possible to specify cloudwatch alarms that will be setup along with the ASG. Note the alarm name will be the
name attribute defined, plus the ASG resource name.

Ensure myasg exists:
  boto_asg.present:
    - name: myasg
    - launch_config_name: mylc
- availability_zones:
  - us-east-1a
  - us-east-1b
- min_size: 1
- max_size: 1
- desired_capacity: 1
- load_balancers:
  - myelb
- profile: myprofile
- alarms:
  
  CPU:
  
  name: 'ASG CPU **MANAGED BY SALT**'
  attributes:
    metric: CPUUtilization
    namespace: AWS/EC2
    statistic: Average
    comparison: '>='
    threshold: 65.0
    period: 60
    evaluation_periods: 30
    unit: null
    description: 'ASG CPU'
    alarm_actions: [ 'arn:aws:sns:us-east-1:12345:myalarm' ]
    insufficient_data_actions: []
    ok_actions: [ 'arn:aws:sns:us-east-1:12345:myalarm' ]

You can also use alarms from pillars, and override values from the pillar alarms by setting overrides on the resource. Note that `boto_asg_alarms` will be used as a default value for all resources, if defined and can be used to ensure alarms are always set for an ASG resource.

Setting the alarms in a pillar:

```
my_asg_alarm:
  CPU:
    name: 'ASG CPU **MANAGED BY SALT**'
    attributes:
      metric: CPUUtilization
      namespace: AWS/EC2
      statistic: Average
      comparison: '>='
      threshold: 65.0
      period: 60
      evaluation_periods: 30
      unit: null
      description: 'ASG CPU'
      alarm_actions: [ 'arn:aws:sns:us-east-1:12345:myalarm' ]
      insufficient_data_actions: []
      ok_actions: [ 'arn:aws:sns:us-east-1:12345:myalarm' ]
```

Overriding the alarm values on the resource:

```
Ensure myasg exists:
  boto_asg.present:
    - name: myasg
    - launch_config_name: mylc
    - availability_zones:
      - us-east-1a
      - us-east-1b
```
- min_size: 1
- max_size: 1
- desired_capacity: 1
- load_balancers:
  - myelb
- profile: myprofile
- alarms_from_pillar: my_asg_alarm
# override CPU:attributes:threshold
- alarms:
  CPU:
  attributes:
  threshold: 50.0

salt.states.boto_asg.absent(name, force=False, region=None, key=None, keyid=None, profile=None, remove_lc=False)

Ensure the named autoscale group is deleted.

name Name of the autoscale group.
force Force deletion of autoscale group.
remove_lc Delete the launch config as well.
region The region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_asg.present(name, launch_config_name, availability_zones, min_size, max_size, launch_config=None, desired_capacity=None, load_balancers=None, default_cooldown=None, health_check_type=None, health_check_period=None, placement_group=None, vpc_zone_identifier=None, subnet_names=None, tags=None, termination_policies=None, termination_policies_from_pillar='boto_asg_termination_policies', scheduled_processes=None, scaling_policies=None, scaling_policies_from_pillar='boto_asg_scaling_policies', scheduled_actions=None, scheduled_actions_from_pillar='boto_asg_scheduled_actions', alarms=None, alarms_from_pillar='boto_asg_alarms', region=None, key=None, keyid=None, profile=None, notification_arn=None, notification_arn_from_pillar='boto_asg_notification_arn', notification_types=None, notification_types_from_pillar='boto_asg_notification_types')

Ensure the autoscale group exists.
name Name of the autoscale group.

launch_config_name Name of the launch config to use for the group. Or, if launch_config is specified, this will be the launch config name's prefix. (see below)

launch_config A dictionary of launch config attributes. If specified, a launch config will be used or created, matching this set of attributes, and the autoscale group will be set to use that launch config. The launch config name will be the launch_config_name followed by a hyphen followed by a hash of the Launch_config dict contents. Example:

```python
my_asg:
  boto_asg.present:
  - launch_config:
    - ebs_optimized: false
    - instance_profile_name: my_iam_profile
    - kernel_id: '
    - ramdisk_id: ''
```
- key_name: my_ssh_key
- image_name: aws2015091-hvm
- instance_type: c3.xlarge
- instance_monitoring: false
- security_groups:
  - my_sec_group_01
  - my_sec_group_02

availability_zones List of availability zones for the group.
min_size Minimum size of the group.
max_size Maximum size of the group.
desired_capacity The desired capacity of the group.
load_balancers List of load balancers for the group. Once set this can not be updated (Amazon restriction).
default_cooldown Number of seconds after a Scaling Activity completes before any further scaling activities can start.
health_check_type The service you want the health status from, Amazon EC2 or Elastic Load Balancer (EC2 or ELB).
health_check_period Length of time in seconds after a new EC2 instance comes into service that Auto Scaling starts checking its health.
placement_group Physical location of your cluster placement group created in Amazon EC2. Once set this can not be updated (Amazon restriction).
vpc_zone_identifier A list of the subnet identifiers of the Virtual Private Cloud.
subnet_names For VPC, a list of subnet names (NOT subnet IDs) to deploy into. Exclusive with vpc_zone_identifier.
tags A list of tags. Example:

```
- key: 'key'
  value: 'value'
  propagate_at_launch: true
```

termination_policies A list of termination policies. Valid values are:
  • OldestInstance
  • NewestInstance
  • OldestLaunchConfiguration
  • ClosestToNextInstanceHour
  • Default

If no value is specified, the Default value is used.
termination_policies_from_pillar: name of pillar dict that contains termination policy settings. Termination policies defined for this specific state will override those from pillar.
suspended_processes List of processes to be suspended. see http://docs.aws.amazon.com/AutoScaling/latest/DeveloperGuide/US_SuspendResume.html
scaling_policies List of scaling policies. Each policy is a dict of key-values described by https://boto.readthedocs.io/en/latest/ref/autoscale.html#boto.ec2.autoscale.policy.ScalingPolicy
scaling_policies_from_pillar: name of pillar dict that contains scaling policy settings. Scaling policies defined for this specific state will override those from pillar.
scheduled_actions: a dictionary of scheduled actions. Each key is the name of scheduled action and each value is dictionary of options. For example:

```
- scheduled_actions:
  scale_up_at_10:
    desired_capacity: 4
    min_size: 3
    max_size: 5
    recurrence: "@ 9 * * 1-5"
  scale_down_at_7:
    desired_capacity: 1
```
scheduled_actions_from_pillar: name of pillar dict that contains scheduled_actions settings. Scheduled actions for this specific state will override those from pillar.
alarms: a dictionary of name->boto_cloudwatch_alarm sections to be associated with this ASG. All attributes should be specified except for dimension which will be automatically set to this ASG.

See the salt.states.boto_cloudwatch_alarm state for information about these attributes.

If any alarm actions include "self:" this will be replaced with the asg name. For example, alarm_actions reading `'[scaling_policy:self:ScaleUp]'` will map to the arn for this asg's scaling policy named 'ScaleUp'. In addition, any alarms that have only scaling_policy as actions will be ignored if min_size is equal to max_size for this ASG.

alarms_from_pillar: name of pillar dict that contains alarm settings. Alarms defined for this specific state will override those from pillar.

region The region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
notification_arn The AWS arn that notifications will be sent to
notification_arn_from_pillar name of the pillar dict that contains notification_arn settings. A notification_arn defined for this specific state will override the one from pillar.
notification_types A list of event names that will trigger a notification. The list of valid notification types is:
  • autoscaling:EC2_INSTANCE_LAUNCH
  • autoscaling:EC2_INSTANCE_LAUNCH_ERROR
  • autoscaling:EC2_INSTANCE_TERMINATE
  • autoscaling:EC2_INSTANCE_TERMINATE_ERROR
  • autoscaling:TEST_NOTIFICATION
notification_types_from_pillar name of the pillar dict that contains notification_types settings. notification_types defined for this specific state will override those from the pillar.

19.19.21 salt.states.boto_cfn

Connection module for Amazon Cloud Formation

New in version 2015.8.0.

depends boto

configuration This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
keyid: GKTADJGHEIQSXMKKRBJ08H
key: askdjghsdfjkghWupUjasdflkdklfklgjsdfjajkghs
```

stack-present:
boto_cfn.present:
  - name: mystack
  - template_body: salt://base/mytemplate.json

2676 Chapter 19. Salt Module Reference
- disable_rollback: true
- region: eu-west-1
- keyid: 'AKIAJHTMQ2ASDFLASDF'
- key: 'fdkjsafkljsASSADFalkfjasdf'

stack_absent:
boto_cfn.absent:
  - name: mystack

salt.states.boto_cfn.absent(name, region=None, key=None, keyid=None, profile=None)
Ensure cloud formation stack is absent.

  name (string) – The name of the stack to delete.

  region (string) - Region to connect to.

  key (string) - Secret key to be used.

  keyid (string) - Access key to be used.

  profile (dict) - A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_cfn.present(name, template_body=None, template_url=None, parameters=None, notification_arns=None, disable_rollback=None, timeout_in_minutes=None, capabilities=None, tags=None, on_failure=None, stack_policy_body=None, stack_policy_url=None, use_previous_template=None, stack_policy_during_update_body=None, stack_policy_during_update_url=None, region=None, key=None, keyid=None, profile=None)
Ensure cloud formation stack is present.

  name (string) - Name of the stack.

  template_body (string) – Structure containing the template body. Can also be loaded from a file by using salt://.

  template_url (string) – Location of file containing the template body. The URL must point to a template located in an S3 bucket in the same region as the stack.

  parameters (list) – A list of key/value tuples that specify input parameters for the stack. A 3-tuple (key, value, bool) may be used to specify the UsePreviousValue option.

  notification_arns (list) – The Simple Notification Service (SNS) topic ARNs to publish stack related events. You can find your SNS topic ARNs using the SNS_console or your Command Line Interface (CLI).

  disable_rollback (bool) – Indicates whether or not to rollback on failure.

  timeout_in_minutes (integer) – The amount of time that can pass before the stack status becomes CREATE_FAILED; if DisableRollback is not set or is set to False, the stack will be rolled back.

  capabilities (list) – The list of capabilities you want to allow in the stack. Currently, the only valid capability is ‘CAPABILITY_IAM’.

  tags (dict) – A set of user-defined Tags to associate with this stack, represented by key/value pairs. Tags defined for the stack are propagated to EC2 resources that are created as part of the stack. A maximum number of 10 tags can be specified.

  on_failure (string) – Determines what action will be taken if stack creation fails. This must be one of: DO NOTHING, ROLLBACK, or DELETE. You can specify either OnFailure or DisableRollback, but not both.
stack_policy_body (string) – Structure containing the stack policy body. Can also be loaded from a file by using salt://.

stack_policy_url (string) – Location of a file containing the stack policy. The URL must point to a policy (max size: 16KB) located in an S3 bucket in the same region as the stack. If you pass StackPolicyBody and StackPolicyURL, only StackPolicyBody is used.

use_previous_template (boolean) – Used only when templates are not the same. Set to True to use the previous template instead of uploading a new one via TemplateBody or TemplateURL.

stack_policy_during_update_body (string) – Used only when templates are not the same. Structure containing the temporary overriding stack policy body. If you pass StackPolicyDuringUpdateBody and StackPolicyDuringUpdateURL, only StackPolicyDuringUpdateBody is used. Can also be loaded from a file by using salt://.

stack_policy_during_update_url (string) – Used only when templates are not the same. Location of a file containing the temporary overriding stack policy. The URL must point to a policy (max size: 16KB) located in an S3 bucket in the same region as the stack. If you pass StackPolicyDuringUpdateBody and StackPolicyDuringUpdateURL, only StackPolicyDuringUpdateBody is used.

region (string) - Region to connect to.

key (string) - Secret key to be used.

keyid (string) - Access key to be used.

profile (dict) - A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 19.19.22 salt.states.boto_cloudtrail module

Manage CloudTrail Objects

New in version 2016.3.0.

Create and destroy CloudTrail objects. Be aware that this interacts with Amazon’s services, and so may incur charges.

**depends**

- boto
- boto3

The dependencies listed above can be installed via package or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:

```
    vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
    vpc.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
    myprofile:
        keyid: GKTADJGHEIQSXMKKRBJ08H
```
Ensure trail exists:
```python
boto_cloudtrail.present:
- Name: mytrail
- S3BucketName: mybucket
- S3KeyPrefix: prefix
- region: us-east-1
- keyid: GKTADJGHEIQSXMKKRBJ08H
- key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
```

salt.states.boto_cloudtrail.absent(name, Name=None, region=None, key=None, keyid=None, profile=None)

- Ensure trail with passed properties is absent.
  name The name of the state definition.
  Name Name of the trail.
  region Region to connect to.
  key Secret key to be used.
  keyid Access key to be used.
  profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_cloudtrail.present(name, Name, S3BucketName, S3KeyPrefix=None, SnsTopicName=None, IncludeGlobalServiceEvents=True, IsMultiRegionTrail=None, EnableLogFileValidation=False, CloudWatchLogsLogGroupArn=None, CloudWatchLogsRoleArn=None, KmsKeyId=None, LoggingEnabled=True, Tags=None, region=None, key=None, keyid=None, profile=None)

- Ensure trail exists.
  name The name of the state definition.
  Name Name of the trail.
  S3BucketName Specifies the name of the Amazon S3 bucket designated for publishing log files.
  S3KeyPrefix Specifies the Amazon S3 key prefix that comes after the name of the bucket you have designated for log file delivery.
  SnsTopicName Specifies the name of the Amazon SNS topic defined for notification of log file delivery. The maximum length is 256 characters.
  IncludeGlobalServiceEvents Specifies whether the trail is publishing events from global services such as IAM to the log files.
  EnableLogFileValidation Specifies whether log file integrity validation is enabled. The default is false.
  CloudWatchLogsLogGroupArn Specifies a log group name using an Amazon Resource Name (ARN), a unique identifier that represents the log group to which CloudTrail logs will be delivered. Not required unless you specify CloudWatchLogsRoleArn.
  CloudWatchLogsRoleArn Specifies the role for the CloudWatch Logs endpoint to assume to write to a user's log group.
  KmsKeyId Specifies the KMS key ID to use to encrypt the logs delivered by CloudTrail. The value can be an alias name prefixed by "alias/", a fully specified ARN to an alias, a fully specified ARN to a key, or a globally unique identifier.
  LoggingEnabled Whether logging should be enabled for the trail.
  Tags A dictionary of tags that should be set on the trail.
  region Region to connect to.
  key Secret key to be used.
  keyid Access key to be used.
  profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
keyid.

19.19.23 salt.states.boto_cloudwatch_alarm

Manage Cloudwatch alarms

New in version 2014.7.0.

Create and destroy cloudwatch alarms. Be aware that this interacts with Amazon’s services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion’s config file:

```
cloudwatch.keyid: GKTADJGHEIQXSXMKRBJ08H
cloudwatch.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It’s also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQXSXMKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

```
my test alarm:
  boto_cloudwatch_alarm.present:
    - name: my test alarm
    - attributes:
      metric: ApproximateNumberOfMessagesVisible
      namespace: AWS/SQS
      statistic: Average
      comparison: ">="
      threshold: 20000.0
      period: 60
      evaluation_periods: 1
      description: test alarm via salt
      dimensions:
        QueueName:
          - the-sqs-queue-name
      alarm_actions:
        - arn:aws:sns:us-east-1:1111111:myalerting-action

salt.states.boto_cloudwatch_alarm.absent(name, region= None, key= None, keyid= None, profile= None)
```

Ensure the named cloudwatch alarm is deleted.

- **name** Name of the alarm.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```
salt.states.boto_cloudwatch_alarm.present(name, attributes, region=None, key=None, keyid=None, profile=None)
```

Ensure the cloudwatch alarm exists.

- **name** Name of the alarm
- **attributes** A dict of key/value cloudwatch alarm attributes.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 19.19.24 salt.states.boto_cloudwatch_event module

**Manage CloudTrail Objects**

New in version 2016.11.0.

Create and destroy CloudWatch event rules. Be aware that this interacts with Amazon’s services, and so may incur charges.

This module uses `boto3`, which can be installed via package, or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](https://aws.amazon.com/)

If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:

```
cloudwatch_event.keyid: GKTADJGHEIQSXMKKRBJ08H
cloudwatch_event.key: askdjghsdfjkgWupUjasdfklkdjgjsdfjajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgWupUjasdfklkdjgjsdfjajkghs
  region: us-east-1
```

Ensure event rule exists:

```
boto_cloudwatch_event.present:
  - Name: mytrail
  - ScheduleExpression: 'rate(120 minutes)'
  - State: 'DISABLED'
  - Targets:
    - Id: "target1"
      Input: '{"arbitrary": "json"}'
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkgWupUjasdfklkdjgjsdfjajkghs
```

19.19. state modules 2681
salt.states.boto_cloudwatch_event.absent(name, Name=None, region=None, key=None, keyid=None, profile=None)

Ensure CloudWatch event rule with passed properties is absent.

name The name of the state definition.
Name Name of the event rule. Defaults to the value of the `name' param if not provided.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and
keyid.

salt.states.boto_cloudwatch_event.present(name, Name=None, ScheduleExpression=None, EventPattern=None, Description=None, RoleArn=None, State=None, Targets=None, region=None, key=None, keyid=None, profile=None)

Ensure trail exists.

name The name of the state definition
Name Name of the event rule. Defaults to the value of the `name' param if not provided.
ScheduleExpression The scheduling expression. For example, cron(0 20 * * ? *), `rate(5 minutes)
EventPattern The event pattern.
Description A description of the rule
State Indicates whether the rule is ENABLED or DISABLED.
RoleArn The Amazon Resource Name (ARN) of the IAM role associated with the rule.
Targets A list of resources to be invoked when the rule is triggered.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and
keyid.

19.19.25 salt.states.boto_cognitoidentity module

Manage CognitoIdentity Functions

New in version 2016.11.0.

Create and destroy CognitoIdentity identity pools. Be aware that this interacts with Amazon's services, and so may
incur charges.

This module uses boto3, which can be installed via package, or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through In-
stance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration
is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull
from pillars or minion config:

myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
Ensure function exists:

```python
salt.states.boto_cognitoidentity.pool_present:
    - PoolName: my_identity_pool
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdfklkdfklgjsdfjajkghs
```

 salt.states.boto_cognitoidentity.pool_absent(name, IdentityPoolName, RemoveAllMatched=False, region=None, key=None, keyid=None, profile=None)

Ensure cognito identity pool with passed properties is absent.

- **name**  The name of the state definition.
- **IdentityPoolName**  Name of the Cognito Identity Pool. Please note that this may match multiple pools with the same given name, in which case, all will be removed.
- **RemoveAllMatched**  If True, all identity pools with the matching IdentityPoolName will be removed. If False and there are more than one identity pool with the matching IdentityPoolName, no action will be taken. If False and there is only one identity pool with the matching IdentityPoolName, the identity pool will be removed.
- **region**  Region to connect to.
- **key**  Secret key to be used.
- **keyid**  Access key to be used.
- **profile**  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

 salt.states.boto_cognitoidentity.pool_present(name, IdentityPoolName, AuthenticatedRole=None, AllowUnauthenticatedIdentities=False, UnauthenticatedRole=None, SupportedLoginProviders=None, DeveloperProviderName=None, OpenIdConnectProviderARNs=None, region=None, key=None, keyid=None, profile=None)

Ensure Cognito Identity Pool exists.

- **name**  The name of the state definition
- **IdentityPoolName**  Name of the Cognito Identity Pool
- **AuthenticatedRole**  An IAM role name or ARN that will be associated with temporary AWS credentials for an authenticated cognito identity.
- **AllowUnauthenticatedIdentities**  Whether to allow anonymous user identities
- **UnauthenticatedRole**  An IAM role name or ARN that will be associated with anonymous user identities
- **SupportedLoginProviders**  A dictionary or pillar that contains key:value pairs mapping provider names to provider app IDs.
- **DeveloperProviderName**  A string which is the domain by which Cognito will refer to your users. This name acts as a placeholder that allows your backend and the Cognito service to communicate about the developer provider. Once you have set a developer provider name, you cannot change it. Please take care in setting this parameter.
- **OpenIdConnectProviderARNs**  A list or pillar name that contains a list of OpenID Connect provider ARNs.
- **region**  Region to connect to.
- **key**  Secret key to be used.
- **keyid**  Access key to be used.
- **profile**  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
19.19.26 salt.states.boto_datapipeline module

Manage Data Pipelines

New in version 2016.3.0.

Be aware that this interacts with Amazon’s services, and so may incur charges.

This module uses boto3, which can be installed via package, or pip.

This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:

```yaml
datapipeline.keyid: GKTADJGHEIQSXMKKRBJ08H
datapipeline.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure daily data pipeline exists:

```yaml
boto_datapipeline.present:
  - name: my-datapipeline
  - pipeline_objects:
      DefaultSchedule:
        name: Every 1 day
        fields:
          period: 1 Day
          type: Schedule
        startAt: FIRST_ACTIVATION_DATE_TIME
  - parameter_values:
      myDDBTableName: my-dynamo-table
```

salt.states.boto_datapipeline.absent(name, region=None, key=None, keyid=None, profile=None)

Ensure a pipeline with the service_name does not exist

name Name of the service to ensure a data pipeline does not exist for.

region Region to connect to.

key Secret key to be used.

keyid Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_datapipeline.present(name,  
pipeline_objects=None,  
pipeline_objects_from_pillars='boto_datapipeline_pipeline_objects',  
parameter_objects=None,  
parameter_objects_from_pillars='boto_datapipeline_parameter_objects',  
parameter_values=None,  
parameter_values_from_pillars='boto_datapipeline_parameter_values',  
region=None, key=None, keyid=None, profile=None)

Ensure the data pipeline exists with matching definition.

name Name of the service to ensure a data pipeline exists for.
pipeline_objects Pipeline objects to use. Will override objects read from pillars.
pipeline_objects_from_pillars The pillar key to use for lookup.
parameter_objects Parameter objects to use. Will override objects read from pillars.
parameter_objects_from_pillars The pillar key to use for lookup.
parameter_values Parameter values to use. Will override values read from pillars.
parameter_values_from_pillars The pillar key to use for lookup.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and
keyid.

19.19.27 salt.states.boto_dynamodb

Manage DynamoDB Tables

New in version 2015.5.0.

Create and destroy DynamoDB tables. Be aware that this interacts with Amazon’s services, and so may incur
charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit DynamoDB credentials but can also utilize IAM roles assigned to the instance through
Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration
is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:

```yaml
keyid: GKTADJGHEIQSXMKKRBJ08H
dkey: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
dregion: us-east-1
```

It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull
from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
dkey: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
dregion: us-east-1
```

Ensure DynamoDB table does not exist:

```yaml
boto_dynamodb.absent:
  - table_name: new_table
dkeyid: GKTADJGHEIQSXMKKRBJ08H
dkey: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
dregion: us-east-1
```

Ensure DynamoDB table exists:

```yaml
boto_dynamodb.present:
  - table_name: new_table
dread_capacity_units: 1
dwrite_capacity_units: 2
dhash_key: primary_id
dhash_key_data_type: N
drange_key: start_timestamp
drange_key_data_type: N
```
It's possible to specify cloudwatch alarms that will be setup along with the DynamoDB table. Note the alarm name will be defined by the name attribute provided, plus the DynamoDB resource name.

Ensure DynamoDB table exists:
```
boto_dynamodb.present:
  - name: new_table
  - read_capacity_units: 1
  - write_capacity_units: 2
  - hash_key: primary_id
  - hash_key_data_type: N
  - range_key: start_timestamp
  - range_key_data_type: N
  - alarms:
    ConsumedWriteCapacityUnits:
      name: 'DynamoDB ConsumedWriteCapacityUnits **MANAGED BY SALT**'
      attributes:
        metric: ConsumedWriteCapacityUnits
        namespace: AWS/DynamoDB
        statistic: Sum
        comparison: '>=
        # threshold_percent is used to calculate the actual threshold
        # based on the provisioned capacity for the table.
        threshold_percent: 0.75
        period: 300
        evaluation_periods: 2
        unit: Count
        description: 'DynamoDB ConsumedWriteCapacityUnits'
        alarm_actions: ['arn:aws:sns:us-east-1:1234:my-alarm']
        insufficient_data_actions: []
        ok_actions: ['arn:aws:sns:us-east-1:1234:my-alarm']
```
You can also use alarms from pillars, and override values from the pillar alarms by setting overrides on the resource. Note that `boto_dynamodb.alarms` will be used as a default value for all resources, if defined and can be used to ensure alarms are always set for a resource.
Setting the alarms in a pillar:

```yaml
boto_dynamodb_alarms:
  ConsumedWriteCapacityUnits:
    name: 'DynamoDB ConsumedWriteCapacityUnits **MANAGED BY SALT**'
    attributes:
      metric: ConsumedWriteCapacityUnits
      namespace: AWS/DynamoDB
      statistic: Sum
      comparison: '>=
# threshold_percent is used to calculate the actual threshold
# based on the provisioned capacity for the table.
      threshold_percent: 0.75
      period: 300
      evaluation_periods: 2
      unit: Count
      description: 'DynamoDB ConsumedWriteCapacityUnits'
      alarm_actions: [ 'arn:aws:sns:us-east-1:1234:my-alarm' ]
      insufficient_data_actions: []
      ok_actions: [ 'arn:aws:sns:us-east-1:1234:my-alarm' ]
```

Ensure DynamoDB table exists:

```yaml
boto_dynamodb.present:
  - name: new_table
  - read_capacity_units: 1
  - write_capacity_units: 2
  - hash_key: primary_id
  - hash_key_data_type: N
  - range_key: start_timestamp
  - range_key_data_type: N
  - alarms:
    ConsumedWriteCapacityUnits:
      attributes:
        threshold_percent: 0.90
        period: 900
```

**exception** `salt.states.boto_dynamodb.GsiNotUpdatableError`
Raised when a global secondary index cannot be updated.

**salt.states.boto_dynamodb.absent**
Ensure the DynamoDB table does not exist.
`name` Name of the DynamoDB table.
`region` Region to connect to.
`key` Secret key to be used.
`keyid` Access key to be used.
`profile` A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**salt.states.boto_dynamodb.present**
Ensure the DynamoDB table exists. Table throughput can be updated after table creation.
`name` Name of the DynamoDB table.
`table_name` Name of the table.
`region` Region to connect to.
`key` Secret key to be used.
`keyid` Access key to be used.
`profile` A dict with region, key and keyid.
`read_capacity_units` Read capacity units.
`write_capacity_units` Write capacity units.
`alarms` Alarms.
`alarms_from_pillar` Alarms from pillar.
`hash_key` Hash key.
`hash_key_data_type` Hash key data type.
`range_key` Range key.
`range_key_data_type` Range key data type.
`local_indexes` Local indexes.
`global_indexes` Global indexes.
`backup_configs_from_pillars` Backup configurations from pillars.

Global secondary indexes (GSIs) are managed with some exceptions:
If a GSI deletion is detected, a failure will occur (deletes should be done manually in the AWS console).
If multiple GSIs are added in a single Salt call, a failure will occur (boto supports one creation at a time).
Note that this only applies after table creation; multiple GSIs can be created during table creation.
Updates to existing GSIs are limited to read/write capacity only (DynamoDB limitation).

name Name of the DynamoDB table
table_name Name of the DynamoDB table (deprecated)
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
read_capacity_units The read throughput for this table
write_capacity_units The write throughput for this table
hash_key The name of the attribute that will be used as the hash key for this table
hash_key_data_type The DynamoDB datatype of the hash key
range_key The name of the attribute that will be used as the range key for this table
range_key_data_type The DynamoDB datatype of the range key
local_indexes The local indexes you would like to create
global_indexes The global indexes you would like to create
backup_configs_from_pillars Pillars to use to configure DataPipeline backups

19.19.28 salt.states.boto_ec2

Manage EC2

New in version 2015.8.0.

This module provides an interface to the Elastic Compute Cloud (EC2) service from AWS.

The below code creates a key pair:

```
create-key-pair:
boto_ec2.key_present:
  - name: mykeypair
  - save_private: /root/
  - region: eu-west-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

```
import-key-pair:
boto_ec2.key_present:
  - name: mykeypair
  - upload_public: 'ssh-rsa AAAA'
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

You can also use salt:// in order to define the public key.

```
import-key-pair:
boto_ec2.key_present:
  - name: mykeypair
  - upload_public: salt://mybase/public_key.pub
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

The below code deletes a key pair:
delete-key-pair:
  boto_ec2.key_absent:
  - name: mykeypair
  - region: eu-west-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkgHwupUjasdfklkdfklglajsdfjajkghs

salt.states.boto_ec2.eni_absent(name, release_eip=False, region=None, key=None, keyid=None, profile=None)

Ensure the EC2 ENI is absent.

New in version 2016.3.0.
name Name tag associated with the ENI.
release_eip True/False - release any EIP associated with the ENI
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_ec2.eni_present(name, subnet_id=None, subnet_name=None, private_ip_address=None, description=None, groups=None, source_dest_check=True, allocate_eip=None, arecords=None, region=None, key=None, keyid=None, profile=None)

Ensure the EC2 ENI exists.

New in version 2016.3.0.
name Name tag associated with the ENI.
subnet_id The VPC subnet ID the ENI will exist within.
subnet_name The VPC subnet name the ENI will exist within.
private_ip_address The private ip address to use for this ENI. If this is not specified AWS will automatically assign a private IP address to the ENI. Must be specified at creation time; will be ignored afterward.
description Description of the key.
groups A list of security groups to apply to the ENI.
source_dest_check Boolean specifying whether source/destination checking is enabled on the ENI.
allocation_eip allocate and associate an EIP to the ENI. Could be `standard' to allocate Elastic IP to EC2 region or `vpc' to get it for a particular VPC
Changed in version 2016.11.0.
arecords A list of arecord dicts with attributes needed for the DNS add_record state. By default the boto_route53.add_record state will be used, which requires: name, zone, ttl, and identifier. See the boto_route53 state for information about these attributes. Other DNS modules can be called by specifying the provider keyword. By default, the private ENI IP address will be used, set `public: True' in the arecord dict to use the ENI's public IP address

New in version 2016.3.0.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_ec2.instance_absent(name, instance_name=None, instance_id=None, release_eip=False, region=None, key=None, keyid=None, profile=None, filters=None)

Ensure an EC2 instance does not exist (is stopped and removed).

Changed in version 2016.11.0.
name (string) - The name of the state definition.
instance_name (string) - The name of the instance.
instance_id (string) - The ID of the instance.
release_eip (bool) - Release any associated EIPs during termination.
region (string) - Region to connect to.
key (string) - Secret key to be used.
keyid (string) - Access key to be used.
profile (variable) - A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
filters (dict) - A dict of additional filters to use in matching the instance to delete.

YAML example fragment:

```yaml
- filters:
  vpc-id: vpc-abcdef12
```

salt.states.boto_ec2.instance_present(name=None, instance_name=None, instance_id=None, image_id=None, image_name=None, tags=None, key_name=None, security_groups=None, user_data=None, instance_type=None, placement=None, kernel_id=None, ramdisk_id=None, vpc_id=None, vpc_name=None, monitoring_enabled=None, subnet_id=None, subnet_name=None, private_ip_address=None, block_device_map=None, disable_api_termination=None, instance_initiated_shutdown_behavior=None, placement_group=None, client_token=None, security_group_ids=None, security_group_names=None, additional_info=None, tenancy=None, instance_profile_arn=None, instance_profile_name=None, ebs_optimized=None, network_interfaces=None, network_interface_name=None, network_interface_id=None, attributes=None, target_state=None, public_ip=None, allocation_id=None, allocate_eip=False, region=None, key=None, keyid=None, profile=None)

Ensure an EC2 instance is running with the given attributes and state.

name (string) - The name of the state definition. Recommended that this match the instance_name attribute (generally the FQDN of the instance).
instance_name (string) - The name of the instance, generally its FQDN. Exclusive with `instance_id'.
instance_id (string) - The ID of the instance (if known). Exclusive with `instance_name'.
image_id (string) - The ID of the AMI image to run.
image_name (string) - The name of the AMI image to run.
tags (dict) - Tags to apply to the instance.
key_name (string) - The name of the key pair with which to launch instances.
security_groups (list of strings) - The names of the EC2 classic security groups with which to associate instances
user_data (string) - The Base64-encoded MIME user data to be made available to the instance(s) in this reservation.
instance_type (string) - The EC2 instance size/type. Note that only certain types are compatible with HVM based AMIs.
placement (string) - The EC2 instance size/type. Note that only certain types are compatible with HVM based AMIs.
kernel_id (string) - The ID of the kernel with which to launch the instances.
ramdisk_id (string) – The ID of the RAM disk with which to launch the instances.

vpc_id (string) - The ID of a VPC to attach the instance to.

vpc_name (string) - The name of a VPC to attach the instance to.

monitoring_enabled (bool) – Enable detailed CloudWatch monitoring on the instance.

subnet_id (string) – The ID of the subnet within which to launch the instances for VPC.

subnet_name (string) – The name of the subnet within which to launch the instances for VPC.

private_ip_address (string) – If you’re using VPC, you can optionally use this parameter to assign the instance a specific available IP address from the subnet (e.g., 10.0.0.25).

block_device_map (boto.ec2.blockdevicemapping.BlockDeviceMapping) – A BlockDeviceMapping data structure describing the EBS volumes associated with the Image.

disable_api_termination (bool) – If True, the instances will be locked and will not be able to be terminated via the API.

instance_initiated_shutdown_behavior (string) – Specifies whether the instance stops or terminates on instance-initiated shutdown. Valid values are:

• `stop`
• `terminate`

placement_group (string) – If specified, this is the name of the placement group in which the instance(s) will be launched.

client_token (string) – Unique, case-sensitive identifier you provide to ensure idempotency of the request. Maximum 64 ASCII characters.

security_group_ids (list of strings) – The IDs of the VPC security groups with which to associate instances.

security_group_names (list of strings) – The names of the VPC security groups with which to associate instances.

additional_info (string) – Specifies additional information to make available to the instance(s).

tenancy (string) – The tenancy of the instance you want to launch. An instance with a tenancy of ‘dedicated’ runs on single-tenant hardware and can only be launched into a VPC. Valid values are: "default" or "dedicated". NOTE: To use dedicated tenancy you MUST specify a VPC subnet-ID as well.

instance_profile_arn (string) – The Amazon resource name (ARN) of the IAM Instance Profile (IIP) to associate with the instances.

instance_profile_name (string) – The name of the IAM Instance Profile (IIP) to associate with the instances.

ebs_optimized (bool) – Whether the instance is optimized for EBS I/O. This optimization provides dedicated throughput to Amazon EBS and a tuned configuration stack to provide optimal EBS I/O performance. This optimization isn’t available with all instance types.

network_interfaces (boto.ec2.networkinterface.NetworkInterfaceCollection) – A NetworkInterfaceCollection data structure containing the ENI specifications for the instance.
	network_interface_name (string) - The name of Elastic Network Interface to attach

New in version 2016.11.0.
	network_interface_id (string) - The id of Elastic Network Interface to attach

New in version 2016.11.0.

attributes (dict) - Instance attributes and value to be applied to the instance. Available options are:

• instanceType - A valid instance type (m1.small)
• kernel - Kernel ID (None)
• ramdisk - Ramdisk ID (None)
• userData - Base64 encoded String (None)
• disableApiTermination - Boolean (true)
• instanceInitiatedShutdownBehavior - stop|terminate
• blockDeviceMapping - List of strings - ie: ['/dev/sda=false']
• sourceDestCheck - Boolean (true)
• groupSet - Set of Security Groups or IDs
• ebsOptimized - Boolean (false)
• sriovNetSupport - String - ie: 'simple'

target_state (string) - The desired target state of the instance. Available options are:
- running
- stopped

Note that this option is currently UNIMPLEMENTED.

**public_ip** (string) - The IP of a previously allocated EIP address, which will be attached to the instance. EC2 Classic instances ONLY - for VCP pass in an allocation_id instead.

**allocation_id** (string) - The ID of a previously allocated EIP address, which will be attached to the instance. VPC instances ONLY - for Classic pass in a public_ip instead.

**allocate_eip** (bool) - Allocate and attach an EIP on-the-fly for this instance. Note you'll want to release this address when terminating the instance, either manually or via the 'release_eip' flag to 'instance_absent'.

**region** (string) - Region to connect to.
**key** (string) - Secret key to be used.
**keyid** (string) - Access key to be used.

**profile** (variable) - A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

New in version 2016.3.0.

```python
salt.states.boto_ec2.key_absent(name, region=None, key=None, keyid=None, profile=None)
```

Deletes a key pair

```python
salt.states.boto_ec2.key_present(name, save_private=None, upload_public=None, region=None, key=None, keyid=None, profile=None)
```

Ensure key pair is present.

```python
salt.states.boto_ec2.snapshot_created(name, ami_name, instance_name, wait_until_available=True, wait_timeout_seconds=300, **kwargs)
```

Create a snapshot from the given instance

New in version 2016.3.0.

```python
salt.states.boto_ec2.volume_absent(name, volume_name=None, volume_id=None, instance_name=None, instance_id=None, device=None, region=None, key=None, keyid=None, profile=None)
```

Ensure the EC2 volume is detached and absent.

New in version 2016.11.0.

**name** State definition name.

**volume_name** Name tag associated with the volume. For safety, if this matches more than one volume, the state will refuse to apply.

**volume_id** Resource ID of the volume.

**instance_name** Only remove volume if it is attached to instance with this Name tag. Exclusive with `instance_id`. Requires `device`.

**instance_id** Only remove volume if it is attached to this instance. Exclusive with `instance_name`. Requires `device`.

**device** Match by device rather than ID. Requires one of `instance_name` or `instance_id`.

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

New in version 2016.11.0.

```python
salt.states.boto_ec2.volumes_tagged(name, tag_maps, authoritative=False, region=None, key=None, keyid=None, profile=None)
```

Ensure EC2 volume(s) matching the given filters have the defined tags.
tag_maps  List of dicts of filters and tags, where 'filters' is a dict suitable for passing to the 'filters' argument of boto.ec2.get_all_volumes(), and 'tags' is a dict of tags to be set on volumes as matched by the given filters. The filter syntax is extended to permit passing either a list of volume_ids or an instance_name (with instance_name being the Name tag of the instance to which the desired volumes are mapped). Each mapping in the list is applied separately, so multiple sets of volumes can be all tagged differently with one call to this function.

YAML example fragment:

```yaml
- filters:
  attachment.instance_id: i-abcdef12
  tags:
    Name: dev-int-abcdef12.aws-foo.com
- filters:
  attachment.device: /dev/sdf
  tags:
    ManagedSnapshots: true
    BillingGroup: bubba.hotep@aws-foo.com
- filters:
  instance_name: prd-foo-01.aws-foo.com
  tags:
    Name: prd-foo-01.aws-foo.com
    BillingGroup: infra-team@aws-foo.com
- filters:
  volume_ids: [ vol-12345689, vol-abcdef12 ]
  tags:
    BillingGroup: infra-team@aws-foo.com
```

authoritative  Should un-declared tags currently set on matched volumes be deleted? Boolean.

region  Region to connect to.

key  Secret key to be used.

keyid  Access key to be used.

profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

19.19.29 salt.states.boto_elasticache

Manage Elasticache

New in version 2014.7.0.

Create, destroy and update Elasticache clusters. Be aware that this interacts with Amazon's services, and so may incur charges.

Note: This module currently only supports creation and deletion of elasticache resources and will not modify clusters when their configuration changes in your state files.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit elasticache credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
elasticache.keyid: GKTADJGHEIQSXMKKRBJ08H
elasticache.key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
```

19.19. state modules
It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdfklgjsdfjajkghs
  region: us-east-1
```

Ensure myelasticache exists:

```python
boto_elasticache.present:
  - name: myelasticache
    engine: redis
    cache_node_type: cache.t1.micro
    num_cache_nodes: 1
    region: us-east-1
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdfklgjsdfjajkghs
```

# Using a profile from pillars

Ensure myelasticache exists:

```python
boto_elasticache.present:
  - name: myelasticache
    engine: redis
    cache_node_type: cache.t1.micro
    num_cache_nodes: 1
    region: us-east-1
    profile: myprofile
```

# Passing in a profile

Ensure myelasticache exists:

```python
boto_elasticache.present:
  - name: myelasticache
    engine: redis
    cache_node_type: cache.t1.micro
    num_cache_nodes: 1
    region: us-east-1
    profile:
      keyid: GKTADJGHEIQSXMKKRBJ08H
      key: askdjghsdfjkghWupUjasdfklgjsdfjajkghs
```

salt.states.boto_elasticache.absent

Ensure the named elasticache cluster is deleted.

name Name of the cache cluster.
wait Boolean. Wait for confirmation from boto that the cluster is in the deleting state.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_elasticache.cache_cluster_absent

salt.states.boto_elasticache.cache_cluster_present
salt.states.boto_elasticache.creategroup(name, primary_cluster_id, replication_group_description, wait=None, region=None, key=None, keyid=None, profile=None)

Ensure the a replication group is create.
name Name of replication group
wait Waits for the group to be available
primary_cluster_id Name of the master cache node
replication_group_description Description for the group
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_elasticache.present(name, engine=None, cache_node_type=None, num_cache_nodes=None, preferred_availability_zone=None, port=None, cache_parameter_group_name=None, cache_security_group_names=None, replication_group_id=None, auto_minor_version_upgrade=True, security_group_ids=None, cache_subnet_group_name=None, engine_version=None, notification_topic_arn=None, preferred_maintenance_window=None, wait=None, region=None, key=None, keyid=None, profile=None)

Ensure the cache cluster exists.
name Name of the cache cluster (cache cluster id).
engine The name of the cache engine to be used for this cache cluster. Valid values are memcached or redis.
cache_node_type The compute and memory capacity of the nodes in the cache cluster. cache.t1.micro, cache.m1.small, etc. See: https://boto.readthedocs.io/en/latest/ref/elasticache.html#boto.elasticache.layer1.ElastiCacheConnection.create_cache_cluster
num_cache_nodes The number of cache nodes that the cache cluster will have.
preferred_availability_zone The EC2 Availability Zone in which the cache cluster will be created. All cache nodes belonging to a cache cluster are placed in the preferred availability zone.
port The port number on which each of the cache nodes will accept connections.
cache_parameter_group_name The name of the cache parameter group to associate with this cache cluster. If this argument is omitted, the default cache parameter group for the specified engine will be used.
cache_security_group_names A list of cache security group names to associate with this cache cluster. Use this parameter only when you are creating a cluster outside of a VPC.
replication_group_id The replication group to which this cache cluster should belong. If this parameter is specified, the cache cluster will be added to the specified replication group as a read replica; otherwise, the cache cluster will be a standalone primary that is not part of any replication group.
auto_minor_version_upgrade Determines whether minor engine upgrades will be applied automatically to the cache cluster during the maintenance window. A value of True allows these upgrades to occur; False disables automatic upgrades.
security_group_ids One or more VPC security groups associated with the cache cluster. Use this parameter only when you are creating a cluster in a VPC.
cache_subnet_group_name The name of the cache subnet group to be used for the cache cluster. Use this parameter only when you are creating a cluster in a VPC.
engine_version The version number of the cache engine to be used for this cluster.
notification_topic_arn The Amazon Resource Name (ARN) of the Amazon Simple Notification Service (SNS) topic to which notifications will be sent. The Amazon SNS topic owner must be the same as the cache cluster owner.
prefereed_maintenance_window The weekly time range (in UTC) during which system maintenance can
occur. Example: sun:05:00-sun:09:00
wait Boolean. Wait for confirmation from boto that the cluster is in the available state.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_elasticache.replication_group_absent(name, tags=\None, region=\None, key=\None, keyid=\None, profile=\None)
salt.states.boto_elasticache.replication_group_present(*args, **kwargs)
salt.states.boto_elasticache.subnet_group_absent(name, tags=\None, region=\None, key=\None, keyid=\None, profile=\None)
salt.states.boto_elasticache.subnet_group_present(name, subnet_ids=\None, subnet_names=\None, description=\None, tags=\None, region=\None, key=\None, keyid=\None, profile=\None)

Ensure ElastiCache subnet group exists.

New in version 2015.8.0.
name The name for the ElastiCache subnet group. This value is stored as a lowercase string.
 subnet_ids A list of VPC subnet IDs for the cache subnet group. Exclusive with subnet_names.
 subnet_names A list of VPC subnet names for the cache subnet group. Exclusive with subnet_ids.
 description Subnet group description.
 tags A list of tags.
 region Region to connect to.
 key Secret key to be used.
 keyid Access key to be used.
 profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

19.19.30 salt.states.boto_elasticsearch_domain module

Manage Elasticsearch Domains

New in version 2016.11.0.
Create and destroy Elasticsearch domains. Be aware that this interacts with Amazon’s services, and so may incur charges.

This module uses boto3, which can be installed via package, or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:

| vpc.keyid: GKTADJGHEIQSXMKKRBJ08H |
| vpc.key: askdjghsdfjkgwupUjasdfsflkdfklgjsdfajkghs |

It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:
myprofile:
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkgwupUjasdfklkgjsdfjajkghs
  - region: us-east-1

Ensure domain exists:
```
boto_elasticsearch_domain.present:
  - DomainName: mydomain
  - profile='user-credentials'
  - ElasticsearchVersion: "2.3"
  - ElasticsearchClusterConfig:
    InstanceType": "t2.micro.elasticsearch"
    InstanceCount: 1
    DedicatedMasterEnabled: False
    ZoneAwarenessEnabled: False
  - EBSOptions:
    EBSEnabled: True
    VolumeType: "gp2"
    VolumeSize: 10
    Iops: 0
  - AccessPolicies:
    Version: "2012-10-17"
    Statement:
      - Effect: "Allow"
        Principal:
          AWS: "*"
        Action: 
          "es:*"
        Condition:
          IpAddress:
            "aws:SourceIp":
              "127.0.0.1"
              "127.0.0.2"
    - SnapshotOptions:
      AutomatedSnapshotStartHour: 0
    - AdvancedOptions:
      rest.action.multi.allow_explicit_index": "true"
  - Tags:
    a: "b"
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkgwupUjasdfklkgjsdfjajkghs
```

salt.states.boto_elasticsearch_domain.absent(name, DomainName, region=None, key=None, keyid=None, profile=None)

Ensure domain with passed properties is absent.

name  The name of the state definition.
DomainName  Name of the domain.
region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_elasticsearch_domain.present(name, DomainName, ElasticsearchClusterConfig=None, EBSOptions=None, AccessPolicies=None, SnapshotOptions=None, AdvancedOptions=None, Tags=None, AdvancedOptions=None, Tags=None, region=None, key=None, keyid=None, profile=None, ElasticsearchVersion='1.5')

Ensure domain exists.
name The name of the state definition
DomainName Name of the domain.
ElasticsearchClusterConfig Configuration options for an Elasticsearch domain. Specifies the instance type and number of instances in the domain cluster.
    InstanceType (string) -- The instance type for an Elasticsearch cluster.
    InstanceCount (integer) -- The number of instances in the specified domain cluster.
    DedicatedMasterEnabled (boolean) -- A boolean value to indicate whether a dedicated master node is enabled. See About Dedicated Master Nodes for more information.
    ZoneAwarenessEnabled (boolean) -- A boolean value to indicate whether zone awareness is enabled. See About Zone Awareness for more information.
    DedicatedMasterType (string) -- The instance type for a dedicated master node.
    DedicatedMasterCount (integer) -- Total number of dedicated master nodes, active and on standby, for the cluster.
EBSOptions Options to enable, disable and specify the type and size of EBS storage volumes.
    EBSEnabled (boolean) -- Specifies whether EBS-based storage is enabled.
    VolumeType (string) -- Specifies the volume type for EBS-based storage.
    VolumeSize (integer) -- Integer to specify the size of an EBS volume.
    Iops (integer) -- Specifies the IOPD for a Provisioned IOPS EBS volume (SSD).
AccessPolicies IAM access policy
SnapshotOptions Option to set time, in UTC format, of the daily automated snapshot. Default value is 0 hours.
    AutomatedSnapshotStartHour (integer) -- Specifies the time, in UTC format, when the service takes a daily automated snapshot of the specified Elasticsearch domain. Default value is 0 hours.
AdvancedOptions Option to allow references to indices in an HTTP request body. Must be false when configuring access to individual sub-resources. By default, the value is true.
    region Region to connect to.
    key Secret key to be used.
    keyid Access key to be used.
    profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
    ElasticsearchVersion String of format XY to specify version for the Elasticsearch domain eg. `1.5` or `2.3`.

19.19.31 salt.states.boto_elb

Manage ELBs
New in version 2014.7.0.
Create and destroy ELBs. Be aware that this interacts with Amazon’s services, and so may incur charges.
This module uses boto, which can be installed via package, or pip.
This module accepts explicit elb credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
elb.keyid: GKTADJGHEIQSXMKKRBJ08H
elb.key: askdjghsdfjkgHwupUjasdfklkdfkglgsdfjakghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgHwupUjasdfklkdfkglgsdfjakghs
  region: us-east-1
```

Ensure myelb ELB exists:

```yaml
boto_elb.present:
  - name: myelb
  - region: us-east-1
  - availability_zones:
    - us-east-1a
    - us-east-1c
    - us-east-1d
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkgHwupUjasdfklkdfkglgsdfjakghs
  - listeners:
    - elb_port: 443
      instance_port: 80
      elb_protocol: HTTPS
      instance_protocol: HTTP
      certificate: 'arn:aws:iam::11111111:server-certificate/mycert'
      policies:
        - my-ssl-policy
        - cookie-policy
    - elb_port: 8210
      instance_port: 8210
      elb_protocol: TCP
  - backends:
    - instance_port: 80
      policies:
        - enable-proxy-protocol
  - health_check:
    - target: 'HTTP:80/'
  - attributes:
    - cross_zone_load_balancing:
      enabled: true
    - access_log:
      enabled: true
    - s3_bucket_name: 'mybucket'
    - s3_bucket_prefix: 'my-logs'
    - emit_interval: 5
    - connecting_settings:
      idle_timeout: 60
  - cnames:
    - name: mycname.example.com.
    - zone: example.com.
```
```
ttl: 60
  - name: myothercname.example.com.
    zone: example.com.
  - security_groups:
    - my-security-group
  - policies:
    - policy_name: my-ssl-policy
      policy_type: SSLNegotiationPolicyType
      policy:
        Protocol-TLSv1.2: true
        Protocol-SSLv3: false
        Server-Defined-Cipher-Order: true
        ECDHE-ECDSA-AES128-GCM-SHA256: true
    - policy_name: cookie-policy
      policy_type: LBCookieStickinessPolicyType
      policy: {}
    - policy_name: enable-proxy-protocol
      policy_type: ProxyProtocolPolicyType
      policy:
        ProxyProtocol: true

# Using a profile from pillars
Ensure myelb ELB exists:
  boto_elb.present:
    - name: myelb
    - region: us-east-1
    - profile: myelbprofile

# Passing in a profile
Ensure myelb ELB exists:
  boto_elb.present:
    - name: myelb
    - region: us-east-1
    - profile:
      keyid: GKTADJGHEIQSXMKKRBJ08H
      key: askdjghsdfjkgWupUjasdflkdflgjsdfjajkghs
```

It's possible to specify attributes from pillars by specifying a pillar. You can override the values defined in the pillar by setting the attributes on the resource. The module will use the default pillar key `boto_elb_attributes', which allows you to set default attributes for all ELB resources.

Setting the attributes pillar:
```
my_elb_attributes:
  cross_zone_load_balancing:
    enabled: true
  connection_draining:
    enabled: true
  timeout: 20
  access_log:
    enabled: true
  s3_bucket_name: 'mybucket'
  s3_bucket_prefix: 'my-logs'
  emit_interval: 5
```

Overriding the attribute values on the resource:
Ensure myelb ELB exists:
```yaml
boto_elb.present:
  - name: myelb
  - region: us-east-1
  - attributes_from_pillar: my_elb_attributes
    # override cross_zone_load_balancing:enabled
  - attributes:
      cross_zone_load_balancing:
        enabled: false
  - profile: myelbprofile
```

It's possible to specify cloudwatch alarms that will be setup along with the ELB. Note the alarm name will be defined by the name attribute provided, plus the ELB resource name.

Ensure myelb ELB exists:
```yaml
boto_elb.present:
  - name: myelb
  - region: us-east-1
  - profile: myelbprofile
  - alarms:
    UnHealthyHostCount:
      name: 'ELB UnHealthyHostCount **MANAGED BY SALT**'
      attributes:
        metric: UnHealthyHostCount
        namespace: AWS/ELB
        statistic: Average
        comparison: '>='
        threshold: 1.0
        period: 600
        evaluation_periods: 6
        unit: null
        description: ELB UnHealthyHostCount
        insufficient_data_actions: []
        ok_actions: ['arn:aws:sns:us-east-1:12345:myalarm']
```

You can also use alarms from pillars, and override values from the pillar alarms by setting overrides on the resource. Note that `'boto_elb_alarms'` will be used as a default value for all resources, if defined and can be used to ensure alarms are always set for a resource.

Setting the alarms in a pillar:

```yaml
my_elb_alarm:
  UnHealthyHostCount:
    name: 'ELB UnHealthyHostCount **MANAGED BY SALT**'
    attributes:
      metric: UnHealthyHostCount
      namespace: AWS/ELB
      statistic: Average
      comparison: '>='
      threshold: 1.0
      period: 600
      evaluation_periods: 6
      unit: null
      description: ELB UnHealthyHostCount
      insufficient_data_actions: []
      ok_actions: ['arn:aws:sns:us-east-1:12345:myalarm']
```

---

19.19. state modules
Overriding the alarm values on the resource:

```python
Ensure myelb ELB exists:
boto_elb.present:
    - name: myelb
    - region: us-east-1
    - profile: myelbprofile
    - alarms_from_pillar: my_elb_alarm
    # override UnHealthyHostCount:attributes:threshold
    - alarms:
        UnHealthyHostCount:
            attributes:
                threshold: 2.0
```

Tags can also be set:

New in version 2016.3.0.

```python
Ensure myelb ELB exists:
boto_elb.present:
    - name: myelb
    - region: us-east-1
    - profile: myelbprofile
    - tags:
        MyTag: 'My Tag Value'
        OtherTag: 'My Other Value'
```

`salt.states.boto_elb.absent(name, region=None, key=None, keyid=None, profile=None)`

Ensure an ELB does not exist

- name name of the ELB

`salt.states.boto_elb.present(name, listeners, availability_zones=None, subnets=None, subnet_names=None, security_groups=None, scheme='internet-facing', health_check=None, attributes=None, attributes_from_pillar='boto_elb_attributes', cnames=None, alarms=None, alarms_from_pillar='boto_elb_alarms', policies=None, policies_from_pillar='boto_elb_policies', backends=None, region=None, key=None, keyid=None, profile=None, wait_for_sync=True, tags=None, instance_ids=None, instance_names=None)`

Ensure the ELB exists.

- name Name of the ELB.
- availability_zones A list of availability zones for this ELB.
- listeners A list of listener lists; example:

```python
[
    ['443', 'HTTPS', 'arn:aws:iam::1111111:server-certificate/mycert'],
    ['8443', '80', 'HTTPS', 'HTTP', 'arn:aws:iam::1111111:server-certificate/...
```

- subnets A list of subnet IDs in your VPC to attach to your LoadBalancer.
- subnet_names A list of subnet names in your VPC to attach to your LoadBalancer.
- security_groups The security groups assigned to your LoadBalancer within your VPC. Must be passed either as a list or a comma-separated string.

For example, a list:
- security_groups:
  - secgroup-one
  - secgroup-two

Or as a comma-separated string:

- security_groups: secgroup-one,secgroup-two

scheme The type of a LoadBalancer, internet-facing or internal. Once set, can not be modified.

health_check A dict defining the health check for this ELB.

attributes A dict defining the attributes to set on this ELB. Unknown keys will be silently ignored.

See the salt.modules.boto_elb.set_attributes function for recognized attributes.

attributes_from_pillar name of pillar dict that contains attributes. Attributes defined for this specific state will override those from pillar.

cnames A list of cname dicts with attributes needed for the DNS add_record state. By default the boto_route53.add_record state will be used, which requires: name, zone, ttl, and identifier. See the boto_route53 state for information about these attributes. Other DNS modules can be called by specifying the provider keyword. the cnames dict will be passed to the state as kwargs.

See the salt.states.boto_route53 state for information about these attributes.

alarms: a dictionary of name->boto_cloudwatch_alarm sections to be associated with this ELB. All attributes should be specified except for dimension which will be automatically set to this ELB.

See the salt.states.boto_cloudwatch_alarm state for information about these attributes.

alarms_from_pillar: name of pillar dict that contains alarm settings. Alarms defined for this specific state will override those from pillar.

region Region to connect to.

dregion Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

wait_for_sync Wait for an INSYNC change status from Route53.

tags dict of tags

instance_ids list of instance ids. The state will ensure that these, and ONLY these, instances are registered with the ELB. This is additive with instance_names.

instance_names list of instance names. The state will ensure that these, and ONLY these, instances are registered with the ELB. This is additive with instance_ids.

salt.states.boto_elb.register_instances(name, instances, region=None, key=None, keyid=None, profile=None)

Add EC2 instance(s) to an Elastic Load Balancer. Removing an instance from the instances list does not remove it from the ELB.

name The name of the Elastic Load Balancer to add EC2 instances to.

instances A list of EC2 instance IDs that this Elastic Load Balancer should distribute traffic to. This state will only ever append new instances to the ELB. EC2 instances already associated with this ELB will not be removed if they are not in the instances list.

New in version 2015.8.0.
19.19.32 salt.states.boto_elbv2 module

Manage AWS Application Load Balancer

New in version 2017.7.0.

Add and remove targets from an ALB target group.

This module uses boto3, which can be installed via package, or pip.

This module accepts explicit alb credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:

```
elbv2.keyid: GKTADJGHEIQSXMKKRBJ08H
elbv2.key: askdjghsdfjkgHwupUjasdfklgjklgsdfjajgks
elbv2.region: us-west-2
```

It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkgHwupUjasdfklgjklgsdfjajgks
    region: us-east-1
```

**salt.states.boto_elbv2.targets_deregistered**

Remove targets to an Application Load Balancer target group.

- **name** The ARN of the Application Load Balancer Target Group to remove targets from.
- **targets** A list of target IDs or a string of a single target registered to the target group to be removed

New in version Unknown.

```
remove-targets:
    boto_elb.targets_deregistered:
        - name: arn:myloadbalancer
        - targets:
            - instance-id1
            - instance-id2
```

**salt.states.boto_elbv2.targets_registered**

Add targets to an Application Load Balancer target group. This state will not remove targets.

- **name** The ARN of the Application Load Balancer Target Group to add targets to.
- **targets** A list of target IDs or a string of a single target that this target group should distribute traffic to.

New in version 2017.7.0.

```
add-targets:
    boto_elb.targets_registered:
        - name: arn:myloadbalancer
        - targets:
            - instance-id1
            - instance-id2
```
19.19.33 salt.states.boto_iam

Manage IAM objects

New in version 2015.8.0.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit IAM credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
delete-user:
    boto_iam.user_absent:
        - name: myuser
        - delete_keys: true

delete-keys:
    boto_iam.keys_absent:
        - access_keys:
            - 'AKIAJHTMIQ2ASDFLASDF'
            - 'PQIAJHTMIQ2ASRTLASFR'
        - user_name: myuser

create-user:
    boto_iam.user_present:
        - name: myuser
        - policies:
            mypolicy: |
                
            "Version": "2012-10-17",
            "Statement": [[
                "Effect": "Allow",
                "Action": "*",
                "Resource": "*"
            ]]
        - password: NewPassword$$1
        - region: eu-west-1
        - keyid: 'AKIAJHTMIQ2ASDFLASDF'
        - key: 'fdkjjsafkljsASSADFalkfjasdf'

create-group:
    boto_iam.group_present:
        - name: mygroup
        - users:
            - myuser
            - myuser1
        - policies:
            mypolicy: |
                
            "Version": "2012-10-17",
            "Statement": [[
                "Effect": "Allow",
                "Action": "*",
                "Resource": "*"
            ]]
```
change-policy:
  boto_iam.account_policy:
    - change_password: True
    - region: eu-west-1
    - keyid: 'AKIAJHTMIQ2ASDFLASDF'
    - key: 'safsdfsas;fdkjsafkljsASSADFalkfj'

create server certificate:
  boto_iam.server_cert_present:
    - name: mycert
    - public_key: salt://base/mycert.crt
    - private_key: salt://base/mycert.key
    - cert_chain: salt://base/mycert_chain.crt
    - region: eu-west-1
    - keyid: 'AKIAJHTMIQ2ASDFLASDF'
    - key: 'fdkjsafkljsASSADFalkfjasdf'

delete server certificate:
  boto_iam.server_cert_absent:
    - name: mycert

create keys for user:
  boto_iam.keys_present:
    - name: myusername
    - number: 2
    - save_dir: /root
    - region: eu-west-1
    - keyid: 'AKIAJHTMIQ2ASDFLASDF'
    - key: 'fdkjsafkljsASSADFalkfjasdf'

create policy:
  boto_iam.policy_present:
    - name: myname
    - region: eu-west-1
    - keyid: 'AKIAJHTMIQ2ASDFLASDF'
    - key: 'fdkjsafkljsASSADFalkfjasdf'

add-saml-provider:
  boto_iam.saml_provider_present:
    - name: my_saml_provider
    - saml_metadata_document: salt://base/files/provider.xml
    - keyid: 'AKIAJHTMIQ2ASDFLASDF'
    - key: 'safsdfsas;fdkjsafkljsASSADFalkfj'
salt.states.boto_iam.account_policy(name=None, allow_users_to_change_password=None, hard_expiry=None, max_password_age=None, minimum_password_length=None, password_reuse_prevention=None, require_lowercase_characters=None, require_numbers=None, require_symbols=None, require_uppercase_characters=None, region=None, key=None, keyid=None, profile=None)

Change account policy.

New in version 2015.8.0.

name (string) The name of the account policy
allow_users_to_change_password (bool) Allows all IAM users in your account to use the AWS Management Console to change their own passwords.
hard_expiry (bool) Prevents IAM users from setting a new password after their password has expired.
max_password_age (int) The number of days that an IAM user password is valid.
minimum_password_length (int) The minimum number of characters allowed in an IAM user password.
password_reuse_prevention (int) Specifies the number of previous passwords that IAM users are prevented from reusing.
require_lowercase_characters (bool) Specifies whether IAM user passwords must contain at least one lowercase character from the ISO basic Latin alphabet (a to z).
require_numbers (bool) Specifies whether IAM user passwords must contain at least one numeric character (0 to 9).
require_symbols (bool) Specifies whether IAM user passwords must contain at least one of the following non-alphanumeric characters: ! @ # $ % ^ & * ( ) _ + - = [ ] { } | `
require_uppercase_characters (bool) Specifies whether IAM user passwords must contain at least one uppercase character from the ISO basic Latin alphabet (A to Z).
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string)

salt.states.boto_iam.group_absent(name, region=None, key=None, keyid=None, profile=None)

New in version 2015.8.0.

Ensure the IAM group is absent.

name (string) The name of the group.
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string)

salt.states.boto_iam.group_present(name, policies=None, policies_from_pillars=None, managed_policies=None, users=None, path='/', region=None, key=None, keyid=None, profile=None, delete_policies=True)

New in version 2015.8.0.

Ensure the IAM group is present

name (string) The name of the new group.
path (string) The path for the group, defaults to `/`
policies (dict) A dict of IAM group policy documents.
policies_from_pillars (list) A list of pillars that contain role policy dicts. Policies in the pillars will be merged in the order defined in the list and key conflicts will be handled by later defined keys overriding earlier defined keys. The policies defined here will be merged with the policies defined in the policies argument. If keys conflict, the keys in the policies argument will override the keys defined in policies_from_pillars.
managed_policies (list) A list of policy names or ARNs that should be attached to this group.
users (list) A list of users to be added to the group.
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key
and keyid.
delete_policies (boolean) Delete or detach existing policies that are not in the given list of policies. Default value is True. If False is specified, existing policies will not be deleted or detached allowing manual modifications on the IAM group to be persistent.

salt.states.boto_iam.keys_absent(access_keys, user_name, region=None, key=None, keyid=None, profile=None)

New in version 2015.8.0.
Ensure the IAM user access_key_id is absent.
access_key_id (list) A list of access key ids
user_name (string) The username of the user
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key
and keyid.

salt.states.boto_iam.keys_present(name, number, save_dir, region=None, key=None, keyid=None, profile=None, save_format='{2}
{0}
{3}
{1}
')

New in version 2015.8.0.
Ensure the IAM access keys are present.
name (string) The name of the new user.
number (int) Number of keys that user should have.
save_dir (string) The directory that the key/keys will be saved. Keys are saved to a file named according to the username privided.
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key
and keyid.
save_format (dict) Save format is repeated for each key. Default format is `''{2}|n{0}|n{3}|n{1}|n''` where {0} and
{1} are placeholders for new key_id and key respectively, whereas {2} and {3} are `''key_id-{number}''` and
`'key-{number}'` strings kept for compatibility.

salt.states.boto_iam.policy_absent(name, region=None, key=None, keyid=None, profile=None)

New in version 2015.8.0.
Ensure the IAM managed policy with the specified name is absent
name (string) The name of the new policy.
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key
and keyid.

salt.states.boto_iam.policy_present(name, policy_document, path=None, description=None, region=None, key=None, keyid=None, profile=None)

New in version 2015.8.0.
Ensure the IAM managed policy is present

name (string) The name of the new policy.

policy_document (dict) The document of the new policy

path (string) The path in which the policy will be created. Default is `/`

description (string) Description

region (string) Region to connect to.

key (string) Secret key to be used.

keyid (string) Access key to be used.

profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iam.saml_provider_absent(name, region=None, key=None, keyid=None, profile=None)

New in version 2016.11.0.

Ensure the SAML provider with the specified name is absent.

name (string) The name of the SAML provider.

saml_metadata_document (string) The xml document of the SAML provider.

region (string) Region to connect to.

key (string) Secret key to be used.

keyid (string) Access key to be used.

profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iam.saml_provider_present(name, saml_metadata_document, region=None, key=None, keyid=None, profile=None)

New in version 2016.11.0.

Ensure the SAML provider with the specified name is present.

name (string) The name of the SAML provider.

saml_metadata_document (string) The xml document of the SAML provider.

region (string) Region to connect to.

key (string) Secret key to be used.

keyid (string) Access key to be used.

profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iam.server_cert_absent(name, region=None, key=None, keyid=None, profile=None)

Deletes a server certificate.

New in version 2015.8.0.

name (string) The name for the server certificate. Do not include the path in this value.

region (string) The name of the region to connect to.

key (string) The key to be used in order to connect

keyid (string) The keyid to be used in order to connect

profile (string) The profile that contains a dict of region, key, keyid

salt.states.boto_iam.server_cert_present(name, public_key, private_key, cert_chain=None, path=None, region=None, key=None, keyid=None, profile=None)

Create server certificate.

New in version 2015.8.0.

name (string) The name for the server certificate. Do not include the path in this value.

public_key (string) The contents of the public key certificate in PEM-encoded format.

private_key (string) The contents of the private key in PEM-encoded format.
cert_chain (string) The contents of the certificate chain. This is typically a concatenation of the PEM-encoded public key certificates of the chain.
path (string) The path for the server certificate.
region (string) The name of the region to connect to.
key (string) The key to be used in order to connect
keyid (string) The keyid to be used in order to connect
profile (string) The profile that contains a dict of region, key, keyid

salt.states.boto_iam.user_absent(name, delete_keys=True, delete_mfa_devices=True, delete_profile=True, region=None, key=None, keyid=None, profile=None)

New in version 2015.8.0.
Ensure the IAM user is absent. User cannot be deleted if it has keys.
name (string) The name of the new user.
delete_keys (bool) Delete all keys from user.
delete_mfa_devices (bool) Delete all mfa devices from user.

delete_profile (bool) Delete profile from user.

New in version 2016.3.0.
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iam.user_present(name, policies=None, policies_from_pillars=None, managed_policies=None, password=None, path=None, region=None, key=None, keyid=None, profile=None)

New in version 2015.8.0.
Ensure the IAM user is present
name (string) The name of the new user.
policies (dict) A dict of IAM group policy documents.
policies_from_pillars (list) A list of pillars that contain role policy dicts. Policies in the pillars will be merged in the order defined in the list and key conflicts will be handled by later defined keys overriding earlier defined keys. The policies defined here will be merged with the policies defined in the policies argument. If keys conflict, the keys in the policies argument will override the keys defined in policies_from_pillars.
managed_policies (list) A list of managed policy names or ARNs that should be attached to this user.
password (string) The password for the new user. Must comply with account policy.
path (string) The path of the user. Default is `/'.

New in version 2015.8.2.
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

19.19.34 salt.states.boto_iam_role

Manage IAM roles

New in version 2014.7.0.
This module uses boto, which can be installed via package, or pip.

This module accepts explicit IAM credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:

```
iam.keyid: GKTADJGHEIQSXMKKRBJ08H
iam.key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
```

It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
  region: us-east-1
```

Creating a role will automatically create an instance profile and associate it with the role. This is the default behavior of the AWS console.

```
myrole:
  boto_iam_role.present:
    - region: us-east-1
    - key: GKTADJGHEIQSXMKKRBJ08H
    - keyid: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
    - policies_from_pillars:
        - shared_iam_bootstrap_policy
    - policies:
        MySQSPolicy:
          Statement:
            - Action:
              - sqs:*
            Effect: Allow
            Resource:
              - arn:aws:sqs:*:*
            Sid: MyPolicySQS1
        MyS3Policy:
          Statement:
            - Action:
              - s3:GetObject
            Effect: Allow
            Resource:
              - arn:aws:s3:*:mybucket/*

# Using a credentials profile from pillars
myrole:
  boto_iam_role.present:
    - profile: myiamprofile

# Passing in a credentials profile
myrole:
  boto_iam_role.present:
    - profile:
        key: GKTADJGHEIQSXMKKRBJ08H
        keyid: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
        region: us-east-1
```
If `delete_policies`: False is specified, existing policies that are not in the given list of policies will not be deleted. This allows manual modifications on the IAM role to be persistent. This functionality was added in 2015.8.0.

---

**Note:** When using the profile parameter and region is set outside of the profile group, region is ignored and a default region will be used.

If region is missing from the profile data set, us-east-1 will be used as the default region.

---

```python
salt.states.boto_iam_role.absent(name, region=None, key=None, keyid=None, profile=None)

Ensure the IAM role is deleted.

name  Name of the IAM role.
region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
```

```python
salt.states.boto_iam_role.present(
    name, 
    policy_document=None, policy_document_from_pillars=None, 
    path=None, 
    policies=None, policies_from_pillars=None, managed_policies=None, 
    create_instance_profile=True, region=None, key=None, keyid=None, profile=None, delete_policies=True)

Ensure the IAM role exists.

name  Name of the IAM role.
policy_document  The policy that grants an entity permission to assume the role. (See https://boto.readthedocs.io/en/latest/ref/iam.html#boto.iam.connection.IAMConnection.create_role)
policy_document_from_pillars  A pillar key that contains a role policy document. The statements defined here will be appended with the policy document statements defined in the policy_document argument.

New in version 2017.7.0.
policy_document_from_pillars  A pillar key that contains a role policy document. The statements defined here will be appended with the policy document statements defined in the policy_document argument.
path  The path to the role/instance profile. (See https://boto.readthedocs.io/en/latest/ref/iam.html#boto.iam.connection.IAMConnection.create_role)
policies  A dict of IAM role policies.
policies_from_pillars  A list of pillars that contain role policy dicts. Policies in the pillars will be merged in the order defined in the list and key conflicts will be handled by later defined keys overriding earlier defined keys. The policies defined here will be merged with the policies defined in the policies argument. If keys conflict, the keys in the policies argument will override the keys defined in policies_from_pillars.
managed_policies  A list of (AWS or Customer) managed policies to be attached to the role.
create_instance_profile  A boolean of whether or not to create an instance profile and associate it with this role.
region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
delete_policies  Deletes existing policies that are not in the given list of policies. Default value is True. If False is specified, existing policies will not be deleted allowing manual modifications on the IAM role to be persistent.

New in version 2015.8.0.
```
19.19.35 salt.states.boto_iot module

Manage IoT Objects

New in version 2016.3.0.

Create and destroy IoT objects. Be aware that this interacts with Amazon's services, and so may incur charges.

depends
  • boto
  • boto3

The dependencies listed above can be installed via package or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure policy exists:

```
boto_iot.policy_present:
  - policyName: mypolicy
  - policyDocument:
    - Version: "2012-10-17"
    Statement:
      - Action:
        - iot:Publish
      - Resource:
        - "*"
      Effect: "Allow"
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

Ensure topic rule exists:

```
boto_iot.topic_rule_present:
  - ruleName: myrule
  - sql: "SELECT * FROM 'iot/test'"
  - description: 'test rule'
  - ruleDisabled: false
  - actions:
    - lambda:
      - functionArn: "arn:aws:us-east-1:1234:function/functionname"
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```
salt.states.boto_iot.policy_absent(  
    name,  
    policyName,  
    region=None,  
    key=None,  
    keyid=None,  
    profile=None  
)

Ensure policy with passed properties is absent.

- **name** The name of the state definition.
- **policyName** Name of the policy.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iot.policy_attached(  
    name,  
    policyName,  
    principal,  
    region=None,  
    key=None,  
    keyid=None,  
    profile=None  
)

Ensure policy is attached to the given principal.

- **name** The name of the state definition
- **policyName** Name of the policy.
- **principal** The principal which can be a certificate ARN or a Cognito ID.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iot.policy_detached(  
    name,  
    policyName,  
    principal,  
    region=None,  
    key=None,  
    keyid=None,  
    profile=None  
)

Ensure policy is detached from the given principal.

- **name** The name of the state definition.
- **policyName** Name of the policy.
- **principal** The principal which can be a certificate ARN or a Cognito ID.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iot.policy_present(  
    name,  
    policyName,  
    policyDocument,  
    region=None,  
    key=None,  
    keyid=None,  
    profile=None  
)

Ensure policy exists.

- **name** The name of the state definition.
- **policyName** Name of the policy.
- **policyDocument** The JSON document that describes the policy. The length of the policyDocument must be a minimum length of 1, with a maximum length of 2048, excluding whitespace.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iot.thing_type_absent(  
    name,  
    thingTypeName,  
    region=None,  
    key=None,  
    keyid=None,  
    profile=None  
)

Ensure thing type with passed properties is absent.

New in version 2016.11.0.

- **name** The name of the state definition.
- **thingTypeName** Name of the thing type.
- **region** Region to connect to.
- **key** Secret key to be used.
keyid  Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_iot.thing_type_present(name, thingTypeName, thingTypeDescription, searchableAttributesList, region=None, key=None, keyid=None, profile=None)

Ensure thing type exists.
New in version 2016.11.0.
name  The name of the state definition
thingTypeName  Name of the thing type
thingTypeDescription  Description of the thing type
searchableAttributesList  List of string attributes that are searchable for the thing type
region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used
profile A dict with region, key, keyid, or a pillar key (string) that contains a dict with region, key, and keyid

salt.states.boto_iot.topic_rule_absent(name, ruleName, region=None, key=None, keyid=None, profile=None)

Ensure topic rule with passed properties is absent.
name  The name of the state definition.
ruleName  Name of the policy.
region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_iot.topic_rule_present(name, ruleName, sql, actions, description='', ruleDisabled=False, region=None, key=None, keyid=None, profile=None)

Ensure topic rule exists.
name  The name of the state definition
ruleName  Name of the rule.
sql  The SQL statement used to query the topic.
actions  The actions associated with the rule.
description  The description of the rule.
ruleDisabled  Specifies whether the rule is disabled.
region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

19.19.36  salt.states.boto_kinesis module

Manage Kinesis Streams

New in version 2017.7.0.
Create and destroy Kinesis streams. Be aware that this interacts with Amazon's services, and so may incur charges.
This module uses boto3, which can be installed via package, or pip.
This module accepts explicit Kinesis credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
keyid: GKTADJGHEIQSXMKKRBJ08H
key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
region: us-east-1
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
  region: us-east-1
```

Ensure Kinesis stream does not exist:

```yaml
boto_kinesis.absent:
  - name: new_stream
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
  - region: us-east-1
```

Ensure Kinesis stream exists:

```yaml
boto_kinesis.present:
  - name: new_stream
  - retention_hours: 168
  - enhanced_monitoring: ["ALL"]
  - num_shards: 2
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
  - region: us-east-1
```

salt.states.boto_kinesis.absent(name, region=None, key=None, keyid=None, profile=None)
Delete the kinesis stream, if it exists.
- **name** (string) Stream name
- **region** (string) Region to connect to.
- **key** (string) Secret key to be used.
- **keyid** (string) Access key to be used.
- **profile** (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_kinesis.present(name, retention_hours=None, enhanced_monitoring=None, num_shards=None, do_reshard=True, region=None, key=None, keyid=None, profile=None)
Ensure the kinesis stream is properly configured and scaled.
- **name** (string) Stream name
- **retention_hours** (int) Retain data for this many hours. AWS allows minimum 24 hours, maximum 168 hours.
- **enhanced_monitoring** (list of string) Turn on enhanced monitoring for the specified shard-level metrics. Pass in ['ALL'] or True for all metrics, [] or False for no metrics. Turn on individual metrics by passing in a list: ['IncomingBytes', 'OutgoingBytes'] Note that if only some metrics are supplied, the remaining metrics will be turned off.
- **num_shards** (int) Reshard stream (if necessary) to this number of shards ‼‼ Resharding is expensive! Each split or merge can take up to 30 seconds, and the reshard method balances the partition space evenly. Resharding from N to N+1 can require 2N operations. Resharding is much faster with powers of 2 (e.g.
Salt Documentation, Release 2017.7.8

[372x748]Salt Documentation, Release 2017.7.8

2^N to 2^N+1) ‼‼!
do_reshard (boolean) If set to False, this script will NEVER reshard the stream, regardless of other input.
Useful for testing.
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key
and keyid.

19.19.37 salt.states.boto_kms

Manage KMS keys, key policies and grants.
New in version 2015.8.0.
Be aware that this interacts with Amazon's services, and so may incur charges.
This module uses boto, which can be installed via package, or pip.
This module accepts explicit kms credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration
is necessary. More information available here.
If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
elb.keyid: GKTADJGHEIQSXMKKRBJ08H
elb.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure mykey key exists:
boto_kms.key_present:
  - name: mykey
    - region: us-east-1

# Using a profile from pillars
Ensure mykey key exists:
boto_kms.key_present:
  - name: mykey
    - region: us-east-1
    - profile: myprofile

# Passing in a profile
Ensure mykey key exists:
boto_key.key_present:
  - name: mykey
    - region: us-east-1
    - profile:
      keyid: GKTADJGHEIQSXMKKRBJ08H
      key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs

19.19. state modules
```
salt.states.boto_kms.key_present(name, policy, description=None, key_usage=None,
grants=None, manage_grants=False, key_rotation=False,
enabled=True, region=None, key=None, keyid=None, profile=None)
```

Ensure the KMS key exists. KMS keys can not be deleted, so this function must be used to ensure the key is enabled or disabled.

**Parameters**
- **name** Name of the key.
- **policy** Key usage policy.
- **description** Description of the key.
- **key_usage** Specifies the intended use of the key. Can only be set on creation, defaults to ENCRYPT_DECRYPT, which is also the only supported option.
- **grants** A list of grants to apply to the key. Not currently implemented.
- **manage_grants** Whether or not to manage grants. False by default, which will not manage any grants.
- **key_rotation** Whether or not key rotation is enabled for the key. False by default.
- **enabled** Whether or not the key is enabled. True by default.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 19.19.38 salt.states.boto_lambda module

**Manage Lambda Functions**

New in version 2016.3.0.

Create and destroy Lambda Functions. Be aware that this interacts with Amazon's services, and so may incur charges.

```
depends
- boto
- boto3
```

The dependencies listed above can be installed via package or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure function exists:
```
boto_lambda.function_present:
```
- **FunctionName**: myfunction
- **Runtime**: python2.7
- **Role**: iam_role_name
- **Handler**: entry_function
- **ZipFile**: code.zip
- **S3Bucket**: bucketname
- **S3Key**: keyname
- **S3ObjectVersion**: version
- **Description**: "My Lambda Function"
- **Timeout**: 3
- **MemorySize**: 128
- **region**: us-east-1
- **keyid**: GKTADJGHEIQSXMKKRBJ08H
- **key**: askdjghsdfjkgHwupUjasdfklkdfklgjdsfjajkgghs

salt.states.boto_lambda.alias_absent(name, FunctionName, Name, region=None, key=None, keyid=None, profile=None)

Ensure alias with passed properties is absent.

- **name** The name of the state definition.
- **FunctionName** Name of the function.
- **Name** Name of the alias.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_lambda.alias_present(name, FunctionName, Name, FunctionVersion, Description='', region=None, key=None, keyid=None, profile=None)

Ensure alias exists.

- **name** The name of the state definition.
- **FunctionName** Name of the function for which you want to create an alias.
- **Name** Name of the alias to be created.
- **FunctionVersion** Function version for which you are creating the alias.
- **Description** A short, user-defined function description. Lambda does not use this value. Assign a meaningful description as you see fit.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_lambda.event_source_mapping_absent(name, EventSourceArn, FunctionName, region=None, key=None, keyid=None, profile=None)

Ensure event source mapping with passed properties is absent.

- **name** The name of the state definition.
- **EventSourceArn** ARN of the event source.
- **FunctionName** Name of the lambda function.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
Ensure event source mapping exists.

name The name of the state definition.

EventSourceArn The Amazon Resource Name (ARN) of the Amazon Kinesis or the Amazon DynamoDB stream that is the event source.

FunctionName The Lambda function to invoke when AWS Lambda detects an event on the stream.

You can specify an unqualified function name (for example, `"Thumbnail"`) or you can specify Amazon Resource Name (ARN) of the function (for example, `"arn:aws:lambda:us-west-2:account-id:function:ThumbNail"`). AWS Lambda also allows you to specify only the account ID qualifier (for example, `"account-id:Thumbnail"`). Note that the length constraint applies only to the ARN. If you specify only the function name, it is limited to 64 character in length.

StartingPosition The position in the stream where AWS Lambda should start reading. (TRIM_HORIZON | LATEST)

Enabled Indicates whether AWS Lambda should begin polling the event source. By default, Enabled is true.

BatchSize The largest number of records that AWS Lambda will retrieve from your event source at the time of invoking your function. Your function receives an event with all the retrieved records. The default is 100 records.

region Region to connect to.

dkey Secret key to be used.

dkeyid Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

Ensure function with passed properties is absent.

name The name of the state definition.

FunctionName Name of the function.

region Region to connect to.

dkey Secret key to be used.

dkeyid Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

Ensure function exists.

name The name of the state definition

FunctionName Name of the Function.

Runtime The Runtime environment for the function. One of `nodejs`, `java8`, or `python2.7`.

Role The name or ARN of the IAM role that the function assumes when it executes your function to access any other AWS resources.

Handler The function within your code that Lambda calls to begin execution. For Node.js it is the module-name."export" value in your function. For Java, it can be package.classname:handler or package.classname.

ZipFile A path to a .zip file containing your deployment package. If this is specified, S3Bucket and S3Key
must not be specified.

**S3Bucket**  Amazon S3 bucket name where the .zip file containing your package is stored. If this is specified, **S3Key** must be specified and **ZipFile** must NOT be specified.

**S3Key**  The Amazon S3 object (the deployment package) key name you want to upload. If this is specified, **S3Key** must be specified and **ZipFile** must NOT be specified.

**S3ObjectVersion**  The version of S3 object to use. Optional, should only be specified if **S3Bucket** and **S3Key** are specified.

**Description**  A short, user-defined function description. Lambda does not use this value. Assign a meaningful description as you see fit.

**Timeout**  The function execution time at which Lambda should terminate this function. Because the execution time has cost implications, we recommend you set this value based on your expected execution time. The default is 3 seconds.

**MemorySize**  The amount of memory, in MB, your function is given. Lambda uses this memory size to infer the amount of CPU and memory allocated to your function. Your function use-case determines your CPU and memory requirements. For example, a database operation might need less memory compared to an image processing function. The default value is 128 MB. The value must be a multiple of 64 MB.

**VpcConfig**  If your Lambda function accesses resources in a VPC, you must provide this parameter identifying the list of security group IDs/Names and subnet IDs/Name. These must all belong to the same VPC. This is a dict of the form:

```
VpcConfig:
    SecurityGroupNames:
      - mysecgroup1
      - mysecgroup2
    SecurityGroupIds:
      - sg-abcdef1234
    SubnetNames:
      - mysubnet1
    SubnetIds:
      - subnet-1234abcd
      - subnet-abcd1234
```

If **VpcConfig** is provided at all, you MUST pass at least one security group and one subnet.

**Permissions**  A list of permission definitions to be added to the function’s policy

**RoleRetries**  IAM Roles may take some time to propagate to all regions once created. During that time function creation may fail; this state will automatically retry this number of times. The default is 5.

**Environment**  The parent object that contains your environment’s configuration settings. This is a dictionary of the form:

```
{
    'Variables': {
        'VariableName': 'VariableValue'
    }
}
```

New in version 2017.7.0.

**region**  Region to connect to.

**key**  Secret key to be used.

**keyid**  Access key to be used.

**profile**  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 19.19.39 salt.states.boto_lc

Manage Launch Configurations
New in version 2014.7.0.

Create and destroy Launch Configurations. Be aware that this interacts with Amazon's services, and so may incur charges.

A limitation of this module is that you cannot modify launch configurations once they have been created. If a launch configuration with the specified name exists, this module will always report success, even if the specified configuration doesn't match. This is due to a limitation in Amazon's launch configuration API, as it only allows launch configurations to be created and deleted.

Also note that a launch configuration that's in use by an autoscale group cannot be deleted until the autoscale group is no longer using it. This may affect the way in which you want to order your states.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit autoscale credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
asg.keyid: GKTADJGHEIQSXMKKRBJ08H
asg.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQXSXMKRBBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Credential information is shared with autoscale groups as launch configurations and autoscale groups are completely dependent on each other.

Ensure `mylc` exists:

```yaml
boto_lc.present:
  - name: mylc
    - image_id:ami-0b9c9f62
    - key_name: mykey
    - security_groups:
      - mygroup
    - instance_type: m1.small
    - instance_monitoring: true
    - block_device_mappings:
      - '/dev/sda1':
        size: 20
        volume_type: 'io1'
        iops: 220
        delete_on_termination: true
    - cloud_init:
      boothooks:
        'disable-master.sh': |
        #!/bin/bash
        echo "manual" > /etc/init/salt-master.override
      scripts:
        'run_salt.sh': |
        #!/bin/bash
        add-apt-repository -y ppa:saltstack/salt
```
apt-get update
apt-get install -y salt-minion
salt-call state.highstate
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs

# Using a profile from pillars.
Ensure mylc exists:
boto_lc.present:
  - name: mylc
  - image_id: ami-0b9c9f62
  - profile: myprofile

# Passing in a profile.
Ensure mylc exists:
boto_lc.present:
  - name: mylc
  - image_id: ami-0b9c9f62
  - profile:
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs
    - region: us-east-1

salt.states.boto_lc.absent(name, region=None, key=None, keyid=None, profile=None)
Ensure the named launch configuration is deleted.
  name  Name of the launch configuration.
  region The region to connect to.
  key  Secret key to be used.
  keyid Access key to be used.
  profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_lc.present(name, image_id, key_name=None, vpc_id=None, vpc_name=None, security_groups=None, user_data=None, cloud_init=None, instance_type='m1.small', kernel_id=None, ramdisk_id=None, block_device_mappings=None, delete_on_termination=None, instance_monitoring=False, spot_price=None, instance_profile_name=None, ebs_optimized=False, associate_public_ip_address=None, region=None, key=None, keyid=None, profile=None)
Ensure the launch configuration exists.
  name  Name of the launch configuration.
  image_id AMI to use for instances. AMI must exist or creation of the launch configuration will fail.
  key_name Name of the EC2 key pair to use for instances. Key must exist or creation of the launch configuration will fail.
  vpc_id The VPC id where the security groups are defined. Only necessary when using named security groups that exist outside of the default VPC. Mutually exclusive with vpc_name.
  vpc_name Name of the VPC where the security groups are defined. Only necessary when using named security groups that exist outside of the default VPC. Mutually exclusive with vpc_id.
  security_groups List of Names or security group id’s of the security groups with which to associate the EC2 instances or VPC instances, respectively. Security groups must exist, or creation of the launch configuration will fail.
  user_data The user data available to launched EC2 instances.
  cloud_init A dict of cloud_init configuration. Currently supported values: scripts, cloud-config. Mutually exclusive with user_data.
instance_type  The instance type. ex: m1.small.
kernel_id  The kernel id for the instance.
rondisk_id  The RAM disk ID for the instance.
block_device_mappings  A dict of block device mappings that contains a dict with volume_type, delete_on_termination, iops, size, encrypted, snapshot_id.

volume_type  Indicates what volume type to use. Valid values are standard, io1, gp2. Default is standard.

delete_on_termination  Whether the volume should be explicitly marked for deletion when its instance is terminated (True), or left around (False). If not provided, or None is explicitly passed, the default AWS behaviour is used, which is True for ROOT volumes of instances, and False for all others.
iops  For Provisioned IOPS (SSD) volumes only. The number of I/O operations per second (IOPS) to provision for the volume.
size  Desired volume size (in GiB).

encrypted  Indicates whether the volume should be encrypted. Encrypted EBS volumes must be attached to instances that support Amazon EBS encryption. Volumes that are created from encrypted snapshots are automatically encrypted. There is no way to create an encrypted volume from an unencrypted snapshot or an unencrypted volume from an encrypted snapshot.

instance_monitoring  Whether instances in group are launched with detailed monitoring.
spot_price  The spot price you are bidding. Only applies if you are building an autoscaling group with spot instances.
instance_profile_name  The name or the Amazon Resource Name (ARN) of the instance profile associated with the IAM role for the instance. Instance profile must exist or the creation of the launch configuration will fail.
ebs_optimized  Specifies whether the instance is optimized for EBS I/O (true) or not (false).
associate_public_ip_address  Used for Auto Scaling groups that launch instances into an Amazon Virtual Private Cloud. Specifies whether to assign a public IP address to each instance launched in a Amazon VPC.
region  The region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

19.19.40  salt.states.boto_rds

Manage RDSs

New in version 2015.8.0.

Create and destroy RDS instances. Be aware that this interacts with Amazon's services, and so may incur charges. This module uses boto, which can be installed via package, or pip.

This module accepts explicit rds credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```python
rds.keyid: GKTADJGHEIQSXMKKRBJ08H
rds.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:
Ensure myrds RDS exists:
```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1

Ensure myrds RDS exists:
```yaml
boto_rds.present:
  - name: myrds
  - allocated_storage: 5
  - storage_type: standard
  - db_instance_class: db.t2.micro
  - engine: MySQL
  - master_username: myuser
  - master_user_password: mypass
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjghWupUjasdflkdfklgjsdfjajkghs
  - tags:
    - key: value
```
Ensure parameter group exists:
```yaml
create-parameter-group:
  boto_rds.parameter_present:
    - name: myparametergroup
    - db_parameter_group_family: mysql5.6
    - description: "parameter group family"
    - parameters:
      - binlog_cache_size: 32768
      - binlog_checksum: CRC32
    - region: eu-west-1
```

```yaml
depends boto3
salt.states.boto_rds.absent(name, skip_final_snapshot=None, final_db_snapshot_identifier=None, tags=None, region=None, key=None, keyid=None, profile=None, wait_for_deletion=True, timeout=180)
```

Ensure RDS instance is absent.
```yaml
name Name of the RDS instance.
skip_final_snapshot Whether a final db snapshot is created before the instance is deleted. If True, no snapshot is created. If False, a snapshot is created before deleting the instance.
final_db_snapshot_identifier If a final snapshot is requested, this is the identifier used for that snapshot.
tags A dict of tags.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
wait_for_deletion (bool) Wait for the RDS instance to be deleted completely before finishing the state.
timeout (in seconds) The amount of time that can pass before raising an Exception.
```
```
```
```yaml
salt.states.boto_rds.parameter_present(name, db_parameter_group_family, description, parameters=None, apply_method='pending-reboot', tags=None, region=None, key=None, keyid=None, profile=None)
```

Ensure DB parameter group exists and update parameters.
name The name for the parameter group.
db_parameter_group_family The DB parameter group family name. A DB parameter group can be associated with one and only one DB parameter group family, and can be applied only to a DB instance running a database engine and engine version compatible with that DB parameter group family.
description Parameter group description.
parameters The DB parameters that need to be changed of type dictionary.
apply_method The *apply-immediate* method can be used only for dynamic parameters; the *pending-reboot* method can be used with MySQL and Oracle DB instances for either dynamic or static parameters. For Microsoft SQL Server DB instances, the *pending-reboot* method can be used only for static parameters.
tags A dict of tags.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_rds.present(name, allocated_storage, db_instance_class, engine, master_username, master_user_password, db_name=None, storage_type=None, db_security_groups=None, vpc_security_group_ids=None, availability_zone=None, db_subnet_group_name=None, preferred_maintenance_window=None, db_parameter_group_name=None, db_cluster_identifier=None, tde_credential_arn=None, tde_credential_password=None, storage_encrypted=None, kms_keyid=None, backup_retention_period=None, preferred_backup_window=None, port=None, multi_az=None, engine_version=None, auto_minor_version_upgrade=None, license_model=None, iops=None, option_group_name=None, character_set_name=None, publicly_accessible=None, wait_status=None, tags=None, copy_tags_to_snapshot=None, region=None, domain=None, key=None, keyid=None, monitoring_interval=None, monitoring_role_arn=None, domain_iam_role_name=None, promotion tier=None, profile=None)

Ensure RDS instance exists.

name Name of the RDS state definition.
allocated_storage The amount of storage (in gigabytes) to be initially allocated for the database instance.
db_instance_class The compute and memory capacity of the Amazon RDS DB instance.
engine The name of the database engine to be used for this instance. Supported engine types are: MySQL, mariadb, oracle-se1, oracle-se, oracle-ee, sqlserver-ee, sqlserver-se, sqlserver-ex, sqlserver-web, postgres and aurora. For more information, please see the `engine` argument in the Boto3 RDS create_db_instance documentation.
master_username The name of master user for the client DB instance.
master_user_password The password for the master database user. Can be any printable ASCII character except `\'/`, `"`, or `"@`.
db_name The meaning of this parameter differs according to the database engine you use. See the Boto3 RDS documentation to determine the appropriate value for your configuration. [https://boto3.readthedocs.io/en/latest/reference/services/rds.html#RDS.Client.create_db_instance](https://boto3.readthedocs.io/en/latest/reference/services/rds.html#RDS.Client.create_db_instance)
storage_type Specifies the storage type to be associated with the DB instance. Options are standard, gp2 and io1. If you specify io1, you must also include a value for the iops parameter.
db_security_groups A list of DB security groups to associate with this DB instance.
vpc_security_group_ids A list of EC2 VPC security groups to associate with this DB instance.
availability_zone The EC2 Availability Zone that the database instance will be created in.
db_subnet_group_name A DB subnet group to associate with this DB instance.
preferred_maintenance_window The weekly time range (in UTC) during which system maintenance can
occur.

db_parameter_group_name  A DB parameter group to associate with this DB instance.
db_cluster_identifier  If the DB instance is a member of a DB cluster, contains the name of the DB cluster that the DB instance is a member of.
tde_credential_arn  The ARN from the Key Store with which the instance is associated for TDE encryption.
tde_credential_password  The password to use for TDE encryption if an encryption key is not used.
storage_encrypted  Specifies whether the DB instance is encrypted.
kms_keyid  If storage_encrypted is true, the KMS key identifier for the encrypted DB instance.
backup_retention_period  The number of days for which automated backups are retained.
preferred_backup_window  The daily time range during which automated backups are created if automated backups are enabled.
port  The port number on which the database accepts connections.
multi_az  Specifies if the DB instance is a Multi-AZ deployment. You cannot set the AvailabilityZone parameter if the MultiAZ parameter is set to true.
engine_version  The version number of the database engine to use.
auto_minor_version_upgrade  Indicates that minor engine upgrades will be applied automatically to the DB instance during the maintenance window.
license_model  License model information for this DB instance.
iops  The amount of Provisioned IOPS (input/output operations per second) to be initially allocated for the DB instance.
option_group_name  Indicates that the DB instance should be associated with the specified option group.
character_set_name  For supported engines, indicates that the DB instance should be associated with the specified CharacterSet.
publicly_accessible  Specifies the accessibility options for the DB instance. A value of true specifies an Internet-facing instance with a publicly resolvable DNS name, which resolves to a public IP address. A value of false specifies an internal instance with a DNS name that resolves to a private IP address.
wait_status  Wait for the RDS instance to reach a desired status before finishing the state. Available states: available, modifying, backing-up
tags  A dict of tags.
copy_tags_to_snapshot  Specifies whether tags are copied from the DB instance to snapshots of the DB instance.
region  Region to connect to.
domain  The identifier of the Active Directory Domain.
key  AWS secret key to be used.
keyid  AWS access key to be used.
monitoring_interval  The interval, in seconds, between points when Enhanced Monitoring metrics are collected for the DB instance.
monitoring_role_arn  The ARN for the IAM role that permits RDS to send Enhanced Monitoring metrics to CloudWatch Logs.
domain_iam_role_name  Specify the name of the IAM role to be used when making API calls to the Directory Service.
promotion_tier  A value that specifies the order in which an Aurora Replica is promoted to the primary instance after a failure of the existing primary instance. For more information, see Fault Tolerance for an Aurora DB Cluster.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_rds.replica_present(name, source, db_instance_class=None, availability_zone=None, port=None, auto_minor_version_upgrade=None, iops=None, option_group_name=None, publicly_accessible=None, tags=None, region=None, key=None, keyid=None, profile=None, db_parameter_group_name=None)

Ensure RDS replica exists.
Ensure myrds replica RDS exists:
```python
boto_rds.create_replica:
  - name: myreplica
  - source: mydb
```

```python
salt.states.boto_rds.subnet_group_absent(name, tags=\None, region=\None, key=\None, keyid=\None, profile=\None)
```

```python
salt.states.boto_rds.subnet_group_present(name, description, subnet_ids=\None, subnet_names=\None, tags=\None, region=\None, key=\None, keyid=\None, profile=\None)
```

Ensure DB subnet group exists.

- `name`: The name for the DB subnet group. This value is stored as a lowercase string.
- `subnet_ids`: A list of the EC2 Subnet IDs for the DB subnet group. Either subnet_ids or subnet_names must be provided.
- `subnet_names`: A list of The EC2 Subnet names for the DB subnet group. Either subnet_ids or subnet_names must be provided.
- `description`: Subnet group description.
- `tags`: A dict of tags.
- `region`: Region to connect to.
- `key`: Secret key to be used.
- `keyid`: Access key to be used.
- `profile`: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 19.19.41 salt.states.boto_route53

Manage Route53 records

New in version 2014.7.0.

Create and delete Route53 records. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit route53 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```python
route53.keyid: GKTADJGHEIQSXMKKRBJ08H
route53.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```python
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

```python
mycnamerrecord:
  boto_route53.present:
    - name: test.example.com.
    - zone: example.com.
```

```python
salt.states.boto_route53.hosted_zone_present(Tôi accept explicit route53 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```python
route53.keyid: GKTADJGHEIQSXMKKRBJ08H
route53.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```python
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

```python
mycnamerrecord:
  boto_route53.present:
    - name: test.example.com.
    - zone: example.com.
```
- ttl: 60
- record_type: CNAME
- region: us-east-1
- keyid: GKTADJGHEIQSXMKKRBJ08H
- key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs

# Using a profile from pillars
myarecord:
boto_route53.present:
  - name: test.example.com.
  - value: 1.1.1.1
  - zone: example.com.
  - ttl: 60
  - record_type: A
  - region: us-east-1
  - profile: myprofile

# Passing in a profile
myarecord:
boto_route53.present:
  - name: test.example.com.
  - value: 1.1.1.1
  - zone: example.com.
  - ttl: 60
  - record_type: A
  - region: us-east-1
  - profile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs

salt.states.boto_route53.absent(name, zone, record_type, identifier=None, region=None, key=None, keyid=None, profile=None, wait_for_sync=True, split_dns=False, private_zone=False)

Ensure the Route53 record is deleted.

name Name of the record.
zone The zone to delete the record from.
record_type The record type (A, NS, MX, TXT, etc.)
identifier An identifier to match for deletion.
region The region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
wait_for_sync Wait for an INSYNC change status from Route53.
split_dns Route53 supports a public and private DNS zone with the same names.
private_zone If using split_dns, specify if this is the private zone.

salt.states.boto_route53.hosted_zone_absent(name, domain_name=None, region=None, key=None, keyid=None, profile=None)

Ensure the Route53 Hosted Zone described is absent

name The name of the state definition.
domain_name The FQDN (including final period) of the zone you wish absent. If not provided, the value of name will be used.
salt.states.boto_route53.hosted_zone_present(name, domain_name=None, private_zone=False, comment='`, vpc_id=None, vpc_name=None, vpc_region=None, region=None, key=None, keyid=None, profile=None)

Ensure a hosted zone exists with the given attributes. Note that most things cannot be modified once a zone is created - it must be deleted and re-spun to update these attributes:

- private_zone (AWS API limitation).
- comment (the appropriate call exists in the AWS API and in boto3, but has not, as of this writing, been added to boto2).
- vpc_id (same story - we really need to rewrite this module with boto3)
- vpc_name (really just a pointer to vpc_id anyway).
- vpc_region (again, supported in boto3 but not boto2).

name The name of the state definition. This will be used as the `caller_ref` param if/when creating the hosted zone.

domain_name The name of the domain. This should be a fully-specified domain, and should terminate with a period. This is the name you have registered with your DNS registrar. It is also the name you will delegate from your registrar to the Amazon Route 53 delegation servers returned in response to this request. Defaults to the value of name if not provided.

comment Any comments you want to include about the hosted zone.

private_zone Set True if creating a private hosted zone.

vpc_id When creating a private hosted zone, either the VPC ID or VPC Name to associate with is required. Exclusive with vpc_name. Ignored if passed for a non-private zone.

vpc_name When creating a private hosted zone, either the VPC ID or VPC Name to associate with is required. Exclusive with vpc_id. Ignored if passed for a non-private zone.

vpc_region When creating a private hosted zone, the region of the associated VPC is required. If not provided, an effort will be made to determine it from vpc_id or vpc_name, if possible. If this fails, you'll need to provide an explicit value for this option. Ignored if passed for a non-private zone.

salt.states.boto_route53.present(name, value, zone, record_type, ttl=None, identifier=None, region=None, key=None, keyid=None, profile=None, wait_for_sync=True, split_dns=False, private_zone=False)

Ensure the Route53 record is present.

name Name of the record.

value Value of the record. As a special case, you can pass in: private:<Name tag> to have the function autodetermine the private IP public:<Name tag> to have the function autodetermine the public IP

zone The zone to create the record in.

record_type The record type (A, NS, MX, TXT, etc.)

ttl The time to live for the record.

identifier The unique identifier to use for this record.

region The region to connect to.

key Secret key to be used.

keyid Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

wait_for_sync Wait for an INSYNC change status from Route53.

split_dns Route53 supports a public and private DNS zone with the same names.

private_zone If using split_dns, specify if this is the private zone.

salt.states.boto_route53.rr_absent(*args, **kwargs)

salt.states.boto_route53.rr_present(*args, **kwargs)
19.19.42 salt.states.boto_s3_bucket module

Manage S3 Buckets

New in version 2016.3.0.

Create and destroy S3 buckets. Be aware that this interacts with Amazon's services, and so may incur charges.

```
depends
  • boto
  • boto3
```

The dependencies listed above can be installed via package or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure bucket exists:

```
boto_s3_bucket.present:
  - Bucket: mybucket
  - LocationConstraint: EU
  - ACL:
    - GrantRead: "uri=http://acs.amazonaws.com/groups/global/AllUsers"
    - CORSRules:
      - AllowedHeaders: []
      - AllowedMethods: ["GET"]

salt.states.boto_s3_bucket.absent(name, Bucket, Force=False, region=None, key=None, keyid=None, profile=None)

Ensure bucket with passed properties is absent.

- **name** The name of the state definition.
- **Bucket** Name of the bucket.
- **Force** Empty the bucket first if necessary - Boolean.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_s3_bucket.present(name, Bucket, LocationConstraint=None, ACL=None, CORSRules=None, LifecycleConfiguration=None, Logging=None, NotificationConfiguration=None, Policy=None, Replication=None, RequestPayment=None, Tagging=None, Versioning=None, Website=None, region=None, key=None, keyid=None, profile=None)

Ensure bucket exists.

- **name** The name of the state definition.
- **Bucket** Name of the bucket.
- **LocationConstraint** `EU'|'eu-west-1'|'us-west-1'|'us-west-2'|'ap-southeast-1'|'ap-southeast-2'|'ap-northeast-1'|'sa-east-1'|'cn-north-1'|'eu-central-1'
- **ACL** The permissions on a bucket using access control lists (ACL).
- **CORSRules** The cors configuration for a bucket.
- **LifecycleConfiguration** Lifecycle configuration for your bucket
- **Logging** The logging parameters for a bucket and to specify permissions for who can view and modify the logging parameters.
- **NotificationConfiguration** notifications of specified events for a bucket
- **Policy** Policy on the bucket
- **Replication** Replication rules. You can add as many as 1,000 rules. Total replication configuration size can be up to 2 MB
- **RequestPayment** The request payment configuration for a bucket. By default, the bucket owner pays for downloads from the bucket. This configuration parameter enables the bucket owner (only) to specify that the person requesting the download will be charged for the download
- **Tagging** A dictionary of tags that should be set on the bucket
- **Versioning** The versioning state of the bucket
- **Website** The website configuration of the bucket
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
19.19.43 salt.states.boto_secgroup

Manage Security Groups

New in version 2014.7.0.

Create and destroy Security Groups. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit EC2 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
secgroup.keyid: GKTADJGHEIQSXMKKRBJ08H
secgroup.key: askdjghsdfjkgHwupUjasdfklkjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgHwupUjasdfklkjsdfjajkghs
  region: us-east-1
```

Ensure mysecgroup exists:

```
boto_secgroup.present:
  - name: mysecgroup
  - description: My security group
  - vpc_name: myvpc
  - rules:
    - ip_protocol: tcp
      from_port: 80
      to_port: 80
      cidr_ip:
        - 10.0.0.0/8
        - 192.168.0.0/16
    - ip_protocol: tcp
      from_port: 8080
      to_port: 8090
      cidr_ip:
        - 10.0.0.0/8
        - 192.168.0.0/16
    - ip_protocol: icmp
      from_port: -1
      to_port: -1
      source_group_name: mysecgroup
  - rules_egress:
    - ip_protocol: all
      from_port: -1
      to_port: -1
      cidr_ip:
        - 10.0.0.0/8
        - 192.168.0.0/16
    - tags:
      SomeTag: 'My Tag Value'
      SomeOtherTag: 'Other Tag Value'
```
- region: us-east-1
- keyid: GKTADJGHEIQSXMKKRBJ08H
- key: askdjghsdfjkgshWupUjasdflkdfklgjsdfjajkghs

# Using a profile from pillars
Ensure mysecgroup exists:
```
boto_secgroup.present:
  - name: mysecgroup
  - description: My security group
  - profile: myprofile
```

# Passing in a profile
Ensure mysecgroup exists:
```
boto_secgroup.present:
  - name: mysecgroup
  - description: My security group
  - profile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkgshWupUjasdflkdfklgjsdfjajkghs
    region: us-east-1
```

Note: When using the profile parameter and region is set outside of the profile group, region is ignored and a default region will be used.

If region is missing from the profile data set, us-east-1 will be used as the default region.

```python
salt.states.boto_secgroup.absent(name, vpc_id=None, vpc_name=None, region=None, key=None, keyid=None, profile=None)
```

Ensure a security group with the specified name does not exist.

- **name** Name of the security group.
- **vpc_id** The ID of the VPC to remove the security group from, if any. Exclusive with vpc_name.
- **vpc_name** The name of the VPC to remove the security group from, if any. Exclusive with vpc_id.

    New in version 2016.3.0.

- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

    New in version 2016.3.0.

```python
salt.states.boto_secgroup.present(name, description, vpc_id=None, vpc_name=None, rules=None, rules_egress=None, region=None, key=None, keyid=None, profile=None, tags=None)
```

Ensure the security group exists with the specified rules.

- **name** Name of the security group.
- **description** A description of this security group.
- **vpc_id** The ID of the VPC to create the security group in, if any. Exclusive with vpc_name.
- **vpc_name** The name of the VPC to create the security group in, if any. Exclusive with vpc_id.

    New in version 2016.3.0.

    New in version 2015.8.2.

- **rules** A list of ingress rule dicts. If not specified, rules= None, the ingress rules will be unmanaged. If set to an empty list, [], then all ingress rules will be removed.
rules_egress  A list of egress rule dicts. If not specified, rules_egress=None, the egress rules will be unmanaged. If set to an empty list, [], then all egress rules will be removed.

region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key, and keyid.
tags  List of key:value pairs of tags to set on the security group

New in version 2016.3.0.

19.19.44 salt.states.boto_sns

Manage SNS Topics

Create and destroy SNS topics. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
sns.keyid: GKTADJGHEIQSXMKKRBJ08H
sns.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

```yaml
mytopic:
  boto_sns.present:
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

# Using a profile from pillars
mytopic:
  boto_sns.present:
    - region: us-east-1
    - profile: mysnsprofile

# Passing in a profile
mytopic:
  boto_sns.present:
    - region: us-east-1
    - profile:
      keyid: GKTADJGHEIQSXMKKRBJ08H
      key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
salt.states.boto_sns.absent(name, region=None, key=None, keyid=None, profile=None, unsubscribe=False)

Ensure the named sns topic is deleted.

**name** Name of the SNS topic.

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**unsubscribe** If True, unsubscribe all subscriptions to the SNS topic before deleting the SNS topic.

New in version 2016.11.0.

salt.states.boto_sns.present(name, subscriptions=None, region=None, key=None, keyid=None, profile=None)

Ensure the SNS topic exists.

**name** Name of the SNS topic.

**subscriptions** List of SNS subscriptions.

Each subscription is a dictionary with a protocol and endpoint key:

```
[
    {'protocol': 'https', 'endpoint': 'https://www.example.com/sns-endpoint'},
    {'protocol': 'sqs', 'endpoint': 'arn:aws:sqs:us-west-2:123456789012:MyQueue'}
]
```

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

19.19.45 salt.states.boto_sqs

Manage SQS Queues

New in version 2014.7.0.

Create and destroy SQS queues. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit SQS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
sqs.keyid: GKTADJGHEIQSXMKKRBJ08H
sqs.key: askdjghsdfjkghWupeUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupeUjasdflkdfklgjsdfjajkghs
    region: us-east-1
```
myqueue:
  boto_sqs.present:
    - region: us-east-1
    - keyid: GKTADJGHEIQXSXMKRRBJ08H
    - key: askdjghsdfjkgHwupUjasdfklkpsdfajkghs
    - attributes:
      ReceiveMessageWaitTimeSeconds: 20

# Using a profile from pillars
myqueue:
  boto_sqs.present:
    - region: us-east-1
    - profile: mysqsprofile

# Passing in a profile
myqueue:
  boto_sqs.present:
    - region: us-east-1
    - profile:
      keyid: GKTADJGHEIQXSXMKRRBJ08H
      key: askdjghsdfjkgHwupUjasdfklkpsdfajkghs

salt.states.boto_sqs.absent(name, region=None, key=None, keyid=None, profile=None)
Ensure the named sqs queue is deleted.
  name Name of the SQS queue.
  region Region to connect to.
  key Secret key to be used.
  keyid Access key to be used.
  profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_sqs.present(name, attributes=None, region=None, key=None, keyid=None, profile=None)
Ensure the SQS queue exists.
  name Name of the SQS queue.
  attributes A dict of key/value SQS attributes.
  region Region to connect to.
  key Secret key to be used.
  keyid Access key to be used.
  profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

19.19.46 salt.states.boto_vpc
Manage VPCs
New in version 2015.8.0.

depends
  - boto >= 2.8.0
  - boto3 >= 1.2.6
Create and destroy VPCs. Be aware that this interacts with Amazon’s services, and so may incur charges.
This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
vpc.keyid: GKTADJGHEIQSXMKRRBJ08H
vpc.key: askdjghsdfjkgHwupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKRRBJ08H
  key: askdjghsdfjkgHwupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure VPC exists:

```yaml
boto_vpc.present:
  - name: myvpc
  - cidr_block: 10.10.11.0/24
  - dns_hostnames: True
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKRRBJ08H
  - key: askdjghsdfjkgHwupUjasdflkdfklgjsdfjajkghs
```

Ensure subnet exists:

```yaml
boto_vpc.subnet_present:
  - name: mysubnet
  - vpc_id: vpc-123456
  - cidr_block: 10.0.0.0/16
  - region: us-east-1
  - profile: myprofile
```

```yaml
{% set profile = salt['pillar.get']('aws:region:us-east-1:profile') %}
```

Ensure internet gateway exists:

```yaml
boto_vpc.internet_gateway_present:
  - name: myigw
  - vpc_name: myvpc
  - profile: {{ profile }}
```

Ensure route table exists:

```yaml
boto_vpc.route_table_present:
  - name: my_route_table
  - vpc_id: vpc-123456
  - routes:
    - destination_cidr_block: 0.0.0.0/0
      instance_id: i-123456
    - subnet_names:
      - subnet1
```

19.19. state modules
New in version 2016.11.0.

Request, accept and delete VPC peering connections. VPC peering connections can be named allowing the name to be used throughout the state file. Following example shows how to request and accept a VPC peering connection.

```python
accept the vpc peering connection:
    boto_vpc.accept_vpc_peering_connection:
        - conn_name: salt_vpc_peering
        - region: us-west-2
        - require:
            - boto_vpc: request a vpc peering connection
```

```python
request a vpc peering connection:
    boto_vpc.request_vpc_peering_connection:
        - requester_vpc_id: vpc-4a3d522e
        - peer_vpc_id: vpc-ae81e9ca
        - region: us-west-2
        - conn_name: salt_vpc_peering
```

VPC peering connections need not be named. In this case the VPC peering connection ID should be used in the state file.

```python
accept the vpc peering connection:
    boto_vpc.accept_vpc_peering_connection:
        - conn_id: pcx-1873c371
        - region: us-west-2
```

VPC peering connections can be deleted, as shown below.

```python
delete a named vpc peering connection:
    boto_vpc.delete_vpc_peering_connection:
        - conn_name: salt_vpc_peering
```

Delete also accepts a VPC peering connection id.

```python
delete a vpc peering connection by id:
    boto_vpc.delete_vpc_peering_connection:
        - conn_id: pcx-1873c371
```

salt.states.boto_vpc.absent(name, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure VPC with passed properties is absent.

- name Name of the VPC.
- tags A list of tags. All tags must match.
- region Region to connect to.
- key Secret key to be used.
- keyid Access key to be used.
- profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_vpc.accept_vpc_peering_connection(name=None, conn_id=None, conn_name=None, region=None, key=None, keyid=None, profile=None)

Accept a VPC pending requested peering connection between two VPCs.

- **name**: Name of this state
- **conn_id**: The connection ID to accept. Exclusive with conn_name. String type.
- **conn_name**: The name of the VPC peering connection to accept. Exclusive with conn_id. String type.
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

New in version 2016.11.0.

Example:

```python
depth=2
boto_vpc.accept_vpc_peering_connection:
  - conn_name: salt_peering_connection

# usage with vpc peering connection id and region
depth=2
boto_vpc.accept_vpc_peering_connection:
  - conn_id: pbx-1873d472
  - region: us-west-2
```

salt.states.boto_vpc.delete_vpc_peering_connection(name, conn_id=None, conn_name=None, region=None, key=None, keyid=None, profile=None)

- **name**: Name of the state
- **conn_id**: ID of the peering connection to delete. Exclusive with conn_name.
- **conn_name**: The name of the peering connection to delete. Exclusive with conn_id.
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

New in version 2016.11.0.

Example:

```python
depth=2
delete a vpc peering connection:
  boto_vpc.delete_vpc_peering_connection:
    - region: us-west-2
    - conn_id: pcx-4613b12e
```

Connection name can be specified (instead of ID). Specifying both conn_name and conn_id will result in an error.

```python
depth=2
delete a vpc peering connection:
  boto_vpc.delete_vpc_peering_connection:
    - conn_name: salt_vpc_peering
```

salt.states.boto_vpc.dhcp_options_absent(name=None, dhcp_options_id=None, region=None, key=None, keyid=None, profile=None)

Ensure a set of DHCP options with the given settings exist.
name (string) Name of the DHCP options set.
dhcp_options_id (string) Id of the DHCP options set.
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (various) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
New in version 2016.3.0.
salt.states.boto_vpc.dhcp_options_present(name, dhcp_options_id=None, vpc_name=None, vpc_id=None, domain_name=None, domain_name_servers=None, ntp_servers=None, netbios_name_servers=None, netbios_node_type=None, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure a set of DHCP options with the given settings exist. Note that the current implementation only SETS values during option set creation. It is unable to update option sets in place, and thus merely verifies the set exists via the given name and/or dhcp_options_id param.
name (string) Name of the DHCP options.
vpc_name (string) Name of a VPC to which the options should be associated. Either vpc_name or vpc_id must be provided.
vpc_id (string) Id of a VPC to which the options should be associated. Either vpc_name or vpc_id must be provided.
domain_name (string) Domain name to be associated with this option set.
domain_name_servers (list of strings) The IP address(es) of up to four domain name servers.
ntp_servers (list of strings) The IP address(es) of up to four desired NTP servers.
netbios_name_servers (list of strings) The IP address(es) of up to four NetBIOS name servers.
netbios_node_type (string) The NetBIOS node type (1, 2, 4, or 8). For more information about the allowed values, see RFC 2132. The recommended is 2 at this time (broadcast and multicast are currently not supported).
tags (dict of key:value pairs) A set of tags to be added.
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (various) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
New in version 2016.3.0.
salt.states.boto_vpc.internet_gateway_absent(name, detach=False, region=None, key=None, keyid=None, profile=None)

Ensure the named internet gateway is absent.
name Name of the internet gateway.
detach First detach the internet gateway from a VPC, if attached.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_vpc.internet_gateway_present(name, vpc_name=None, vpc_id=None, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure an internet gateway exists.
name Name of the internet gateway.
vpc_name Name of the VPC to which the internet gateway should be attached.
vpc_id Id of the VPC to which the internet_gateway should be attached. Only one of vpc_name or vpc_id
may be provided.
tags  A list of tags.
region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_vpc.nat_gatewayAbsent(name=None, subnet_name=None, subnet_id=None, region=None, key=None, keyid=None, profile=None, wait_for_delete_retries=0)

Ensure the nat gateway in the named subnet is absent.

This function requires boto3.

New in version 2016.11.0.

name  Name of the state.
subnet_name  Name of the subnet within which the nat gateway should exist
subnet_id  Id of the subnet within which the nat gateway should exist. Either subnet_name or subnet_id must be provided.
region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
wait_for_delete_retries  NAT gateway may take some time to be go into deleted or failed state. During the deletion process, subsequent release of elastic IPs may fail; this state will automatically retry this number of times to ensure the NAT gateway is in deleted or failed state before proceeding. Default is set to 0 for backward compatibility.

salt.states.boto_vpc.nat_gatewayPresent(name, subnet_name=None, subnet_id=None, region=None, key=None, keyid=None, profile=None, allocation_id=None)

Ensure a nat gateway exists within the specified subnet

This function requires boto3.

New in version 2016.11.0.

Example:

```
boto_vpc.nat_gateway_present:
  - subnet_name: my-subnet
```

name  Name of the state
subnet_name  Name of the subnet within which the nat gateway should exist
subnet_id  Id of the subnet within which the nat gateway should exist. Either subnet_name or subnet_id must be provided.
allocation_id  If specified, the elastic IP address referenced by the ID is associated with the gateway. Otherwise, a new allocation_id is created and used.
region  Region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_vpc.present(name, cidr_block, instance_tenancy=None, dns_support=None, dns_hostnames=None, tags=None, region=None, key=None, keyid=None, profile=None)
Ensure VPC exists.

name Name of the VPC.
cidr_block The range of IPs in CIDR format, for example: 10.0.0.0/24. Block size must be between /16 and /28 netmask.
instance_tenancy Instances launched in this VPC will be single-tenant or dedicated hardware.
dns_support Indicates whether the DNS resolution is supported for the VPC.
dns_hostnames Indicates whether the instances launched in the VPC get DNS hostnames.
tags A list of tags.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_vpc.request_vpc_peering_connection(name, requester_vpc_id=None, requester_vpc_name=None, peer_vpc_id=None, peer_vpc_name=None, conn_name=None, peer_owner_id=None, region=None, key=None, keyid=None, profile=None)

name Name of the state
requester_vpc_id ID of the requesting VPC. Exclusive with requester_vpc_name. String type.
requester_vpc_name Name tag of the requesting VPC. Exclusive with requester_vpc_id. String type.
peer_vpc_id ID of the VPC to create VPC peering connection with. This can be a VPC in another account. Exclusive with peer_vpc_name. String type.
peer_vpc_name Name tag of the VPC to create VPC peering connection with. This can only be a VPC the same account. Exclusive with peer_vpc_id. String type.
conn_name The (optional) name to use for this VPC peering connection. String type.
peer_owner_id ID of the owner of the peer VPC. String type. If this isn’t supplied AWS uses your account ID. Required if peering to a different account.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

New in version 2016.11.0.

Example:

```
request a vpc peering connection:
boto_vpc.request_vpc_peering_connection:
    - requester_vpc_id: vpc-4b3522e
    - peer_vpc_id: vpc-ae83f9ca
    - conn_name: salt_peering_connection
```

salt.states.boto_vpc.route_table_absent(name, region=None, key=None, keyid=None, profile=None)

Ensure the named route table is absent.

name Name of the route table.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_vpc.route_table_present(name, vpc_name=None, vpc_id=None, routes=None, subnet_ids=None, subnet_names=None, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure route table with routes exists and is associated to a VPC.

This function requires boto3 to be installed if nat gateways are specified.

Example:

```yaml
boto_vpc.route_table_present:
  - name: my_route_table
  - vpc_id: vpc-123456
  - routes:
    - destination_cidr_block: 0.0.0.0/0
      internet_gateway_name: InternetGateway
      instance_id: 1-123456
    - destination_cidr_block: 10.10.11.0/24
      instance_id: i-123456
    - destination_cidr_block: 10.10.12.0/24
      interface_id: eni-123456
    - destination_cidr_block: 10.10.13.0/24
      instance_name: mygatewayserver
  - subnet_names:
    - subnet1
    - subnet2
```

name Name of the route table.

vpc_name Name of the VPC with which the route table should be associated.

vpc_id Id of the VPC with which the route table should be associated. Either vpc_name or vpc_id must be provided.

routes A list of routes. Each route has a cidr and a target.

subnet_ids A list of subnet ids to associate

subnet_names A list of subnet names to associate

tags A list of tags.

region Region to connect to.

key Secret key to be used.

keyid Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_vpcsubnet_absent(name=None, subnet_id=None, region=None, key=None, keyid=None, profile=None)

Ensure subnet with passed properties is absent.

name Name of the subnet.

region Region to connect to.

key Secret key to be used.

keyid Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_vpc.subnet_present(name, cidr_block, vpc_name=None, vpc_id=None, availability_zone=None, tags=None, region=None, key=None, keyid=None, profile=None, route_table_id=None, route_table_name=None)

Ensure a subnet exists.

name Name of the subnet.

cidr_block The range if IPs for the subnet, in CIDR format. For example: 10.0.0.0/24. Block size must be between /16 and /28 netmask.
vpc_name Name of the VPC in which the subnet should be placed. Either vpc_name or vpc_id must be provided.
vpc_id Id of the VPC in which the subnet should be placed. Either vpc_name or vpc_id must be provided.
availability_zone AZ in which the subnet should be placed.
tags A list of tags.
route_table_id A route table ID to explicitly associate the subnet with. If both route_table_id and route_table_name are specified, route_table_id will take precedence.
    New in version 2016.11.0.
route_table_name A route table name to explicitly associate the subnet with. If both route_table_id and route_table_name are specified, route_table_id will take precedence.
    New in version 2016.11.0.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_vpc.vpc_peering_connection_absent(name, conn_id=None, conn_name=None, region=None, key=None, keyid=None, profile=None)
salt.states.boto_vpc.vpc_peering_connection_present(name, requester_vpc_id=None, requester_vpc_name=None, peer_vpc_id=None, peer_vpc_name=None, conn_name=None, peer_owner_id=None, region=None, key=None, keyid=None, profile=None)

name Name of the state
requester_vpc_id ID of the requesting VPC. Exclusive with requester_vpc_name.
requester_vpc_name Name tag of the requesting VPC. Exclusive with requester_vpc_id.
peer_vpc_id ID of the VPC to create VPC peering connection with. This can be a VPC in another account. Exclusive with peer_vpc_name.
peer_vpc_name Name tag of the VPC to create VPC peering connection with. This can only be a VPC in the same account, else resolving it into a vpc ID will fail. Exclusive with peer_vpc_id.
conn_name The name to use for this VPC peering connection.
peer_owner_id ID of the owner of the peer VPC. Defaults to your account ID, so a value is required if peering with a VPC in a different account.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
    New in version 2016.11.0.

Example:

```bash
ensure peering twixt local vpc and the other guys:
    boto_vpc.vpc_peering_connection_present:
        - requester_vpc_name: my_local_vpc
        - peer_vpc_name: some_other_guys_vpc
        - conn_name: peering_from_here_to_there
        - peer_owner_id: 012345654321
```
19.19.47  salt.states.bower

Installation of Bower Packages

These states manage the installed packages using Bower. Note that npm, git and bower must be installed for these states to be available, so bower states should include requisites to pkg.installed states for the packages which provide npm and git (simply npm and git in most cases), and npm.installed state for the package which provides bower.

Example:

```
npm:
  pkg.installed
git:
  pkg.installed
bower:  
  npm.installed
    require:
      - pkg: npm
      - pkg: git

underscore:
  bower.installed:
    - dir: /path/to/project
    - require:
      - npm: bower

salt.states.bower.bootstrap(name, user=None)
  Bootstraps a frontend distribution.
    Will execute `bower install' on the specified directory.
    user The user to run Bower with

salt.states.bower.installed(name, dir, pkgs=None, user=None, env=None)
  Verify that the given package is installed and is at the correct version (if specified).
    underscore:
      bower.installed:
        - dir: /path/to/project
        - user: someuser
    jquery#2.0:
      bower.installed:
        - dir: /path/to/project

  name The package to install
  dir The target directory in which to install the package
  pkgs A list of packages to install with a single Bower invocation; specifying this argument will ignore the
        name argument
  user The user to run Bower with
  env A list of environment variables to be set prior to execution. The format is the same as the cmd.run.
        state function.

salt.states.bower.pruned(name, user=None, env=None)
  New in version 2017.7.0.
    Cleans up local bower_components directory.
    Will execute `bower prune' on the specified directory (param: name)
    user The user to run Bower with
**salt.states.bower**.removed(name, dir, user=None)
Verify that the given package is not installed.
  
  **dir** The target directory in which to install the package
  
  **user** The user to run Bower with

### 19.19.48 salt.states.cabal

**Installation of Cabal Packages**

New in version 2015.8.0.

These states manage the installed packages for Haskell using cabal. Note that cabal-install must be installed for these states to be available, so cabal states should include a requisite to a pkg.installed state for the package which provides cabal (cabal-install in case of Debian based distributions). Example:

```yaml
.cabalist: pkg.installed

ShellChek:
  cabal.installed:
    - require: - pkg: cabal-install
```

**salt.states.cabal**.installed(name, pkgs=None, user=None, install_global=False, env=None)
Verify that the given package is installed and is at the correct version (if specified).

```yaml
ShellCheck-0.3.5:
  cabal:
    - installed:
```

**name** The package to install

**user** The user to run cabal install with

**install_global** Install package globally instead of locally

**env** A list of environment variables to be set prior to execution. The format is the same as the `cmd.run` state function.

**salt.states.cabal**.removed(name, user=None, env=None)
Verify that given package is not installed.

### 19.19.49 salt.states.ceph module

Manage ceph with salt.

New in version 2016.11.0.

**salt.states.ceph**.quorum(name, **kwargs)
Quorum state

This state checks the mon daemons are in quorum. It does not alter the cluster but can be used in formula as a dependency for many cluster operations.

Example usage in sls file:

```yaml
quorum:
  sesceph.quorum:
```
- require:
  - sesceph: mon_running

### 19.19.50 `salt.states.chef`

### Execute Chef client runs

Run `chef-client` or `chef-solo`

```python
my-chef-run:
  chef.client:
    - override-runlist: 'demo1,demo2'
    - server: 'https://chef.domain.com'

default-chef-run:
  chef.client: []

my-solo-run:
  chef.solo:
    - environment: dev
```

```python
salt.states.chef.client(name, **kwargs)
  name Unique identifier for the state. Does not affect the Chef run.
  server The chef server URL
  client_key Set the client key file location
  config The configuration file to use
  config-file-jail Directory under which config files are allowed to be loaded (no client.rb or knife.rb outside this path will be loaded).
  environment Set the Chef Environment on the node
  group Group to set privilege to
  json-attributes Load attributes from a JSON file or URL
  localmode Point chef-client at local repository if True
  log_level Set the log level (debug, info, warn, error, fatal)
  logfile Set the log file location
  node-name The node name for this client
  override-runlist Replace current run list with specified items for a single run
  pid Set the PID file location, defaults to /tmp/chef-client.pid
  run-lock-timeout Set maximum duration to wait for another client run to finish, default is indefinitely.
  runlist Permanently replace current run list with specified items
  user User to set privilege to
  validation_key Set the validation key file location, used for registering new clients
```

```python
salt.states.chef.solo(name, **kwargs)
  name Unique identifier for the state. Does not affect the Chef run.
  config The configuration file to use
  environment Set the Chef Environment on the node
  group Group to set privilege to
  json-attributes Load attributes from a JSON file or URL
  log_level Set the log level (debug, info, warn, error, fatal)
  logfile Set the log file location
  node-name The node name for this client
  override-runlist Replace current run list with specified items for a single run
  recipe-url Pull down a remote gzipped tarball of recipes and untar it to the cookbook cache
  run-lock-timeout Set maximum duration to wait for another client run to finish, default is indefinitely.
```
user User to set privilege to

19.19.51 salt.states.chocolatey module

Manage Chocolatey package installs .. versionadded:: 2016.3.0

**salt.states.chocolatey.installed** *(name, version=None, source=None, force=False, pre_versions=False, install_args=None, override_args=False, force_x86=False, package_args=None, allow_multiple=False)*

Installs a package if not already installed

**Parameters**

- **name** *(str)* -- The name of the package to be installed. Required.
- **version** *(str)* -- Install a specific version of the package. Defaults to latest version. If the version is different to the one installed then the specified version will be installed. Default is None.
- **source** *(str)* -- Chocolatey repository (directory, share or remote URL, feed). Defaults to the official Chocolatey feed. Default is None.
- **force** *(bool)* -- Reinstall the current version of an existing package. Do not use with **allow_multiple**. Default is False.
- **pre_versions** *(bool)* -- Include pre-release packages. Default is False.
- **install_args** *(str)* -- Install arguments you want to pass to the installation process, ie product key or feature list. Default is None.
- **override_args** *(bool)* -- Set to True if you want to override the original install arguments (for the native installer) in the package and use your own. When this is set to False install_args will be appended to the end of the default arguments. Default is False.
- **force_x86** *(bool)* -- Force x86 (32bit) installation on 64 bit systems. Default is False.
- **package_args** *(str)* -- Arguments you want to pass to the package. Default is None.
- **allow_multiple** *(bool)* -- Allow multiple versions of the package to be installed. Do not use with **force**. Does not work with all packages. Default is False.

New in version 2017.7.0.

```python
Installsomepackage:
    chocolatey.installed:
    - name: packagename
    - version: '12.04'
    - source: 'mychocolatey/source'
    - force: True
```

**salt.states.chocolatey.uninstalled** *(name, version=None, uninstall_args=None, override_args=False)*

Uninstalls a package

**name** The name of the package to be uninstalled

**version** Uninstalls a specific version of the package. Defaults to latest version installed.

**uninstall_args** A list of uninstall arguments you want to pass to the uninstallation process i.e product key or feature list

**override_args** Set to true if you want to override the original uninstall arguments (for the native uninstaller) in the package and use your own. When this is set to False uninstall_args will be appended to the end of the default arguments
19.19.52 salt.states.chronos_job module

Configure Chronos jobs via a salt proxy.

```python
my_job:
    chronos_job.config:
        - config:
            schedule: "R//PT2S"
            command: "echo 'hi!"
            owner: "me@example.com"
```

New in version 2015.8.2.

**salt.states.chronos_job.absent**(*name*)

Ensure that the chronos job with the given name is not present.

- **Parameters**
  - name -- The app name
- **Returns**
  - A standard Salt changes dictionary

**salt.states.chronos_job.config**(*name, config*)

Ensure that the chronos job with the given name is present and is configured to match the given config values.

- **Parameters**
  - name -- The job name
  - config -- The configuration to apply (dict)
- **Returns**
  - A standard Salt changes dictionary

19.19.53 salt.states.cisconso

State module for Cisco NSO Proxy minions

For documentation on setting up the cisconso proxy minion look in the documentation for `salt.proxy.cisconso`.

**salt.states.cisconso.value_present**(*name, datastore, path, config*)

Ensure a specific value exists at a given path

- **Parameters**
  - name (str) -- The name for this rule
  - datastore (DatastoreType (str enum).) -- The datastore, e.g. running, operational. One of the NETCONF store IETF types
  - path (list, str OR tuple) -- The device path to set the value at, a list of element names in order, / separated
  - config (dict) -- The new value at the given path

**Examples:**

```python
enable pap auth:
    cisconso.config_present:
        - name: enable_pap_auth
        - datastore: running
        - path: devices/device/ex0/config/sys/interfaces/serial/ppp0/authentication
        - config:
            authentication:
                method: pap
                "list-name": foobar
```
19.19.54 salt.states.cloud

Using states instead of maps to deploy clouds

New in version 2014.1.0.

Use this minion to spin up a cloud instance:

```
my-ec2-instance:
    cloud.profile:
        my-ec2-config
```

salt.states.cloud.absent(name, onlyif=None, unless=None)

Ensure that no instances with the specified names exist.

CAUTION: This is a destructive state, which will search all configured cloud providers for the named instance, and destroy it.

- **name**: The name of the instance to destroy
- **onlyif**: Do run the state only if is unless succeed
- **unless**: Do not run the state at least unless succeed

salt.states.cloud.present(name, cloud_provider, onlyif=None, unless=None, opts=None, **kwargs)

Spin up a single instance on a cloud provider, using salt-cloud. This state does not take a profile argument; rather, it takes the arguments that would normally be configured as part of the state.

Note that while this function does take any configuration argument that would normally be used to create an instance, it will not verify the state of any of those arguments on an existing instance. Stateful properties of an instance should be configured using their own individual state (i.e., cloud.tagged, cloud.un tagged, etc).

- **name**: The name of the instance to create
- **cloud_provider**: The name of the cloud provider to use
- **onlyif**: Do run the state only if is unless succeed
- **unless**: Do not run the state at least unless succeed
- **opts**: Any extra opts that need to be used

salt.states.cloud.profile(name, profile, onlyif=None, unless=None, opts=None, **kwargs)

Create a single instance on a cloud provider, using a salt-cloud profile.

Note that while profiles used this function do take any configuration argument that would normally be used to create an instance using a profile, this state will not verify the state of any of those arguments on an existing instance. Stateful properties of an instance should be configured using their own individual state (i.e., cloud.tagged, cloud.un tagged, etc).

- **name**: The name of the instance to create
- **profile**: The name of the cloud profile to use
- **onlyif**: Do run the state only if is unless succeed
- **unless**: Do not run the state at least unless succeed
- **kwargs**: Any profile override or addition
- **opts**: Any extra opts that need to be used

salt.states.cloud.volume_absent(name, provider=None, **kwargs)

Check that a block volume exists.

salt.states.cloud.volume_attached(name, server_name, provider=None, **kwargs)

Check if a block volume is attached.

salt.states.cloud.volume_detached(name, server_name=None, provider=None, **kwargs)

Check if a block volume is attached.

Returns True if server or Volume do not exist.
salt.states.cloud.volume_present(name, provider=None, **kwargs)

Check that a block volume exists.

19.19.55 salt.states.cmd

Execution of arbitrary commands

The cmd state module manages the enforcement of executed commands, this state can tell a command to run under certain circumstances.

A simple example to execute a command:

```
# Store the current date in a file
date > /tmp/salt-run:

cmd.run
```

Only run if another execution failed, in this case truncate syslog if there is no disk space:

```
> /var/log/messages/:
cmd.run:
  - unless: echo 'foo' > /tmp/.test && rm -f /tmp/.test
```

Only run if the file specified by creates does not exist, in this case touch /tmp/foo if it does not exist:

```
touch /tmp/foo:
  cmd.run:
    - creates: /tmp/foo
```

creates also accepts a list of files:

```
"echo 'foo' | tee /tmp/bar > /tmp/baz":
cmd.run:
  - creates:
    - /tmp/bar
    - /tmp/baz
```

**Note:** The creates option was added to version 2014.7.0

Sometimes when running a command that starts up a daemon, the init script doesn’t return properly which causes Salt to wait indefinitely for a response. In situations like this try the following:

```
run_installer:
  cmd.run:
    - name: /tmp/installer.bin > /dev/null 2>&1
```

Salt determines whether the cmd state is successfully enforced based on the exit code returned by the command. If the command returns a zero exit code, then salt determines that the state was successfully enforced. If the script returns a non-zero exit code, then salt determines that it failed to successfully enforce the state. If a command returns a non-zero exit code but you wish to treat this as a success, then you must place the command in a script and explicitly set the exit code of the script to zero.

Please note that the success or failure of the state is not affected by whether a state change occurred nor the stateful argument.

When executing a command or script, the state (i.e., changed or not) of the command is unknown to Salt’s state system. Therefore, by default, the cmd state assumes that any command execution results in a changed state.
This means that if a cmd state is watched by another state then the state that's watching will always be executed due to the changed state in the cmd state.

Using the `"Stateful"` Argument

Many state functions in this module now also accept a stateful argument. If stateful is specified to be true then it is assumed that the command or script will determine its own state and communicate it back by following a simple protocol described below:

1. **If there's nothing in the stdout of the command, then assume no changes.** Otherwise, the stdout must be either in JSON or its last non-empty line must be a string of key=value pairs delimited by spaces (no spaces on either side of =).
2. **If it's JSON then it must be a JSON object (e.g., {}).** If it's key=value pairs then quoting may be used to include spaces. (Python's shlex module is used to parse the key=value string)

   Two special keys or attributes are recognized in the output:

   - `changed`: bool (i.e., 'yes', 'no', 'true', 'false', case-insensitive)
   - `comment`: str (i.e., any string)

So, only if changed is True then assume the command execution has changed the state, and any other key values or attributes in the output will be set as part of the changes.

3. **If there's a comment then it will be used as the comment of the state.**

   Here's an example of how one might write a shell script for use with a stateful command:

   ```bash
   #!/bin/bash
   # echo "Working hard..."
   # writing the state line
   echo "changed=yes comment='something has changed' whatever=123"
   ```

   And an example SLS file using this module:

   ```yaml
   Run myscript:
   cmd.run:
   - name: /path/to/myscript
   - cwd: /
   - stateful: True

   Run only if myscript changed something:
   cmd.run:
   - name: echo hello
   - cwd: /
   - onchanges:
     - cmd: Run myscript
   ```

   Note that if the second cmd.run state also specifies stateful: True it can then be watched by some other states as well.

4. **The stateful argument can optionally include a test_name parameter.**

   This is used to specify a command to run in test mode. This command should return stateful data for changes that would be made by the command in the name parameter.
New in version 2015.2.0.

Run myscript:
```yaml
cmd.run:
    - name: /path/to/myscript
    - cwd: /
    - stateful:
      - test_name: /path/to/myscript test
```

Run masterscript:
```yaml
cmd.script:
    - name: masterscript
    - source: salt://path/to/masterscript
    - cwd: /
    - stateful:
      - test_name: masterscript test
```

Should I use `cmd.run` or `cmd.wait`?

**Note:** Use `cmd.run` together with `onchanges` instead of `cmd.wait`.

These two states are often confused. The important thing to remember about them is that `cmd.run` states are run each time the SLS file that contains them is applied. If it is more desirable to have a command that only runs after some other state changes, then `cmd.wait` does just that. `cmd.wait` is designed to watch other states, and is executed when the state it is watching changes. Example:

```
/usr/local/bin/postinstall.sh:
  cmd.wait:
    - watch:
      - pkg: mycustompkg
  file.managed:
    - source: salt://utils/scripts/postinstall.sh

mycustompkg:
  pkg.installed:
    - require:
      - file: /usr/local/bin/postinstall.sh
```

`cmd.wait` itself does not do anything; all functionality is inside its `mod_watch` function, which is called by `watch` on changes.

The preferred format is using the `onchanges Requisite`, which works on `cmd.run` as well as on any other state. The example would then look as follows:

```
/usr/local/bin/postinstall.sh:
  cmd.run:
    - onchanges:
      - pkg: mycustompkg
  file.managed:
    - source: salt://utils/scripts/postinstall.sh

mycustompkg:
  pkg.installed:
    - require:
      - file: /usr/local/bin/postinstall.sh
```
How do I create an environment from a pillar map?

The map that comes from a pillar can be directly consumed by the env option! To use it, one may pass it like this.

Example:

```python
printenv:
  cmd.run:
    - env: {{ salt['pillar.get']('example: key', {}) }}
```

salt.states.cmd.call(name, func, args=(), kws=None, onlyif=None, unless=None, creates=None, output_loglevel='debug', use_vt=False, **kwargs)

Invoke a pre-defined Python function with arguments specified in the state declaration. This function is mainly used by the salt.renderers.pydsl renderer.

The interpretation of onlyif and unless arguments are identical to those of cmd.run, and all other arguments(cwd, runas, ...) allowed by cmd.run are allowed here, except that their effects apply only to the commands specified in onlyif and unless rather than to the function to be invoked.

In addition, the stateful argument has no effects here.

The return value of the invoked function will be interpreted as follows.

If it's a dictionary then it will be passed through to the state system, which expects it to have the usual structure returned by any salt state function.

Otherwise, the return value (denoted as result in the code below) is expected to be a JSON serializable object, and this dictionary is returned:

```python
{
  'name': name,
  'changes': {'retval': result},
  'result': True if result is None else bool(result),
  'comment': result if isinstance(result, string_types) else ''
}
```

salt.states.cmd.mod_run_check(cmd_kwargs, onlyif, unless, creates)

Execute the onlyif and unless logic. Return a result dict if: * onlyif failed (onlyif != 0) * unless succeeded (unless == 0) else return True

salt.states.cmd.mod_watch(name, **kwargs)

Execute a cmd function based on a watch call

---

**Note:** This state exists to support special handling of the watch requisite. It should not be called directly.

Parameters for this function should be set by the state being triggered.

---

salt.states.cmd.run(name, onlyif=None, unless=None, creates=None, cwd=None, runas=None, shell=None, env=None, stateful=False, umask=None, output_loglevel='debug', quiet=False, timeout=None, ignore_timeout=False, use_vt=False, **kwargs)

Run a command if certain circumstances are met. Use cmd.wait if you want to use the watch requisite.

**name** The command to execute, remember that the command will execute with the path and permissions of the salt-minion.

**onlyif** A command to run as a check, run the named command only if the command passed to the onlyif option returns true

**unless** A command to run as a check, only run the named command if the command passed to the unless option returns false

**cwd** The current working directory to execute the command in, defaults to /root
runas  The user name to run the command as

shell  The shell to use for execution, defaults to the shell grain

env  A list of environment variables to be set prior to execution. Example:

```yaml
script-foo:
  cmd.run:
    - env:
      - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false
are all loaded as boolean True and False values, and must be enclosed in quotes to be used as
strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH`

```yaml
script-bar:
  cmd.run:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```jinja
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

stateful  The command being executed is expected to return data about executing a state. For more informa-
tion, see the [Using the "Stateful" Argument](#) section.

umask  The umask (in octal) to use when running the command.

output_loglevel  Control the loglevel at which the output from the command is logged. Note that the com-
mand being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

quiet  The command will be executed quietly, meaning no log entries of the actual command or its return
data. This is deprecated as of the 2014.1.0 release, and is being replaced with output_loglevel: quiet.

timeout  If the command has not terminated after timeout seconds, send the subprocess sigterm, and if
sigterm is ignored, follow up with sigkill

ignore_timeout  Ignore the timeout of commands, which is useful for running nohup processes.

   New in version 2015.8.0.

creates  Only run if the file or files specified by creates do not exist.

   New in version 2014.7.0.

use_vt  Use VT utils (saltstack) to stream the command output more interactively to the console and the logs.

   This is experimental.

bg  If True, run command in background and do not await or deliver it's results.

   New in version 2016.3.6.

**Note:** cmd.run supports the usage of reload_modules. This functionality allows you to force Salt to
reload all modules. You should only use reload_modules if your cmd.run does some sort of installation
(such as pip), if you do not reload the modules future items in your state which rely on the software being
installed will fail.
getpip:
  cmd.run:
    - name: /usr/bin/python /usr/local/sbin/get-pip.py
    - unless: which pip
    - require:
      - pkg: python
      - file: /usr/local/sbin/get-pip.py
    - reload_modules: True

salt.states.cmd.script(name, source=None, template=None, onlyif=None, unless=None, creates=None, cwd=None, runas=None, env=None, stateful=False, umask=None, timeout=None, use_vt=False, output_loglevel='debug', defaults=None, context=None, **kwargs)

Download a script and execute it with specified arguments.

**source** The location of the script to download. If the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs

**template** If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported

**name** Either ``cmd arg1 arg2 arg3...'' (cmd is not used) or a source ``salt://...''.

**onlyif** Run the named command only if the command passed to the onlyif option returns true

**unless** Run the named command only if the command passed to the unless option returns false

**cwd** The current working directory to execute the command in, defaults to /root

**runas** The name of the user to run the command as

**shell** The shell to use for execution. The default is set in grains['shell']

**env** A list of environment variables to be set prior to execution. Example:

```
salt://scripts/foo.sh:
  cmd.script:
    - env:
      - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH':

```
salt://scripts/bar.sh:
  cmd.script:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ current_path, '/my/special/bin'|join(':') }}
```

**saltenv** [base] The Salt environment to use

**umask** The umask (in octal) to use when running the command.
stateful The command being executed is expected to return data about executing a state. For more information, see the Using the "Stateful" Argument section.

timeout If the command has not terminated after timeout seconds, send the subprocess sigterm, and if sigterm is ignored, follow up with sigkill

args String of command line args to pass to the script. Only used if no args are specified as part of the name argument. To pass a string containing spaces in YAML, you will need to doubly-quote it: ``arg1 'arg two' arg3"

creates Only run if the file or files specified by creates do not exist.

New in version 2014.7.0.

use_vt Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

context New in version 2016.3.0.

Overrides default context variables passed to the template.

defaults New in version 2016.3.0.

Default context passed to the template.

output_loglevel Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

salt.states.cmd.wait(name, onlyif=None, unless=None, creates=None, cwd=None, runas=None, shell=None, env=(), stateful=False, umask=None, output_loglevel='debug', use_vt=False, **kwargs)

Run the given command only if the watch statement calls it.

**Note:** Use cmd.run with onchange instead.

name The command to execute, remember that the command will execute with the path and permissions of the salt-minion.

onlyif A command to run as a check, run the named command only if the command passed to the onlyif option returns true

unless A command to run as a check, only run the named command if the command passed to the unless option returns false

cwd The current working directory to execute the command in, defaults to /root

runas The user name to run the command as

shell The shell to use for execution, defaults to /bin/sh

env A list of environment variables to be set prior to execution. Example:

```
script-foo:
  cmd.wait:
    env:
      BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH`:

```
script-bar:
  cmd.wait:
    env: "PATH=/some/path:$PATH"
```
One can still use the existing $PATH by using a bit of Jinja:

```python
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}
```

```yaml
mycommand:
    cmd.run:
      - name: ls -l /
      - env:
        - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

**umask**  The umask (in octal) to use when running the command.

**stateful**  The command being executed is expected to return data about executing a state. For more information, see the Using the `"Stateful"` Argument section.

**creates**  Only run if the file or files specified by creates do not exist.

New in version 2014.7.0.

**output_loglevel**  Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

**use_vt**  Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

```
salt.states.cmd.wait_call(name, func, args=(), kws=None, onlyif=None, unless=None, creates=None, stateful=False, use_vt=False, output_loglevel='debug', **kwargs)
salt.states.cmd.wait_script(name, source=None, template=None, onlyif=None, unless=None, cwd=None, runas=None, shell=None, env=None, stateful=False, umask=None, use_vt=False, output_loglevel='debug', **kwargs)
```

Download a script from a remote source and execute it only if a watch statement calls it.

**source**  The source script being downloaded to the minion, this source script is hosted on the salt master server. If the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs

**template**  If this setting is applied then the named templating engine will be used to render the downloaded file, currently jinja, mako, and wempy are supported

**name**  The command to execute, remember that the command will execute with the path and permissions of the salt-minion.

**onlyif**  A command to run as a check, run the named command only if the command passed to the onlyif option returns true

**unless**  A command to run as a check, only run the named command if the command passed to the unless option returns false

**cwd**  The current working directory to execute the command in, defaults to /root

**runas**  The user name to run the command as

**shell**  The shell to use for execution, defaults to the shell grain

**env**  A list of environment variables to be set prior to execution. Example:

```
salt://scripts/foo.sh:
    cmd.wait_script:
      - env:
        - BATCH: 'yes'
```

**Warning:**  The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH`:
One can still use the existing $PATH by using a bit of Jinja:

```python
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

### 19.19.56 salt.states.composer

**Installation of Composer Packages**

These states manage the installed packages for composer for PHP. Note that either composer is installed and accessible via a bin directory or you can pass the location of composer in the state.

```python
get-composer:
  cmd.run:
    - name: 'CURL=`which curl`; $CURL -sS https://getcomposer.org/installer | php'
    - unless: test -f /usr/local/bin/composer
    - cwd: /root/

install-composer:
  cmd.wait:
    - name: mv /root/composer.phar /usr/local/bin/composer
    - cwd: /root/
    - watch:
      - cmd: get-composer

/path/to/project:
  composer.installed:
    - no_dev: true
    - require:
      - cmd: install-composer

# Without composer installed in your PATH
# Note: composer.phar must be executable for state to work properly
/path/to/project:
  composer.installed:
```
- composer: /path/to/composer.phar
- php: /usr/local/bin/php
- no_dev: true

salt.states.composer.installed

```
(name, composer=None, php=None, user=None, prefer_source=None, prefer_dist=None, no_scripts=None, no_plugins=None, optimize=None, no_dev=None, quiet=False, composer_home='/root', always_check=True)
```

Verify that the correct versions of composer dependencies are present.

- **name** Directory location of the composer.json file.
- **composer** Location of the composer.phar file. If not set composer will just execute composer as if it is installed globally. (i.e. /path/to/composer.phar)
- **php** Location of the php executable to use with composer. (i.e. /usr/bin/php)
- **user** Which system user to run composer as.

  New in version 2014.1.4.

  - **prefer_source** --prefer-source option of composer.
  - **prefer_dist** --prefer-dist option of composer.
  - **no_scripts** --no-scripts option of composer.
  - **no_plugins** --no-plugins option of composer.
  - **optimize** --optimize-autoloader option of composer. Recommended for production.
  - **no_dev** --no-dev option for composer. Recommended for production.
  - **quiet** --quiet option for composer. Whether or not to return output from composer.
  - **composer_home** $COMPOSER_HOME environment variable
  - **always_check** If True, always run composer install in the directory. This is the default behavior. If False, only run composer install if there is no vendor directory present.

salt.states.composer.update

```
(name, composer=None, php=None, user=None, prefer_source=None, prefer_dist=None, no_scripts=None, no_plugins=None, optimize=None, no_dev=None, quiet=False, composer_home='/root')
```

Composer update the directory to ensure we have the latest versions of all project dependencies.

- **name** Directory location of the composer.json file.
- **composer** Location of the composer.phar file. If not set composer will just execute composer as if it is installed globally. (i.e. /path/to/composer.phar)
- **php** Location of the php executable to use with composer. (i.e. /usr/bin/php)
- **user** Which system user to run composer as.

  New in version 2014.1.4.

  - **prefer_source** --prefer-source option of composer.
  - **prefer_dist** --prefer-dist option of composer.
  - **no_scripts** --no-scripts option of composer.
  - **no_plugins** --no-plugins option of composer.
  - **optimize** --optimize-autoloader option of composer. Recommended for production.
  - **no_dev** --no-dev option for composer. Recommended for production.
  - **quiet** --quiet option for composer. Whether or not to return output from composer.
  - **composer_home** $COMPOSER_HOME environment variable

19.19.57 salt.states.cron

Management of cron, the Unix command scheduler

Cron declarations require a number of parameters. The following are the parameters used by Salt to define the various timing values for a cron job:

- **minute**
• hour
• daymonth
• month
• dayweek (0 to 6 are Sunday through Saturday, 7 can also be used for Sunday)

**Warning:** Any timing arguments not specified take a value of *. This means that setting **hour** to 5, while not defining the **minute** param, will result in Salt adding a job that will execute every minute between 5 and 6 A.M.!

Additionally, the default user for these states is **root**. Therefore, if the cron job is for another user, it is necessary to specify that user with the **user** parameter.

A long time ago (before 2014.2), when making changes to an existing cron job, the name declaration is the parameter used to uniquely identify the job, so if an existing cron that looks like this:

```bash
date > /tmp/crontest:
    cron.present:
        - user: root
        - minute: 5
```

Is changed to this:

```bash
date > /tmp/crontest:
    cron.present:
        - user: root
        - minute: 7
        - hour: 2
```

Then the existing cron will be updated, but if the cron command is changed, then a new cron job will be added to the user's crontab.

The current behavior is still relying on that mechanism, but you can also specify an identifier to identify your crontabs:

```bash
date > /tmp/crontest:
    cron.present:
        - identifier: SUPERCRON
        - user: root
        - minute: 7
        - hour: 2
```

New in version 2014.1.2.

And, some months later, you modify it:

```bash
superscript > /tmp/crontest:
    cron.present:
        - identifier: SUPERCRON
        - user: root
        - minute: 3
        - hour: 4
```

New in version 2014.1.2.

The old **date > /tmp/crontest** will be replaced by **superscript > /tmp/crontest**.
Additionally, Salt also supports running a cron every \( x \) minutes very similarly to the Unix convention of using \( */5 \) to have a job run every five minutes. In Salt, this looks like:

```
date > /tmp/crontest:
cron.present:
   - user: root
   - minute: '\*/5'
```

The job will now run every 5 minutes.

Additionally, the temporal parameters (minute, hour, etc.) can be randomized by using `random` instead of using a specific value. For example, by using the `random` keyword in the `minute` parameter of a cron state, the same cron job can be pushed to hundreds or thousands of hosts, and they would each use a randomly-generated minute. This can be helpful when the cron job accesses a network resource, and it is not desirable for all hosts to run the job concurrently.

```
/path/to/cron/script:
cron.present:
   - user: root
   - minute: random
   - hour: 2
```

New in version 0.16.0.

Since Salt assumes a value of `*` for unspecified temporal parameters, adding a parameter to the state and setting it to `random` will change that value from `*` to a randomized numeric value. However, if that field in the cron entry on the minion already contains a numeric value, then using the `random` keyword will not modify it.

Added the opportunity to set a job with a special keyword like `@reboot` or `@hourly`. Quotes must be used, otherwise PyYAML will strip the `@` sign.

```
/path/to/cron/script:
cron.present:
   - user: root
   - special: '@hourly'
```

The script will be executed every reboot if cron daemon support this option.

```
/path/to/cron/otherscript:
cron.absent:
   - user: root
   - special: '@daily'
```

This counter part definition will ensure than a job with a special keyword is not set.

`salt.states.cron.absent(name, user='root', identifier=False, special=None, **kwargs)`

Verifies that the specified cron job is absent for the specified user; only the name is matched when removing a cron job.

- `name` The command that should be absent in the user crontab.
- `user` The name of the user whose crontab needs to be modified, defaults to the root user
- `identifier` Custom-defined identifier for tracking the cron line for future crontab edits. This defaults to the state name
- `special` The special keyword used in the job (eg. @reboot, @hourly...). Quotes must be used, otherwise PyYAML will strip the `@` sign.

`salt.states.cron.env_absent(name, user='root')`

Verifies that the specified environment variable is absent from the crontab for the specified user

- `name` The name of the environment variable to remove from the user crontab
- `user` The name of the user whose crontab needs to be modified, defaults to the root user
salt.states.cron.env_present
(name, value=None, user='root')
Verifies that the specified environment variable is present in the crontab for the specified user.

- name: The name of the environment variable to set in the user crontab
- user: The name of the user whose crontab needs to be modified, defaults to the root user
- value: The value to set for the given environment variable

salt.states.cron.file
(name, source_hash='`, source_hash_name=None, user='root', template=None,
context=None, replace=True, defaults=None, backup='`, **kwargs)
Provides file.managed-like functionality (templating, etc.) for a pre-made crontab file, to be assigned to a
given user.

- name: The source file to be used as the crontab. This source file can be hosted on either the salt master server,
or on an HTTP or FTP server. For files hosted on the salt file server, if the file is located on the master
in the directory named spam, and is called eggs, the source string is salt://spam/eggs

If the file is hosted on a HTTP or FTP server then the source_hash argument is also required

- source_hash: This can be either a file which contains a source hash string for the source, or a source
hash string. The source hash string is the hash algorithm followed by the hash of the file:
md5=e138491e9d5b97023ce823fe17bac22

- source_hash_name: When source_hash refers to a hash file, Salt will try to find the correct hash by matching
the filename/URI associated with that hash. By default, Salt will look for the filename being managed.
When managing a file at path /tmp/foo.txt, then the following line in a hash file would match:

  acbd18db4cc2f85cedef654fccc4a4d8   foo.txt

However, sometimes a hash file will include multiple similar paths:

  37b51d194a7513e45b56f6524f2d51f2   ./dir1/foo.txt
  acbd18db4cc2f85cedef654fccc4a4d8   ./dir2/foo.txt
  73f2ff4a4b7f6bb68e44c984c85f6e88   ./dir3/foo.txt

In cases like this, Salt may match the incorrect hash. This argument can be used to tell Salt which
filename to match, to ensure that the correct hash is identified. For example:

foo_crontab:
cron.file:
  - name: https://mydomain.tld/dir2/foo.txt
  - source_hash: https://mydomain.tld/hashes
  - source_hash_name: ./dir2/foo.txt

Note: This argument must contain the full filename entry from the checksum file, as this argument
is meant to disambiguate matches for multiple files that have the same basename. So, in the example
above, simply using foo.txt would not match.

New in version 2016.3.5.

- user: The user to whom the crontab should be assigned. This defaults to root.
- template: If this setting is applied then the named templating engine will be used to render the downloaded
file. Currently, jinja and mako are supported.
- context: Overrides default context variables passed to the template.
- replace: If the crontab should be replaced, if False then this command will be ignored if a crontab exists for
the specified user. Default is True.
- defaults: Default context passed to the template.
- backup: Overrides the default backup mode for the user's crontab.
Verifies that the specified cron job is present for the specified user. For more advanced information about what exactly can be set in the cron timing parameters, check your cron system's documentation. Most Unix-like systems' cron documentation can be found via the crontab man page: `man 5 crontab`.

- **name** The command that should be executed by the cron job.
- **user** The name of the user whose crontab needs to be modified, defaults to the root user.
- **minute** The information to be set into the minute section, this can be any string supported by your cron system's minute field. Default is `*`.
- **hour** The information to be set in the hour section. Default is `*`.
- **daymonth** The information to be set in the day of month section. Default is `*`.
- **month** The information to be set in the month section. Default is `*`.
- **dayweek** The information to be set in the day of week section. Default is `*`.
- **comment** User comment to be added on line previous the cron job.
- **commented** The cron job is set commented (prefixed with `#DISABLED#`). Defaults to False.
- **identifier** Custom-defined identifier for tracking the cron line for future crontab edits. This defaults to the state name.
- **special** A special keyword to specify periodicity (eg. `@reboot`, `@hourly...`). Quotes must be used, otherwise PyYAML will strip the `@` sign.

New in version 2016.3.0.

---

19.19.58 salt.states.csf module

- **salt.states.csf.nics_skip**(name, nics, ipv6)
  Alias for `csf.nics_skipped`

- **salt.states.csf.nics_skipped**(name, nics, ipv6=False)
  - **name** Meaningless arg, but required for state.
  - **nics** A list of nics to skip.
  - **ipv6** Boolean. Set to true if you want to skip the ipv6 interface. Default false (ipv4).

- **salt.states.csf.option_present**(name, value, reload=False)
  Ensure the state of a particular option/setting in csf.
  - **name** The option name in csf.conf
  - **value** The value it should be set to.
  - **reload** Boolean. If set to true, csf will be reloaded after.

- **salt.states.csf.pports_open**(name, ports, proto='tcp', direction='in')
  Ensure ports are open for a protocol, in a direction. e.g. - proto='tcp', direction='in' would set the values for TCP_IN in the csf.conf file.
  - **ports** A list of ports that should be open.
  - **proto** The protocol. May be one of `tcp`, `udp`, `tcp6`, or `udp6`.
  - **direction** Choose `in`, `out`, or both to indicate the port should be opened for inbound traffic, outbound traffic, or both.

- **salt.states.csf.rule_absent**(name, method, port=None, proto='tcp', direction='in', port_origin='d', ip_origin='s', ttl=None, reload=False)
  Ensure iptable is not present.
  - **name** The ip address or CIDR for the rule.
  - **method** The type of rule. Either `allow` or `deny`.
  - **port** Optional port to be open or closed for the iptables rule.
  - **proto** The protocol. Either `tcp`, `udp`. Only applicable if port is specified.
direction The direction of traffic to apply the rule to. Either `in', or `out'. Only applicable if port is specified.

port_origin Specifies either the source or destination port is relevant for this rule. Only applicable if port is specified. Either `s', or `d'.

ip_origin Specifies whether the ip in this rule refers to the source or destination ip. Either `s', or `d'. Only applicable if port is specified.

ttl How long the rule should exist. If supplied, csf.tempallow() or csf.tempdeny() are used.

reload Reload the csf service after applying this rule. Default false.

salt.states.csf.rule_present(name, method, port=None, proto='tcp', direction='in', port_origin='d',
ip_origin='s', ttl=None, comment=' ', reload=False)

Ensure iptable rule exists.

name The ip address or CIDR for the rule.

method The type of rule. Either `allow' or `deny'.

port Optional port to be open or closed for the iptables rule.

proto The protocol. Either `tcp', or `udp'. Only applicable if port is specified.

direction The direction of traffic to apply the rule to. Either `in', or `out'. Only applicable if port is specified.

port_origin Specifies either the source or destination port is relevant for this rule. Only applicable if port is specified. Either `s', or `d'.

ip_origin Specifies whether the ip in this rule refers to the source or destination ip. Either `s', or `d'. Only applicable if port is specified.

ttl How long the rule should exist. If supplied, csf.tempallow() or csf.tempdeny() are used.

comment An optional comment to appear after the rule as a #comment .

reload Reload the csf service after applying this rule. Default false.

salt.states.csf.testing_off(name, reload=False)

Ensure testing mode is enabled in csf.

reload Reload CSF after changing the testing status. Default false.

salt.states.csf.testing_on(name, reload=False)

Ensure testing mode is enabled in csf.

reload Reload CSF after changing the testing status. Default false.

19.19.59 salt.states.cyg

Installation of Cygwin packages.

A state module to manage cygwin packages. Packages can be installed or removed.

dos2unix:

cyg.installed

class salt.states.cyg.DictDiffer(current_dict, past_dict)

Calculate the difference between two dictionaries.

1.items added
2.items removed
3.keys same in both but changed values
4.keys same in both and unchanged values

added()
Return a set of additions to past_dict.

changed()
Return a set of the keys with changed values.

removed()
Return a set of things removed from past_dict.
same()
    True if the two dicts are the same.

unchanged()
    Return a set of the keys with unchanged values.
salt.states.cyg.installed(name, cyg_arch='x86_64', mirrors=None)
    Make sure that a package is installed.
    name The name of the package to install
cyg_arch [x86_64] The cygwin architecture to install the package into. Current options are x86 and x86_64
    mirrors [None] List of mirrors to check. None will use a default mirror (kernel.org)
    CLI Example:

    rsync:
    cyg.installed:
        - mirrors:
            - http://mirror/without/public/key: ""

salt.states.cyg.removed(name, cyg_arch='x86_64', mirrors=None)
    Make sure that a package is not installed.
    name The name of the package to uninstall
cyg_arch [x86_64] The cygwin architecture to remove the package from. Current options are x86 and x86_64
    mirrors [None] List of mirrors to check. None will use a default mirror (kernel.org)
    CLI Example:

    rsync:
    cyg.removed:
        - mirrors:
            - http://mirror/without/public/key: ""

salt.states.cyg.updated(name=None, cyg_arch='x86_64', mirrors=None)
    Make sure all packages are up to date.
    name [None] No affect, salt fails poorly without the arg available
cyg_arch [x86_64] The cygwin architecture to update. Current options are x86 and x86_64
    mirrors [None] List of mirrors to check. None will use a default mirror (kernel.org)
    CLI Example:

    rsync:
    cyg.updated:
        - mirrors:
            - http://mirror/without/public/key: ""

19.19.60 salt.states.ddns

Dynamic DNS updates

Ensure a DNS record is present or absent utilizing RFC 2136 type dynamic updates.

    depends
        • dnspython
Note: The dnspython module is required when managing DDNS using a TSIG key. If you are not using a TSIG key, DDNS is allowed by ACLs based on IP address and the dnspython module is not required.

Example:

```
webserver:
  ddns.present:
    - zone: example.com
    - ttl: 60
    - data: 111.222.333.444
    - nameserver: 123.234.345.456
    - keyfile: /srv/salt/dnspy_tsig_key.txt
```

salt.states.ddns.absent(name, zone, data=None, rdtype=None, **kwargs)
Ensures that the named DNS record is absent.

- name: The host portion of the DNS record, e.g., `webserver'. Name and zone are concatenated when the entry is created unless name includes a trailing dot, so make sure that information is not duplicated in these two arguments.
- zone: The zone to check
- data: Data for the DNS record. E.g., the IP address for an A record. If omitted, all records matching name (and rdtype, if provided) will be purged.
- rdtype: DNS resource type. If omitted, all types will be purged.
- **kwargs: Additional arguments the ddns.update function may need (e.g. nameserver, keyfile, keyname).
  Note that the nsupdate key file can’t be reused by this function, the keyfile and other arguments must follow the dnspython spec.

salt.states.ddns.present(name, zone, ttl, data, rdtype='A', **kwargs)
Ensures that the named DNS record is present with the given ttl.

- name: The host portion of the DNS record, e.g., `webserver'. Name and zone are concatenated when the entry is created unless name includes a trailing dot, so make sure that information is not duplicated in these two arguments.
- zone: The zone to check/update
- ttl: TTL for the record
- data: Data for the DNS record. E.g., the IP address for an A record.
- rdtype: DNS resource type. Default `A'.
- **kwargs: Additional arguments the ddns.update function may need (e.g. nameserver, keyfile, keyname).
  Note that the nsupdate key file can’t be reused by this function, the keyfile and other arguments must follow the dnspython spec.

19.19.61 salt.states.debconfmod

Management of debconf selections

depends
- debconf-utils package

The debconfmod state module manages the enforcement of debconf selections, this state can set those selections prior to package installation.

Available Functions

The debconfmod state has two functions, the set and set_file functions
**set**  Set debconf selections from the state itself

**set_file**  Set debconf selections from a file

```yaml
nullmailer-debconf:
  debconf.set:
    - name: nullmailer
    - data:
      'shared/mailname': {'type': 'string', 'value': 'server.domain.tld'}
      'nullmailer/relayhost': {'type': 'string', 'value': 'mail.domain.tld'}

ferm-debconf:
  debconf.set:
    - name: ferm
    - data:
      'ferm/enable': {'type': 'boolean', 'value': True}
```

**Note:** Due to how PyYAML imports nested dicts (see [here](#)), the values in the `data` dict must be indented four spaces instead of two.

salt.states.debconfmod.set(name, data, **kwargs)
Set debconf selections

```python
<state_id>:
  debconf.set:
    - name: <name>
    - data:
      <question>: {'type': <type>, 'value': <value>}
      <question>: {'type': <type>, 'value': <value>}
```

**name:** The package name to set answers for.

**data:** A set of questions/answers for debconf. Note that everything under this must be indented twice.

**question:** The question the is being pre-answered

**type:** The type of question that is being asked (string, boolean, select, etc.)

**value:** The answer to the question

salt.states.debconfmod.set_file(name, source, template=None, context=None, defaults=None, **kwargs)
Set debconf selections from a file or a template

```python
<state_id>:
  debconf.set_file:
    - source: salt://path/to/pkg.selections

<state_id>:
  debconf.set_file:
    - source: salt://path/to/pkg.selections?saltenv=myenvironment

<state_id>:
  debconf.set_file:
    - source: salt://path/to/pkg.selections.jinja2
```
source: The location of the file containing the package selections

template: If this setting is applied then the named templating engine will be used to render the package selections file, currently jinja, mako, and wempy are supported

context: Overrides default context variables passed to the template.

defaults: Default context passed to the template.

### 19.19.62 `salt.states.dellchassis`

Manage chassis via Salt Proxies.

New in version 2015.8.2.

Below is an example state that sets basic parameters:

```yaml
my-dell-chassis:
  dellchassis.chassis:
    - chassis_name: my-dell-chassis
    - datacenter: dc-1-us
    - location: my-location
    - mode: 2
    - idrac_launch: 1
    - slot_names:
      - server-1: my-slot-name
      - server-2: my-other-slot-name
    - blade_power_states:
      - server-1: on
      - server-2: off
      - server-3: powercycle
```

However, it is possible to place the entire set of chassis configuration data in pillar. Here's an example pillar structure:

```yaml
proxy:
  host: 10.27.20.18
  admin_username: root
  fallback_admin_username: root
  passwords:
    - super-secret
    - old-secret
  proxytype: fx2

chassis:
  name: fx2-1
  username: root
  password: saltstack1
  datacenter: london
  location: rack-1-shelf-3
  management_mode: 2
  idrac_launch: 0
  slot_names: 
    - 'server-1': blade1
    - 'server-2': blade2

servers:
```

19.19. state modules
server-1:
  idrac_password: saltstack1
  ipmi_over_lan: True
  ip: 172.17.17.132
  netmask: 255.255.0.0
  gateway: 172.17.17.1

server-2:
  idrac_password: saltstack1
  ipmi_over_lan: True
  ip: 172.17.17.2
  netmask: 255.255.0.0
  gateway: 172.17.17.1

server-3:
  idrac_password: saltstack1
  ipmi_over_lan: True
  ip: 172.17.17.20
  netmask: 255.255.0.0
  gateway: 172.17.17.1

server-4:
  idrac_password: saltstack1
  ipmi_over_lan: True
  ip: 172.17.17.2
  netmask: 255.255.0.0
  gateway: 172.17.17.1

switches:
  switch-1:
    ip: 192.168.1.2
    netmask: 255.255.255.0
    gateway: 192.168.1.1
    snmp: nonpublic
    password: saltstack1

  switch-2:
    ip: 192.168.1.3
    netmask: 255.255.255.0
    gateway: 192.168.1.1
    snmp: nonpublic
    password: saltstack1

And to go with it, here's an example state that pulls the data from the pillar stated above:

```python
{% set details = pillar.get('proxy:chassis', {}) %}

standup-step1:
  dellchassis.chassis:
    - name: {{ details['name'] }}
    - location: {{ details['location'] }}
    - mode: {{ details['management_mode'] }}
    - idrac_launch: {{ details['idrac_launch'] }}
    - slot_names:
      {% for entry in details['slot_names'] %}
        - {{ entry.keys()[0] }}: {{ entry[entry.keys()[0]] }}
      {% endfor %}

blade_powercycle:
  dellchassis.chassis:
    - blade_power_states:
      - server-1: powercycle
      - server-2: powercycle
```
- server-3: powercycle
- server-4: powercycle

# Set idrac_passwords for blades. racadm needs them to be called 'server-x'
{% for k, v in details['servers'].iteritems() %}
  {{ k }}:
  - idrac_password: {{ v['idrac_password'] }}
{% endfor %}

# Set management ip addresses, passwords, and snmp strings for switches
{% for k, v in details['switches'].iteritems() %}
  {{ k }}-switch-setup:
    dellchassis.switch:
      - name: {{ k }}
      - ip: {{ v['ip'] }}
      - netmask: {{ v['netmask'] }}
      - gateway: {{ v['gateway'] }}
      - password: {{ v['password'] }}
      - snmp: {{ v['snmp'] }}
{% endfor %}

Note: This state module relies on the dracr.py execution module, which runs racadm commands on the chassis, blades, etc. The racadm command runs very slowly and, depending on your state, the proxy minion return might timeout before the racadm commands have completed. If you are repeatedly seeing minions timeout after state calls, please use the -t CLI argument to increase the timeout variable.

For example:
salt '*' state.sls my-dell-chasis-state-name -t 60

---

Note: The Dell CMC units perform adequately but many iDRACs are excruciatingly slow. Some functions can take minutes to execute.

salt.states.dellchassis.blade_idrac(name, idrac_password=None, idrac_ipmi=None, idrac_ip=None, idrac_netmask=None, idrac_gateway=None, idrac_dnsname=None, idrac_dhcp=None)

Set parameters for iDRAC in a blade.

Parameters
- **idrac_password** -- Password to use to connect to the iDRACs directly (idrac_ipmi and idrac_dnsname must be set directly on the iDRAC. They can't be set through the CMC. If this password is present, use it instead of the CMC password)
- **idrac_ipmi** -- Enable/Disable IPMI over LAN
- **idrac_ip** -- Set IP address for iDRAC
- **idrac_netmask** -- Set netmask for iDRAC
- **idrac_gateway** -- Set gateway for iDRAC
- **idrac_dhcp** -- Turn on DHCP for iDRAC (True turns on, False does nothing because setting a static IP will disable DHCP).

Returns A standard Salt changes dictionary

NOTE: If any of the IP address settings is configured, all of ip, netmask, and gateway must be present
salt.states.dellchassis.chassis(name, chassis_name=None, password=None, datacenter=None, location=None, mode=None, idrac_launch=None, slot_names=None, blade_power_states=None)

Manage a Dell Chassis.

chassis_name  The name of the chassis.
datacenter  The datacenter in which the chassis is located
location  The location of the chassis.
password  Password for the chassis. Note: If this password is set for the chassis, the current implementation of this state will set this password both on the chassis and the iDrac passwords on any configured blades. If the password for the blades should be distinct, they should be set separately with the blade_idrac function.
mode  The management mode of the chassis. Viable options are:
  • 0: None
  • 1: Monitor
  • 2: Manage and Monitor
idrac_launch  The iDRAC launch method of the chassis. Viable options are:
  • 0: Disabled (launch iDRAC using IP address)
  • 1: Enabled (launch iDRAC using DNS name)
slot_names  The names of the slots, provided as a list identified by their slot numbers.
blade_power_states  The power states of a blade server, provided as a list and identified by their server numbers. Viable options are:
  • on: Ensure the blade server is powered on.
  • off: Ensure the blade server is powered off.
  • powercycle: Power cycle the blade server.

Example:

my-dell-chassis:
  dellchassis.chassis:
    - chassis_name: my-dell-chassis
    - location: my-location
    - datacenter: london
    - mode: 2
    - idrac_launch: 1
    - slot_names:
      - 1: my-slot-name
      - 2: my-other-slot-name
    - blade_power_states:
      - server-1: on
      - server-2: off
      - server-3: powercycle

salt.states.dellchassis.firmware_update(hosts=None, directory='"')

State to update the firmware on host using the racadm command
firmwarefile  filename (string) starting with salt://
host  string representing the hostname supplied to the racadm command
directory  Directory name where firmwarefile will be downloaded

dell-chassis-firmware-update:
  dellchassis.firmware_update:
    hosts:
      cmc:
        salt://firmware_cmc.exe
      server-1:
        salt://firmware.exe
    directory: /opt/firmwares
salt.states.dellchassis.switch(name, ip=None, netmask=None, gateway=None, dhcp=None, password=None, snmp=None)

Manage switches in a Dell Chassis.

- **name** The switch designation (e.g. switch-1, switch-2)
- **ip** The Static IP Address of the switch
- **netmask** The netmask for the static IP
- **gateway** The gateway for the static IP
- **dhcp** True: Enable DHCP False: Do not change DHCP setup (disabling DHCP is automatic when a static IP is set)
- **password** The access (root) password for the switch
- **snmp** The SNMP community string for the switch

Example:

```yaml
my-dell-chassis:
  dellchassis.switch:
    - switch: switch-1
    - ip: 192.168.1.1
    - netmask: 255.255.255.0
    - gateway: 192.168.1.254
    - dhcp: True
    - password: secret
    - snmp: public
```

19.19.63  salt.states.disk

Disk monitoring state

Monitor the state of disk resources.

The disk.status function can be used to report that the used space of a filesystem is within the specified limits.

```yaml
used_space:
  disk.status:
    - name: /dev/xda1
      maximum: 79%
      minimum: 11%
```

It can be used with an onfail requisite, for example, to take additional action in response to or in preparation for other states.

```yaml
storage_threshold:
  disk.status:
    - name: /dev/xda1
      maximum: 97%

clear_cache:
  cmd.run:
    - name: rm -r /var/cache/app
    - onfail:
      - disk: storage_threshold
```

To use kilobytes (KB) for minimum and maximum rather than percents, specify the absolute flag:

```yaml
used_space:
  disk.status:
    - name: /dev/xda1
      minimum: 1024 KB
```

19.19. state modules
salt.states.disk.status(name, maximum=None, minimum=None, absolute=False)

Return the current disk usage stats for the named mount point

- **name**: Disk mount with which to check used space
- **maximum**: The maximum disk utilization
- **minimum**: The minimum disk utilization
- **absolute**: By default, the utilization is measured in percentage. Set the absolute flag to use kilobytes.

New in version 2016.11.0.

### 19.19.64 salt.states.docker

States to manage Docker containers, images, volumes, and networks

Changed in version 2017.7.0: The legacy Docker state and execution module have been removed, and the new modules (formerly called dockerng have taken their places).

**Important**: As of the 2017.7.0 release, the states in this module have been separated into the following four state modules:

- **docker_container**: States to manage Docker containers
- **docker_image**: States to manage Docker images
- **docker_volume**: States to manage Docker volumes
- **docker_network**: States to manage Docker networks

The reason for this change was to make states and requisites more clear. For example, imagine this SLS:

```yaml
myuser/appimage:
  docker.image_present:
    - sls: docker.images.appimage

myapp:
  docker.running:
    - image: myuser/appimage
    - require:
      - docker: myuser/appimage
```

The new syntax would be:

```yaml
myuser/appimage:
  docker_image.present:
    - sls: docker.images.appimage

myapp:
  docker_container.running:
    - image: myuser/appimage
    - require:
      - docker_image: myuser/appimage
```

This is similar to how Salt handles MySQL, MongoDB, Zabbix, and other cases where the same execution module is used to manage several different kinds of objects (users, databases, roles, etc.).
The old syntax will continue to work until the **Fluorine** release of Salt.

```python
salt.states.docker.absent(name, **kwargs)

Deprecated since version 2017.7.0: This state has been moved to docker_container.absent.
```

```python
salt.states.docker.image_absent(**kwargs)

Deprecated since version 2017.7.0: This state has been moved to docker_image.absent.
```

```python
salt.states.docker.image_present(name, **kwargs)

Deprecated since version 2017.7.0: This state has been moved to docker_image.present.
```

```python
salt.states.docker.mod_watch(name, sfun=None, **kwargs)
```

```python
salt.states.docker.network_absent(name, **kwargs)

Deprecated since version 2017.7.0: This state has been moved to docker_network.absent.
```

```python
salt.states.docker.network_present(name, **kwargs)

Deprecated since version 2017.7.0: This state has been moved to docker_network.present.
```

```python
salt.states.docker.running(name, **kwargs)

Deprecated since version 2017.7.0: This state has been moved to docker_container.running.
```

```python
salt.states.docker.stopped(**kwargs)

Deprecated since version 2017.7.0: This state has been moved to docker_container.stopped.
```

```python
salt.states.docker.volume_absent(name, driver=None)

Deprecated since version 2017.7.0: This state has been moved to docker_volume.absent.
```

```python
salt.states.docker.volume_present(name, driver=None, driver_opts=None, force=False)

Deprecated since version 2017.7.0: This state has been moved to docker_volume.present.
```

### 19.19.65 salt.states.docker_container

Management of Docker containers

New in version 2017.7.0.

```python
depends docker Python module
```

**Note:** Older releases of the Python bindings for Docker were called **docker-py** in PyPI. All releases of docker, and releases of **docker-py >= 1.6.0** are supported. These python bindings can easily be installed using **pip install**:

```bash
salt myminion pip.install docker
```

To upgrade from **docker-py** to docker, you must first uninstall **docker-py**, and then install docker:

```bash
salt myminion pip.uninstall docker-py
salt myminion pip.install docker
```

These states were moved from the **docker** state module (formerly called **dockerng**) in the 2017.7.0 release. When running the **docker_container.running** state for the first time after upgrading to 2017.7.0, your container(s) may be replaced. The changes may show diffs for certain parameters which say that the old value was an empty string, and the new value is **None**. This is due to the fact that in prior releases Salt was passing empty strings for these values when creating the container if they were undefined in the SLS file, where now Salt simply does not pass any arguments not explicitly defined in the SLS file. Subsequent runs of the state should not replace the container if the configuration remains unchanged.
**Note:** To pull from a Docker registry, authentication must be configured. See [here](#) for more information on how to configure access to docker registries in Pillar data.

```python
salt.states.docker_container.absent(name, force=False)
    Ensure that a container is absent
    name Name of the container
    force [False] Set to True to remove the container even if it is running
Usage Examples:

mycontainer:
    - docker_container.absent

multiple_containers:
    - docker_container.absent:
      - names:
        - foo
        - bar
        - baz
```

```python
salt.states.docker_container.mod_watch(name, sfun=None, **kwargs)
The docker_container watcher, called to invoke the watch command.

**Note:** This state exists to support special handling of the watch requisite. It should not be called directly. Parameters for this function should be set by the state being triggered.

```python
salt.states.docker_container.running(name, image=None, force=False, validate_ip_addrs=True, validate_deps=True, watch_action='force', start=True, shutdown_timeout=10, client_timeout=60, **kwargs)
    Ensure that a container with a specific configuration is present and running
    name Name of the container
    image Image to use for the container. Image names can be specified either using repo:tag notation, or just the repo name (in which case a tag of latest is assumed).

**Note:** This state will pull the image if it is not present. However, if the image needs to be built from a Dockerfile or loaded from a saved image, or if you would like to use requisites to trigger a replacement of the container when the image is updated, then the docker_image.present state should be used to manage the image.

**skip_translate** This function translates Salt CLI or SLS input into the format which docker-py expects. However, in the event that Salt’s translation logic fails (due to potential changes in the Docker Remote API, or to bugs in the translation code), this argument can be used to exert granular control over which arguments are translated and which are not.

Pass this argument as a comma-separated list (or Python list) of arguments, and translation for each passed argument name will be skipped. Alternatively, pass True and all translation will be skipped.

Skipping translation allows for arguments to be formatted directly in the format which docker-py expects. This allows for API changes and other issues to be more easily worked around. An example of using this option to skip translation would be:

For example, imagine that there is an issue with processing the port_bindings argument, and the following configuration no longer works as expected:
Salt Documentation, Release 2017.7.8

mycontainer:
  docker_container.running:
  - image: 7.3.1611
  - port_bindings:
    - 10.2.9.10:8080:80

By using `skip_translate`, you can forego the input translation and configure the port binding in the format `docker-py` needs:

mycontainer:
  docker_container.running:
  - image: 7.3.1611
  - skip_translate: port_bindings
  - port_bindings: {8080: [('10.2.9.10', 80)], '4193/udp', 9314}

See the following links for more information:
- `docker-py` Low-level API
- Docker Engine API

**ignore_collisions** [False] Since many of `docker-py`'s arguments differ in name from their CLI counterparts (with which most Docker users are more familiar), Salt detects usage of these and aliases them to the `docker-py` version of that argument so that both CLI and API versions of a given argument are supported. However, if both the alias and the `docker-py` version of the same argument (e.g. `env` and `environment`) are used, an error will be raised. Set this argument to `True` to suppress these errors and keep the `docker-py` version of the argument.

**validate_ip_addrs** [True] For parameters which accept IP addresses as input, IP address validation will be performed. To disable, set this to `False`.

**force** [False] Set this parameter to `True` to force Salt to re-create the container irrespective of whether or not it is configured as desired.

**watch_action** [force] Control what type of action is taken when this state watches another state that has changes. The default action is `force`, which runs the state with `force` set to `True`, triggering a rebuild of the container.

If any other value is passed, it will be assumed to be a kill signal. If the container matches the specified configuration, and is running, then the action will be to send that signal to the container. Kill signals can be either strings or numbers, and are defined in the **Standard Signals** section of the `signal(7)` manpage. Run `man 7 signal` on a Linux host to browse this manpage. For example:

mycontainer:
  docker_container.running:
  - image: busybox
  - watch_action: SIGHUP
  - watch:
    - file: some_file

**Note:** If the container differs from the specified configuration, or is not running, then instead of sending a signal to the container, the container will be re-created/started and no signal will be sent.

**start** [True] Set to `False` to suppress starting of the container if it exists, matches the desired configuration, but is not running. This is useful for data-only containers, or for non-daemonized container processes, such as the Django `migrate` and `collectstatic` commands. In instances such as this, the container only needs to be started the first time.

**shutdown_timeout** [10] If the container needs to be replaced, the container will be stopped using `docker.stop`. The value of this parameter will be passed to `docker.stop` as the `timeout` value, telling Docker how long to wait for a graceful shutdown before killing the container.
Changed in version 2017.7.0: This option was renamed from `stop_timeout` to `shutdown_timeout` to accommodate the `stop_timeout` container configuration setting.

`client_timeout` [60] Timeout in seconds for the Docker client. This is not a timeout for this function, but for receiving a response from the API.

**Note:** This is only used if Salt needs to pull the requested image.

### CONTAINER CONFIGURATION PARAMETERS

**auto_remove (or `rm`)** [False] Enable auto-removal of the container on daemon side when the container's process exits (analogous to running a docker container with `--rm` on the CLI).

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - auto_remove: True
```

**binds** Files/directories to bind mount. Each bind mount should be passed in one of the following formats:

- `<host_path>:` `<container_path>` - `host_path` is mounted within the container as `container_path` with read-write access.
- `<host_path>:` `<container_path>:` `<selinux_context>` - `host_path` is mounted within the container as `container_path` with read-write access. Additionally, the specified selinux context will be set within the container.
- `<host_path>:` `<container_path>:` `<read_only>` - `host_path` is mounted within the container as `container_path`, with the read-only or read-write setting explicitly defined.
- `<host_path>:` `<container_path>:` `<read_only>,<selinux_context>` - `host_path` is mounted within the container as `container_path`, with the read-only or read-write setting explicitly defined. Additionally, the specified selinux context will be set within the container.

 `<read_only>` can be either `ro` for read-write access, or `ro` for read-only access. When omitted, it is assumed to be read-write.

 `<selinux_context>` can be `z` if the volume is shared between multiple containers, or `Z` if the volume should be private.

**Note:** When both `<read_only>` and `<selinux_context>` are specified, there must be a comma before `<selinux_context>`.

Binds can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - binds: /srv/www:/var/www:ro,/etc/foo.conf:/usr/local/etc/foo.conf:rw

foo:
  docker_container.running:
    - image: bar/baz:latest
    - binds:
        - /srv/www:/var/www:ro
        - /home/myuser/conf/foo.conf:/etc/foo.conf:rw
```

However, in cases where both `ro/rw` and an selinux context are combined, the only option is to use a YAML list, like so:
foo:
  docker_container.running:
  - image: bar/baz:latest
  - binds:
    - /srv/www:/var/www:ro,Z
    - /home/myuser/conf/foo.conf:/etc/foo.conf:rw,Z

Since the second bind in the previous example is mounted read-write, the \texttt{rw} and comma can be dropped. For example:

foo:
  docker_container.running:
  - image: bar/baz:latest
  - binds:
    - /srv/www:/var/www:ro,Z
    - /home/myuser/conf/foo.conf:/etc/foo.conf:Z

\textbf{blkio_weight} Block IO weight (relative weight), accepts a weight value between 10 and 1000.

foo:
  docker_container.running:
  - image: bar/baz:latest
  - blkio_weight: 100

\textbf{blkio_weight_device} Block IO weight (relative device weight), specified as a list of expressions in the format \texttt{PATH:RATE}

foo:
  docker_container.running:
  - image: bar/baz:latest
  - blkio_weight_device: /dev/sda:100

\textbf{cap_add} List of capabilities to add within the container. Can be expressed as a comma-separated list or a Python list. The below two examples are equivalent:

foo:
  docker_container.running:
  - image: bar/baz:latest
  - cap_add: SYS_ADMIN,MKNOD

foo:
  docker_container.running:
  - image: bar/baz:latest
  - cap_add:
    - SYS_ADMIN
    - MKNOD

\textbf{Note:} This option requires Docker 1.2.0 or newer.

\textbf{cap_drop} List of capabilities to drop within the container. Can be expressed as a comma-separated list or a Python list. The below two examples are equivalent:

foo:
  docker_container.running:
  - image: bar/baz:latest
  - cap_drop: SYS_ADMIN,MKNOD
foo:
  docker_container.running:
  - image: bar/baz:latest
  - cap_drop:
    - SYS_ADMIN
    - MKNOD

Note: This option requires Docker 1.2.0 or newer.

command (or cmd) Command to run in the container

foo:
  docker_container.running:
  - image: bar/baz:latest
  - command: bash

cpuset_cpus (or cpuset) CPUs on which to allow execution, specified as a string containing a range (e.g. 0-3) or a comma-separated list of CPUs (e.g. 0,1).

foo:
  docker_container.running:
  - image: bar/baz:latest
  - cpuset_cpus: "0,1"

cpuset_mems Memory nodes on which to allow execution, specified as a string containing a range (e.g. 0-3) or a comma-separated list of MEMs (e.g. 0,1). Only effective on NUMA systems.

foo:
  docker_container.running:
  - image: bar/baz:latest
  - cpuset_mems: "0,1"

cpu_group The length of a CPU period in microseconds

foo:
  docker_container.running:
  - image: bar/baz:latest
  - cpu_group: 100000

cpu_period Microseconds of CPU time that the container can get in a CPU period

foo:
  docker_container.running:
  - image: bar/baz:latest
  - cpu_period: 50000

cpu_shares CPU shares (relative weight), specified as an integer between 2 and 1024.

foo:
  docker_container.running:
  - image: bar/baz:latest
  - cpu_shares: 512

detach [False] If True, run the container's command in the background (daemon mode)

foo:
  docker_container.running:
  - image: bar/baz:latest
  - detach: True
**devices** List of host devices to expose within the container. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices: /dev/net/tun,/dev/xvda1:/dev/xvda1,/dev/xvdb1:/dev/xvdb1:r
```

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices:
      - /dev/net/tun
      - /dev/xvda1
      - /dev/xvdb1:r
```

**device_read_bps** Limit read rate (bytes per second) from a device, specified as a list of expressions in the format `PATH:RATE`, where `RATE` is either an integer number of bytes, or a string ending in `kb`, `mb`, or `gb`. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices_read_bps: /dev/sda:1mb,/dev/sdb:5mb
```

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices_read_bps:
      - /dev/sda:1mb
      - /dev/sdb:5mb
```

**device_read_iops** Limit read rate (I/O per second) from a device, specified as a list of expressions in the format `PATH:RATE`, where `RATE` is a number of I/O operations. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices_read_iops: /dev/sda:1000,/dev/sdb:500
```

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices_read_iops:
      - /dev/sda:1000
      - /dev/sdb:500
```

**device_write_bps** Limit write rate (bytes per second) from a device, specified as a list of expressions in the format `PATH:RATE`, where `RATE` is either an integer number of bytes, or a string ending in `kb`, `mb`, or `gb`. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```
foo:
  docker_container.running:
    - image: bar/baz:latest
    - devices_write_bps: /dev/sda:1mb,/dev/sdb:5mb
```
device_read_iops  Limit write rate (I/O per second) from a device, specified as a list of expressions in the format PATH:RATE, where RATE is a number of I/O operations. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
docker_container.running:
  - image: bar/baz:latest
  - devices_read_iops: /dev/sda:1000,/dev/sdb:500
```

```yaml
foo:
docker_container.running:
  - image: bar/baz:latest
  - devices_read_iops:
    - /dev/sda:1000
    - /dev/sdb:500
```

dns  List of DNS nameservers. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
docker_container.running:
  - image: bar/baz:latest
  - dns: 8.8.8.8,8.8.4.4
```

```yaml
foo:
docker_container.running:
  - image: bar/baz:latest
  - dns:
    - 8.8.8.8
    - 8.8.4.4
```

**Note:** To skip IP address validation, use `validate_ip_addrs=False`

dns_opt  Additional options to be added to the container’s resolv.conf file. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
docker_container.running:
  - image: bar/baz:latest
  - dns_opt: ndots:9
```

```yaml
foo:
docker_container.running:
  - image: bar/baz:latest
  - dns_opt:
    - ndots:9
```

dns_search  List of DNS search domains. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:
foo:
  docker_container.running:
  - image: bar/baz:latest
  - dns_search: foo1.domain.tld,foo2.domain.tld

foo:
  docker_container.running:
  - image: bar/baz:latest
  - dns_search:
    - foo1.domain.tld
    - foo2.domain.tld

domainname  The domain name to use for the container

foo:
  docker_container.running:
  - image: bar/baz:latest
  - domainname: domain.tld

entrypoint  Entrypoint for the container

foo:
  docker_container.running:
  - image: bar/baz:latest
  - entrypoint: "mycmd --arg1 --arg2"

This argument can also be specified as a list:

foo:
  docker_container.running:
  - image: bar/baz:latest
  - entrypoint:
    - mycmd
    - --arg1
    - --arg2

environment  Either a list of variable/value mappings, or a list of strings in the format VARNAME=value. The below three examples are equivalent:

foo:
  docker_container.running:
  - image: bar/baz:latest
  - environment:
    - VAR1: value
    - VAR2: value

foo:
  docker_container.running:
  - image: bar/baz:latest
  - environment: 'VAR1=value,VAR2=value'

foo:
  docker_container.running:
  - image: bar/baz:latest
  - environment:
    - VAR1=value
    - VAR2=value
**extra_hosts**  Additional hosts to add to the container’s `/etc/hosts` file. Can be expressed as a comma-separated list or a Python list. The below two examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - extra_hosts: web1:10.9.8.7,web2:10.9.8.8

foo:
  docker_container.running:
    - image: bar/baz:latest
    - extra_hosts: 
      - web1:10.9.8.7
      - web2:10.9.8.8
```

**Note:** To skip IP address validation, use `validate_ip_addrs=False`.

**Note:** This option requires Docker 1.3.0 or newer.

**group_add**  List of additional group names and/or IDs that the container process will run as. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - group_add: web,network

foo:
  docker_container.running:
    - image: bar/baz:latest
    - group_add: 
      - web
      - network
```

**hostname**  Hostname of the container. If not provided, the value passed as the container’s `'name'` will be used for the hostname.

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - hostname: web1
```

**Warning:** `hostname` cannot be set if `network_mode` is set to `host`. The below example will result in an error:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - hostname: web1
    - network_mode: host
```

**interactive** (or `stdin_open`)  [False] Leave stdin open, even if not attached
foo:
  docker_container.running:
  - image: bar/baz:latest
  - interactive: True

**ipc_mode** (or **ipc**)  Set the IPC mode for the container. The default behavior is to create a private IPC namespace for the container, but this option can be used to change that behavior:
  - `container:<container_name_or_id>` reuses another container shared memory, semaphores and message queues
  - `host`: use the host's shared memory, semaphores and message queues

foo:
  docker_container.running:
  - image: bar/baz:latest
  - ipc_mode: container:foo

foo:
  docker_container.running:
  - image: bar/baz:latest
  - ipc_mode: host

**Warning**: Using **host** gives the container full access to local shared memory and is therefore considered insecure.

**isolation**  Specifies the type of isolation technology used by containers

foo:
  docker_container.running:
  - image: bar/baz:latest
  - isolation: hyperv

**Note**: The default value on Windows server is **process**, while the default value on Windows client is **hyperv**. On Linux, only **default** is supported.

**labels**  Add metadata to the container. Labels can be set both with and without values:

**WITH VALUES**

The below three examples are equivalent:

foo:
  docker_container.running:
  - image: bar/baz:latest
  - labels: label1=value1,label2=value2

foo:
  docker_container.running:
  - image: bar/baz:latest
  - labels:
    - label1=value1
    - label2=value2

foo:
  docker_container.running:
  - image: bar/baz:latest
The labels can also simply be passed as a dictionary, though this can be error-prone due to some idiosyncrasies with how PyYAML loads nested data structures:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - labels:
      label1: value1
      label2: value2
```

**WITHOUT VALUES**

The below two examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - labels: label1,label2
```

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - labels:
      - label1
      - label2
```

**Links**

Link this container to another. Links can be specified as a list of mappings or a comma-separated or Python list of expressions in the format `<container_name_or_id>:<link_alias>`. The below three examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - links:
      - web1: link1
      - web2: link2
```

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - links: web1:link1,web2:link2
```

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - links:
      - web1:link1
      - web2:link2
```

**log_driver and log_opt**

Set container's logging driver and options to configure that driver. Requires Docker 1.6 or newer.

```yaml
foo:
  docker_container.running:
```
- image: bar/baz:latest
- log_driver: syslog
- log_opt:
  - syslog-address: tcp://192.168.0.42
  - syslog-facility: daemon

The `log_opt` can also be expressed as a comma-separated or YAML list of `key=value` pairs. The below two examples are equivalent to the above one:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - log_driver: syslog
    - log_opt: "syslog-address=tcp://192.168.0.42,syslog-facility=daemon"

foo:
  docker_container.running:
    - image: bar/baz:latest
    - log_driver: syslog
    - log_opt:
      - syslog-address=tcp://192.168.0.42
      - syslog-facility=daemon
```

**Note:** The logging driver feature was improved in Docker 1.13 introducing option name changes. Please see Docker's [Configure logging drivers](https://docs.docker.com/config/containers/Configure-Logging/) documentation for more information.

**lxc_conf** Additional LXC configuration parameters to set before starting the container. Either a list of variable/value mappings, or a list of strings in the format `VARNAME=value`. The below three examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - lxc_conf:
      - lxc.utsname: docker
      - lxc.arch: x86_64

foo:
  docker_container.running:
    - image: bar/baz:latest
    - lxc_conf: lxc.utsname=docker,lxc.arch=x86_64

foo:
  docker_container.running:
    - image: bar/baz:latest
    - lxc_conf:
      - lxc.utsname=docker
      - lxc.arch=x86_64
```

**Note:** These LXC configuration parameters will only have the desired effect if the container is using the LXC execution driver, which has been deprecated for some time.

**mac_address** MAC address to use for the container. If not specified, a random MAC address will be used.
mem_limit (or memory) [0] Memory limit. Can be specified in bytes or using single-letter units (i.e. 512M, 2G, etc.). A value of 0 (the default) means no memory limit.

```
foo:
    docker_container.running:
      - image: bar/baz:latest
      - mem_limit: 512M
```

mem_swappiness Tune a container's memory swappiness behavior. Accepts an integer between 0 and 100.

```
foo:
    docker_container.running:
      - image: bar/baz:latest
      - mem_swappiness: 60
```

memswap_limit (or memory_swap) [-1] Total memory limit (memory plus swap). Set to -1 to disable swap. A value of 0 means no swap limit.

```
foo:
    docker_container.running:
      - image: bar/baz:latest
      - memswap_limit: 1G
```

network_disabled [False] If True, networking will be disabled within the container

```
foo:
    docker_container.running:
      - image: bar/baz:latest
      - network_disabled: True
```

network_mode [bridge] One of the following:
- bridge - Creates a new network stack for the container on the docker bridge
- none - No networking (equivalent of the Docker CLI argument --net=none). Not to be confused with Python's None.
- container:<name_or_id> - Reuses another container's network stack
- host - Use the host's network stack inside the container
- Any name that identifies an existing network that might be created with docker.network_present.

**Warning:** Using host mode gives the container full access to the hosts system's services (such as D-bus), and is therefore considered insecure.

```
foo:
    docker_container.running:
      - image: bar/baz:latest
      - network_mode: "none"
```

```
foo:
    docker_container.running:
      - image: bar/baz:latest
      - network_mode: container:web1
```

oom_kill_disable Whether to disable OOM killer
### oom_score_adj

An integer value containing the score given to the container in order to tune OOM killer preferences.

```yaml
foo:
docker_container.running:
  - image: bar/baz:latest
  - oom_score_adj: 500
```

### pid_mode

Set to host to use the host container's PID namespace within the container. Requires Docker 1.5.0 or newer.

```yaml
foo:
docker_container.running:
  - image: bar/baz:latest
  - pid_mode: host
```

**Note:** This option requires Docker 1.5.0 or newer.

### pids_limit

Set the container's PID limit. Set to -1 for unlimited.

```yaml
foo:
docker_container.running:
  - image: bar/baz:latest
  - pids_limit: 2000
```

### port_bindings (or publish)

Bind exposed ports. Port bindings should be passed in the same way as the `--publish` argument to the `docker run` CLI command:

- `ip:hostPort:containerPort` - Bind a specific IP and port on the host to a specific port within the container.
- `ip::containerPort` - Bind a specific IP and an ephemeral port to a specific port within the container.
- `hostPort:containerPort` - Bind a specific port on all of the host's interfaces to a specific port within the container.
- `containerPort` - Bind an ephemeral port on all of the host's interfaces to a specific port within the container.

Multiple bindings can be separated by commas, or expressed as a YAML list, and port ranges can be defined using dashes. The below two examples are equivalent:

```yaml
foo:
docker_container.running:
  - image: bar/baz:latest
  - port_bindings: "4505-4506:14505-14506,2123:2123/udp,8080"
```

```yaml
foo:
docker_container.running:
  - image: bar/baz:latest
  - port_bindings:
    - 4505-4506:14505-14506
    - 2123:2123/udp
    - 8080
```
Note: When specifying a protocol, it must be passed in the containerPort value, as seen in the examples above.

ports A list of ports to expose on the container. Can either be a comma-separated list or a YAML list. If the protocol is omitted, the port will be assumed to be a TCP port. The below two examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
      ports: 1111,2222/udp
```

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - ports:
      - 1111
      - 2222/udp
```

privileged [False] If True, runs the exec process with extended privileges

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - privileged: True
```

publish_all_ports (or publish_all) [False] Publish all ports to the host

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
      ports: 8080
      - publish_all_ports: True
```

read_only [False] If True, mount the container's root filesystem as read only

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - read_only: True
```

restart_policy (or restart) Set a restart policy for the container. Must be passed as a string in the format policy[:retry_count] where policy is one of always, unless-stopped, or on-failure, and retry_count is an optional limit to the number of retries. The retry count is ignored when using the always or unless-stopped restart policy.

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - restart_policy: on-failure:5
```

```yaml
bar:
  docker_container.running:
    - image: bar/baz:latest
    - restart_policy: always
```

security_opt (or security_opts): Security configuration for MLS systems such as SELinux and AppArmor. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:
foo:

docker_container.running:
- image: bar/baz:latest
- security_opt: apparmor:unconfined

foo:

docker_container.running:
- image: bar/baz:latest
- security_opt:
  - apparmor:unconfined

**Important:** Some security options can contain commas. In these cases, this argument *must* be passed as a Python list, as splitting by comma will result in an invalid configuration.

**Note:** See the documentation for security_opt at [https://docs.docker.com/engine/reference/run/#security-configuration](https://docs.docker.com/engine/reference/run/#security-configuration)

**shm_size** Size of /dev/shm

foo:

docker_container.running:
- image: bar/baz:latest
  - shm_size: 128M

**stop_signal** Specify the signal docker will send to the container when stopping. Useful when running systemd as PID 1 inside the container.

foo:

docker_container.running:
- image: bar/baz:latest
  - stop_signal: SIGRTMIN+3

**Note:** This option requires Docker 1.9.0 or newer and docker-py 1.7.0 or newer.

New in version 2016.11.0.

**stop_timeout** Timeout to stop the container, in seconds

foo:

docker_container.running:
- image: bar/baz:latest
  - stop_timeout: 5

**Note:** In releases prior to 2017.7.0, this option was not set in the container configuration, but rather this timeout was enforced only when shutting down an existing container to replace it. To remove the ambiguity, and to allow for the container to have a stop timeout set for it, the old stop_timeout argument has been renamed to shutdown_timeout, while stop_timeout now refers to the container's configured stop timeout.

**storage_opt** Storage driver options for the container. Can be either a list of strings in the format option=value, or a list of mappings between option and value. The below three examples are equivalent:
foo:
  docker_container.running:
  - image: bar/baz:latest
  - storage_opt:
    - dm.basesize: 40G

foo:
  docker_container.running:
  - image: bar/baz:latest
  - storage_opt: dm.basesize=40G

foo:
  docker_container.running:
  - image: bar/baz:latest
  - storage_opt:
    - dm.basesize=40G

**sysctls** (or **sysctl**) Set sysctl options for the container. Can be either a list of strings in the format `option=value`, or a list of mappings between option and value. The below three examples are equivalent:

foo:
  docker_container.running:
  - image: bar/baz:latest
  - sysctls:
    - fs.nr_open: 1048576
    - kernel.pid_max: 32768

foo:
  docker_container.running:
  - image: bar/baz:latest
  - sysctls: fs.nr_open=1048576,kernel.pid_max=32768

foo:
  docker_container.running:
  - image: bar/baz:latest
  - sysctls:
    - fs.nr_open=1048576
    - kernel.pid_max=32768

**tmpfs** A map of container directories which should be replaced by tmpfs mounts and their corresponding mount options.

foo:
  docker_container.running:
  - image: bar/baz:latest
  - tmpfs:
    - /run: rw,noexec,nosuid,size=65536k

**tty** [False] Attach TTYs

foo:
  docker_container.running:
  - image: bar/baz:latest
  - tty: True

**ulimits** List of ulimits. These limits should be passed in the format `<ulimit_name>::<soft_limit>::<hard_limit>`, with the hard limit being optional. Can be
expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - ulimits:
      - nofile=1024:1024
      - nproc=60
```

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - ulimits: nofile=1024:1024,nproc=60
```

**user**  User under which to run exec process

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - user: foo
```

**userns_mode (or user_ns_mode)**  Sets the user namespace mode, when the user namespace remapping option is enabled

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - userns_mode: host
```

**volumes (or volume)**  List of directories to expose as volumes. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - volumes: /mnt/vol1,/mnt/vol2
```

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - volumes:
      - /mnt/vol1
      - /mnt/vol2
```

**volumes_from**  Container names or IDs from which the container will get volumes. Can be expressed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - volumes_from: foo
```

```yaml
foo:
  docker_container.running:
    - image: bar/baz:latest
    - volumes_from:
      - foo
```

**volume_driver**  sets the container's volume driver
foo:
  docker_container.running:
    - image: bar/baz:latest
    - volume_driver: foobar

working_dir (or workdir) Working directory inside the container

foo:
  docker_container.running:
    - image: bar/baz:latest
    - working_dir: /var/log/nginx

salt.states.docker_container.stopped(name=None, containers=None, shutdown_timeout=10, unpause=False, error_on_absent=True)

Ensure that a container (or containers) is stopped

name Name or ID of the container
containers Run this state on more than one container at a time. The following two examples accomplish the same thing:

stopped_containers:
  docker_container.stopped:
    - names:
      - foo
      - bar
      - baz

stopped_containers:
  docker_container.stopped:
    - containers:
      - foo
      - bar
      - baz

However, the second example will be a bit quicker since Salt will stop all specified containers in a single run, rather than executing the state separately on each image (as it would in the first example).

shutdown_timeout [10] Timeout for graceful shutdown of the container. If this timeout is exceeded, the container will be killed.

unpause [False] Set to True to unpause any paused containers before stopping. If unset, then an error will be raised for any container that was paused.

error_on_absent [True] By default, this state will return an error if any of the specified containers are absent. Set this to False to suppress that error.

19.19.66 salt.states.docker_image

Management of Docker images

New in version 2017.7.0.

depends docker Python module

Note: Older releases of the Python bindings for Docker were called docker-py in PyPI. All releases of docker, and releases of docker-py >= 1.6.0 are supported. These python bindings can easily be installed using pip.install:

salt myminion pip.install docker

To upgrade from docker-py to docker, you must first uninstall docker-py, and then install docker:
These states were moved from the *docker* state module (formerly called *dockerng*) in the 2017.7.0 release.

**Note:** To pull from a Docker registry, authentication must be configured. See [here](#) for more information on how to configure access to docker registries in Pillar data.

salt.states.docker_image.absent(name=None, images=None, force=False)

Ensure that an image is absent from the Minion. Image names can be specified either using repo:tag notation, or just the repo name (in which case a tag of latest is assumed).

`images` Run this state on more than one image at a time. The following two examples accomplish the same thing:

```yaml
remove_images:
  docker_image.absent:
    - names:
      - busybox
      - centos:6
      - nginx

remove_images:
  docker_image.absent:
    - images:
      - busybox
      - centos:6
      - nginx
```

However, the second example will be a bit quicker since Salt will do all the deletions in a single run, rather than executing the state separately on each image (as it would in the first example).

`force` [False] Salt will fail to remove any images currently in use by a container. Set this option to true to remove the image even if it is already present.

**Note:** This option can also be overridden by Pillar data. If the Minion has a pillar variable named `docker.running.force` which is set to `True`, it will turn on this option. This pillar variable can even be set at runtime. For example:

```yaml
salt myminion state.sls docker_stuff pillar="{docker.force: True}"
```

If this pillar variable is present and set to `False`, then it will turn off this option.

For more granular control, setting a pillar variable named `docker.force.image_name` will affect only the named image.

salt.states.docker_image.mod_watch(name, sfun=None, **kwargs)

The docker_image watcher, called to invoke the watch command.

**Note:** This state exists to support special handling of the watch `requisite`. It should not be called directly. Parameters for this function should be set by the state being triggered.
salt.states.docker_image.present(name, build=None, load=None, force=False, insecure Registry=False, client_timeout=60, dockerfile=None, sls=None, base='opensuse/python', saltenv='base', **kwargs)

Ensure that an image is present. The image can either be pulled from a Docker registry, built from a Dockerfile, or loaded from a saved image. Image names can be specified either using repo:tag notation, or just the repo name (in which case a tag of latest is assumed). Repo identifier is mandatory, we don't assume the default repository is docker hub.

If neither of the build or load arguments are used, then Salt will pull from the configured registries. If the specified image already exists, it will not be pulled unless force is set to True. Here is an example of a state that will pull an image from the Docker Hub:

```
myuser/myimage:mytag:
    docker_image.present
```

**build** Path to directory on the Minion containing a Dockerfile

```
myuser/myimage:mytag:
    docker_image.present:
        - build: /home/myuser/docker/myimage

myuser/myimage:mytag:
    docker_image.present:
        - build: /home/myuser/docker/myimage
        - dockerfile: Dockerfile.alternative
```

New in version 2016.11.0.

The image will be built using docker.build and the specified image name and tag will be applied to it.

**load** Loads a tar archive created with docker.load (or the docker load Docker CLI command), and assigns it the specified repo and tag.

```
myuser/myimage:mytag:
    docker_image.present:
        - load: salt://path/to/image.tar
```

**force** [False] Set this parameter to True to force Salt to pull/build/load the image even if it is already present.

**client_timeout** Timeout in seconds for the Docker client. This is not a timeout for the state, but for receiving a response from the API.

**dockerfile** Allows for an alternative Dockerfile to be specified. Path to alternative Dockerfile is relative to the build path for the Docker container.

New in version 2016.11.0.

**sls** Allow for building of image with docker.sls_build by specifying the SLS files with which to build. This can be a list or comma-separated string.

```
myuser/myimage:mytag:
    docker_image.present:
        - sls:
            - webapp1
            - webapp2
            - base: centos
            - saltenv: base
```

**base** Base image with which to start docker.sls_build

**saltenv** Environment from which to pull SLS files for docker.sls_build
19.19.67 salt.states.docker_network

Management of Docker networks
New in version 2017.7.0.

    depends docker Python module

**Note:** Older releases of the Python bindings for Docker were called docker-py in PyPI. All releases of docker, and releases of docker-py >= 1.6.0 are supported. These python bindings can easily be installed using `pip.install`:

```
salt myminion pip.install docker
```

To upgrade from docker-py to docker, you must first uninstall docker-py, and then install docker:

```
salt myminion pip.uninstall docker-py
salt myminion pip.install docker
```

These states were moved from the docker state module (formerly called dockerng) in the 2017.7.0 release.

salt.states.docker_network.absent(name, driver=None)

Ensure that a network is absent.

   name Name of the network

Usage Examples:

```
network_foo:
  docker_network.absent
```

salt.states.docker_network.present(name, driver=None, containers=None)

Ensure that a network is present.

   name Name of the network
   driver Type of driver for that network.
   containers: List of container names that should be part of this network

Usage Examples:

```
network_foo:
  docker_network.present
```

```
network_bar:
  docker_network.present
  - name: bar
  - containers:
    - cont1
    - cont2
```

19.19.68 salt.states.docker_volume

Management of Docker volumes
New in version 2017.7.0.

    depends docker Python module

**Note:** Older releases of the Python bindings for Docker were called docker-py in PyPI. All releases of docker, and releases of docker-py >= 1.6.0 are supported. These python bindings can easily be installed using `pip.install`:
To upgrade from docker-py to docker, you must first uninstall docker-py, and then install docker:

```bash
salt myminion pip.uninstall docker-py
salt myminion pip.install docker
```

These states were moved from the docker state module (formerly called dockerng) in the 2017.7.0 release.

### salt.states.docker_volume.absent(name, driver=None)

Ensure that a volume is absent.

- **New in version 2015.8.4.**
- **Changed in version 2017.7.0:** This state was renamed from docker.volume_absent to docker_volume.absent

**Usage Examples:**

```yaml
volume_foo:
  docker_volume.absent
```

### salt.states.docker_volume.present(name, driver=None, driver_opts=None, force=False)

Ensure that a volume is present.

- **New in version 2015.8.4.**
- **Changed in version 2015.8.6:** This state no longer deletes and re-creates a volume if the existing volume's driver does not match the driver parameter (unless the force parameter is set to True).
- **Changed in version 2017.7.0:** This state was renamed from docker.volume_present to docker_volume.present

**Usage Examples:**

```yaml
volume_foo:
  docker_volume.absent

volume_bar:
  docker_volume.present
  - name: bar
  - driver: local
  - driver_opts:
    foo: bar

volume_bar:
  docker_volume.present
```
salt.states.drac

Management of Dell DRAC

The DRAC module is used to create and manage DRAC cards on Dell servers

Ensure the user damian is present

```yaml
name: damian
drac.present:
  - name: damian
  - password: secret
  - permission: login,test_alerts,clear_logs
```

Ensure the user damian does not exist

```yaml
name: damian
drac.absent:
  - name: damian
```

Ensure DRAC network is in a consistent state

```yaml
name: my_network
drac.network:
  - ip: 10.225.108.29
  - netmask: 255.255.255.224
  - gateway: 10.225.108.1
```

salt.states.drac.absent(name)
Ensure a user does not exist on the Dell DRAC

- name: The users username

salt.states.drac.network(ip, netmask, gateway)
Ensure the DRAC network settings are consistent

salt.states.drac.present(name, password, permission)
Ensure the user exists on the Dell DRAC

- name: The users username
- password: The password used to authenticate
- permission: The permissions that should be assigned to a user

salt.states.elasticsearch

State module to manage Elasticsearch.

New in version 2017.7.0.

salt.states.elasticsearch.alias_absent(name, index)
Ensure that the index alias is absent.

- name: Name of the index alias to remove
index  Name of the index for the alias

salt.states.elasticsearch.alias_present(name, index, definition=None)
    Ensure that the named index alias is present.
    name  Name of the alias
    index  Name of the index

Example:

    mytestalias:
        elasticsearch.alias_present:
            - index: testindex
            - definition:
                filter:
                    term:
                        user: kimchy

salt.states.elasticsearch.index_absent(name)
    Ensure that the named index is absent.
    name  Name of the index to remove

salt.states.elasticsearch.index_present(name, definition=None)
    Ensure that the named index is present.
    name  Name of the index to add
    definition  Optional dict for creation parameters as per https://www.elastic.co/guide/en/elasticsearch/reference/current/indices-create-index.html

Example:

    # Default settings
    mytestindex:
        elasticsearch_index.present

    # Extra settings
    mytestindex2:
        elasticsearch_index.present:
            - definition:
                settings:
                    index:
                        number_of_shards: 10

salt.states.elasticsearch.index_template_absent(name)
    Ensure that the named index template is absent.
    name  Name of the index to remove

salt.states.elasticsearch.index_template_present(name, definition)
    Ensure that the named index template is present.
    name  Name of the index to add
    definition  Required dict for creation parameters as per https://www.elastic.co/guide/en/elasticsearch/reference/current/indices-templates.html

Example:

    mytestindex2_template:
        elasticsearch_index_template.present:
            - definition:
                template: logstash-*
                order: 1
settings:
    number_of_shards: 1

salt.states.elasticsearch.pipeline_absent(name)
    Ensure that the named pipeline is absent
    name  Name of the pipeline to remove

salt.states.elasticsearch.pipeline_present(name, definition)
    Ensure that the named pipeline is present.
    name  Name of the index to add
    definition  Required dict for creation parameters as per https://www.elastic.co/guide/en/elasticsearch/reference/master/pipeline.html

    Example:
    test_pipeline:
        elasticsearch.pipeline_present:
            - definition:
                description: example pipeline
                processors:
                    - set:
                        field: collector_timestamp_millis
                        value: '{{ ingest.timestamp }}'

salt.states.elasticsearch.search_template_absent(name)
    Ensure that the search template is absent
    name  Name of the search template to remove

salt.states.elasticsearch.search_template_present(name, definition)
    Ensure that the named search template is present.
    name  Name of the search template to add
    definition  Required dict for creation parameters as per http://www.elastic.co/guide/en/elasticsearch/reference/current/search-template.html

    Example:
    test_pipeline:
        elasticsearch.search_template_present:
            - definition:
                inline:
                    size: 10

19.19.71  salt.states.elasticsearch_index

State module to manage Elasticsearch indices

New in version 2015.8.0.

Deprecated since version 2017.7.0: Use elasticsearch state instead

salt.states.elasticsearch_index.absent(name)
    Ensure that the named index is absent.
    name  Name of the index to remove

salt.states.elasticsearch_index.present(name, definition=None)
    New in version 2015.8.0.
    Changed in version 2017.3.0: Marked definition as optional.
    Ensure that the named index is present.
name Name of the index to add

definition Optional dict for creation parameters as per https://www.elastic.co/guide/en/elasticsearch/reference/current/indices-create-index.html

Example:

```yaml
# Default settings
mytestindex:
  elasticsearch_index.present

# Extra settings
mytestindex2:
  elasticsearch_index.present:
    - definition:
      settings:
        index:
          number_of_shards: 10
```

19.19.72 `salt.states.elasticsearch_index_template`

State module to manage Elasticsearch index templates

New in version 2015.8.0.

Deprecated since version 2017.7.0: Use `elasticsearch` state instead

```python
salt.states.elasticsearch_index_template.absent(name)
```

Ensure that the named index template is absent.

- name Name of the index to remove

```python
salt.states.elasticsearch_index_template.present(name, definition)
```

Ensure that the named index template is present.

- name Name of the index to add

Example:

```yaml
mytestindex2_template:
  elasticsearch_index_template.present:
    - definition:
      template: logstash-*
      order: 1
      settings:
        number_of_shards: 1
```

19.19.73 `salt.states.environ`

Support for getting and setting the environment variables of the current salt process.

```python
salt.states.environ.setenv(name, value, false_unsets=False, clear_all=False, update_minion=False, permanent=False)
```

Set the salt process environment variables.

- name The environment key to set. Must be a string.
value  Either a string or dict. When string, it will be the value set for the environment key of `name' above. When a dict, each key/value pair represents an environment variable to set.
false_unsets  If a key's value is False and false_unsets is True, then the key will be removed from the salt processes environment dict entirely. If a key's value is False and false_unsets is not True, then the key's value will be set to an empty string. Default: False
clear_all  USE WITH CAUTION! This option can unset environment variables needed for salt to function properly. If clear_all is True, then any environment variables not defined in the environ dict will be deleted. Default: False
update_minion  If True, apply these environ changes to the main salt-minion process. If False, the environ changes will only affect the current salt subprocess. Default: False
permanent  On Windows minions this will set the environment variable in the registry so that it is always added as a environment variable when applications open. If you want to set the variable to HKLM instead of HKCU just pass in `HKLM' for this parameter. On all other minion types this will be ignored. Note: This will only take affect on applications opened after this has been set.
Example:

```
a_string_env:
  environ.setenv:
    - name: foo
    - value: bar
    - update_minion: True

da_dict_env:
  environ.setenv:
    - name: does_not_matter
    - value:
      foo: bar
      baz: quux
```

19.19.74 salt.states.eselect

Management of Gentoo configuration using eselect

A state module to manage Gentoo configuration via eselect

```
salt.states.eselect.set(name, target, module_parameter=None, action_parameter=None)
```
Verify that the given module is set to the given target
name  The name of the module
target  The target to be set for this module
module_parameter  additional params passed to the defined module
action_parameter  additional params passed to the defined action

```
profile:
  eselect.set:
    - target: hardened/linux/amd64
```

19.19.75 salt.states.etcd_mod

Manage etcd Keys

New in version 2015.8.0.

depends
This state module supports setting and removing keys from etcd.

**Configuration**

To work with an etcd server you must configure an etcd profile. The etcd config can be set in either the Salt Minion configuration file or in pillar:

```yaml
my_etcd_config:
    etcd.host: 127.0.0.1
    etcd.port: 4001
```

It is technically possible to configure etcd without using a profile, but this is not considered to be a best practice, especially when multiple etcd servers or clusters are available.

```yaml
etcd.host: 127.0.0.1
etcd.port: 4001
```

**Note:** The etcd configuration can also be set in the Salt Master config file, but in order to use any etcd configurations defined in the Salt Master config, the `pillar_opts` must be set to `True`.

Be aware that setting `pillar_opts` to `True` has security implications as this makes all master configuration settings available in all minion's pillars.

**Available Functions**

- **set**

  This will set a value to a key in etcd. Changes will be returned if the key has been created or the value of the key has been updated. This means you can watch these states for changes.

  ```yaml
  /foo/bar/baz:
  etcd.set:
    - value: foo
    - profile: my_etcd_config
  ```

- **wait_set**

  Performs the same functionality as `set` but only if a watch requisite is `True`.

  ```yaml
  /some/file.txt:
  file.managed:
    - source: salt://file.txt
  
  /foo/bar/baz:
  etcd.wait_set:
    - value: foo
    - profile: my_etcd_config
    - watch:
      - file: /some/file.txt
  ```

- **rm**
This will delete a key from etcd. If the key exists then changes will be returned and thus you can watch for changes on the state, if the key does not exist then no changes will occur.

```yaml
/foo/bar/baz:
  etcd.rm:
    - profile: my_etcd_config
```

- **wait_rm**

  Performs the same functionality as `rm` but only if a watch requisite is `True`.

```yaml
/some/file.txt:
  file.managed:
    - source: salt://file.txt

/foo/bar/baz:
  etcd.wait_rm:
    - profile: my_etcd_config
    - watch:
      - file: /some/file.txt
```

**salt.states.etcd_mod.mod_watch(name, **kwargs)**

The etcd watcher, called to invoke the watch command. When called, execute a etcd function based on a watch call requisite.

**Note:** This state exists to support special handling of the `watch` requisite. It should not be called directly. Parameters for this function should be set by the state being triggered.

**salt.states.etcd_mod.rm(name, recurse=False, profile=None)**

Deletes a key from etcd

- **name** The etcd key name to remove, for example `/foo/bar/baz`.
- **recurse** Optional, defaults to `False`. If `True` performs a recursive delete.
- **profile** Optional, defaults to `None`. Sets the etcd profile to use which has been defined in the Salt Master config.

**salt.states.etcd_mod.set_(name, value, profile=None)**

Set a key in etcd

- **name** The etcd key name, for example: `/foo/bar/baz`.
- **value** The value the key should contain.
- **profile** Optional, defaults to `None`. Sets the etcd profile to use which has been defined in the Salt Master config.

**salt.states.etcd_mod.wait_rm(name, recurse=False, profile=None)**

Deletes a key from etcd only if the watch statement calls it. This function is also aliased as `wait_rm`.

- **name** The etcd key name to remove, for example `/foo/bar/baz`.
- **recurse** Optional, defaults to `False`. If `True` performs a recursive delete, see: [https://python-etcd.readthedocs.io/en/latest/#delete-a-key](https://python-etcd.readthedocs.io/en/latest/#delete-a-key).
- **profile** Optional, defaults to `None`. Sets the etcd profile to use which has been defined in the Salt Master config.

**salt.states.etcd_mod.wait_set(name, value, profile=None)**

Set a key in etcd only if the watch statement calls it. This function is also aliased as `wait_set`.

- **name** The etcd key name, for example: `/foo/bar/baz`.
- **value** The value the key should contain.
- **profile** The etcd profile to use that has been configured on the Salt Master, this is optional and defaults to `None`. 

---

19.19. state modules 2807
19.19.76 salt.states.ethtool module

Configuration of network device

New in version 2016.11.0.

**codeauthor** Krzysztof Pawlowski <msciciel@msciciel.eu>

**maturity** new

**depends** python-ethtool

**platform** linux

```yaml
eth0:
  ethtool.coalesce:
    - name: eth0
      - rx_usecs: 24
      - tx_usecs: 48

eth0:
  ethtool.ring:
    - name: eth0
      - rx: 1024
      - tx: 1024

eth0:
  ethtool.offload:
    - name: eth0
      - tcp_segmentation_offload: on
```

salt.states.ethtool.coalesce(name, **kwargs)

Manage coalescing settings of network device

**name** Interface name to apply coalescing settings

```yaml
eth0:
  ethtool.coalesce:
    - name: eth0
    - adaptive_rx: on
    - adaptive_tx: on
    - rx_usecs: 24
    - rx_frame: 0
    - rx_usecs_irq: 0
    - rx_frames_irq: 0
    - tx_usecs: 48
    - tx_frames: 0
    - tx_usecs_irq: 0
    - tx_frames_irq: 0
    - stats_block_usecs: 0
    - pkt_rate_low: 0
    - rx_usecs_low: 0
    - rx_frames_low: 0
    - tx_usecs_low: 0
    - tx_frames_low: 0
    - pkt_rate_high: 0
    - rx_usecs_high: 0
    - rx_frames_high: 0
    - tx_usecs_high: 0
    - tx_frames_high: 0
    - sample_interval: 0
```
salt.states.ethtool.offload(name, **kwargs)
Manage protocol offload and other features of network device

name Interface name to apply coalescing settings

```
eth0:
ethtool.offload:
  - name: eth0
  - tcp_segmentation_offload: on
```

salt.states.ethtool.ring(name, **kwargs)
Manage rx/tx ring parameters of network device

name Interface name to apply ring parameters

```
eth0:
ethtool.ring:
  - name: eth0
  - rx: 1024
  - rx_mini: 0
  - rx_jumbo: 0
  - tx: max
```

19.19.77 salt.states.esxi

Manage VMware ESXi Hosts.

New in version 2015.8.4.

Dependencies

- pyVmomi Python Module
- ESXCLI

pyVmomi

PyVmomi can be installed via pip:

```
pip install pyVmomi
```

**Note:** Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, Python 2.6, Python 2.7.9, or newer must be present. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the following:

```
pip install pyVmomi==5.5.0.2014.1.1
```

The 5.5.0.2014.1.1 is a known stable version that this original ESXi State Module was developed against.
Currently, about a third of the functions used in the vSphere Execution Module require the ESXCLI package be installed on the machine running the Proxy Minion process.

The ESXCLI package is also referred to as the VMware vSphere CLI, or vCLI. VMware provides vCLI package installation instructions for vSphere 5.5 and vSphere 6.0.

Once all of the required dependencies are in place and the vCLI package is installed, you can check to see if you can connect to your ESXi host or vCenter server by running the following command:

```
esxcli -s <host-location> -u <username> -p <password> system syslog config get
```

If the connection was successful, ESXCLI was successfully installed on your system. You should see output related to the ESXi host's syslog configuration.

**Note:** Be aware that some functionality in this state module may depend on the type of license attached to the ESXi host.

For example, certain services are only available to manipulate service state or policies with a VMware vSphere Enterprise or Enterprise Plus license, while others are available with a Standard license. The ntpd service is restricted to an Enterprise Plus license, while ssh is available via the Standard license.

Please see the vSphere Comparison page for more information.

**About**

This state module was written to be used in conjunction with Salt’s ESXi Proxy Minion. For a tutorial on how to use Salt’s ESXi Proxy Minion, please refer to the ESXi Proxy Minion Tutorial for configuration examples, dependency installation instructions, how to run remote execution functions against ESXi hosts via a Salt Proxy Minion, and a larger state example.

```
salt.states.esxi.coredump_configured(name, enabled, dump_ip, host_vnic='vmk0', dump_port=6500)
```

Ensures a host’s core dump configuration.

- **name** Name of the state.
- **enabled** Sets whether or not ESXi core dump collection should be enabled. This is a boolean value set to True or False to enable or disable core dumps.
  
  Note that ESXi requires that the core dump must be enabled before any other parameters may be set. This also affects the changes results in the state return dictionary. If enabled is False, we can’t obtain any previous settings to compare other state variables, resulting in many old references returning None.
  
  Once enabled is True the changes dictionary comparisons will be more accurate. This is due to the way the system coredemp network configuration command returns data.

- **dump_ip** The IP address of host that will accept the dump.

- **host_vnic** Host VNic port through which to communicate. Defaults to vmk0.

- **dump_port** TCP port to use for the dump. Defaults to 6500.

**Example:**

```
configure-host-coredump:
  esxi.coredump_configured:
    - enabled: True
    - dump_ip: 'my-coredump-ip.example.com'
```
**salt.states.esxi.ntp_configured**

Ensures a host’s NTP server configuration such as setting NTP servers, ensuring the NTP daemon is running or stopped, or restarting the NTP daemon for the ESXi host.

- **name** Name of the state.
- **service_running** Ensures the running state of the ntp daemon for the host. Boolean value where True indicates that ntpd should be running and False indicates that it should be stopped.
- **ntp_servers** A list of servers that should be added to the ESXi host’s NTP configuration.
- **service_policy** The policy to set for the NTP service.

**Note:** When setting the service policy to off or on, you must quote the setting. If you don’t, the yaml parser will set the string to a boolean, which will cause trouble checking for stateful changes and will error when trying to set the policy on the ESXi host.

- **service_restart** If set to True, the ntp daemon will be restarted, regardless of its previous running state. Default is False.
- **update_datetime** If set to True, the date/time on the given host will be updated to UTC. Default setting is False. This option should be used with caution since network delays and execution delays can result in time skews.

Example:

```yaml
configure-host-ntp:
  esxi.ntp_configured:
    - service_running: True
    - ntp_servers:
      - 192.174.1.100
      - 192.174.1.200
    - service_policy: 'on'
    - service_restart: True
```

**salt.states.esxi.password_present**

Ensures the given password is set on the ESXi host. Passwords cannot be obtained from host, so if a password is set in this state, the vsphere.update_host_password function will always run (except when using test=True functionality) and the state's changes dictionary will always be populated.

The username for which the password will change is the same username that is used to authenticate against the ESXi host via the Proxy Minion. For example, if the pillar definition for the proxy username is defined as root, then the username that the password will be updated for via this state is root.

- **name** Name of the state.
- **password** The new password to change on the host.

Example:

```yaml
configure-host-password:
  esxi.password_present:
    - password: 'new-bad-password'
```

**salt.states.esxi.ssh_configured**

Manage the SSH configuration for a host including whether or not SSH is running or the presence of a given SSH key. Note: Only one ssh key can be uploaded for root. Uploading a second key will replace any existing key.

- **name** Name of the state.
- **service_running** Ensures whether or not the SSH service should be running on a host. Represented as a boolean value where True indicates that SSH should be running and False indicates that SSH should stopped.
In order to update SSH keys, the SSH service must be running.

**ssh_key** Public SSH key to added to the authorized_keys file on the ESXi host. You can use ssh_key or ssh_key_file, but not both.

**ssh_key_file** File containing the public SSH key to be added to the authorized_keys file on the ESXi host. You can use ssh_key_file or ssh_key, but not both.

**service_policy** The policy to set for the NTP service.

**Note:** When setting the service policy to off or on, you must quote the setting. If you don’t, the yaml parser will set the string to a boolean, which will cause trouble checking for stateful changes and will error when trying to set the policy on the ESXi host.

**service_restart** If set to True, the SSH service will be restarted, regardless of its previous running state. Default is False.

**certificate_verify** If set to True, the SSL connection must present a valid certificate. Default is False.

Example:

```yaml
configure-host-ssh:
esxi.ssh_configured:
  - service_running: True
  - ssh_key_file: /etc/salt/ssh_keys/my_key.pub
  - service_policy: 'on'
  - service_restart: True
  - certificate_verify: True
```

```bash
salt.states.esxi.syslog_configured(name, syslog_configs, firewall=True, reset_service=True, reset_syslog_config=False, reset_configs=None)
```

Ensures the specified syslog configuration parameters. By default, this state will reset the syslog service after any new or changed parameters are set successfully.

**name** Name of the state.

**syslog_configs** Name of parameter to set (corresponds to the command line switch for esxcli without the double dashes (--))

Valid syslog_config values are logdir, loghost, logdir-unique, default-rotate, default-size, and default-timeout.

Each syslog_config option also needs a configuration value to set. For example, loghost requires URLs or IP addresses to use for logging. Multiple log servers can be specified by listing them, comma-separated, but without spaces before or after commas

**firewall** Enable the firewall rule set for syslog. Defaults to True.

**reset_service** After a successful parameter set, reset the service. Defaults to True.

**reset_syslog_config** Resets the syslog service to its default settings. Defaults to False. If set to True, default settings defined by the list of syslog configs in reset_configs will be reset before running any other syslog settings.

**reset_configs** A comma-delimited list of parameters to reset. Only runs if reset_syslog_config is set to True. If reset_syslog_config is set to True, but no syslog configs are listed in reset_configs, then reset_configs will be set to all by default.

See syslog_configs parameter above for a list of valid options.

Example:

```yaml
configure-host-syslog:
esxi.syslog_configured:
  - syslog_configs:
```
```yaml
default-timeout: 120
- firewall: True
- reset_service: True
- reset_syslog_config: True
- reset_configs: loghost,default-timeout
```

salt.states.esxi.vmotion_configured(name, enabled, device='vmk0')

Configures a host's VMotion properties such as enabling VMotion and setting the device VirtualNic that VMotion will use.

- **name** Name of the state.
- **enabled** Ensures whether or not VMotion should be enabled on a host as a boolean value where `True` indicates that VMotion should be enabled and `False` indicates that VMotion should be disabled.
- **device** The device that uniquely identifies the VirtualNic that will be used for VMotion for the host. Defaults to `vmk0`.

Example:
```yaml
configure-vmotion:
esxi.vmotion_configured:
  - enabled: True
  - device: sample-device
```

salt.states.esxi.vsan_configured(name, enabled, add_disks_to_vsan=False)

Configures a host's VSAN properties such as enabling or disabling VSAN, or adding VSAN-eligible disks to the VSAN system for the host.

- **name** Name of the state.
- **enabled** Ensures whether or not VSAN should be enabled on a host as a boolean value where `True` indicates that VSAN should be enabled and `False` indicates that VSAN should be disabled.
- **add_disks_to_vsan** If set to `True`, any VSAN-eligible disks for the given host will be added to the host's VSAN system. Default is `False`.

Example:
```yaml
configure-host-vsan:
esxi.vsan_configured:
  - enabled: True
  - add_disks_to_vsan: True
```

### 19.19.78 salt.states.event

Send events through Salt's event system during state runs

salt.states.event.send(name, data=None, preload=None, with_env=False, with_grains=False, with_pillar=False, **kwargs)

Send an event to the Salt Master

New in version 2014.7.0.

Accepts the same arguments as the `event.send` execution module of the same name.

Example:
```python
# ...snip bunch of states above
mycompany/mystaterun/status/update:
event.send:
  - data:
    status: "Half-way through the state run!"
```
salt.states.event.wait(name, sfun=None)

Fire an event on the Salt master event bus if called from a watch statement

New in version 2014.7.0.

Example:

```yaml
# Stand up a new web server.
apache:
  pkg:
    - installed
    - name: httpd
  service:
    - running
    - enable: True
    - name: httpd

# Notify the load balancer to update the pool once Apache is running.
refresh_pool:
  event:
    - wait
    - name: mycompany/loadbalancer/pool/update
    - data:
      new_web_server_ip: {{ grains['ipv4'] | first() }}
    - watch:
      - pkg: apache
```

19.19.79 salt.states.file

Operations on regular files, special files, directories, and symlinks

Salt States can aggressively manipulate files on a system. There are a number of ways in which files can be managed.

Regular files can be enforced with the `file.managed` state. This state downloads files from the salt master and places them on the target system. Managed files can be rendered as a jinja, mako, or wempy template, adding a dynamic component to file management. An example of `file.managed` which makes use of the jinja templating system would look like this:

```yaml
/etc/http/conf/http.conf:
  file.managed:
    - source: salt://apache/http.conf
    - user: root
    - group: root
    - mode: 644
    - template: jinja
    - defaults:
      custom_var: "default value"
      other_var: 123
{# if grains['os'] == 'Ubuntu' #}
    - context:
      custom_var: "override"
{# endif #}
```
It is also possible to use the `py renderer` as a templating option. The template would be a Python script which would need to contain a function called `run()`, which returns a string. All arguments to the state will be made available to the Python script as globals. The returned string will be the contents of the managed file. For example:

```python
def run():
    lines = ['foo', 'bar', 'baz']
    lines.extend([source, name, user, context])  # Arguments as globals
    return '\n\n'.join(lines)
```

**Note:** The `defaults` and `context` arguments require extra indentation (four spaces instead of the normal two) in order to create a nested dictionary. [More information.]

If using a template, any user-defined template variables in the file defined in `source` must be passed in using the `defaults` and/or `context` arguments. The general best practice is to place default values in `defaults`, with conditional overrides going into `context`, as seen above.

The template will receive a variable `custom_var`, which would be accessed in the template using `{{ custom_var }}`. If the operating system is Ubuntu, the value of the variable `custom_var` would be `override`, otherwise it is the default `default value`.

The `source` parameter can be specified as a list. If this is done, then the first file to be matched will be the one that is used. This allows you to have a default file on which to fall back if the desired file does not exist on the salt fileserver. Here’s an example:

```
/etc/foo.conf:
  file.managed:
    - source:
      - salt://foo.conf{{ grains['fqdn'] }}
      - salt://foo.conf.fallback
      - user: foo
      - group: users
      - mode: 644
      - backup: minion
```

**Note:** Salt supports backing up managed files via the backup option. For more details on this functionality please review the [backup_mode documentation](#).

The `source` parameter can also specify a file in another Salt environment. In this example `foo.conf` in the dev environment will be used instead.

```
/etc/foo.conf:
  file.managed:
    - source:
      - 'salt://foo.conf?saltenv=dev'
      - user: foo
      - group: users
      - mode: '0644'
```

**Warning:** When using a mode that includes a leading zero you must wrap the value in single quotes. If the value is not wrapped in quotes it will be read by YAML as an integer and evaluated as an octal.

The `names` parameter, which is part of the state compiler, can be used to expand the contents of a single state
declaration into multiple, single state declarations. Each item in the names list receives its own individual state
name and is converted into its own low-data structure. This is a convenient way to manage several files with similar
attributes.

There is more documentation about this feature in the Names declaration section of the Highstate docs.

Special files can be managed via the mknod function. This function will create and enforce the permissions on a
special file. The function supports the creation of character devices, block devices, and FIFO pipes. The function will
create the directory structure up to the special file if it is needed on the minion. The function will not overwrite or
operate on (change major/minor numbers) existing special files with the exception of user, group, and permissions.
In most cases the creation of some special files require root permissions on the minion. This would require that the
minion to be run as the root user. Here is an example of a character device:

```
/var/named/chroot/dev/random:
  file.mknod:
    - ntype: c
    - major: 1
    - minor: 8
    - user: named
    - group: named
    - mode: 660
```

Here is an example of a block device:

```
/var/named/chroot/dev/loop0:
  file.mknod:
    - ntype: b
    - major: 7
    - minor: 0
    - user: named
    - group: named
    - mode: 660
```

Here is an example of a fifo pipe:

```
/var/named/chroot/var/log/logfifo:
  file.mknod:
    - ntype: p
    - user: named
    - group: named
    - mode: 660
```

Directories can be managed via the directory function. This function can create and enforce the permissions on
a directory. A directory statement will look like this:

```
/srv/stuff/substuff:
  file.directory:
    - user: fred
    - group: users
    - mode: 755
    - makedirs: True
```

If you need to enforce user and/or group ownership or permissions recursively on the directory's contents, you can
do so by adding a recurse directive:

```
/srv/stuff/substuff:
  file.directory:
    - user: fred
```

As a default, mode will resolve to dir_mode and file_mode, to specify both directory and file permissions, use this form:

```yaml
/srv/stuff/substuf:
  file.directory:
    - user: fred
    - group: users
    - file_mode: 744
    - dir_mode: 755
    - makedirs: True
    - recurse:
      - user
      - group
      - mode
```

Symlinks can be easily created; the symlink function is very simple and only takes a few arguments:

```yaml
/etc/grub.conf:
  file.symlink:
    - target: /boot/grub/grub.conf
```

Recursive directory management can also be set via the recurse function. Recursive directory management allows for a directory on the salt master to be recursively copied down to the minion. This is a great tool for deploying large code and configuration systems. A state using recurse would look something like this:

```yaml
/opt/code/flask:
  file.recurse:
    - source: salt://code/flask
    - include_empty: True
```

A more complex recurse example:

```yaml
{% set site_user = 'testuser' %}
{% set site_name = 'test_site' %}
{% set project_name = 'test_proj' %}
{% set sites_dir = 'test_dir' %}

django-project:
  file.recurse:
    - name: {{ sites_dir }}/{{ site_name }}/ {{ project_name }}
    - user: {{ site_user }}
    - dir_mode: 2775
    - file_mode: '0644'
    - template: jinja
    - source: salt://project/templates_dir
    - include_empty: True
```

Retention scheduling can be applied to manage contents of backup directories. For example:
/var/backups/example_directory:
  file.retention_schedule:
    - strftime_format: example_name_%Y%m%dT%H%M%S.tar.bz2
    - retain:
      most_recent: 5
      first_of_hour: 4
      first_of_day: 14
      first_of_week: 6
      first_of_month: 6
      first_of_year: all

salt.states.file.absent(name)
Make sure that the named file or directory is absent. If it exists, it will be deleted. This will work to reverse
any of the functions in the file state module. If a directory is supplied, it will be recursively deleted.
name The path which should be deleted

salt.states.file.accumulated(name, filename, text, **kwargs)
Prepare accumulator which can be used in template in file.managed state. Accumulator dictionary becomes
available in template. It can also be used in file.blockreplace.
name Accumulator name
filename Filename which would receive this accumulator (see file.managed state documentation about
name)
text String or list for adding in accumulator
require_in / watch_in One of them required for sure we fill up accumulator before we manage the file. Prob-
ably the same as filename
Example:
Given the following:

animals_doing_things:
  file.accumulated:
    - filename: /tmp/animal_file.txt
    - text: 'jumps over the lazy dog.'
    - require_in:
      - file: animal_file

animal_file:
  file.managed:
    - name: /tmp/animal_file.txt
    - source: salt://animal_file.txt
    - template: jinja

One might write a template for animal_file.txt like the following:

```
The quick brown fox{% for animal in accumulator['animals_doing_things'] %}{% if animal %}{% endfor %}
```

Collectively, the above states and template file will produce:

```
The quick brown fox jumps over the lazy dog.
```

Multiple accumulators can be `chained` together.

**Note:** The `accumulator` data structure is a Python dictionary. Do not expect any loop over the keys in a
deterministic order!
salt.states.file.append(name, text=None, makedirs=False, source=None, source_hash=None, template='jinja', sources=None, source_hashes=None, defaults=None, context=None, ignore_whitespace=True)

Ensure that some text appears at the end of a file.

The text will not be appended if it already exists in the file. A single string of text or a list of strings may be appended.

name The location of the file to append to.

text The text to be appended, which can be a single string or a list of strings.
makedirs If the file is located in a path without a parent directory, then the state will fail. If makedirs is set to True, then the parent directories will be created to facilitate the creation of the named file. Defaults to False.

source A single source file to append. This source file can be hosted on either the salt master server, or on an HTTP or FTP server. Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials (see s3.get state documentation). File retrieval from Openstack Swift object storage is supported via swift://container/object_path URLs (see swift.get documentation).

For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs.

If the file is hosted on an HTTP or FTP server, the source_hash argument is also required.

source_hash
This can be one of the following:
1. a source hash string
2. the URI of a file that contains source hash strings

The function accepts the first encountered long unbroken alphanumeric string of correct length as a valid hash, in order from most secure to least secure:

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>sha512</td>
<td>128</td>
</tr>
<tr>
<td>sha384</td>
<td>96</td>
</tr>
<tr>
<td>sha256</td>
<td>64</td>
</tr>
<tr>
<td>sha224</td>
<td>56</td>
</tr>
<tr>
<td>sha1</td>
<td>40</td>
</tr>
<tr>
<td>md5</td>
<td>32</td>
</tr>
</tbody>
</table>

See the source_hash parameter description for file.managed function for more details and examples.

template The named templating engine will be used to render the appended-to file. Defaults to jinja. The following templates are supported:
- cheetah
- genshi
- jinja
- mako
- py
- wempy

sources A list of source files to append. If the files are hosted on an HTTP or FTP server, the source_hashes argument is also required.

source_hashes A list of source_hashes corresponding to the sources list specified in the sources argument.

defaults Default context passed to the template.

context Overrides default context variables passed to the template.

ignore_whitespace New in version 2015.8.4.

Spaces and Tabs in text are ignored by default, when searching for the appending content, one space or multiple tabs are the same for salt. Set this option to False if you want to change this behavior.
Multi-line example:

```
/etc/motd:
  file.append:
    - text: |
      Thou hadst better eat salt with the Philosophers of Greece,
      than sugar with the Courtiers of Italy.
    - text: |

--Benjamin Franklin
```

Multiple lines of text:

```
/etc/motd:
  file.append:
    - text:
      - Trust no one unless you have eaten much salt with him.
      - "Salt is born of the purest of parents: the sun and the sea."
```

Gather text from multiple template files:

```
/etc/motd:
  file:
    - append
    - template: jinja
    - sources:
      - salt://motd/devops-messages.tmpl
      - salt://motd/hr-messages.tmpl
      - salt://motd/general-messages.tmpl
```

New in version 0.9.5.

`salt.states.file.blockreplace` 

```
(name, marker_start="-- start managed zone --", marker_end="-- end managed zone --", source=None, source_hash=None, template='jinja', sources=None, source_hashes=None, defaults=None, context=None, content='', append_if_not_found=False, prepend_if_not_found=False, backup='.bak', show_changes=True, append_newline=None)
```

Maintain an edit in a file in a zone delimited by two line markers

New in version 2014.1.0.

Changed in version 2017.7.5, 2018.3.1: append_newline argument added. Additionally, to improve idempotence, if the string represented by marker_end is found in the middle of the line, the content preceding the marker will be removed when the block is replaced. This allows one to remove append_newline: False from the SLS and have the block properly replaced if the end of the content block is immediately followed by the marker_end (i.e. no newline before the marker).

A block of content delimited by comments can help you manage several lines entries without worrying about old entries removal. This can help you maintaining an un-managed file containing manual edits. Note: this function will store two copies of the file in-memory (the original version and the edited version) in order to detect changes and only edit the targeted file if necessary.

- **name** Filesystem path to the file to be edited
- **marker_start** The line content identifying a line as the start of the content block. Note that the whole line containing this marker will be considered, so whitespace or extra content before or after the marker is included in final output
- **marker_end** The line content identifying a line as the end of the content block. Note that the whole line containing this marker will be considered, so whitespace or extra content before or after the marker is included in final output. Note: you can use file.accumulated and target this state. All accumulated data dictionaries content will be added as new lines in the content

2820 Chapter 19. Salt Module Reference
content The content to be used between the two lines identified by marker_start and marker_end

source The source file to download to the minion, this source file can be hosted on either the salt master server, or on an HTTP or FTP server. Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials. (see s3.get state documentation) File retrieval from Openstack Swift object storage is supported via swift://container/object_path URLs, see swift.get documentation. For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs. If source is left blank or None (use ~ in YAML), the file will be created as an empty file and the content will not be managed. This is also the case when a file already exists and the source is undefined; the contents of the file will not be changed or managed.

If the file is hosted on a HTTP or FTP server then the source_hash argument is also required.

A list of sources can also be passed in to provide a default source and a set of fallbacks. The first source in the list that is found to exist will be used and subsequent entries in the list will be ignored.

```
file_override_example:
  file.blockreplace:
    - name: /etc/example.conf
      source:
        - salt://file_that_does_not_exist
        - salt://file_that_exists
```

source_hash

This can be one of the following:

1. a source hash string
2. the URI of a file that contains source hash strings

The function accepts the first encountered long unbroken alphanumeric string of correct length as a valid hash, in order from most secure to least secure:

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>sha512</td>
<td>128</td>
</tr>
<tr>
<td>sha384</td>
<td>96</td>
</tr>
<tr>
<td>sha256</td>
<td>64</td>
</tr>
<tr>
<td>sha224</td>
<td>56</td>
</tr>
<tr>
<td>sha1</td>
<td>40</td>
</tr>
<tr>
<td>md5</td>
<td>32</td>
</tr>
</tbody>
</table>

See the source_hash parameter description for file.managed function for more details and examples.

template [jinja] Templating engine to be used to render the downloaded file. The following engines are supported:

- cheetah
- genshi
- jinja
- mako
- py
- wempy

context Overrides default context variables passed to the template

defaults Default context passed to the template

append_if_not_found [False] If markers are not found and this option is set to True, the content block will be appended to the file.

prepend_if_not_found [False] If markers are not found and this option is set to True, the content block will be prepended to the file.

backup The file extension to use for a backup of the file if any edit is made. Set this to False to skip making a backup.
dry_run [False] If True, do not make any edits to the file and simply return the changes that would be made.

show_changes [True] Controls how changes are presented. If True, the Changes section of the state return will contain a unified diff of the changes made. If False, then it will contain a boolean (True if any changes were made, otherwise False).

append_newline Controls whether or not a newline is appended to the content block. If the value of this argument is True then a newline will be added to the content block. If it is False, then a newline will not be added to the content block. If it is unspecified, then a newline will only be added to the content block if it does not already end in a newline.

New in version 2017.7.5, 2018.3.1.

Example of usage with an accumulator and with a variable:

```
{% set myvar = 42 %
hosts-config-block-{{ myvar }}:
  file.blockreplace:
    - name: /etc/hosts
    - marker_start: "# START managed zone {{ myvar }} -DO-NOT-EDIT-"
    - marker_end: "# END managed zone {{ myvar }} --"
    - content: 'First line of content'
    - append_if_not_found: True
    - backup: '.bak'
    - show_changes: True

hosts-config-block-{{ myvar }}-accumulated1:
  file.accumulated:
    - filename: /etc/hosts
    - name: my-accumulator-{{ myvar }}
    - text: "text 2"
    - require_in:
      - file: hosts-config-block-{{ myvar }}

hosts-config-block-{{ myvar }}-accumulated2:
  file.accumulated:
    - filename: /etc/hosts
    - name: my-accumulator-{{ myvar }}
    - text: |
      text 3
      text 4
    - require_in:
      - file: hosts-config-block-{{ myvar }}
```

will generate and maintain a block of content in /etc/hosts:

```
# START managed zone 42 -DO-NOT-EDIT-
First line of content
text 2
text 3
text 4
# END managed zone 42 --
```

salt.states.file.cached(name, source_hash=`, source_hash_name=None, skip_verify=False, saltenv=`base`)  

New in version 2017.7.3.

Ensures that a file is saved to the minion's cache. This state is primarily invoked by other states to ensure that we do not re-download a source file if we do not need to.

name The URL of the file to be cached. To cache a file from an environment other than
base, either use the saltenv argument or include the saltenv in the URL (e.g. `salt://path/to/file.conf?saltenv=dev`).

**Note:** A list of URLs is not supported, this must be a single URL. If a local file is passed here, then the state will obviously not try to download anything, but it will compare a hash if one is specified.

**source_hash** See the documentation for this same argument in the `file.managed` state.

**source_hash_name** See the documentation for this same argument in the `file.managed` state.

**skip_verify** See the documentation for this same argument in the `file.managed` state.

**saltenv** Used to specify the environment from which to download a file from the Salt fileserver (i.e. those with `salt://` URL).

This state will in most cases not be useful in SLS files, but it is useful when writing a state or remote-execution module that needs to make sure that a file at a given URL has been downloaded to the cachedir. One example of this is in the `archive.extracted` state:

```python
result = __states__['file.cached'](
    source_match, 
    source_hash=source_hash, 
    source_hash_name=source_hash_name, 
    skip_verify=skip_verify, 
    saltenv=__env__)
```

This will return a dictionary containing the state's return data, including a `result` key which will state whether or not the state was successful. Note that this will not catch exceptions, so it is best used within a `try/except`.

Once this state has been run from within another state or remote-execution module, the actual location of the cached file can be obtained using `cp.is_cached`:

```python
cached = __salt__['cp.is_cached'](
    source_match, saltenv=__env__)
```

This function will return the cached path of the file, or an empty string if the file is not present in the minion cache.

salt.states.file.comment(name, regex, char='#', backup='.bak')

Comment out specified lines in a file.

**name** The full path to the file to be edited

**regex** A regular expression used to find the lines that are to be commented; this pattern will be wrapped in parenthesis and will move any preceding/trailing `^` or `$` characters outside the parenthesis (e.g., the pattern `^foo$` will be rewritten as `^\(foo\)$`) Note that you _need_ the leading `^`, otherwise each time you run highstate, another comment char will be inserted.

**char** [#] The character to be inserted at the beginning of a line in order to comment it out

**backup** [.bak] The file will be backed up before edit with this file extension
Warning: This backup will be overwritten each time `sed / comment / uncomment` is called. Meaning the backup will only be useful after the first invocation.

Set to False/None to not keep a backup.

Usage:

```
/etc/fstab:
  file.comment:
    - regex: ^bind 127.0.0.1
```

New in version 0.9.5.

salt.states.file.copy(name, source, force=False, makedirs=False, preserve=False, user=None, group=None, mode=None, subdir=False, **kwargs)

If the file defined by the source option exists on the minion, copy it to the named path. The file will not be overwritten if it already exists, unless the force option is set to True.

Note: This state only copies files from one location on a minion to another location on the same minion. For copying files from the master, use a `file.managed` state.

name The location of the file to copy to
source The location of the file to copy to the location specified with name
force If the target location is present then the file will not be moved, specify `force: True` to overwrite the target file
makedirs If the target subdirectories don't exist create them
preserve New in version 2015.5.0.
  Set preserve: True to preserve user/group ownership and mode after copying. Default is False. If preserve is set to True, then user/group/mode attributes will be ignored.
user New in version 2015.5.0.
  The user to own the copied file, this defaults to the user salt is running as on the minion. If preserve is set to True, then this will be ignored

group New in version 2015.5.0.
  The group to own the copied file, this defaults to the group salt is running as on the minion. If preserve is set to True or on Windows this will be ignored
mode New in version 2015.5.0.
  The permissions to set on the copied file, aka 644, `0775`, `4664`. If preserve is set to True, then this will be ignored. Not supported on Windows.
  The default mode for new files and directories corresponds umask of salt process. For existing files and directories it's not enforced.
subdir New in version 2015.5.0.
  If the name is a directory then place the file inside the named directory

Note: The copy function accepts paths that are local to the Salt minion. This function does not support `salt://`, `http://`, or the other additional file paths that are supported by `states.file.managed` and `states.file.recurse`.

salt.states.file.decode(name, encoded_data=None, contents_pillar=None, encoding_type='base64', checksum='md5')

Decode an encoded file and write it to disk
New in version 2016.3.0.

**name** Path of the file to be written.

**encoded_data** The encoded file. Either this option or contents_pillar must be specified.

**contents_pillar** A Pillar path to the encoded file. Uses the same path syntax as pillar.get. The hashutil.base64_encodefile function can load encoded content into Pillar. Either this option or encoded_data must be specified.

**encoding_type** [base64] The type of encoding.

**checksum** [md5] The hashing algorithm to use to generate checksums. Wraps the hashutil.digest execution function.

Usage:

```yaml
write_base64_encoded_string_to_a_file:
  file.decode:
    - name: /tmp/new_file
    - encoding_type: base64
    - contents_pillar: mypillar:thefile

# or
write_base64_encoded_string_to_a_file:
  file.decode:
    - name: /tmp/new_file
    - encoding_type: base64
    - encoded_data: |
      Z2V0IHNhbHRlZAo=
```

Be careful with multi-line strings that the YAML indentation is correct. E.g.,

```yaml
write_base64_encoded_string_to_a_file:
  file.decode:
    - name: /tmp/new_file
    - encoding_type: base64
    - encoded_data: |
      {{ salt.pillar.get('path:to:datapath') | indent(8) }}
```

salt.states.file.directory(name, user=None, group=None, recurse=None, max_depth=None, dir_mode=None, file_mode=None, makedirs=False, clean=False, require=None, exclude_pat=None, follow_symlinks=False, force=False, backupname=None, allow_symlink=True, children_only=False, win_owner=None, win_perms=None, win_deny_perms=None, win_inheritance=True, **kwargs)

Ensure that a named directory is present and has the right perms

**name** The location to create or manage a directory, as an absolute path

**user** The user to own the directory; this defaults to the user salt is running as on the minion

**group** The group ownership set for the directory; this defaults to the group salt is running as on the minion.

On Windows, this is ignored

**recurse** Enforce user/group ownership and mode of directory recursively. Accepts a list of strings representing what you would like to recurse. If mode is defined, will recurse on both file_mode and dir_mode if they are defined. If ignore_files or ignore_dirs is included, files or directories will be left unchanged respectively. Example:

```yaml
/var/log/httpd:
  file.directory:
    - user: root
    - group: root
    - dir_mode: 755
    - file_mode: 644
```
- recurse:
  - user
  - group
  - mode

Leave files or directories unchanged:

```
/var/log/httpd:
  file.directory:
  - user: root
  - group: root
  - dir_mode: 755
  - file_mode: 644
  - recurse:
    - user
    - group
    - mode
    - ignore_dirs
```

New in version 2015.5.0.

**max_depth** Limit the recursion depth. The default is no limit=None. `max_depth` and `clean` are mutually exclusive.

New in version 2016.11.0.

**dir_mode** / **mode** The permissions mode to set any directories created. Not supported on Windows.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it's not enforced.

**file_mode** The permissions mode to set any files created if `mode` is run in `recurse`. This defaults to `dir_mode`. Not supported on Windows.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it's not enforced.

**makedirs** If the directory is located in a path without a parent directory, then the state will fail. If makedirs is set to True, then the parent directories will be created to facilitate the creation of the named file.

**clean** Make sure that only files that are set up by salt and required by this function are kept. If this option is set then everything in this directory will be deleted unless it is required. `clean` and `max_depth` are mutually exclusive.

**require** Require other resources such as packages or files

**exclude_pat** When `clean` is set to True, exclude this pattern from removal list and preserve in the destination.

**follow_symlinks** [False] If the desired path is a symlink or `recurse` is defined and a symlink is encountered while recursing), follow it and check the permissions of the directory/file to which the symlink points.

New in version 2014.1.4.

**force** If the name of the directory exists and is not a directory and force is set to False, the state will fail. If force is set to True, the file in the way of the directory will be deleted to make room for the directory, unless backupname is set, then it will be renamed.

New in version 2014.7.0.

**backupname** If the name of the directory exists and is not a directory, it will be renamed to the backupname. If the backupname already exists and force is False, the state will fail. Otherwise, the backupname will be removed first.

New in version 2014.7.0.

**allow_symlink** [True] If allow_symlink is True and the specified path is a symlink, it will be allowed to remain if it points to a directory. If allow_symlink is False then the state will fail, unless force is also set to True, in which case it will be removed or renamed, depending on the value of the backupname argument.
New in version 2014.7.0.

**children_only** [False] If children_only is True the base of a path is excluded when performing a recursive operation. In case of /path/to/base, base will be ignored while all of /path/to/base/* are still operated on.

**win_owner** [None] The owner of the directory. If this is not passed, user will be used. If user is not passed, the account under which Salt is running will be used.

New in version 2017.7.0.

**win_perms** [None] A dictionary containing permissions to grant and their propagation. For example: {'Administrators': {'perms': 'full_control','applies_to': 'this_folder_only'}} Can be a single basic perm or a list of advanced perms. perms must be specified. applies_to is optional and defaults to this_folder_subfoler_files.

New in version 2017.7.0.

**win_deny_perms** [None] A dictionary containing permissions to deny and their propagation. For example: {'Administrators': {'perms': 'full_control','applies_to': 'this_folder_only'}} Can be a single basic perm or a list of advanced perms.

New in version 2017.7.0.

**win_inheritance** [True] True to inherit permissions from the parent directory, False not to inherit permission.

New in version 2017.7.0.

Here's an example using the above `win_*` parameters:

```yaml
create_config_dir:
  file.directory:
    - name: 'C:\config\'
    - win_owner: Administrators
    - win_perms:
        # Basic Permissions
        dev_ops:
          perms: full_control
        # List of advanced permissions
        appuser:
          perms:
            - read_attributes
            - read_ea
            - create_folders
            - read_permissions
            applies_to: this_folder_only
        joe_snuffy:
          perms: read
          applies_to: this_folder_files
    - win_deny_perms:
      fred_snuffy:
        perms: full_control
    - win_inheritance: False
```

salt.states.file.exists(name)
Verify that the named file or directory is present or exists. Ensures pre-requisites outside of Salt’s purview (e.g., keytabs, private keys, etc.) have been previously satisfied before deployment.

name Absolute path which must exist
	salt.states.file.line(name, content=None, match=None, mode=None, location=None, before=None, after=None, show_changes=True, backup=False, quiet=False, indent=True, create=False, user=None, group=None, file_mode=None)

Line-based editing of a file.

New in version 2015.8.0.
name  Filesistem path to the file to be edited.
content  Content of the line. Allowed to be empty if mode=delete.
match  Match the target line for an action by a fragment of a string or regular expression.

If neither before nor after are provided, and match is also None, match becomes the content value.
mode  Defines how to edit a line. One of the following options is required:

- ensure  If line does not exist, it will be added.
- replace  If line already exists, it will be replaced.
- delete  Delete the line, once found.
- insert  Insert a line.

**Note:** If mode=insert is used, at least one of the following options must also be defined: location, before, or after. If location is used, it takes precedence over the other two options.

location  Defines where to place content in the line. Note this option is only used when mode=insert is specified. If a location is passed in, it takes precedence over both the before and after kwargs. Valid locations are:

- start  Place the content at the beginning of the file.
- end  Place the content at the end of the file.

before  Regular expression or an exact case-sensitive fragment of the string. This option is only used when either the ensure or insert mode is defined.

after  Regular expression or an exact case-sensitive fragment of the string. This option is only used when either the ensure or insert mode is defined.

show_changes  Output a unified diff of the old file and the new file. If False return a boolean if any changes were made. Default is True.

**Note:** Using this option will store two copies of the file in-memory (the original version and the edited version) in order to generate the diff.

backup  Create a backup of the original file with the extension: `Year-Month-Day-Hour-Minutes-Seconds`.
quiet  Do not raise any exceptions. E.g. ignore the fact that the file that is tried to be edited does not exist and nothing really happened.
indent  Keep indentation with the previous line. This option is not considered when the delete mode is specified.

**Parameters**

- create  -- Create an empty file if doesn’t exists.
  
  New in version 2016.11.0.

- user  -- The user to own the file, this defaults to the user salt is running as on the minion.
  
  New in version 2016.11.0.

- group  -- The group ownership set for the file, this defaults to the group salt is running as on the minion On Windows, this is ignored.
  
  New in version 2016.11.0.

- file_mode  -- The permissions to set on this file, aka 644, 0775, 4664. Not supported on Windows.
  
  New in version 2016.11.0.

If an equal sign (=) appears in an argument to a Salt command, it is interpreted as a keyword argument in the format of `key=val`. That processing can be bypassed in order to pass an equal sign through to the remote shell command by manually specifying the kwarg:
update_config:
  file.line:
  - name: /etc/myconfig.conf
  - mode: ensure
  - content: my key = my value
  - before: somekey.*?

salt.states.file.managed(name, source=None, source_hash=None, source_hash_name=None, keep_source=True, user=None, group=None, mode=None, template=None, makedirs=False, dir_mode=None, context=None, replace=True, defaults=None, backup='', show_changes=True, create=True, contents=None, tmp_ext='', contents_pillar=None, contents_grains=None, contents_newline=True, contents_delimiter=':', encoding=None, encoding_errors='strict', allow_empty=True, follow_symlinks=True, check_cmd=None, skip_verify=False, win_owner=None, win_perms=None, win_deny_perms=None, win_inheritance=True, **kwargs)

Manage a given file, this function allows for a file to be downloaded from the salt master and potentially run through a templating system.

name  The location of the file to manage, as an absolute path.
source The source file to download to the minion, this source file can be hosted on either the salt master server (salt://), the salt minion local file system (/), or on an HTTP or FTP server (http(s)//, ftp://).

Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials. (see s3.get state documentation) File retrieval from Openstack Swift object storage is supported via swift://container/object_path URLs, see swift.get documentation. For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs. If source is left blank or None (use ~ in YAML), the file will be created as an empty file and the content will not be managed. This is also the case when a file already exists and the source is undefined; the contents of the file will not be changed or managed.

If the file is hosted on a HTTP or FTP server then the source_hash argument is also required.

A list of sources can also be passed in to provide a default source and a set of fallbacks. The first source in the list that is found to exist will be used and subsequent entries in the list will be ignored. Source list functionality only supports local files and remote files hosted on the salt master server or retrievable via HTTP, HTTPS, or FTP.

source_hash

This can be one of the following:

1. a source hash string
2. the URL of a file that contains source hash strings

The function accepts the first encountered long unbroken alphanumeric string of correct length as a valid hash, in order from most secure to least secure:

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>sha512</td>
<td>128</td>
</tr>
<tr>
<td>sha384</td>
<td>96</td>
</tr>
<tr>
<td>sha256</td>
<td>64</td>
</tr>
</tbody>
</table>
Using a Source Hash File

The file can contain several checksums for several files. Each line must contain both the file name and the hash. If no file name is matched, the first hash encountered will be used, otherwise the most secure hash with the correct source file name will be used.

When using a source hash file the source_hash argument needs to be a url, the standard download urls are supported, ftp, http, salt etc:

Example:

```
tomdroid-src-0.7.3.tar.gz:
  file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
    - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7.3.tar.gz
    - source_hash: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7.3.hash
```

The following lines are all supported formats:

```
/etc/rc.conf ef6e82e4006dee563d98ada2a2a80a27
sha254c8525aee419eb649f0233be91c151178b30f0df8ebbdcc8de71b1d5c8bcc06a /
/etc/resolv.conf
ead482423703509d37c4a90e6a8d53e143b6fc268
```

Debian file type *.dsc files are also supported.

Inserting the Source Hash in the SLS Data

The source_hash can be specified as a simple checksum, like so:

```
tomdroid-src-0.7.3.tar.gz:
  file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
    - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7.3.tar.gz
    - source_hash: 79eef25f9b0b2c642c62b7f737d4f53f
```

Note: Releases prior to 2016.11.0 must also include the hash type, like in the below example:

```
tomdroid-src-0.7.3.tar.gz:
  file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
    - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7.3.tar.gz
    - source_hash: md5=79eef25f9b0b2c642c62b7f737d4f53f
```

Known issues: If the remote server URL has the hash file as an apparent sub-directory of the source file, the module will discover that it has already cached a directory where a file should be cached. For example:

```
tomdroid-src-0.7.3.tar.gz:
  file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
```
source_hash_name

When `source_hash` refers to a hash file, Salt will try to find the correct hash by matching the filename/URI associated with that hash. By default, Salt will look for the filename being managed. When managing a file at path `/tmp/foo.txt`, then the following line in a hash file would match:

```
acbd18db4cc2f85cedef654fccc4a4d8 foo.txt
```

However, sometimes a hash file will include multiple similar paths:

```
37b51d194a7513e45b56f6524f2d51f2 ./dir1/foo.txt
acbd18db4cc2f85cedef654fccc4a4d8 ./dir2/foo.txt
73feffa4b7f6bb68e44cf984c85f6e88 ./dir3/foo.txt
```

In cases like this, Salt may match the incorrect hash. This argument can be used to tell Salt which filename to match, to ensure that the correct hash is identified. For example:

```
/tmp/foo.txt:
file.managed:
  - source: https://mydomain.tld/dir2/foo.txt
  - source_hash: https://mydomain.tld/hashes
  - source_hash_name: ./dir2/foo.txt
```

**Note:** This argument must contain the full filename entry from the checksum file, as this argument is meant to disambiguate matches for multiple files that have the same basename. So, in the example above, simply using `foo.txt` would not match.

New in version 2016.3.5.

**keep_source**  [True] Set to `False` to discard the cached copy of the source file once the state completes. This can be useful for larger files to keep them from taking up space in minion cache. However, keep in mind that discarding the source file will result in the state needing to re-download the source file if the state is run again.

New in version 2017.7.3.

**user**  The user to own the file, this defaults to the user salt is running as on the minion

**group**  The group ownership set for the file, this defaults to the group salt is running as on the minion. On Windows, this is ignored

**mode**  The permissions to set on this file, e.g. 644, 0775, or 4664.

The default mode for new files and directories corresponds to the umask of the salt process. The mode of existing files and directories will only be changed if `mode` is specified.

**Note:** This option is not supported on Windows.

Changed in version 2016.11.0: This option can be set to `keep`, and Salt will keep the mode from the Salt filesaver. This is only supported when the `source` URL begins with `salt://`, or for files local to the minion. Because the `source` option cannot be used with any of the `contents` options, setting the `mode` to `keep` is also incompatible with the `contents` options.

**Note:** `keep` does not work with salt-ssh.
As a consequence of how the files are transferred to the minion, and the inability to connect back to the master with salt-ssh, salt is unable to stat the file as it exists on the fileserver and thus cannot mirror the mode on the salt-ssh minion.

**template** If this setting is applied, the named templating engine will be used to render the downloaded file. The following templates are supported:

- `cheetah`
- `genshi`
- `jinja`
- `mako`
- `py`
- `wempy`

**makedirs** [False] If set to True, then the parent directories will be created to facilitate the creation of the named file. If False, and the parent directory of the destination file doesn’t exist, the state will fail.

**dir_mode** If directories are to be created, passing this option specifies the permissions for those directories. If this is not set, directories will be assigned permissions by adding the execute bit to the mode of the files.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it’s not enforced.

**replace** [True] If set to False and the file already exists, the file will not be modified even if changes would otherwise be made. Permissions and ownership will still be enforced, however.

**context** Overrides default context variables passed to the template.

**defaults** Default context passed to the template.

**backup** Overrides the default backup mode for this specific file. See *backup_mode documentation* for more details.

**show_changes** Output a unified diff of the old file and the new file. If False return a boolean if any changes were made.

**create** [True] If set to False, then the file will only be managed if the file already exists on the system.

**contents** Specify the contents of the file. Cannot be used in combination with `source`. Ignores hashes and does not use a templating engine.

This value can be either a single string, a multiline YAML string or a list of strings. If a list of strings, then the strings will be joined together with newlines in the resulting file. For example, the below two example states would result in identical file contents:

```
/path/to/file1:
  file.managed:
    - contents:
      - This is line 1
      - This is line 2

/path/to/file2:
  file.managed:
    - contents: |
      This is line 1
      This is line 2
```

**contents_pillar** New in version 0.17.0.

Changed in version 2016.11.0: contents_pillar can also be a list, and the pillars will be concatenated together to form one file.

Operates like contents, but draws from a value stored in pillar, using the pillar path syntax used in `pillar.get`. This is useful when the pillar value contains newlines, as referencing a pillar variable using a jinja/mako template can result in YAML formatting issues due to the newlines causing indentation mismatches.
For example, the following could be used to deploy an SSH private key:

```yaml
/home/deployer/.ssh/id_rsa:
  file.managed:
    - user: deployer
    - group: deployer
    - mode: 600
    - contents_pillar: userdata:deployer:id_rsa
```

This would populate `/home/deployer/.ssh/id_rsa` with the contents of pillar['userdata']['deployer']['id_rsa']. An example of this pillar setup would be like so:

```yaml
userdata:
  deployer:
    id_rsa: |
      -----BEGIN RSA PRIVATE KEY-----
      MIIEowIBAAKCAQEAoQiw03JhBquPAalQF9qP1llZNVvYMISwMe2HcWUVBgh+vY
      UTsxqH+iVvNwMcOqmMnP+8gTPKGl1vgAObJAnMT623dMXjKvnenEagZPRJiDy
      B/HaAre9euNiY3lVzSTtWR5eMT+rWvIKVBpvwLgGrfgz70mopqxuUyfbAGLin+
      6pxZAMaFpZw4sSBIRuissXZj/shPQb9p9MSie04Z3rjkcPC1cX
      -----END RSA PRIVATE KEY-----
```

**Note:** The private key above is shortened to keep the example brief, but shows how to do multiline string in YAML. The key is followed by a pipe character, and the multiline string is indented two more spaces.

To avoid the hassle of creating an indented multiline YAML string, the `file_tree external pillar` can be used instead. However, this will not work for binary files in Salt releases before 2015.8.4.

**contents_grains** New in version 2014.7.0.

Operates like `contents`, but draws from a value stored in grains, using the grains path syntax used in `grains.get`. This functionality works similarly to `contents_pillar`, but with grains.

For example, the following could be used to deploy a `message of the day` file:

```yaml
write_motd:
  file.managed:
    - name: /etc/motd
    - contents_grains: motd
```

This would populate `/etc/motd` file with the contents of the `motd` grain. The `motd` grain is not a default grain, and would need to be set prior to running the state:

```bash
salt '*' grains.set motd 'Welcome! This system is managed by Salt.'
```

**contents_newline** [True] New in version 2014.7.0.

Changed in version 2015.8.4: This option is now ignored if the contents being deployed contain binary data.

If True, files managed using `contents`, `contents_pillar`, or `contents_grains` will have a newline added to the end of the file if one is not present. Setting this option to False will omit this final newline.

**contents_delimiter** New in version 2015.8.4.

Can be used to specify an alternate delimiter for `contents_pillar` or `contents_grains`. This delimiter will be passed through to `pillar.get` or `grains.get` when retrieving the contents.
encoding Encoding used for the file, e.g. `UTF-8`, `base64`. Default is None, which means str() will be applied to contents to ensure an ascii encoded file and backwards compatibility. See https://docs.python.org/3/library/codecs.html#standard-encodings for available encodings.

New in version 2017.7.0.

encoding_errors ['strict'] Error encoding scheme. Default is `strict`. See https://docs.python.org/2/library/codecs.html#codec-base-classes for the list of available schemes.

New in version 2017.7.0.

If set to False, then the state will fail if the contents specified by contents_pillar or contents_grains are empty.

If the desired path is a symlink follow it and make changes to the file to which the symlink points.

check_cmd New in version 2014.7.0.

The specified command will be run with an appended argument of a temporary file containing the new managed contents. If the command exits with a zero status the new managed contents will be written to the managed destination. If the command exits with a nonzero exit code, the state will fail and no changes will be made to the file.

For example, the following could be used to verify sudoers before making changes:

```
/etc/sudoers:
    file.managed:
        - user: root
        - group: root
        - mode: 0440
        - source: salt://sudoers/files/sudoers.jinja
        - template: jinja
        - check_cmd: /usr/sbin/visudo -c -f
```

**NOTE:** This check_cmd functions differently than the requisite check_cmd.

tmp_ext Suffix for temp file created by check_cmd. Useful for checkers dependent on config file extension (e.g. the init-checkconf upstart config checker).

```
/etc/init/test.conf:
    file.managed:
        - user: root
        - group: root
        - mode: 0440
        - tmp_ext: '.conf'
        - contents:
            - 'description "Salt Minion"
            - 'start on started mountall'
            - 'stop on shutdown'
            - 'respawn'
            - 'exec salt-minion'
        - check_cmd: init-checkconf -f
```

skip_verify [False] If True, hash verification of remote file sources (http://, https://, ftp://) will be skipped, and the source_hash argument will be ignored.

New in version 2016.3.0.

win_owner [None] The owner of the directory. If this is not passed, user will be used. If user is not passed, the account under which Salt is running will be used.

New in version 2017.7.0.
**win_perms** [None] A dictionary containing permissions to grant and their propagation. For example: `{"Administrators": {'perms': 'full_control'}}` Can be a single basic perm or a list of advanced perms. `perms` must be specified. `applies_to` does not apply to file objects.

New in version 2017.7.0.

**win_deny_perms** [None] A dictionary containing permissions to deny and their propagation. For example: `{"Administrators": {'perms': 'full_control'}}` Can be a single basic perm or a list of advanced perms. `perms` must be specified. `applies_to` does not apply to file objects.

New in version 2017.7.0.

**win_inheritance** [True] True to inherit permissions from the parent directory, False not to inherit permission.

New in version 2017.7.0.

Here's an example using the above `win_*` parameters:

```
create_config_file:
  file.managed:
    - name: C:\config\settings.cfg
    - source: salt://settings.cfg
    - win_owner: Administrators
    - win_perms:
      # Basic Permissions

      fred_snuffy:
        perms: full_control
    - win_inheritance: False
```

salt.states.file.missing(name)
Verify that the named file or directory is missing, this returns True only if the named file is missing but does not remove the file if it is present.

name Absolute path which must NOT exist

salt.states.file.mknod(name, ntype, major=0, minor=0, user=None, group=None, mode=`0600`) Create a special file similar to the `nix mknod` command. The supported device types are p (fifo pipe), c (character device), and b (block device). Provide the major and minor numbers when specifying a character device or block device. A fifo pipe does not require this information. The command will create the necessary dirs if needed. If a file of the same name not of the same type/major/minor exists, it will not be overwritten or unlinked (deleted). This is logically in place as a safety measure because you can really shoot yourself in the foot here and it is the behavior of `nix mknod`. It is also important to note that not just anyone can create special devices. Usually this is only done as root. If the state is executed as none other than root on a minion, you may receive a permission error.

name name of the file
ntype node type `p` (fifo pipe), `c` (character device), or `b` (block device)
major major number of the device does not apply to a fifo pipe
minor minor number of the device does not apply to a fifo pipe
user owning user of the device/pipe
group owning group of the device/pipe
mode permissions on the device/pipe
Usage:

```
/dev/chr:
  file.mknod:
    - ntype: c
      - major: 180
      - minor: 31
      - user: root
      - group: root
      - mode: 660

/dev/blk:
  file.mknod:
    - ntype: b
      - major: 8
      - minor: 999
      - user: root
      - group: root
      - mode: 660

/dev/fifo:
  file.mknod:
    - ntype: p
    - user: root
    - group: root
    - mode: 660
```

New in version 0.17.0.

salt.states.file.mod_run_check_cmd(cmd, filename, **check_cmd_opts)
  Execute the check_cmd logic.
  Return a result dict if check_cmd succeeds (check_cmd == 0) otherwise return True

salt.states.file.not_cached(name, saltenv='base')
  Ensures that a file is saved to the minion's cache. This state is primarily invoked by other states to ensure
  that we do not re-download a source file if we do not need to.
  name The URL of the file to be cached. To cache a file from an environment other than
  base, either use the saltenv argument or include the saltenv in the URL (e.g.

  Note: A list of URLs is not supported, this must be a single URL. If a local file is passed here, the state
  will take no action.

  saltenv Used to specify the environment from which to download a file from the Salt fileserver (i.e. those
  with salt:// URL).

salt.states.file.patch(name, source=None, options='', dry_run_first=True, **kwargs)
  Ensure that a patch has been applied to the specified file

  Note: A suitable patch executable must be available on the minion

  name The file to which the patch should be applied
  source The source patch to download to the minion, this source file must be hosted on the salt master server.
  If the file is located in the directory named spam, and is called eggs, the source string is salt://spam/eggs.
  A source is required.
hash The hash of the patched file. If the hash of the target file matches this value then the patch is assumed to have been applied. For versions 2016.11.4 and newer, the hash can be specified without an accompanying hash type (e.g. e138491e9d5b97023cea823fe17bac22), but for earlier releases it is necessary to also specify the hash type in the format <hash_type>:<hash_value> (e.g. md5:e138491e9d5b97023cea823fe17bac22).

options Extra options to pass to patch.
dry_run_first [True] Run patch with --dry-run first to check if it will apply cleanly.
saltenv Specify the environment from which to retrieve the patch file indicated by the source parameter. If not provided, this defaults to the environment from which the state is being executed.

Usage:

```salt
# Equivalent to `''patch --forward /opt/file.txt file.patch''`
/opt/file.txt:
    file.patch:
       - source: salt://file.patch
       - hash: e138491e9d5b97023cea823fe17bac22
```

Note: For minions running version 2016.11.3 or older, the hash in the example above would need to be specified with the hash type (i.e. md5:e138491e9d5b97023cea823fe17bac22).

```python
salt.states.file.prepend(name=None, text=None, makedirs=False, source=None, source_hash=None, template='jinja', sources=None, source_hashes=None, context=None, header=None)
```

Ensure that some text appears at the beginning of a file

The text will not be prepended again if it already exists in the file. You may specify a single line of text or a list of lines to append.
nname The location of the file to append to.
text The text to be appended, which can be a single string or a list of strings.
makedirs If the file is located in a path without a parent directory, then the state will fail. If makedirs is set to True, then the parent directories will be created to facilitate the creation of the named file. Defaults to False.
source A single source file to append. This source file can be hosted on either the salt master server, or on an HTTP or FTP server. Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials (see s3.get state documentation). File retrieval from Openstack Swift object storage is supported via swift://container/object_path URLs (see swift.get documentation).

For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs.

If the file is hosted on an HTTP or FTP server, the source_hash argument is also required.
source_hash

This can be one of the following:

1. a source hash string
2. the URI of a file that contains source hash strings

The function accepts the first encountered long unbroken alphanumeric string of correct length as a valid hash, in order from most secure to least secure:

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>sha512</td>
<td>128</td>
</tr>
<tr>
<td>sha384</td>
<td>96</td>
</tr>
<tr>
<td>sha256</td>
<td>64</td>
</tr>
<tr>
<td>sha224</td>
<td>56</td>
</tr>
</tbody>
</table>
See the `source_hash` parameter description for `file.managed` function for more details and examples.

**template** The named templating engine will be used to render the appended-to file. Defaults to `jinja`. The following templates are supported:

- `cheetah`
- `genshi`
- `jinja`
- `mako`
- `py`
- `wempy`

**sources** A list of source files to append. If the files are hosted on an HTTP or FTP server, the `source_hashes` argument is also required.

**source_hashes** A list of source hashes corresponding to the sources list specified in the `sources` argument.

**defaults** Default context passed to the template.

**context** Overrides default context variables passed to the template.

**ignore_whitespace** New in version 2015.8.4.

Spaces and Tabs in text are ignored by default, when searching for the appending content, one space or multiple tabs are the same for salt. Set this option to `False` if you want to change this behavior.

Multi-line example:

```
/etc/motd:
file.prepend:
- text: |
  Thou hadst better eat salt with the Philosophers of Greece,
  than sugar with the Courtiers of Italy.
  - Benjamin Franklin
```

Multiple lines of text:

```
/etc/motd:
file.prepend:
- text:
  - Trust no one unless you have eaten much salt with him.
  - "Salt is born of the purest of parents: the sun and the sea."
```

Optionally, require the text to appear exactly as specified (order and position). Combine with multi-line or multiple lines of input.

```
/etc/motd:
file.prepend:
- header: True
- text:
  - This will be the very first line in the file.
  - The 2nd line, regardless of duplicates elsewhere in the file.
  - These will be written anew if they do not appear verbatim.
```

Gather text from multiple template files:

```
/etc/motd:
file:
- prepend
- template: jinja
- sources:
```
salt://motd/devops-messages.tmpl
salt://motd/hr-messages.tmpl
salt://motd/general-messages.tmpl

New in version 2014.7.0.

salt.states.file.recurse(name, source, keep_source=True, clean=False, require=None, user=None, group=None, dir_mode=None, file_mode=None, sym_mode=None, template=None, context=None, defaults=None, include_empty=False, backup='`', include_pat=None, exclude_pat=None, maxdepth=None, keep_symlinks=False, force_symlinks=False, win_owner=None, win_perms=None, win_deny_perms=None, win_inheritance=True, **kwargs)

Recurse through a subdirectory on the master and copy said subdirectory over to the specified path.

**name**  The directory to set the recursion in

**source**  The source directory, this directory is located on the salt master file server and is specified with the salt:// protocol. If the directory is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs

**keep_source**  [True] Set to False to discard the cached copy of the source file once the state completes. This can be useful for larger files to keep them from taking up space in minion cache. However, keep in mind that discarding the source file will result in the state needing to re-download the source file if the state is run again.

New in version 2017.7.3.

**clean**  Make sure that only files that are set up by salt and required by this function are kept. If this option is set then everything in this directory will be deleted unless it is required.

**require**  Require other resources such as packages or files

**user**  The user to own the directory. This defaults to the user salt is running as on the minion

**group**  The group ownership set for the directory. This defaults to the group salt is running as on the minion.

On Windows, this is ignored

**dir_mode**  The permissions mode to set on any directories created.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it’s not enforced.

---

**Note:**  This option is **not** supported on Windows.

**file_mode**  The permissions mode to set on any files created.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it’s not enforced.

---

**Note:**  This option is **not** supported on Windows.

Changed in version 2016.11.0: This option can be set to keep, and Salt will keep the mode from the Salt fileserver. This is only supported when the source URL begins with salt://, or for files local to the minion. Because the source option cannot be used with any of the contents options, setting the mode to keep is also incompatible with the contents options.

**sym_mode**  The permissions mode to set on any symlink created.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it’s not enforced.
**Note:** This option is **not** supported on Windows.

**template** If this setting is applied, the named templating engine will be used to render the downloaded file. The following templates are supported:

- `cheetah`
- `genshi`
- `jinja`
- `mako`
- `py`
- `wempy`

**Note:** The template option is required when recursively applying templates.

**context** Overrides default context variables passed to the template.

**defaults** Default context passed to the template.

**include_empty** Set this to True if empty directories should also be created (default is False).

**backup** Overrides the default backup mode for all replaced files. See `backup_mode documentation` for more details.

**include_pat** When copying, include only this pattern from the source. Default is glob match; if prefixed with `E@`, then regexp match. Example:

```plaintext
- include_pat: hello* : glob matches 'hello01', 'hello02'
  ... but not 'otherhello'
- include_pat: E@hello : regexp matches 'otherhello',
  'hello01' ...
```

**exclude_pat** Exclude this pattern from the source when copying. If both `includePat` and `excludePat` are supplied, then it will apply conditions cumulatively. i.e. first select based on include_pat, and then within that result apply exclude_pat.

Also, when 'clean=True', exclude this pattern from the removal list and preserve in the destination. Example:

```plaintext
- exclude_pat: APPDATA* : glob matches APPDATA.01, APPDATA.02,.. for exclusion
- exclude_pat: E@(APPDATA)|(TEMPDATA) : regexp matches APPDATA or TEMPDATA for exclusion
```

**maxdepth** When copying, only copy paths which are of depth `maxdepth` from the source path. Example:

```plaintext
- maxdepth: 0 : Only include files located in the source directory
- maxdepth: 1 : Only include files located in the source or immediate subdirectories
```

**keep_symlinks** Keep symlinks when copying from the source. This option will cause the copy operation to terminate at the symlink. If desire behavior similar to rsync, then set this to True.

**force_symlinks** Force symlink creation. This option will force the symlink creation. If a file or directory is obstructing symlink creation it will be recursively removed so that symlink creation can proceed. This option is usually not needed except in special circumstances.

**win_owner** [None] The owner of the symlink and directories if `makedirs` is True. If this is not passed, `user` will be used. If `user` is not passed, the account under which Salt is running will be used.

New in version 2017.7.7.

**win_perms** [None] A dictionary containing permissions to grant

New in version 2017.7.7.

**win_deny_perms** [None] A dictionary containing permissions to deny
New in version 2017.7.7.

**win_inheritance**  [None] True to inherit permissions from parent, otherwise False

New in version 2017.7.7.

```python
salt.states.file.rename
(name, source, force=False, makedirs=False)
```

If the source file exists on the system, rename it to the named file. The named file will not be overwritten if it already exists unless the force option is set to True.

- **name**  The location of the file to rename to
- **source**  The location of the file to move to the location specified with name
- **force**  If the target location is present then the file will not be moved, specify `force: True` to overwrite the target file
- **makedirs**  If the target subdirectories don't exist create them

```python
salt.states.file.replace
(name, pattern, repl, count=0, flags=8, bufsize=1, append_if_not_found=False, prepend_if_not_found=False, not_found_content=None, backup='.bak', show_changes=True, ignore_if_missing=False, backslash_literal=False)
```

Maintain an edit in a file.

New in version 0.17.0.

- **name**  Filesystem path to the file to be edited. If a symlink is specified, it will be resolved to its target.
- **pattern**  A regular expression, to be matched using Python's `search()`.

**Note:** If you need to match a literal string that contains regex special characters, you may want to use salt's custom Jinja filter, `regex_escape`.

```java
{{ 'http://example.com?foo=bar%20baz' | regex_escape }}
```

- **repl**  The replacement text
- **count**  Maximum number of pattern occurrences to be replaced. Defaults to 0. If count is a positive integer n, no more than n occurrences will be replaced, otherwise all occurrences will be replaced.
- **flags**  A list of flags defined in the `re` module documentation from the Python standard library. Each list item should be a string that will correlate to the human-friendly flag name. E.g., `['IGNORECASE', 'MULTILINE']`. Optionally, **flags** may be an int, with a value corresponding to the XOR of all the desired flags. Defaults to 8 (which equates to `['MULTILINE']`).

**Note:** `file.replace` reads the entire file as a string to support multiline regex patterns. Therefore, when using anchors such as `^` or `$` in the pattern, those anchors may be relative to the line OR relative to the file. The default for `file.replace` is to treat anchors as relative to the line, which is implemented by setting the default value of **flags** to `['MULTILINE']`. When overriding the default value for **flags**, if `'MULTILINE'` is not present then anchors will be relative to the file. If the desired behavior is for anchors to be relative to the line, then simply add `'MULTILINE'` to the list of flags.

- **bufsize**  How much of the file to buffer into memory at once. The default value 1 processes one line at a time. The special value `file` may be specified which will read the entire file into memory before processing.
- **append_if_not_found**  [False] If set to `True`, and pattern is not found, then the content will be appended to the file.

New in version 2014.7.0.

- **prepend_if_not_found**  [False] If set to `True` and pattern is not found, then the content will be prepended to the file.

New in version 2014.7.0.

- **not_found_content**  Content to use for append/prepend if not found. If None (default), uses `repl`. Useful when `repl` uses references to group in pattern.
New in version 2014.7.0.

**backup** The file extension to use for a backup of the file before editing. Set to `False` to skip making a backup.

**show_changes** `[True]` Output a unified diff of the old file and the new file. If `False` return a boolean if any changes were made. Returns a boolean or a string.

**ignore_if_missing** `[False]` New in version 2016.3.4.

Controls what to do if the file is missing. If set to `False`, the state will display an error raised by the execution module. If set to `True`, the state will simply report no changes.

**backslash_literal** `[False]` New in version 2016.11.7.

Interpret backslashes as literal backslashes for the repl and not escape characters. This will help when using append/prepend so that the backslashes are not interpreted for the repl on the second run of the state.

For complex regex patterns, it can be useful to avoid the need for complex quoting and escape sequences by making use of YAML's multiline string syntax.

```yaml
complex_search_and_replace:
    file.replace:
        # <...snip...>
        - pattern: |
          CentOS  \((2.6.32[^\n]+\n\s+root[^\n]+\n)+
```

**Note:** When using YAML multiline string syntax in `pattern:`, make sure to also use that syntax in the `repl:` part, or you might lose line feeds.

---

**salt.states.file.retain_to_schedule**(name, retain, strptime_format=None, timezone=None)

Apply retention scheduling to backup storage directory.

New in version 2016.11.0.

**Parameters**

- **name** -- The filesystem path to the directory containing backups to be managed.
- **retain** -- Delete the backups, except for the ones we want to keep. The N below should be an integer but may also be the special value of `all`, which keeps all files matching the criteria. All of the retain options default to `None`, which means to not keep files based on this criteria.
  - `most_recent N` Keep the most recent N files.
  - `first_of_hour N` For the last N hours from now, keep the first file after the hour.
  - `first_of_day N` For the last N days from now, keep the first file after midnight. See also `timezone`.
  - `first_of_week N` For the last N weeks from now, keep the first file after Sunday midnight.
  - `first_of_month N` For the last N months from now, keep the first file after the start of the month.
  - `first_of_year N` For the last N years from now, keep the first file after the start of the year.
- **strptime_format** -- A python `strptime` format string used to first match the filenames of backups and then parse the filename to determine the date-time of the file. [https://docs.python.org/2/library/datetime.html#datetime.datetime.strptime](https://docs.python.org/2/library/datetime.html#datetime.datetime.strptime) Defaults to `None`, which considers all files in the directory to be backups eligible for deletion and uses `os.path.getmtime()` to determine the date-time.
- **timezone** -- The timezone to use when determining midnight. This is only used when datetime is pulled from `os.path.getmtime()`. Defaults to `None` which uses the timezone from the locale.

Usage example:
salt.states.file.serialize(name, dataset=None, dataset_pillar=None, user=None, group=None, mode=None, backup='`, makedirs=False, show_diff=None, show_changes=True, create=True, merge_if_exists=False, encoding=None, encoding_errors='strict', **kwargs)

Serializes dataset and store it into managed file. Useful for sharing simple configuration files.

name The location of the file to create

dataset The dataset that will be serialized
dataset_pillar Operates like dataset, but draws from a value stored in pillar, using the pillar path syntax used in pillar.get. This is useful when the pillar value contains newlines, as referencing a pillar variable using a jinja/mako template can result in YAML formatting issues due to the newlines causing indentation mismatches.

New in version 2015.8.0.

formatter Write the data as this format. See the list of serializer modules for supported output formats.

encoding Encoding used for the file, e.g. `UTF-8`, `base64`. Default is None, which means str() will be applied to contents to ensure an ascii encoded file. See https://docs.python.org/3/library/codecs.html#standard-encodings for available encodings.

New in version 2017.7.0.

encoding_errors `strict` Error encoding scheme. Default is `strict`. See https://docs.python.org/2/library/codecs.html#codecs-base-classes for the list of available schemes.

New in version 2017.7.0.

user The user to own the directory, this defaults to the user salt is running as on the minion

group The group ownership set for the directory, this defaults to the group salt is running as on the minion

mode The permissions to set on this file, e.g. 644, 0775, or 4664.

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it's not enforced.

**Note**: This option is not supported on Windows.

backup Overrides the default backup mode for this specific file.
makedirs Create parent directories for destination file.

New in version 2014.1.3.

show_diff DEPRECATED: Please use show_changes.

If set to False, the diff will not be shown in the return data if changes are made.

show_changes Output a unified diff of the old file and the new file. If False return a boolean if any changes were made.

create Default is True, if create is set to False then the file will only be managed if the file already exists on the system.
merge_if_exists  Default is False, if merge_if_exists is True then the existing file will be parsed and the dataset passed in will be merged with the existing content

New in version 2014.7.0.

For example, this state:

```
/etc/dummy/package.json:
  file.serialize:
    - dataset:
      name: naive
      description: A package using naive versioning
      author: A confused individual <iam@confused.com>
      dependencies:
        express: '>= 1.2.0'
        optimist: '>= 0.1.0'
      engine: node 0.4.1
    - formatter: json
```

will manage the file /etc/dummy/package.json:

```
{
  "author": "A confused individual <iam@confused.com>",
  "dependencies": {
    "express": ">= 1.2.0",
    "optimist": ">= 0.1.0"
  },
  "description": "A package using naive versioning",
  "engine": "node 0.4.1",
  "name": "naive"
}
```

salt.states.file.shortcut(name, target, arguments=None, working_dir=None, description=None, icon_location=None, force=False, backupname=None, makedirs=False, user=None, **kwargs)

Create a Windows shortcut

If the file already exists and is a shortcut pointing to any location other than the specified target, the shortcut will be replaced. If it is a regular file or directory then the state will return False. If the regular file or directory is desired to be replaced with a shortcut pass force: True, if it is to be renamed, pass a backupname.

name  The location of the shortcut to create. Must end with either ".lnk" or ".url"

target  The location that the shortcut points to

arguments  Any arguments to pass in the shortcut

working_dir  Working directory in which to execute target

description  Description to set on shortcut

icon_location  Location of shortcut’s icon

force  If the name of the shortcut exists and is not a file and force is set to False, the state will fail. If force is set to True, the link or directory in the way of the shortcut file will be deleted to make room for the shortcut, unless backupname is set, when it will be renamed.

backupname  If the name of the shortcut exists and is not a file, it will be renamed to the backupname. If the backupname already exists and force is False, the state will fail. Otherwise, the backupname will be removed first.

makedirs  If the location of the shortcut does not already have a parent directory then the state will fail, setting makedirs to True will allow Salt to create the parent directory. Setting this to True will also create the parent for backupname if necessary.

user  The user to own the file, this defaults to the user salt is running as on the minion

The default mode for new files and directories corresponds umask of salt process. For existing files and directories it’s not enforced.
salt.states.file.symlink(name, target, force=False, backupname=None, makedirs=False, user=None, group=None, win_owner=None, win_perms=None, win_deny_perms=None, win_inheritance=None, **kwargs)

Create a symbolic link (symlink, soft link)

If the file already exists and is a symlink pointing to any location other than the specified target, the symlink will be replaced. If the symlink is a regular file or directory then the state will return False. If the regular file or directory is desired to be replaced with a symlink pass force: True, if it is to be renamed, pass a backupname.

**name** The location of the symlink to create

**target** The location that the symlink points to

**force** If the name of the symlink exists and is not a symlink and force is set to False, the state will fail. If force is set to True, the file or directory in the way of the symlink file will be deleted to make room for the symlink, unless backupname is set, when it will be renamed

**backupname** If the name of the symlink exists and is not a symlink, it will be renamed to the backupname. If the backupname already exists and force is False, the state will fail. Otherwise, the backupname will be removed first.

**makedirs** If the location of the symlink does not already have a parent directory then the state will fail, setting makedirs to True will allow Salt to create the parent directory

**user** The user to own the file, this defaults to the user salt is running as on the minion

**group** The group ownership set for the file, this defaults to the group salt is running as on the minion. On Windows, this is ignored

**mode** The permissions to set on this file, aka 644, 0775, 4664. Not supported on Windows.

  The default mode for new files and directories corresponds umask of salt process. For existing files and directories it's not enforced.

**win_owner** [None] The owner of the symlink and directories if makedirs is True. If this is not passed, user will be used. If user is not passed, the account under which Salt is running will be used.

  New in version 2017.7.7.

**win_perms** [None] A dictionary containing permissions to grant

  New in version 2017.7.7.

**win_deny_perms** [None] A dictionary containing permissions to deny

  New in version 2017.7.7.

**win_inheritance** [None] True to inherit permissions from parent, otherwise False

  New in version 2017.7.7.

case:

case:

salt.states.file.touch(name, atime=None, mtime=None, makedirs=False)

Replicate the `nix `touch'' command to create a new empty file or update the atime and mtime of an existing file.

Note that if you just want to create a file and don't care about atime or mtime, you should use file.managed instead, as it is more feature-complete. (Just leave out the source/template/contents arguments, and it will just create the file and/or check its permissions, without messing with contents)

**name** name of the file

**atime** atime of the file

**mtime** mtime of the file

**makedirs** whether we should create the parent directory/directories in order to touch the file

Usage:

```
/var/log/httpd/logrotate.empty:
  file.touch
```

New in version 0.9.5.

case:

case:

salt.states.file.uncomment(name, regex, char='#', backup='.bak')

Uncomment specified commented lines in a file
name  The full path to the file to be edited
regex  A regular expression used to find the lines that are to be uncommented. This regex should not include
the comment character. A leading ^ character will be stripped for convenience (for easily switching
between comment() and uncomment()). The regex will be searched for from the beginning of the line,
ignoring leading spaces (we prepend '^[' and '][')
char  [#] The character to remove in order to uncomment a line
backup  [.bak] The file will be backed up before edit with this file extension;

**Warning:** This backup will be overwritten each time `sed` / `comment` / `uncomment` is called.
Meaning the backup will only be useful after the first invocation.

Set to False/None to not keep a backup.

Usage:

```
/etc/adduser.conf:
  file.uncomment:
    - regex: EXTRA_GROUPS
```

New in version 0.9.5.

### 19.19.80 salt.states.firewall module

State to check firewall configurations .. versionadded:: 2016.3.0

salt.states.firewall.check(name, port=None, **kwargs)

Checks if there is an open connection from the minion to the defined host on a specific port.

- **name** host name or ip address to test connection to
- **port** The port to test the connection on

Additional parameters, parameters allowed are: `proto` (tcp or udp) `family` (ipv4 or ipv6) `timeout`

```
testgoogle:
  firewall.check:
    - name: 'google.com'
    - port: 80
    - proto: 'tcp'
```

### 19.19.81 salt.states.firewalld

Management of firewalld

New in version 2015.8.0.

The following example applies changes to the public zone, blocks echo-reply and echo-request packets, does not set
the zone to be the default, enables masquerading, and allows ports 22/tcp and 25/tcp. It will be applied permanently
and directly before restart/reload.

```
public:
  firewalld.present:
    - name: public
    - block_icmp:
    - echo-reply
    - echo-request
```
The following example applies changes to the public zone, enables masquerading and configures port forwarding TCP traffic from port 22 to 2222, and forwards TCP traffic from port 80 to 443 at 192.168.0.1.

```yaml
my_zone:
  firewalld.present:
    - name: public
    - masquerade: True
    - port_fwd:
      - 22:2222:tcp
      - 80:443:tcp:192.168.0.1
```

The following example binds the public zone to interface eth0 and to all packets coming from the 192.168.1.0/24 subnet. It also removes the zone from all other interfaces or sources.

```yaml
public:
  firewalld.present:
    - name: public
    - interfaces:
      - eth0
    - sources:
      - 192.168.1.0/24
```

Here, we define a new service that encompasses TCP ports 4505 4506:

```yaml
saltmaster:
  firewalld.service:
    - name: saltmaster
    - ports:
      - 4505/tcp
      - 4506/tcp
```

To make this new service available in a zone, the following can be used, which would allow access to the salt master from the 10.0.0.0/8 subnet:

```yaml
saltzone:
  firewalld.present:
    - name: saltzone
    - services:
      - saltmaster
    - sources:
      - 10.0.0.0/8
```

class salt.states.firewalld.ForwardingMapping(srcport, destport, protocol, destaddr)

Represents a port forwarding statement mapping a local port to a remote port for a specific protocol (TCP or UDP)

todict()

Returns a pretty dictionary meant for command line output.

salt.states.firewalld.present(name, block_icmp=None, default=None, masquerade=False, ports=None, port_fwd=None, services=None, prune_services=True, interfaces=None, sources=None, rich_rules=None)
Ensure a zone has specific attributes.

```
salt.states.firewalld.service(name, ports=None, protocols=None)
```
Ensure the service exists and encompasses the specified ports and protocols.
New in version 2016.11.0.

**19.19.82 salt.states.gem**

**Installation of Ruby modules packaged as gems**

A state module to manage rubygems. Gems can be set up to be installed or removed. This module will use RVM or rbenv if they are installed. In that case, you can specify what ruby version and gemset to target.

```
addressable:
  gem.installed:
    - user: rvm
    - ruby: jruby@jgemset
```

```
salt.states.gem.installed(name, ruby=None, gem_bin=None, user=None, version=None, rdoc=False, ri=False, pre_releases=False, proxy=None, source=None)
```
Make sure that a gem is installed.
name The name of the gem to install
ruby: None Only for RVM or rbenv installations: the ruby version and gemset to target.
gem_bin: None Custom gem command to run instead of the default. Use this to install gems to a non-default ruby install. If you are using rvm or rbenv use the ruby argument instead.
user: None The user under which to run the gem command
version [None] Specify the version to install for the gem. Doesn't play nice with multiple gems at once
rdoc [False] Generate RDoc documentation for the gem(s).
ri [False] Generate RI documentation for the gem(s).
pre_releases [False] Install pre-release version of gem(s) if available.
proxy [None] Use the specified HTTP proxy server for all outgoing traffic. Format: http://hostname[:port]
source [None] Use the specified HTTP gem source server to download gem. Format: http://hostname[:port]

```
salt.states.gem.removed(name, ruby=None, user=None, gem_bin=None)
```
Make sure that a gem is not installed.
name The name of the gem to uninstall
gem_bin [None] Full path to gem binary to use.
ruby [None] If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
user: None The user under which to run the gem command

New in version 0.17.0.

```
salt.states.gem.sources_add(name, ruby=None, user=None)
```
Make sure that a gem source is added.
name The URL of the gem source to be added
ruby: None For RVM or rbenv installations: the ruby version and gemset to target.
user: None The user under which to run the gem command

New in version 0.17.0.

```
salt.states.gem.sources_remove(name, ruby=None, user=None)
```
Make sure that a gem source is removed.
name The URL of the gem source to be removed
ruby: None For RVM or rbenv installations: the ruby version and gemset to target.
user: None  The user under which to run the `gem` command

New in version 0.17.0.

19.19.83  salt.states.git

States to manage git repositories and git configuration

**Important:** Before using git over ssh, make sure your remote host fingerprint exists in your 

~/.ssh/known_hosts file.

Changed in version 2015.8.8: This state module now requires git 1.6.5 (released 10 October 2009) or newer.

salt.states.git.config_set(name, value=None, multivar=None, repo=None, user=None, password=None, **kwargs)

New in version 2014.7.0.

Changed in version 2015.8.0: Renamed from `git.config` to `git.config_set`. For earlier versions, use `git.config`.

Ensure that a config value is set to the desired value(s)

name  Name of the git config value to set

value  Set a single value for the config item

multivar  Set multiple values for the config item

**Note:** The order matters here, if the same parameters are set but in a different order, they will be removed and replaced in the order specified.

New in version 2015.8.0.

repo  Location of the git repository for which the config value should be set. Required unless `global` is set to True.

user  User under which to run git commands. By default, the commands are run by the user under which the minion is running.

password  Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

global  [False] If True, this will set a global git config option

Local Config Example:

```
# Single value
mylocalrepo:
  git.config_set:
    - name: user.email
    - value: foo@bar.net
    - repo: /path/to/repo

# Multiple values
mylocalrepo:
  git.config_set:
    - name: mysection.myattribute
    - multivar:
      - foo
      - bar
```
- baz
- repo: /path/to/repo

**Global Config Example (User ``foo``):**

```yaml
mylocalrepo:
  git.config_set:
    - name: user.name
    - value: Foo Bar
    - user: foo
    - global: True

salt.states.git.config_unset(name, value_regex=None, repo=None, user=None, password=None, **kwargs)
```

New in version 2015.8.0.

Ensure that the named config key is not present

- **name** The name of the configuration key to unset. This value can be a regex, but the regex must match the entire key name. For example, `foo\.` would not match all keys in the `foo` section, it would be necessary to use `foo\..+` to do so.
- **value_regex** Regex indicating the values to unset for the matching key(s)

| Note: | This option behaves differently depending on whether or not `all` is set to `True`. If it is, then all values matching the regex will be deleted (this is the only way to delete multiple values from a multivar). If `all` is set to `False`, then this state will fail if the regex matches more than one value in a multivar. |

- **all** [False] If `True`, unset all matches
- **repo** Location of the git repository for which the config value should be set. Required unless `global` is set to `True`.
- **user** User under which to run git commands. By default, commands are run by the user under which the minion is running.
- **password** Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

- **global** [False] If `True`, this will set a global git config option

**Examples:**

```yaml
# Value matching 'baz'
mylocalrepo:
  git.config_unset:
    - name: foo.bar
    - value_regex: 'baz'
    - repo: /path/to/repo

# Ensure entire multivar is unset
mylocalrepo:
  git.config_unset:
    - name: foo.bar
    - all: True

# Ensure all variables in 'foo' section are unset, including multivars
mylocalrepo:
  git.config_unset:
    - name: 'foo\..+'
    - all: True
```
salt.states.git.detached

New in version 2016.3.0.

Make sure a repository is cloned to the given target directory and is a detached HEAD checkout of the commit ID resolved from `rev`.

- `name` Address of the remote repository.
- `rev` The branch, tag, or commit ID to checkout after clone. If a branch or tag is specified it will be resolved to a commit ID and checked out.
- `ref` Deprecated since version 2017.7.0: Use `rev` instead.
- `target` Name of the target directory where repository is about to be cloned.
- `remote` [origin] Git remote to use. If this state needs to clone the repo, it will clone it using this value as the initial remote name. If the repository already exists, and a remote by this name is not present, one will be added.
- `user` User under which to run git commands. By default, commands are run by the user under which the minion is running.
- `password` Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.
- `force_clone` [False] If the target directory exists and is not a git repository, then this state will fail. Set this argument to `True` to remove the contents of the target directory and clone the repo into it.
- `force_checkout` [False] When checking out the revision ID, the state will fail if there are unwritten changes. Set this argument to `True` to discard unwritten changes when checking out.
- `fetch_remote` [True] If `False` a fetch will not be performed and only local refs will be reachable.
- `hard_reset` [False] If `True` a hard reset will be performed before the checkout and any uncommitted modifications to the working directory will be discarded. Untracked files will remain in place.

Note: Changes resulting from a hard reset will not trigger requisites.

- `submodules` [False] Update submodules
- `identity` A path on the minion (or a SaltStack fileserver URL, e.g. `salt://path/to/identity_file`) to a private key to use for SSH authentication.
- `https_user` HTTP Basic Auth username for HTTPS (only) clones
- `https_pass` HTTP Basic Auth password for HTTPS (only) clones
- `onlyif` A command to run as a check, run the named command only if the command passed to the `onlyif` option returns true
- `unless` A command to run as a check, only run the named command if the command passed to the `unless` option returns false

salt.states.git.latest

New in version 2016.3.0.
Make sure the repository is cloned to the given directory and is up-to-date.

name Address of the remote repository, as passed to `git clone`

**Note:** From the Git documentation, there are two URL formats supported for SSH authentication. The below two examples are equivalent:

```
# ssh:// URL
ssh://user@server/project.git

# SCP-like syntax
user@server:project.git
```

A common mistake is to use an `ssh://` URL, but with a colon after the domain instead of a slash. This is invalid syntax in Git, and will therefore not work in Salt. When in doubt, confirm that a `git clone` works for the URL before using it in Salt.

It has been reported by some users that SCP-like syntax is incompatible with git repos hosted on Atlassian Stash/BitBucket Server. In these cases, it may be necessary to use `ssh://` URLs for SSH authentication.

**rev** [HEAD] The remote branch, tag, or revision ID to checkout after clone / before update. If specified, then Salt will also ensure that the tracking branch is set to `<remote>/<rev>`, unless `rev` refers to a tag or SHA1, in which case Salt will ensure that the tracking branch is unset.

If `rev` is not specified, it will be assumed to be HEAD, and Salt will not manage the tracking branch at all.

Changed in version 2015.8.0: If not specified, `rev` now defaults to the remote repository’s HEAD.

**target** Name of the target directory where repository is about to be cloned

**branch** Name of the local branch into which to checkout the specified `rev`. If not specified, then Salt will not care what branch is being used locally and will just use whatever branch is currently there.

New in version 2015.8.0.

**Note:** If this argument is not specified, this means that Salt will not change the local branch if the repository is reset to another branch/tag/SHA1. For example, assume that the following state was run initially:

```
foo_app:
  git.latest:
    - name: https://mydomain.tld/apps/foo.git
    - target: /var/www/foo
    - user: www
```

This would have cloned the HEAD of that repo (since a `rev` wasn’t specified), and because `branch` is not specified, the branch in the local clone at `/var/www/foo` would be whatever the default branch is on the remote repository (usually master, but not always). Now, assume that it becomes necessary to switch this checkout to the `dev` branch. This would require `rev` to be set, and probably would also require `force_reset` to be enabled:

```
foo_app:
  git.latest:
    - name: https://mydomain.tld/apps/foo.git
    - target: /var/www/foo
    - user: www
    - rev: dev
    - force_reset: True
```
The result of this state would be to perform a hard-reset to origin/dev. Since branch was not specified though, while /var/www/foo would reflect the contents of the remote repo’s dev branch, the local branch would still remain whatever it was when it was cloned. To make the local branch match the remote one, set branch as well, like so:

```
foo_app:
  git.latest:
    - name: https://mydomain.tld/apps/foo.git
    - target: /var/www/foo
    - user: www
    - rev: dev
    - branch: dev
    - force_reset: True
```

This may seem redundant, but Salt tries to support a wide variety of use cases, and doing it this way allows for the use case where the local branch doesn’t need to be strictly managed.

**user**

Local system user under which to run git commands. By default, commands are run by the user under which the minion is running.

**Note:** This is not to be confused with the username for http(s)/SSH authentication.

New in version 0.17.0.

**password**

Windows only. Required when specifying user. This parameter will be ignored on non-Windows platforms.

New in version 2016.3.4.

**update_head** [True] If set to False, then the remote repository will be fetched (if necessary) to ensure that the commit to which rev points exists in the local checkout, but no changes will be made to the local HEAD.

New in version 2015.8.3.

**force_checkout** [False] When checking out the local branch, the state will fail if there are unwritten changes. Set this argument to True to discard unwritten changes when checking out.

**force_clone** [False] If the target directory exists and is not a git repository, then this state will fail. Set this argument to True to remove the contents of the target directory and clone the repo into it.

**force_fetch** [False] If a fetch needs to be performed, non-fast-forward fetches will cause this state to fail. Set this argument to True to force the fetch even if it is a non-fast-forward update.

New in version 2015.8.0.

**force_reset** [False] If the update is not a fast-forward, this state will fail. Set this argument to True to force a hard-reset to the remote revision in these cases.

**submodules** [False] Update submodules on clone or branch change.

**bare** [False] Set to True if the repository is to be a bare clone of the remote repository.

**mirror** Set to True if the repository is to be a mirror of the remote repository. This implies that bare set to True, and thus is incompatible with rev.

**remote** [origin] Git remote to use. If this state needs to clone the repo, it will clone it using this value as the initial remote name. If the repository already exists, and a remote by this name is not present, one will be added.

**fetch_tags** [True] If True, then when a fetch is performed all tags will be fetched, even those which are not reachable by any branch on the remote.

**depth** Defines depth in history when git a clone is needed in order to ensure latest. E.g. depth: 1 is useful when deploying from a repository with a long history. Use rev to specify branch. This is not compatible with tags or revision IDs.

**identity** Path to a private key to use for ssh URLs. This can be either a single string, or a list of strings. For
example:

```
# Single key
git@github.com:user/repo.git:
git.latest:
  - user: deployer
  - identity: /home/deployer/.ssh/id_rsa

# Two keys
git@github.com:user/repo.git:
git.latest:
  - user: deployer
  - identity:
    - /home/deployer/.ssh/id_rsa
    - /home/deployer/.ssh/id_rsa_alternate
```

If multiple keys are specified, they will be tried one-by-one in order for each git command which needs to authenticate.

**Warning:** Unless Salt is invoked from the minion using `salt-call`, the key(s) must be passphraseless. For greater security with passphraseless private keys, see the `sshd(8)` manpage for information on securing the keypair from the remote side in the `authorized_keys` file.

Changed in version 2015.8.7: Salt will no longer attempt to use passphrase-protected keys unless invoked from the minion using `salt-call`, to prevent blocking waiting for user input.

Changed in version 2016.3.0: Key can now be specified as a SaltStack fileserver URL (e.g. `salt://path/to/identity_file`).

**https_user** HTTP Basic Auth username for HTTPS (only) clones

New in version 2015.5.0.

**https_pass** HTTP Basic Auth password for HTTPS (only) clones

New in version 2015.5.0.

**onlyif** A command to run as a check, run the named command only if the command passed to the `onlyif` option returns true

**unless** A command to run as a check, only run the named command if the command passed to the `unless` option returns false

**refspec_branch** ['*'] A glob expression defining which branches to retrieve when fetching. See `git-fetch(1)` for more information on how refspecs work.

New in version 2017.7.0.

**refspec_tag** ['*'] A glob expression defining which tags to retrieve when fetching. See `git-fetch(1)` for more information on how refspecs work.

New in version 2017.7.0.

**Note:** Clashing ID declarations can be avoided when including different branches from the same git repository in the same SLS file by using the `name` argument. The example below checks out the gh-pages and gh-pages-prod branches from the same repository into separate directories. The example also sets up the `ssh_known_hosts` ssh key required to perform the git checkout.

Also, it has been reported that the SCP-like syntax for

```
gitlab.example.com:
  ssh_known_hosts:
    - present
```
- user: root
- enc: ecdsa

```yaml
# Salt Documentation

salt.states.git.mod_run_check(cmd_kwargs, onlyif, unless)

Execute the onlyif and unless logic. Return a result dict if:
- onlyif failed (onlyif != 0)
- unless succeeded (unless == 0)

Otherwise, returns True

salt.states.git.present(name, force=False, bare=True, template=None, separate_git_dir=None, shared=None, user=None, password=None)

Ensure that a repository exists in the given directory

**Warning:** If the minion has Git 2.5 or later installed, name points to a worktree, and force is set to True, then the worktree will be deleted. This has been corrected in Salt 2015.8.0.

**name**  Path to the directory

Changed in version 2015.8.0: This path must now be absolute

**force** [False] If True, and if name points to an existing directory which does not contain a git repository, then the contents of that directory will be recursively removed and a new repository will be initialized in its place.

**bare** [True] If True, and a repository must be initialized, then the repository will be a bare repository.
**Note:** This differs from the default behavior of `git.init`, make sure to set this value to `False` if a bare repo is not desired.

- **template** If a new repository is initialized, this argument will specify an alternate template directory.
  - New in version 2015.8.0.
- **separate_git_dir** If a new repository is initialized, this argument will specify an alternate $GIT_DIR
  - New in version 2015.8.0.
- **shared** Set sharing permissions on git repo. See `git-init(1)` for more details.
  - New in version 2015.5.0.
- **user** User under which to run git commands. By default, commands are run by the user under which the minion is running.
  - New in version 0.17.0.
- **password**
  - Windows only. Required when specifying `user`. This parameter will be ignored on non-Windows platforms.
  - New in version 2016.3.4.

### 19.19.84 salt.states.github module

Github User State Module

New in version 2016.3.0.. This state is used to ensure presence of users in the Organization.

```python
ensure user test is present in github:
    github.present:
        - name: 'Example TestUser1'
        - email: example@domain.com
        - username: 'gitexample'
```

```python
salt.states.github.absent(name, profile='github', **kwargs)
Ensure a github user is absent
```

```python
ensure user test is absent in github:
    github.absent:
        - name: 'Example TestUser1'
        - email: example@domain.com
        - username: 'gitexample'
```

The following parameters are required:
- **name** Github handle of the user in organization

```python
salt.states.github.present(name, profile='github', **kwargs)
Ensure a user is present
```

```python
ensure user test is present in github:
    github.present:
        - name: 'gitexample'
```

The following parameters are required:
- **name** This is the github handle of the user in the organization
salt.states.github.repo_absent(name, profile='github', **kwargs)
Ensure a repo is absent.

Example:

```
ensure repo test is absent in github:
  github.repo_absent:
    - name: 'test'
```

The following parameters are required:
name This is the name of the repository in the organization.
New in version 2016.11.0.

salt.states.github.repo_present(name, description=None, homepage=None, private=None, has_issues=None, has_wiki=None, has_downloads=None, auto_init=False, gitignore_template=None, license_template=None, teams=None, profile='github', **kwargs)
Ensure a repository is present

name This is the name of the repository.
description The description of the repository.
homepage The URL with more information about the repository.
private The visiblity of the repository. Note that private repositories require a paid GitHub account.
has_issues Whether to enable issues for this repository.
has_wiki Whether to enable the wiki for this repository.
has_downloads Whether to enable downloads for this repository.
auto_init Whether to create an initial commit with an empty README.
gitignore_template The desired language or platform for a .gitignore, e.g `Haskell`.
license_template The desired LICENSE template to apply, e.g `mit` or `mozilla`.
teams The teams for which this repo should belong to, specified as a dict of team name to permission (`pull`, `push` or `admin`).

New in version 2017.7.0.
Example:

```
Ensure repo my-repo is present in github:
  github.repo_present:
    - name: 'my-repo'
    - description: 'My very important repository'
```

New in version 2016.11.0.

salt.states.github.team_absent(name, profile='github', **kwargs)
Ensure a team is absent.

Example:

```
ensure team test is present in github:
  github.team_absent:
    - name: 'test'
```

The following parameters are required:
name This is the name of the team in the organization.
New in version 2016.11.0.

salt.states.github.team_present(name, description=None, repo_names=None, privacy='secret', permission='pull', members=None, enforce_mfa=False, no_mfa_grace_seconds=0, profile='github', **kwargs)
Ensure a team is present

name This is the name of the team in the organization.
description The description of the team.
repo_names The names of repositories to add the team to.
privacy The level of privacy for the team, can be `secret' or `closed'. Defaults to secret.
permission The default permission for new repositories added to the team, can be `pull', `push' or `admin'.
    Defaults to pull.
members The members belonging to the team, specified as a dict of member name to optional configuration.
    Options include `enforce_mfa_from' and `mfa_exempt'.
enforce_mfa Whether to enforce MFA requirements on members of the team. If True then all members
    without mfa_exempt: True configured will be removed from the team. Note that no_mfa_grace_seconds
    may be set to allow members a grace period.
no_mfa_grace_seconds The number of seconds of grace time that a member will have to enable MFA before
    being removed from the team. The grace period will begin from enforce_mfa_from on the member
    configuration, which defaults to 1970/01/01.

Example:

| Ensure team test is present in github: |
|    github.team_present: |
|        - name: 'test' |
|        - members: |
|            user1: {} |
|            user2: {} |

| Ensure team test_mfa is present in github: |
|    github.team_present: |
|        - name: 'test_mfa' |
|        - members: |
|            user1: |
|                enforce_mfa_from: 2016/06/15 |
|            - enforce_mfa: True |

New in version 2016.11.0.

19.19.85 salt.states.glance

Managing Images in OpenStack Glance

salt.states.glance.image_present(name, visibility='public', protected=None, checksum=None, location=None, disk_format='raw', wait_for=None, timeout=30)

Checks if given image is present with properties set as specified.

An image should go through the stages `queued', `saving' before becoming `active'. The attribute `checksum'
can only be checked once the image is active. If you don't specify `wait_for' but `checksum' the function will
wait for the image to become active before comparing checksums. If you don't specify checksum either the
function will return when the image reached `saving'. The default timeout for both is 30 seconds.

Supported properties:
• visibility (`public' or `private')
• protected (bool)
• checksum (string, md5sum)
• location (URL, to copy from)
• disk_format (`raw' (default), `vhd', `vhdx', `vmdk', `vdi', `iso', `qcow2', `aki', `ari' or `ami')

19.19.86 salt.states.glusterfs

Manage GlusterFS pool.
salt.states.glusterfs.add_volume_bricks(name, bricks)
Add brick(s) to an existing volume
name  Volume name
bricks List of bricks to add to the volume

```
myvolume:
  glusterfs.add_volume_bricks:
    - bricks:
      - host1:/srv/gluster/drive1
      - host2:/srv/gluster/drive2

Replicated Volume:
  glusterfs.add_volume_bricks:
    - name: volume2
    - bricks:
      - host1:/srv/gluster/drive2
      - host2:/srv/gluster/drive3
```

salt.states.glusterfs.peered(name)
Check if node is peered.
nname  The remote host with which to peer.

```
peer-cluster:
  glusterfs.peered:
    - name: two

peer-clusters:
  glusterfs.peered:
    - names:
      - one
      - two
      - three
      - four
```

salt.states.glusterfs.started(name)
Check if volume has been started
name  name of the volume

```
mycluster:
  glusterfs.started: []
```

salt.states.glusterfs.volume_present(name, bricks, stripe=False, replica=False, device_vg=False, transport='tcp', start=False, force=False)
Ensure that the volume exists
name  name of the volume
bricks list of brick paths
start ensure that the volume is also started

```
myvolume:
  glusterfs.volume_present:
    - bricks:
      - host1:/srv/gluster/drive1
      - host2:/srv/gluster/drive2

Replicated Volume:
  glusterfs.volume_present:
    - name: volume2
    - bricks:
```
- host1:/srv/gluster/drive2
- host2:/srv/gluster/drive3
- replica: 2
- start: True

19.19.87 salt.states.gnomedesktop

Configuration of the GNOME desktop

Control the GNOME settings

```yaml
localdesktop_wm_prefs:
    gnomedesktop.wm_preferences:
        - user: username
        - audible_bell: false
        - action_double_click_titlebar: 'toggle-maximize'
        - visual_bell: true
        - num_workspaces: 6

localdesktop_lockdown:
    gnomedesktop.desktop_lockdown:
        - user: username
        - disable_user_switching: true

localdesktop_interface:
    gnomedesktop.desktop_interface:
        - user: username
        - clock_show_date: true
        - clock_format: 12h
```
salt.states.gnomedesktop.

desktop_interface

(name, user=None, automatic_mnemonics=None, buttons_have_icons=None, can_change_accels=None, clock_format=None, clock_show_date=None, clock_show_seconds=None, cursor_blink=None, cursor_blink_time=None, cursor_blink_timeout=None, cursor_size=None, cursor_theme=None, document_font_name=None, enable_animations=None, font_name=None, gtk_color_palette=None, gtk_color_scheme=None, gtk_im_module=None, gtk_im_preedit_style=None, gtk_im_status_style=None, gtk_key_theme=None, gtk_theme=None, gtk_timeout_initial=None, gtk_timeout_repeat=None, icon_theme=None, menubar_accel=None, menubar_detachable=None, menus_have_icons=None, menus_have_tearoff=None, monospace_font_name=None, show_input_method_menu=None, show_unicode_menu=None, text_scaling_factor=None, toolbar_detachable=None, toolbar_icons_size=None, toolbar_style=None, toolkit_accessibility=None, **kwargs)

desktop_interface: sets values in the org.gnome.desktop.interface schema

salt.states.gnomedesktop.

desktop_lockdown

(name, user=None, disable_application_handlers=None, disable_command_line=None, disable_lock_screen=None, disable_log_out=None, disable_print_setup=None, disable_printing=None, disable_save_to_disk=None, disable_user_switching=None, user_administration_disabled=None, **kwargs)

desktop_lockdown: sets values in the org.gnome.desktop.lockdown schema
salt.states.gnomedesktop.wm_preferences(name, user=None, action_double_click_titlebar=None, action_middle_click_titlebar=None, action_right_click_titlebar=None, application_based=None, audibleBell=None, auto_raise=None, auto_raise_delay=None, button_layout=None, disable_workarounds=None, focus_mode=None, focus_new_windows=None, mouse_button_modifier=None, num_workspaces=None, raise_on_click=None, resize_with_right_button=None, theme=None, titlebar_font=None, titlebar_uses_system_font=None, visual_bell=None, visual_bell_type=None, workspace_names=None, **kwargs)

wm_preferences: sets values in the org.gnome.desktop.wm.preferences schema

19.19.88 salt.states.gpg module

Management of the GPG keychains

New in version 2016.3.0.

salt.states.gpg.absent(name, keys=None, user=None, gnupghome=None, **kwargs)
    Ensure GPG public key is absent in keychain
    name The unique name or keyid for the GPG public key.
    keys The keyid or keyids to add to the GPG keychain.
    user Remove GPG keys from the specified user's keychain
    gnupghome Override GNUPG Home directory

salt.states.gpg.present(name, keys=None, user=None, keyserver=None, gnupghome=None, trust=None, **kwargs)
    Ensure GPG public key is present in keychain
    name The unique name or keyid for the GPG public key.
    keys The keyid or keyids to add to the GPG keychain.
    user Add GPG keys to the specified user's keychain
    keyserver The keyserver to retrieve the keys from.
    gnupghome Override GNUPG Home directory
    trust Trust level for the key in the keychain, ignored by default. Valid trust levels: expired, unknown, not_trusted, marginally, fully, ultimately

19.19.89 salt.states.grafana

Manage Grafana Dashboards

This module uses `elasticsearch`, which can be installed via package, or pip.

You can specify elasticsearch hosts directly to the module, or you can use an elasticsearch profile via pillars:

```yaml
mygrafanaprofile:
    hosts:
        - es1.example.com:9200
        - es2.example.com:9200
    index: grafana-dash
```
# Basic usage (uses default pillar profile key 'grafana')
Ensure myservice dashboard is managed:

```yaml
grafana.dashboard_present:
  - name: myservice
    dashboard_from_pillar: default
    rows_from_pillar:
      - systemhealth
      - requests
```

# Passing hosts in
Ensure myservice dashboard is managed:

```yaml
grafana.dashboard_present:
  - name: myservice
    dashboard_from_pillar: default
    rows:
      - collapse: false
        editable: true
        height: 150px
        title: System Health
        panels:
          - aliasColors: {}
            id: 200000
            annotate:
              enable: false
              bars: false
              datasource: null
            editable: true
            error: false
            fill: 7
            grid:
              leftMax: 100
              leftMin: null
              rightMax: null
              rightMin: null
              threshold1: 60
              threshold1Color: rgb(216, 27, 27)
              threshold2: null
              threshold2Color: rgba(234, 112, 112, 0.22)
            leftYAxisLabel: ''
            legend:
              avg: false
              current: false
              max: false
              min: false
              show: false
              total: false
              values: false
            lines: true
            lineWidth: 1
            nullPointMode: connected
            percentage: false
            pointRadius: 5
            points: false
            renderer: flot
            resolution: 100
            scale: 1

      - es2.example.com:9200
    index: grafana-dash

# Using a profile from pillars
Ensure myservice dashboard is managed:
grafana.dashboard_present:
  - name: myservice
  - dashboard:
    annotations:
      enable: true
      list: []
    editable: true
    hideAllLegends: false
    hideControls: false
    nav:
      - collapse: false
        enable: true
        notice: false
        now: true
        refresh_intervals:
          - 10s
          - 30s
          - 1m
          - 5m
          - 15m
          - 30m
          - 1h
          - 2h
          - 1d
    status: Stable
    time_options:
      - 5m
      - 15m
      - 1h
      - 2h
      - 3h
The behavior of this module is to create dashboards if they do not exist, to add rows if they do not exist in existing dashboards, and to update rows if they exist in dashboards. The module will not manage rows that are not defined, allowing users to manage their own custom rows.

```
salt.states.grafana.dashboard_absent(name, hosts=None, profile='grafana')
```

Ensure the named grafana dashboard is deleted.

- **name** Name of the grafana dashboard.
- **profile** A pillar key or dict that contains a list of hosts and an elasticsearch index to use.

```
salt.states.grafana.dashboard_present(name, dashboard=None, dashboard_from_pillar=None, rows=None, rows_from_pillar=None, profile='grafana')
```

Ensure the grafana dashboard exists and is managed.

- **name** Name of the grafana dashboard.
- **dashboard** A dict that defines a dashboard that should be managed.
- **dashboard_from_pillar** A pillar key that contains a grafana dashboard dict. Mutually exclusive with dashboard.
- **rows** A list of grafana rows.
- **rows_from_pillar** A list of pillar keys that contain lists of grafana dashboard rows. Rows defined in the pillars will be appended to the rows defined in the state.
- **profile** A pillar key or dict that contains a list of hosts and an elasticsearch index to use.

### 19.19.90 salt.states.grafana4_dashboard module

Manage Grafana v4.0 Dashboards

New in version 2017.7.0.
configuration This state requires a configuration profile to be configured in the minion config, minion pillar, or master config. The module will use the `grafana` key by default, if defined.

Example configuration using basic authentication:

```
grafana:
   grafana_url: http://grafana.localhost
   grafana_user: admin
   grafana_password: admin
   grafana_timeout: 3
```

Example configuration using token based authentication:

```
grafana:
   grafana_url: http://grafana.localhost
   grafana_token: token
   grafana_timeout: 3
```

The behavior of this module is to create dashboards if they do not exist, to add rows if they do not exist in existing dashboards, and to update rows if they exist in dashboards. The module will not manage rows that are not defined, allowing users to manage their own custom rows.

```
Ensure minimum dashboard is managed:
grafana4_dashboard.present:
   - name: insightful-dashboard
   - base_dashboards_from_pillar:
     - default_dashboard
   - base_rows_from_pillar:
     - default_row
   - base_panels_from_pillar:
     - default_panel
   - dashboard:
     - rows:
       - title: Usage
       - panels:
         - targets:
           - target: alias(constantLine(50), 'max')
       title: Imaginary
       type: graph
```

```
salt.states.grafana4_dashboard.absent(name, orgname=None, profile='grafana')

Ensure the named grafana dashboard is absent.
name Name of the grafana dashboard.
orgname Name of the organization in which the dashboard should be present.
profile Configuration profile used to connect to the Grafana instance. Default is `grafana`.
```

```
salt.states.grafana4_dashboard.present(name, base_dashboards_from_pillar=None, base_panels_from_pillar=None, base_rows_from_pillar=None, dashboard=None, orgname=None, profile='grafana')

Ensure the grafana dashboard exists and is managed.
name Name of the grafana dashboard.
base_dashboards_from_pillar A pillar key that contains a list of dashboards to inherit from
base_panels_from_pillar A pillar key that contains a list of panels to inherit from
base_rows_from_pillar A pillar key that contains a list of rows to inherit from
dashboard A dict that defines a dashboard that should be managed.
orgname Name of the organization in which the dashboard should be present.
profile Configuration profile used to connect to the Grafana instance. Default is `grafana`.
```
19.19.91 salt.states.grafana4_datasource module

Manage Grafana v4.0 data sources

New in version 2017.7.0.

**configuration**  This state requires a configuration profile to be configured in the minion config, minion pillar, or master config. The module will use the `grafana` key by default, if defined.

Example configuration using basic authentication:

```
grafana:
grafana_url: http://grafana.localhost
grafana_user: admin
grafana_password: admin
grafana_timeout: 3
```

Example configuration using token based authentication:

```
grafana:
grafana_url: http://grafana.localhost
grafana_token: token
grafana_timeout: 3
```

The behavior of this module is to create data sources if the do not exists, and to update data sources if the already exists.

```
Ensure influxdb data source is present:
grafana4_datasource.present:
  - name: influxdb
  - type: influxdb
  - url: http://localhost:8086
  - access: proxy
  - basic_auth: true
  - basic_auth_user: myuser
  - basic_auth_password: mypass
  - is_default: true
```

salt.states.grafana4_datasource.absent(name, orgname=None, profile='grafana')

Ensure that a data source is present.

name Name of the data source to remove.
orgname Name of the organization from which the data source should be absent.
profile Configuration profile used to connect to the Grafana instance. Default is ‘grafana’.

salt.states.grafana4_datasource.present(name, type, url, access=None, user=None, password=None, database=None, basic_auth=None, basic_auth_user=None, basic_auth_password=None, tls_auth=None, json_data=None, is_default=None, with_credentials=None, type_logo_url=None, orgname=None, profile='grafana')

Ensure that a data source is present.

name Name of the data source.
type Type of the datasource (‘graphite’, ‘influxdb’ etc.).
access Use proxy or direct. Default: proxy
url The URL to the data source API.
user Optional - user to authenticate with the data source.
password Optional - password to authenticate with the data source.
database Optional - database to use with the data source.
basic_auth  Optional - set to True to use HTTP basic auth to authenticate with the data source.
basic_auth_user  Optional - HTTP basic auth username.
basic_auth_password  Optional - HTTP basic auth password.
json_data  Optional - additional json data to post (eg. ```timeInterval```).
is_default  Optional - set data source as default.
with_credentials  Optional - Whether credentials such as cookies or auth headers should be sent with cross-site requests.
type_logo_url  Optional - Logo to use for this datasource.
orgname  Name of the organization in which the data source should be present.
profile  Configuration profile used to connect to the Grafana instance. Default is `grafana`.

### 19.19.92 salt.states.grafana4_org module

Manage Grafana v4.0 orgs

New in version 2017.7.0.

**configuration** This state requires a configuration profile to be configured in the minion config, minion pillar, or master config. The module will use the `grafana` key by default, if defined.

Example configuration using basic authentication:

```yaml
grafana:
    grafana_url: http://grafana.localhost
    grafana_user: admin
    grafana_password: admin
    grafana_timeout: 3
```

Example configuration using token based authentication:

```yaml
grafana:
    grafana_url: http://grafana.localhost
    grafana_token: token
    grafana_timeout: 3
```

Ensure foobar org is present:

```yaml
grafana4_org.present:
    - name: foobar
      - theme: ""
      - home_dashboard_id: 0
      - timezone: "utc"
      - address1: ""
      - address2: ""
      - city: ""
      - zip_code: ""
      - state: ""
      - country: ""
```

salt.states.grafana4_org.absent(name, profile='grafana')

Ensure that a org is present.

**name** Name of the org to remove.

**profile** Configuration profile used to connect to the Grafana instance. Default is `grafana`.

salt.states.grafana4_org.present(name, users=None, theme=None, home_dashboard_id=None, timezone=None, address1=None, address2=None, city=None, zip_code=None, address_state=None, country=None, profile='grafana')
Ensure that an organization is present.

**name** Name of the org.

**users** Optional - Dict of user/role associated with the org. Example:

```python
users:
    foo: Viewer
    bar: Editor
```

**theme** Optional - Selected theme for the org.

**home_dashboard_id** Optional - Home dashboard for the org.

**timezone** Optional - Timezone for the org (one of: `browser`, `utc`, or `''`).

**address1** Optional - address1 of the org.

**address2** Optional - address2 of the org.

**city** Optional - city of the org.

**zip_code** Optional - zip_code of the org.

**country** Optional - country of the org.

**profile** Configuration profile used to connect to the Grafana instance. Default is `grafana`.

---

### 19.19.93 salt.states.grafana4_user module

Manage Grafana v4.0 users

New in version 2017.7.0.

**configuration** This state requires a configuration profile to be configured in the minion config, minion pillar, or master config. The module will use the `grafana` key by default, if defined.

Example configuration using basic authentication:

```yaml
grafana:
    grafana_url: http://grafana.localhost
    grafana_user: admin
    grafana_password: admin
    grafana_timeout: 3
```

Example configuration using token based authentication:

```yaml
grafana:
    grafana_url: http://grafana.localhost
    grafana_token: token
    grafana_timeout: 3
```

Ensure foobar user is present:

```yaml
grafana4_user.present:
    - name: foobar
    - password: mypass
    - email: "foobar@localhost"
    - fullname: Foo Bar
    - is_admin: true
```

salt.states.grafana4_user.absent(name, profile='grafana')

Ensure that a user is present.

**name** Name of the user to remove.

**profile** Configuration profile used to connect to the Grafana instance. Default is `grafana`. 

---

19.19. state modules 2869
salt.states.grafana4_user.present(name, password, email, is_admin=False, fullname=None, theme=None, profile='grafana')

Ensure that a user is present.
name Name of the user.
password Password of the user.
email Email of the user.
is_admin Optional - Set user as admin user. Default: False
fullname Optional - Full name of the user.
theme Optional - Selected theme of the user.
profile Configuration profile used to connect to the Grafana instance. Default is `grafana`.

19.19.94 salt.states.grafana_dashboard module

Manage Grafana v2.0 Dashboards
New in version 2016.3.0.

```yaml
grafana:
  grafana_timeout: 3
  grafana_token: qwertyuiop
  grafana_url: 'https://url.com'
```

Ensure minimum dashboard is managed:
grafana_dashboard.present:
  - name: insightful-dashboard
  - base_dashboards_from_pillar:
  - default_dashboard
  - base_rows_from_pillar:
  - default_row
  - base_panels_from_pillar:
  - default_panel
  - dashboard:
    rows:
      - title: Usage
        panels:
          - targets:
            - target: alias(constantLine(50), 'max')
            title: Imaginary
            type: graph
```

The behavior of this module is to create dashboards if they do not exist, to add rows if they do not exist in existing dashboards, and to update rows if they exist in dashboards. The module will not manage rows that are not defined, allowing users to manage their own custom rows.

salt.states.grafana_dashboard.absent(name, profile='grafana')
Ensure the named grafana dashboard is absent.
name Name of the grafana dashboard.
profile A pillar key or dict that contains grafana information

salt.states.grafana_dashboard.present(name, base_dashboards_from_pillar=None, base_panels_from_pillar=None, base_rows_from_pillar=None, dashboard=None, profile='grafana')

Ensure the grafana dashboard exists and is managed.
name Name of the grafana dashboard.
base_dashboards_from_pillar A pillar key that contains a list of dashboards to inherit from
base_panels_from_pillar A pillar key that contains a list of panels to inherit from

**base_rows_from_pillar** A pillar key that contains a list of rows to inherit from

**dashboard** A dict that defines a dashboard that should be managed.

**profile** A pillar key or dict that contains grafana information

### 19.19.95 salt.states.grafana_datasource module

Manage Grafana v2.0 data sources

New in version 2016.3.0.

```yaml
grafana:
    grafana_timeout: 3
    grafana_token: qwertyuiop
    grafana_url: 'https://url.com'
```

Ensure influxdb data source is present:

```yaml
grafana_datasource.present:
    - name: influxdb
    - type: influxdb
    - url: http://localhost:8086
    - access: proxy
    - basic_auth: true
    - basic_auth_user: myuser
    - basic_auth_password: mypass
    - is_default: true
```

salt.states.grafana_datasource.absent(name, profile='grafana')

Ensure that a data source is present.

name Name of the data source to remove.

salt.states.grafana_datasource.present(name, type, url, access='proxy', user='', password='', database='', basic_auth=False, basic_auth_user='', basic_auth_password='', is_default=False, json_data=None, profile='grafana')

Ensure that a data source is present.

name Name of the data source.

type Which type of data source it is (u'graphite', u'influxdb' etc.).

url The URL to the data source API.

user Optional - user to authenticate with the data source

password Optional - password to authenticate with the data source

basic_auth Optional - set to True to use HTTP basic auth to authenticate with the data source.

basic_auth_user Optional - HTTP basic auth username.

basic_auth_password Optional - HTTP basic auth password.

is_default Default: False

### 19.19.96 salt.states.grains

Manage grains on the minion

This state allows for grains to be set.

Grains set or altered with this module are stored in the `grains` file on the minions. By default, this file is located at: `/etc/salt/grains`

---

19.19. state modules 2871
Note: This does NOT override any grains set in the minion config file.

```
salt.states.grains.absent(name, destructive=False, delimiter=':', force=False)
```

New in version 2014.7.0.

Delete a grain from the grains config file

- **name** The grain name
- **destructive** If destructive is True, delete the entire grain. If destructive is False, set the grain's value to None. Defaults to False.
- **force** If force is True, the existing grain will be overwritten regardless of its existing or provided value type. Defaults to False

New in version v2015.8.2.

```
salt.states.grains.append(name, value, convert=False, delimiter=':')
```

New in version 2014.7.0.

Append a value to a list in the grains config file. The grain that is being appended to (name) must exist before the new value can be added.

- **name** The grain name
- **value** The value to append
- **convert** If convert is True, convert non-list contents into a list. If convert is False and the grain contains non-list contents, an error is given. Defaults to False.
- **delimiter** A delimiter different from the default can be provided.

New in version v2015.8.2.

```
salt.states.grains.exists(name, delimiter=':')
```

Ensure that a grain is set

- **name** The grain name
- **delimiter** A delimiter different from the default can be provided.

Check whether a grain exists. Does not attempt to check or set the value.

```
salt.states.grains.list_absent(name, value, delimiter=':')
```

Delete a value from a grain formed as a list.

New in version 2014.1.0.

- **name** The grain name.
- **value** The value to delete from the grain list.
- **delimiter** A delimiter different from the default : can be provided.

New in version v2015.8.2.

The grain should be list type
salt.states.grains.list_absent:
  - value: db

For multiple grains, the syntax looks like:

salt.states.grains.list_present(name, value, delimiter=': ')

New in version 2014.1.0.

Ensure the value is present in the list-type grain. Note: If the grain that is provided in name is not present on the system, this new grain will be created with the corresponding provided value.

name The grain name.
value The value is present in the list type grain.
delimiter A delimiter different from the default : can be provided.

The grain should be list type

salt.states.grains.list_present:
  - value: web

For multiple grains, the syntax looks like:

salt.states.grains.present(name, value, delimiter=': ', force=False)

Ensure that a grain is set

Changed in version v2015.8.2.

name The grain name
value The value to set on the grain
force If force is True, the existing grain will be overwritten regardless of its existing or provided value type.
  Defaults to False

delimiter A delimiter different from the default can be provided.

It is now capable to set a grain to a complex value (ie. lists and dicts) and supports nested grains as well.

If the grain does not yet exist, a new grain is set to the given value. For a nested grain, the necessary keys are created if they don't exist. If a given key is an existing value, it will be converted, but an existing value different from the given key will fail the state.

If the grain with the given name exists, its value is updated to the new value unless its existing or provided value is complex (list or dict). Use force: True to overwrite.
19.19.97 salt.states.group

Management of user groups

The group module is used to create and manage group settings, groups can be either present or absent. User/Group names can be passed to the adduser, deluser, and members parameters. adduser and deluser can be used together but not with members.

In Windows, if no domain is specified in the user or group name (ie: DOMAIN\Username) the module will assume a local user or group.

salt.states.group.absent(name)

Ensure that the named group is absent

Parameters name (str) -- The name of the group to remove

Example:

# Removes the local group `db_admin`
```
db_admin:
  group.absent
```
salt.states.group.present(name, gid=None, system=False, addusers=None, delusers=None, members=None)

Ensure that a group is present

Parameters

- **name (str)** -- The name of the group to manage
- **gid (str)** -- The group id to assign to the named group; if left empty, then the next available group id will be assigned. Ignored on Windows
- **system (bool)** -- Whether or not the named group is a system group. This is essentially the `-r` option of `groupadd`. Ignored on Windows
- **addusers (list)** -- List of additional users to be added as a group members. Cannot conflict with names in delusers. Cannot be used in conjunction with members.
- **delusers (list)** -- Ensure these user are removed from the group membership. Cannot conflict with names in addusers. Cannot be used in conjunction with members.
- **members (list)** -- Replace existing group members with a list of new members. Cannot be used in conjunction with addusers or delusers.

Example:

```python
# Adds DOMAIN\db_admins and Administrators to the local db_admin group
# Removes Users
db_admin:  
group.present:  
  - addusers:  
    - DOMAIN\db_admins  
    - Administrators  
    - delusers:  
      - Users

# Ensures only DOMAIN\domain_admins and the local Administrator are members of the local Administrators group. All other users are removed
Administrators:  
group.present:  
  - members:  
    - DOMAIN\domain_admins  
    - Administrator
```

19.19.98 salt.states.heat module

Management of Heat

New in version 2017.7.0.

```
heat.deployed:
  - name:  
    - template: #Required  
    - environment:  
    - params: {}  
    - poll: 5
```

19.19. state modules
- rollback: False
- timeout: 60

heat.absent:
- name:
- poll: 5

mysql:

  heat.deployed:
  - template: salt://templates/mysql.heat.yaml
  - params: image: Debian 7
  - rollback: True

New in version 2017.7.5,2018.3.1: The spelling mistake in parameter environment was corrected to environment. The misspelled version is still supported for backward compatibility, but will be removed in Salt Neon.

salt.states.heat.absent(name, poll=5, timeout=60, profile=None)
Ensure that the named stack is absent

name The name of the stack to remove
poll Poll(in sec.) and report events until stack complete
timeout Stack creation timeout in minutes
profile Profile to use

salt.states.heat.deployed(name, template=None, environment=None, params=None, poll=5, rollback=False, timeout=60, update=False, profile=None, **connection_args)
Deploy stack with the specified properties

name The name of the stack
template File of template
environment File of environment
params Parameter dict used to create the stack
poll Poll (in sec.) and report events until stack complete
rollback Enable rollback on create failure
timeout Stack creation timeout in minutes
profile Profile to use

New in version 2017.7.5,2018.3.1: The spelling mistake in parameter environment was corrected to environment. The misspelled version is still supported for backward compatibility, but will be removed in Salt Neon.

19.19.99 salt.states.hg

Interaction with Mercurial repositories

Before using hg over ssh, make sure the remote host fingerprint already exists in ~/.ssh/known_hosts, and the remote host has this host's public key.

https://bitbucket.org/example_user/example_repo:

  hg.latest:
  - rev: tip
  - target: /tmp/example_repo

salt.states.hg.latest(name, rev=None, target=None, clean=False, user=None, identity=None, force=False, opts=False, update_head=True)
Make sure the repository is cloned to the given directory and is up to date
name Address of the remote repository as passed to `''hg clone``
**rev** The remote branch, tag, or revision hash to clone/pull
**target** Target destination directory path on minion to clone into
**clean** Force a clean update with -C (Default: False)
**user** Name of the user performing repository management operations

New in version 0.17.0.

**identity** Private SSH key on the minion server for authentication (ssh://)

New in version 2015.5.0.

**force** Force hg to clone into pre-existing directories (deletes contents)
**opts** Include additional arguments and options to the hg command line
**update_head** Should we update the head if new changes are found? Defaults to True

New in version 2017.7.0.

### 19.19.100 `salt.states.hipchat`

**Send a message to Hipchat**

This state is useful for sending messages to Hipchat during state runs.

The property `api_url` is optional. By default will use the public HipChat API at [https://api.hipchat.com](https://api.hipchat.com)

New in version 2015.5.0.

```python
hipchat-message:
    hipchat.send_message:
        - room_id: 123456
        - from_name: SuperAdmin
        - message: 'This state was executed successfully.'
        - api_url: https://hipchat.myteam.com
        - api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
        - api_version: v1
```

The `api_key` can be specified in the master or minion configuration like below:

```python
class:
    api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
    api_version: v1
```

salt.states.hipchat.send_message(name, room_id, from_name, message, api_url=None, api_key=None, api_version=None, message_color='yellow', notify=False)

Send a message to a Hipchat room.

```python
hipchat-message:
    hipchat.send_message:
        - room_id: 123456
        - from_name: SuperAdmin
        - message: 'This state was executed successfully.'
        - api_url: https://hipchat.myteam.com
        - api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
        - api_version: v1
        - message_color: green
        - notify: True
```

The following parameters are required:
**name** The unique name for this event.
room_id The room to send the message to. Can either be the ID or the name.
from_name The name of that is to be shown in the `from` field. If not specified, defaults to.
message The message that is to be sent to the Hipchat room.
The following parameters are optional:
api_url The API URI to be used. If not specified here or in the configuration options of master or minion, will
use the public HipChat API: https://api.hipchat.com
api_key The api key for Hipchat to use for authentication, if not specified in the configuration options of
master or minion.
api_version The api version for Hipchat to use, if not specified in the configuration options of master or
minion.
message_color The color the Hipchat message should be displayed in. One of the following, default: yellow
``yellow'', ``red'', ``green'', ``purple'', ``gray'', or ``random''.
notify Should a notification in the room be raised.

19.19.101 salt.states.host

Management of addresses and names in hosts file

The /etc/hosts file can be managed to contain definitions for specific hosts:

```
salt-master:
  host.present:
    - ip: 192.168.0.42
```

Or using the `names` directive, you can put several names for the same IP. (Do not try one name with space-separated
values).

```
server1:
  host.present:
    - ip: 192.168.0.42
    - names:
      - server1
      - florida
```

**Note:** Changing the names in `host.present` does not cause an update to remove the old entry.

```
server1:
  host.present:
    - ip:
      - 192.168.0.42
      - 192.168.0.43
      - 192.168.0.44
    - names:
      - server1
```

You can replace all existing names for a particular IP address:

```
127.0.1.1:
  host.only:
    - hostnames:
      - foo.example.com
      - foo
```
Or delete all existing names for an address:

```yaml
203.0.113.25:
    host.only:
        - hostnames: []
```

```python
salt.states.host.absent(name, ip)
Ensure that the named host is absent
name The host to remove
ip The ip addr(s) of the host to remove
```

```python
salt.states.host.only(name, hostnames)
Ensure that only the given hostnames are associated with the given IP address.
New in version 2016.3.0.
name The IP address to associate with the given hostnames.
hostnames Either a single hostname or a list of hostnames to associate with the given IP address in the given order. Any other hostname associated with the IP address is removed. If no hostnames are specified, all hostnames associated with the given IP address are removed.
```

```python
salt.states.host.present(name, ip)
Ensures that the named host is present with the given ip
name The host to assign an ip to
ip The ip addr(s) to apply to the host
```

### 19.19.102 salt.states.htpasswd

Support for htpasswd module. Requires the apache2-utils package for Debian-based distros.

New in version 2014.7.0.

```python
username:
    webutil.user_exists:
        - password: secr3t
        - htpasswd_file: /etc/nginx/htpasswd
        - options: d
        - force: true
```

```python
salt.states.htpasswd.user_absent(name, htpasswd_file=None, runas=None)
Make sure the user is not in the specified htpasswd file
name User name
htpasswd_file Path to the htpasswd file
runas The system user to run htpasswd command with
```

```python
salt.states.htpasswd.user_exists(name, password=None, htpasswd_file=None, options=",", force=False, runas=None, update=False)
Make sure the user is inside the specified htpasswd file
name User name
password User password
htpasswd_file Path to the htpasswd file
options See salt.modules.htpasswd.useradd
force Touch the file even if user already created
runas The system user to run htpasswd command with
update Update an existing user's password if it's different from what's in the htpasswd file (unlike force, which updates regardless)
```

19.19. state modules
19.19.103  salt.states.http

HTTP monitoring states

Perform an HTTP query and statefully return the result

New in version 2015.5.0.

```
salt.states.http.query(name, match=None, match_type='string', status=None, wait_for=None, **kwargs)
```

Perform an HTTP query and statefully return the result

New in version 2015.5.0.

- **name**: The name of the query.
- **match**: Specifies a pattern to look for in the return text. By default, this will perform a string comparison of looking for the value of match in the return text.
- **match_type**: Specifies the type of pattern matching to use. Default is `string`, but can also be set to `pcre` to use regular expression matching if a more complex pattern matching is required.

**Note**: Despite the name of `match_type` for this argument, this setting actually uses Python’s `re.search()` function rather than Python’s `re.match()` function.

- **status**: The status code for a URL for which to be checked. Can be used instead of or in addition to the `match` setting.

If both `match` and `status` options are set, both settings will be checked. However, note that if only one option is `True` and the other is `False`, then `False` will be returned. If this case is reached, the comments in the return data will contain troubleshooting information.

For more information about the `http.query` state, refer to the [HTTP Tutorial](http://docs.saltstack.com/en/latest/topics/doc/tutorials/http.html).

```
query_example:
    http.query:
        - name: 'http://example.com/
        - status: 200
```

```
salt.states.http.wait_for_successful_query(name, wait_for=300, **kwargs)
```

Like query but, repeat and wait until match/match_type or status is fulfilled. State returns result from last query state in case of success or if no successful query was made within `wait_for` timeout.

- **name**: The name of the query.
- **wait_for**: Total time to wait for requests that succeed.

**Note**: All other arguments are passed to the `http.query` state.

19.19.104  salt.states.icinga2 module

Icinga2 state

New in version 2017.7.0.

- **depends**: Icinga2 Python module

- **configuration**: See `salt.modules.icinga2` for setup instructions.
The icinga2 module is used to execute commands. Its output may be stored in a file or in a grain.

```
command_id:
  icinga2.generate_ticket
  - name: domain.tld
  - output: "/tmp/query_id.txt"
```

salt.states.icinga2.generate_cert(name)
Generate an icinga2 certificate and key on the client.

  name  The domain name for which this certificate and key will be generated

salt.states.icinga2.generate_ticket(name, output=None, grain=None, key=None, overwrite=True)
Generate an icinga2 ticket on the master.

  name  The domain name for which this ticket will be generated
  output  grain: output in a grain other: the file to store results None: output to the result comment (default)
  grain: grain to store the output (need output=grain)
  key:  the specified grain will be treated as a dictionary, the result of this state will be stored under the specified key.
  overwrite:  The file or grain will be overwritten if it already exists (default)

crate an event in IFTTT

This state is useful for trigging events in IFTTT.

New in version 2015.8.0.

```
ifttt-event:
  ifttt.trigger_event:
    - event: TestEvent
    - value1: 'This state was executed successfully.'
    - value2: 'Another value we can send.'
    - value3: 'A third value we can send.'
```

The api key can be specified in the master or minion configuration like below: .. code-block:: yaml

    ifttt: secret_key: bzMRb-KKIAaNOwKEEw792J7Eb-B3z7muhdhYblJn4V6

salt.states.ifttt.trigger_event(name, event, value1=None, value2=None, value3=None)

Trigger an event in IFTTT

ifttt-event:
  ifttt.trigger_event:
    - event: TestEvent
    - value1: 'A value that we want to send.'
    - value2: 'A second value that we want to send.'
    - value3: 'A third value that we want to send.'

The following parameters are required:
name  The unique name for this event.
event  The name of the event to trigger in IFTTT.
The following parameters are optional:
value1 One of the values that we can send to IFTTT.
value2 One of the values that we can send to IFTTT.
value3 One of the values that we can send to IFTTT.

19.19.106 salt.states.incron

Management of incron, the inotify cron

The incron state module allows for user incrontabs to be cleanly managed.

Incron declarations require a number of parameters. The parameters needed to be declared: path, mask, and cmd. The user whose incrontab is to be edited also needs to be defined.

When making changes to an existing incron job, the path declaration is the unique factor, so if an existing cron that looks like this:

Watch for modifications in /home/user:
  incron.present:
    - user: root
    - path: /home/user
    - mask:
      - IN_MODIFY
      - cmd: 'echo "$$ $@"'

Is changed to this:

Watch for modifications and access in /home/user:
  incron.present:
    - user: root
    - path: /home/user
    - mask:
      - IN_MODIFY
      - IN_ACCESS
      - cmd: 'echo "$$ $@"'

Then the existing cron will be updated, but if the cron command is changed, then a new cron job will be added to the user's crontab.

New in version 0.17.0.

salt.states.incron.absent(name, path, mask, cmd, user='root')

Verifies that the specified incron job is absent for the specified user; only the name is matched when removing a incron job.
name  Unique comment describing the entry
path  The path that should be watched
user  The name of the user who's crontab needs to be modified, defaults to the root user
mask  The mask of events that should be monitored for
cmd   The cmd that should be executed

salt.states.incron.present(name, path, mask, cmd, user='root')
Verifies that the specified incron job is present for the specified user. For more advanced information about
what exactly can be set in the cron timing parameters, check your incron system's documentation. Most
Unix-like systems' incron documentation can be found via the incrontab man page: man 5 incrontab.
name  Unique comment describing the entry
path  The path that should be watched
user  The name of the user who's crontab needs to be modified, defaults to the root user
mask  The mask of events that should be monitored for
cmd   The cmd that should be executed

19.19.107  salt.states.influxdb08_database module

Management of Influxdb 0.8 databases

(compatible with InfluxDB version 0.5-0.8)
New in version 2014.7.0.
salt.states.influxdb08_database.absent(name, user=None, password=None, host=None, port=None)
Ensure that the named database is absent
name  The name of the database to remove
user  The user to connect as (must be able to remove the database)
password  The password of the user
host  The host to connect to
port  The port to connect to

customstates.influxdb08_database.present(name, user=None, password=None, host=None, port=None)
Ensure that the named database is present
name  The name of the database to create
user  The user to connect as (must be able to remove the database)
password  The password of the user
host  The host to connect to
port  The port to connect to

19.19.108  salt.states.influxdb08_user module

Management of InfluxDB 0.8 users

(compatible with InfluxDB version 0.5-0.8)
New in version 2014.7.0.
salt.states.influxdb08_user.absent(name, database=None, user=None, password=None, host=None, port=None)
Ensure that the named cluster admin or database user is absent.
name  The name of the user to remove
database  The database to remove the user from
user  The user to connect as (must be able to remove the user)
password  The password of the user
host  The host to connect to
port  The port to connect to

salt.states.influxdb08_user.present(name, passwd, database=None, user=None, password=None, host=None, port=None)

Ensure that the cluster admin or database user is present.
name  The name of the user to manage
passwd  The password of the user
database  The database to create the user in
user  The user to connect as (must be able to create the user)
password  The password of the user
host  The host to connect to
port  The port to connect to

19.19.109  salt.states.influxdb_continuous_query module

Management of Influxdb continuous queries

New in version 2017.7.0.
(compatible with InfluxDB version 0.9+)
salt.states.influxdb_continuous_query.absent(name, database, **client_args)

Ensure that given continuous query is absent.
name  Name of the continuous query to remove.
database  Name of the database that the continuous query was defined on.
salt.states.influxdb_continuous_query.present(name, database, query, resample_time=None, coverage_period=None, **client_args)

Ensure that given continuous query is present.
name  Name of the continuous query to create.
database  Database to create continuous query on.
query  The query content
resample_time  [None] Duration between continuous query resampling.
coverage_period  [None] Duration specifying time period per sample.

19.19.110  salt.states.influxdb_database

Management of Influxdb databases

(compatible with InfluxDB version 0.9+)
salt.states.influxdb_database.absent(name, **client_args)

Ensure that given database is absent.
name  Name of the database to remove.
salt.states.influxdb_database.present(name, **client_args)

Ensure that given database is present.
name  Name of the database to create.
19.19.111 salt.states.influxdb_retention_policy module

Management of Influxdb retention policies

New in version 2017.7.0.

(compatible with InfluxDB version 0.9+)

salt.states.influxdb_retention_policy.absent(name, database, **client_args)

Ensure that given retention policy is absent.

name Name of the retention policy to remove.
database Name of the database that the retention policy was defined on.

salt.states.influxdb_retention_policy.present(name, database, duration=`7d', replication=1, default=False, **client_args)

Ensure that given retention policy is present.

name Name of the retention policy to create.
database Database to create retention policy on.

19.19.112 salt.states.influxdb_user

Management of InfluxDB users

(compatible with InfluxDB version 0.9+)

salt.states.influxdb_user.absent(name, **client_args)

Ensure that given user is absent.

name The name of the user to manage

salt.states.influxdb_user.present(name, password, admin=False, grants=None, **client_args)

Ensure that given user is present.

name Name of the user to manage
password Password of the user
admin [False] Whether the user should have cluster administration privileges or not.
grants Optional - Dict of database:privilege items associated with the user. Example:
grants: foo_db: read bar_db: all

Example:

```
example user present in influxdb:
influxdb_user.present:
  - name: example
    - password: somepassword
    - admin: False
    - grants:
      foo_db: read
      bar_db: all
```

19.19.113 salt.states.infoblox module

states for infoblox stuff

ensures a record is either present or absent in an Infoblox DNS system

New in version 2016.3.0.
salt.states.infoblox.absent(name, record_type, dns_view, infoblox_server=None, infoblox_user=None, infoblox_password=None, infoblox_api_version='v1.4.2', sslVerify=True)

Ensure a record does not exists

name Name of the record
record_type record type (host, a, cname, etc)
dns_view DNS View
infoblox_server infoblox server to connect to (will try pillar if not specified)
infoblox_user username to use to connect to infoblox (will try pillar if not specified)
infoblox_password password to use to connect to infoblox (will try pillar if not specified)
verify_ssl verify SSL certificates

Example:

```
some-state:
    infoblox.absent:
        - name: some.dns.record
        - record_type: host
        - dns_view: MyView
        - sslVerify: False
```

salt.states.infoblox.present(name, value, record_type, dns_view, infoblox_server=None, infoblox_user=None, infoblox_password=None, infoblox_api_version='v1.4.2', sslVerify=True)

Ensure a record exists

name Name of the record
value Value of the record
record_type record type (host, a, cname, etc)
dns_view DNS View
infoblox_server infoblox server to connect to (will try pillar if not specified)
infoblox_user username to use to connect to infoblox (will try pillar if not specified)
infoblox_password password to use to connect to infoblox (will try pillar if not specified)
verify_ssl verify SSL certificates

Example:

```
some-state:
    infoblox.present:
        - name: some.dns.record
        - value: 10.1.1.3
        - record_type: host
        - sslVerify: False
```

19.19.114 salt.states.ini_manage

Manage ini files

maintainer <akilesh1597@gmail.com>
maturity new
depends re
platform all

salt.states.ini_manage.options_absent(name, sections=None, separator='=')
options present in file and not specified in sections dict will be untouched
changes dict will contain the list of changes made

salt.states.ini_manage.options_present(name, sections=None, separator='=', strict=False)

options present in file and not specified in sections dict will be untouched, unless strict: True flag is used
changes dict will contain the list of changes made

salt.states.ini_manage.sections_absent(name, sections=None, separator='=')

options present in file and not specified in sections will be deleted changes dict will contain the sections that
changed

salt.states.ini_manage.sections_present(name, sections=None, separator='=')

This will only create empty sections. To also create options, use options_present state
options present in file and not specified in sections will be deleted changes dict will contain the sections that
changed

19.19. state modules 2887
19.19.115 salt.states.ipmi

Manage IPMI devices over LAN

The following configuration defaults can be defined in the minion, master config or pillar:

```
ipmi.config:
  api_host: 127.0.0.1
  api_user: admin
  api_pass: apassword
  api_port: 623
  api_kg: None
```

Every call can override the config defaults:

```
ensure myipmi system is set to network boot:
  ipmi.boot_device:
    - name: network
    - api_host: myipmi.hostname.com
    - api_user: root
    - api_pass: apassword
    - api_kg: None

ensure myipmi system is powered on:
  ipmi.power:
    - name: boot
    - api_host: myipmi.hostname.com
    - api_user: root
    - api_pass: apassword
```

**salt.states.ipmi.boot_device**(name=`default`, **kwargs)
Request power state change

- name = **default**
  - network -- Request network boot
  - hd -- Boot from hard drive
  - safe -- Boot from hard drive, requesting `safe mode`
  - optical -- boot from CD/DVD/BD drive
  - setup -- Boot into setup utility
  - default -- remove any IPMI directed boot device request

  kwargs
  - api_host=localhost
  - api_user=admin
  - api_pass=
  - api_port=623
  - api_kg=None

**salt.states.ipmi.power**(name=`power_on`, wait=300, **kwargs)
Request power state change

- name
  Ensure power state one of:
  - power_on -- system turn on
  - power_off -- system turn off (without waiting for OS)
  - shutdown -- request OS proper shutdown
  - reset -- reset (without waiting for OS)
  - boot -- If system is off, then `on`; else `reset`

  wait wait X seconds for the job to complete before forcing. (defaults to 300 seconds)
**salt.states.ipmi.user_absent** *(name, channel=14, **kwargs)*
Remove user Delete all user (uid) records having the matching name.

- **name** string name of user to delete
- **channel** channel to remove user access from defaults to 14 for auto

**kwargs**
- api_host=localhost
- api_user=admin
- api_pass=
- api_port=623
- api_kg=None

**salt.states.ipmi.user_present** *(name, uid, password, channel=14, callback=False, link_auth=True, ipmi_msg=True, privilege_level='administrator', **kwargs)*
Ensure IPMI user and user privileges.

- **name** name of user (limit 16 bytes)
- **uid** user id number (1 to 7)
- **password** user password (limit 16 bytes)
- **channel** ipmi channel defaults to 14 for auto
- **callback** User Restricted to Callback
  - False = User Privilege Limit is determined by the User Privilege Limit parameter privilege_level, for both callback and non-callback connections.
  - True = User Privilege Limit is determined by the privilege_level parameter for callback connections, but is restricted to Callback level for non-callback connections. Thus, a user can only initiate a Callback when they `call in' to the BMC, but once the callback connection has been made, the user could potentially establish a session as an Operator.
- **link_auth** User Link authentication True/False user name and password information will be used for link authentication, e.g. PPP CHAP) for the given channel. Link authentication itself is a global setting for the channel and is enabled/disabled via the serial/modem configuration parameters.
- **ipmi_msg** User IPMI Messaging True/False user name and password information will be used for IPMI Messaging. In this case, 'IPMI Messaging' refers to the ability to execute generic IPMI commands that are not associated with a particular payload type. For example, if IPMI Messaging is disabled for a user, but that user is enabled for activating the SOL payload type, then IPMI commands associated with SOL and session management, such as Get SOL Configuration Parameters and Close Session are available, but generic IPMI commands such as Get SEL Time are unavailable. ipmi_msg
- **privilege_level**
  - callback
  - user
  - operator
  - administrator
  - proprietary
  - no_access

**kwargs**
- api_host=localhost
- api_user=admin
- api_pass=
- api_port=623
- api_kg=None
19.19.116 salt.states.ipset

Management of ipsets

This is an ipset-specific module designed to manage IPSets for use in IPTables Firewalls.

```python
setname:
ipset.set_present:
  - set_type: bitmap:ip
  - range: 192.168.0.0/16
  - comment: True
def setname:
ipset.set_absent:
  - set_type: bitmap:ip
  - range: 192.168.0.0/16
  - comment: True
def setname_entries:
ipset.present:
  - set_name: setname
  - entry: 192.168.0.3
  - comment: Hello
  - require:
    - ipset: baz
def setname_entries:
ipset.present:
  - set_name: setname
  - entry:
    - 192.168.0.3
    - 192.168.1.3
  - comment: Hello
  - require:
    - ipset: baz
def setname_entries:
ipset.absent:
  - set_name: setname
  - entry:
    - 192.168.0.3
    - 192.168.1.3
  - comment: Hello
  - require:
    - ipset: baz
def setname:
ipset.flush:
```

salt.states.ipset.absent(name, entry=None, entries=None, family='ipv4', **kwargs)

New in version 2014.7.0.

Remove a entry or entries from a chain

name A user-defined name to call this entry by in another part of a state or formula. This should not be an actual entry.

family Network family, ipv4 or ipv6.

class salt.states.ipset.flush(name, family='ipv4', **kwargs)
Flush current ipset set

family Networking family, either ipv4 or ipv6

salt.states.ipset.present(name, entry=None, family='ipv4', **kwargs)

New in version 2014.7.0.

Append a entry to a set

name A user-defined name to call this entry by in another part of a state or formula. This should not be an actual entry.

entry A single entry to add to a set or a list of entries to add to a set

family Network family, ipv4 or ipv6.

salt.states.ipset.set_absent(name, family='ipv4', **kwargs)

New in version 2014.7.0.

Verify the set is absent.

family Networking family, either ipv4 or ipv6

salt.states.ipset.set_present(name, set_type, family='ipv4', **kwargs)

New in version 2014.7.0.

Verify the set exists.

name A user-defined set name.

set_type The type for the set.

family Networking family, either ipv4 or ipv6

19.19.117 salt.states.iptables

Management of iptables

This is an iptables-specific module designed to manage Linux firewalls. It is expected that this state module, and other system-specific firewall states, may at some point be deprecated in favor of a more generic firewall state.

httpd:
  iptables.append:
    - table: filter

    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - protocol: tcp
    - sport: 1025:65535
    - save: True

httpd:
  iptables.delete:
    - table: filter
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
- protocol: tcp
- sport: 1025:65535
- save: True

httpd:
    iptables.delete:
        - position: 1
        - table: filter
        - chain: INPUT
        - jump: ACCEPT
        - match: state
        - connstate: NEW
        - dport: 80
        - protocol: tcp
        - sport: 1025:65535
        - save: True

httpd:
    iptables.delete:
        - table: filter
        - family: ipv6
        - chain: INPUT
        - jump: ACCEPT
        - match: state
        - connstate: NEW
        - dport: 80
        - protocol: tcp
        - sport: 1025:65535
        - save: True

default to accept:
    iptables.set_policy:
        - chain: INPUT
        - policy: ACCEPT

**Note**: Whereas iptables will accept `-p/--proto[c[o[l]]]` as synonyms of `--protocol`, if `--proto` appears in an iptables command after the appearance of `-m policy`, it is interpreted as the `--proto` option of the policy extension (see the `iptables-extensions(8)` man page).

Example rules for IPSec policy:

```python
accept.esp_in:
    iptables.append:
        - table: filter
        - chain: INPUT
        - jump: ACCEPT
        - source: 10.20.0.0/24
        - destination: 10.10.0.0/24
        - in-interface: eth0
        - match: policy
        - dir: in
        - pol: ipsec
        - reqid: 1
        - proto: esp

accept.esp_forward_in:
    iptables.append:
```
- use:
  - iptables: accept esp in
- chain: FORWARD

accept esp out:
  iptables.append:
  - table: filter
  - chain: OUTPUT
  - jump: ACCEPT
  - source: 10.10.0.0/24
  - destination: 10.20.0.0/24
  - out-interface: eth0
  - match: policy
  - dir: out
  - pol: ipsec
  - reqid: 1
  - proto: esp

accept esp forward out:
  iptables.append:
  - use:
    - iptables: accept esp out
  - chain: FORWARD

Note: Various functions of the iptables module use the --check option. If the version of iptables on the target system does not include this option, an alternate version of this check will be performed using the output of iptables-save. This may have unintended consequences on legacy releases of iptables.

salt.states.iptables.append(name, table='filter', family='ipv4', **kwargs)
New in version 0.17.0.
Add a rule to the end of the specified chain.
name A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.
table The table that owns the chain which should be modified
family Network family, ipv4 or ipv6.
All other arguments are passed in with the same name as the long option that would normally be used for iptables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).

Jump options that doesn't take arguments should be passed in with an empty string.

salt.states.iptables.chain_absent(name, table='filter', family='ipv4')
New in version 2014.1.0.
Verify the chain is absent.
table The table to remove the chain from
family Networking family, either ipv4 or ipv6

salt.states.iptables.chain_present(name, table='filter', family='ipv4')
New in version 2014.1.0.
Verify the chain is exist.
name A user-defined chain name.
table The table to own the chain.
family Networking family, either ipv4 or ipv6
salt.states.iptables.delete(name, table='filter', family='ipv4', **kwargs)
    New in version 2014.1.0.
    Delete a rule to a chain
    name A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.
    table The table that owns the chain that should be modified
    family Networking family, either ipv4 or ipv6
    All other arguments are passed in with the same name as the long option that would normally be used for iptables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).
    Jump options that doesn't take arguments should be passed in with an empty string.

salt.states.iptables.flush(name, table='filter', family='ipv4', **kwargs)
    New in version 2014.1.0.
    Flush current iptables state
    table The table that owns the chain that should be modified
    family Networking family, either ipv4 or ipv6

salt.states.iptables.insert(name, table='filter', family='ipv4', **kwargs)
    New in version 2014.1.0.
    Insert a rule into a chain
    name A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.
    table The table that owns the chain that should be modified
    family Networking family, either ipv4 or ipv6
    position The numerical representation of where the rule should be inserted into the chain. Note that -1 is not a supported position value.
    All other arguments are passed in with the same name as the long option that would normally be used for iptables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).
    Jump options that doesn't take arguments should be passed in with an empty string.

salt.states.iptables.mod_aggregate(low, chunks, running)
    The mod_aggregate function which looks up all rules in the available low chunks and merges them into a single rules ref in the present low data

salt.states.iptables.set_policy(name, table='filter', family='ipv4', **kwargs)
    New in version 2014.1.0.
    Sets the default policy for iptables firewall tables
    table The table that owns the chain that should be modified
    family Networking family, either ipv4 or ipv6
    policy The requested table policy

19.19.118 salt.states.jboss7

Manage JBoss 7 Application Server via CLI interface

New in version 2015.5.0.

This state uses the jboss-cli.sh script from a JBoss or Wildfly installation and parses its output to determine the execution result.

In order to run each state, a jboss_config dictionary with the following properties must be passed:
If the controller doesn’t require a password, then the cli_user and cli_password parameters are optional.

Since same dictionary with configuration will be used in all the states, it may be more convenient to move JBoss configuration and other properties to the pillar.

Example of application deployment from local filesystem:

```
application_deployed:
  jboss7.deployed:
    - salt_source:
      target_file: '/tmp/webapp.war'
    - jboss_config: {{ pillar['jboss'] }}
```

For the sake of brevity, examples for each state assume that jboss_config is contained in the pillar.

salt.states.jboss7.bindings_exist(name, jboss_config, bindings, profile=None)

Ensures that given JNDI binding are present on the server. If a binding doesn’t exist on the server it will be created. If it already exists its value will be changed.

- **jboss_config**: Dict with connection properties (see state description)
- **bindings**: Dict with bindings to set.
- **profile**: The profile name (domain mode only)

Example:

```
jndi_entries_created:
  jboss7.bindings_exist:
    - bindings:
      - 'java:global/sampleapp/environment': 'DEV'
      - 'java:global/sampleapp/configurationFile': '/var/opt/sampleapp/config.
    - jboss_config: {{ pillar['jboss'] }}
```

salt.states.jboss7.datasource_exists(name, jboss_config, datasource_properties, recreate=False, profile=None)

Ensures that a datasource with given properties exist on the jboss instance. If datasource doesn’t exist, it is created, otherwise only the properties that are different will be updated.

- **name**: Datasource property name
- **jboss_config**: Dict with connection properties (see state description)
- **datasource_properties**: Dict with datasource properties
- **recreate**: [False] If set to True and datasource exists it will be removed and created again. However, if there are deployments that depend on the datasource, it will not me possible to remove it.
- **profile**: [None] The profile name for this datasource (domain mode only)

Example:

```
sampleDS:
  jboss7.datasource_exists:
    - recreate: False
    - datasource_properties:
      - driver-name: mysql
      - connection-url: 'jdbc:mysql://localhost:3306/sampleDatabase'
      - jndi-name: 'java:jboss/datasources/sampleDS'
      - user-name: sampleuser
      - password: secret
```
```yaml
min-pool-size: 3
use-java-context: True
- jboss_config: {{ pillar['jboss'] }}
- profile: full-ha

salt.states.jboss7.deployed(name, jboss_config, salt_source=None)
Ensures that the given application is deployed on server.

**jboss_config**: Dict with connection properties (see state description)
**salt_source**: How to find the artifact to be deployed.

- **target_file**: Where to look in the minion's file system for the artifact to be deployed (e.g. `/tmp/application-web-0.39.war`). When source is specified, also specifies where to save the retrieved file.
- **source**: (optional) File on salt master (e.g. `salt://application-web-0.39.war`). If absent, no files will be retrieved and the artifact in target_file will be used for the deployment.
- **undeploy**: (optional) Regular expression to match against existing deployments. When present, if there is a deployment that matches the regular expression, it will be undeployed before the new artifact is deployed.

**Examples:**

Deployment of a file from minion's local file system:

```yaml
application_deployed:
  jboss7.deployed:
    - salt_source:
      target_file: '/tmp/webapp.war'
    - jboss_config: {{ pillar['jboss'] }}
```

It is assumed that `/tmp/webapp.war` was made available by some other means. No applications will be undeployed; if an existing deployment that shares that name exists, then it will be replaced with the updated version.

Deployment of a file from the Salt master's file system:

```yaml
application_deployed:
  jboss7.deployed:
    - salt_source:
      source: salt://application-web-0.39.war
      target_file: '/tmp/application-web-0.39.war'
      undeploy: 'application-web-.*' 
    - jboss_config: {{ pillar['jboss'] }}
```

Here, `application-web-0.39.war` file is downloaded from Salt file system to `/tmp/application-web-0.39.war` file on minion. Existing deployments are checked if any of them matches `application-web-.*` regular expression, and if so then it is undeployed before deploying the application. This is useful to automate deployment of new application versions.

If the source parameter of salt_source is specified, it can use any protocol that the file states use. This includes not only downloading from the master but also HTTP, HTTPS, FTP, Amazon S3, and OpenStack Swift.

salt.states.jboss7.reloaded(name, jboss_config, timeout=60, interval=5)
Reloads configuration of jboss server.

**jboss_config**: Dict with connection properties (see state description)
**timeout**: Time to wait until jboss is back in running state. Default timeout is 60s.
**interval**: Interval between state checks. Default interval is 5s. Decreasing the interval may slightly decrease waiting time but be aware that every status check is a call to jboss-cli which is a java process. If interval is smaller than process cleanup time it may easily lead to excessive resource consumption.
This step performs the following operations:
• Ensures that server is in running or reload-required state (by reading server-state attribute)
• Reloads configuration
• Waits for server to reload and be in running state

Example:

```
class configuration_reloaded:
    def jboss7.reloaded:
        - jboss_config: {{ pillar['jboss'] }}
```

### 19.19.119 salt.states.jenkins module

Management of Jenkins

New in version 2016.3.0.

```python
salt.states.jenkins.absent(name, **kwargs)
Ensure the job is absent from the Jenkins configured jobs
name The name of the Jenkins job to remove
```

```python
salt.states.jenkins.present(name, config=None, **kwargs)
Ensure the job is present in the Jenkins configured jobs
name The unique name for the Jenkins job
config The Salt URL for the file to use for configuring the job
```

### 19.19.120 salt.states.junos module

State modules to interact with Junos devices.

```
maturity new
dependencies junos-eznc, jxmlease
```

**Note:** Those who wish to use junos-eznc (PyEZ) version >= 2.1.0, must use the latest salt code from github until the next release.

Refer to junos for information on connecting to junos proxy.

```python
salt.states.junos.cli(name, format='text', **kwargs)
Executes the CLI commands and returns the text output.
```

```
show version:
  junos:
  - cli
  - format: xml
```

**Parameters**

- **Required** --
  - command: The command that need to be executed on Junos CLI. (default = None)

- **Optional** --
  - format: Format in which to get the CLI output. (text or xml, default = `text`)
* timeout: Set NETCONF RPC timeout. Can be used for commands which take a while to execute. (default = 30 seconds)
* dest: The destination file where the CLI output can be stored. (default = None)

```
salt.states.junos.commit(name, **kwargs)
```
Commits the changes loaded into the candidate configuration.

```
commit the changes:
junos:
  - commit
  - confirm: 10
```

Parameters **Optional** --

- **kwargs**: Keyworded arguments which can be provided like-
  - timeout: Set NETCONF RPC timeout. Can be used for commands which take a while to execute. (default = 30 seconds)
  - comment: Provide a comment to the commit. (default = None)
  - confirm: Provide time in minutes for commit confirmation. If this option is specified, the commit will be rollbacked in the given time unless the commit is confirmed.
  - sync: On dual control plane systems, requests that the candidate configuration on one control plane be copied to the other control plane, checked for correct syntax, and committed on both Routing Engines. (default = False)
  - force_sync: On dual control plane systems, force the candidate configuration on one control plane to be copied to the other control plane.
  - full: When set to True requires all the daemons to check and evaluate the new configuration.
  - detail: When true return commit detail.

```
salt.states.junos.commit_check(name)
```
Perform a commit check on the configuration.

```
perform commit check:
junos.commit_check
```

```
salt.states.junos.diff(name, d_id)
```
Gets the difference between the candidate and the current configuration.

```
get the diff:
junos:
  - diff
  - id: 10
```

Parameters **Optional** --

- id: The rollback id value [0-49]. (default = 0)

```
salt.states.junos.file_copy(name, dest=None, **kwargs)
```
Copies the file from the local device to the junos device.

```
/home/m2/info.txt:
junos:
  - file_copy
  - dest: info_copy.txt
```

Parameters **Required** --
• src: The source path where the file is kept.
• dest: The destination path where the file will be copied.

```
salt.states.junos.install_config(name, **kwargs)
```

Loads and commits the configuration provided.

```
Install the mentioned config:
    junos:
      - install_config
      - path: salt://configs/interface.set
      - timeout: 100
      - diffs_file: 'var/log/diff'
```

```
Install the mentioned config:
    junos:
      - install_config
      - template_path: salt://configs/interface.set
      - timeout: 100
      - template_vars:
        - interface_name: lo0
        - description: Creating interface via SaltStack.
```

name Path where the configuration/template file is present. If the file has a *.conf extension, the content is treated as text format. If the file has a *.xml extension, the content is treated as XML format. If the file has a *.set extension, the content is treated as Junos OS set commands

template_vars The dictionary of data for the jinja variables present in the jinja template

timeout [30] Set NETCONF RPC timeout. Can be used for commands which take a while to execute.

overwrite [False] Set to True if you want this file is to completely replace the configuration file.

replace [False] Specify whether the configuration file uses `replace:` statements. Only those statements under the `replace` tag will be changed.

comment Provide a comment to the commit. (default = None)

confirm Provide time in minutes for commit confirmation. If this option is specified, the commit will be rolled back in the given time unless the commit is confirmed.

diffs_file Path to the file where the diff (difference in old configuration and the committed configuration) will be stored.

Note: The file will be stored on the proxy minion. To push the files to the master use `cp.push`.

```
salt.states.junos.install_os(name, **kwargs)
```

Installs the given image on the device. After the installation is complete the device is rebooted, if reboot=True is given as a keyworded argument.

```
salt://images/junos_image.tgz:
    junos:
      - install_os
      - timeout: 100
      - reboot: True
```

Parameters

- Required --
  - path: Path where the image file is present on the proxy minion.
- Optional --
  - kwargs: keyworded arguments to be given such as timeout, reboot etc
* timeout: Set NETCONF RPC timeout. Can be used to RPCs which take a while to execute. (default = 30 seconds)
* reboot: Whether to reboot after installation (default = False)
* no_copy: When True the software package will not be SCP’d to the device. (default = False)

salt.states.junos.load(name, **kwargs)
Loads the configuration provided onto the junos device.

Install the mentioned config:
  junos:
  - load
  - path: salt://configs/interface.set

Install the mentioned config:
  junos:
  - load
  - template_path: salt://configs/interface.set
  - template_vars:
    - interface_name: lo0
    - description: Creating interface via SaltStack.

name Path where the configuration/template file is present. If the file has a *.conf extension, the content is treated as text format. If the file has a *.xml extension, the content is treated as XML format. If the file has a *.set extension, the content is treated as Junos OS set commands.
overwrite [False] Set to True if you want this file is to completely replace the configuration file.
replace [False] Specify whether the configuration file uses `replace:` statements. Only those statements under the `replace` tag will be changed.
format: Determines the format of the contents.
update [False] Compare a complete loaded configuration against the candidate configuration. For each hierarchy level or configuration object that is different in the two configurations, the version in the loaded configuration replaces the version in the candidate configuration. When the configuration is later committed, only system processes that are affected by the changed configuration elements parse the new configuration. This action is supported from PyEZ 2.1 (default = False)
template_vars Variables to be passed into the template processing engine in addition to those present in __pillar__, __opts__, __grains__, etc. You may reference these variables in your template like so: {{ template_vars['var_name'] }}

salt.states.junos.lock(name)
Attempts an exclusive lock on the candidate configuration. This is a non-blocking call.

Note: Any user who wishes to use lock, must necessarily unlock the configuration too. Ensure unlock is called in the same orchestration run in which the lock is called.

lock the config:
  junos.lock

salt.states.junos.rollback(name, id, **kwargs)
Rollbacks the committed changes.

rollback the changes:
  junos:
  - rollback
  - id: 5
Parameters **Optional** --
- **id**: The rollback id value [0-49]. (default = 0)
- **kwargs**: Keyworded arguments which can be provided like-
  - **timeout**: Set NETCONF RPC timeout. Can be used for commands which take a while to execute. (default = 30 seconds)
  - **comment**: Provide a comment to the commit. (default = None)
  - **confirm**: Provide time in minutes for commit confirmation. If this option is specified, the commit will be rollbacked in the given time unless the commit is confirmed.
  - **difs_file**: Path to the file where any diffs will be written. (default = None)

```
salt.states.junos.rpc(name, dest=None, format='xml', args=None, **kwargs)
```
Executes the given rpc. The returned data can be stored in a file by specifying the destination path with dest as an argument

```
get-interface-information:
  junos:
    - rpc
    - dest: /home/user/rpc.log
    - interface_name: lo0
```

Parameters

- **Required** --
  - **cmd**: The rpc to be executed. (default = None)
- **Optional** --
  - **dest**: Destination file where the rpc output is stored. (default = None) Note that the file will be stored on the proxy minion. To push the files to the master use the salt's following execution module: `cp.push`
  - **format**: The format in which the rpc reply must be stored in file specified in the dest (used only when dest is specified) (default = xml)
  - **kwargs**: keyworded arguments taken by rpc call like-
    * **timeout**: Set NETCONF RPC timeout. Can be used for commands which take a while to execute. (default = 30 seconds)
    * **filter**: Only to be used with `get-config` rpc to get specific configuration.
    * **terse**: Amount of information you want.
    * **interface_name**: Name of the interface whose information you want.

```
salt.states.junos.set_hostname(name, **kwargs)
```
Changes the hostname of the device.

```
device_name:
  junos:
    - set_hostname
    - comment: "Host-name set via saltstack."
```

Parameters

- **Required** --
  - **hostname**: The name to be set. (default = None)
- **Optional** --
  - **kwargs**: Keyworded arguments which can be provided like-
    * **timeout**: Set NETCONF RPC timeout. Can be used for commands which take a while to execute. (default = 30 seconds)
    * **comment**: Provide a comment to the commit. (default = None)
    * **confirm**: Provide time in minutes for commit confirmation. If this
option is specified, the commit will be rollbaked in the given time unless the commit is confirmed.

salt.states.junos.shutdown(name, **kwargs)
Shuts down the device.

```
shut the device:
  junos:
    - shutdown
    - in_min: 10
```

Parameters **Optional** --
  • **kwargs:
    - reboot: Whether to reboot instead of shutdown. (default=False)
    - at: Specify time for reboot. (To be used only if reboot=yes)
    - in_min: Specify delay in minutes for shutdown

salt.states.junos.unlock(name)
Unlocks the candidate configuration.

```
unlock the config:
  junos.unlock
```

salt.states.junos.zeroize(name)
Resets the device to default factory settings.

```
reset my device:
  junos.zeroize
```

name: can be anything

19.19.121 salt.states.k8s

Manage Kubernetes

New in version 2016.3.0.

```
kube_label_1:
  k8s.label_present:
    - name: mylabel
    - value: myvalue
    - node: myothernodename
    - apiserver: http://mykubeapiserver:8080

kube_label_2:
  k8s.label_absent:
    - name: mylabel
    - node: myothernodename
    - apiserver: http://mykubeapiserver:8080

kube_label_3:
  k8s.label_folder_present:
    - name: mylabel
    - node: myothernodename
    - apiserver: http://mykubeapiserver:8080
```
salt.states.k8s.label_absent(name, node=None, apiserver=None)

Deprecated since version 2017.7.0: This state has been moved to kubernetes.node_label_absent
<salt.states.kubernetes.node_label_absent()

Ensure the label doesn't exist on the kube node.
name Name of the label.
node Override node ID.
apiserver K8S api server URL.

salt.states.k8s.label_folder_absent(name, node=None, apiserver=None)

Deprecated since version 2017.7.0: This state has been moved to kubernetes.node_label_folder_absent
<salt.states.kubernetes.node_label_folder_absent()

Ensure the label folder doesn't exist on the kube node.
name Name of the label folder.
node Override node ID.
apiserver K8S api server URL.

salt.states.k8s.label_present(name, value, node=None, apiserver=None)

Deprecated since version 2017.7.0: This state has been moved to kubernetes.node_label_present
<salt.states.kubernetes.node_label_present()

Ensure the label exists on the kube node.
name Name of the label.
value Value of the label.
node Override node ID.
apiserver K8S api server URL.

19.19.122  salt.states.kapacitor module

Kapacitor state module.

configuration This module accepts connection configuration details either as parameters or as config-
uration settings in /etc/salt/minion on the relevant minions:

kapacitor.host: 'localhost'
kapacitor.port: 9092

This data can also be passed into pillar. Options passed into opts will overwrite options passed
into pillar.

New in version 2016.11.0.

salt.states.kapacitor.task_absent(name)

Ensure that a task is absent from Kapacitor.
name Name of the task.

salt.states.kapacitor.task_present(name, tick_script, task_type='stream', database=None, re-
tention_policy='default', enable=True)

Ensure that a task is present and up-to-date in Kapacitor.
name Name of the task.
tick_script Path to the TICK script for the task. Can be a salt:// source.
task_type Task type. Defaults to 'stream'
database Which database to fetch data from. Defaults to None, which will use the default database in In-
fluxDB.
retention_policy Which retention policy to fetch data from. Defaults to 'default'.
enable Whether to enable the task or not. Defaults to True.
19.19.123 salt.states.keyboard

Management of keyboard layouts

The keyboard layout can be managed for the system:

```python
us:
  keyboard.system
```

Or it can be managed for XOrg:

```python
us:
  keyboard.xorg
```

```python
salt.states.keyboard.system(name)
  Set the keyboard layout for the system
  name  The keyboard layout to use
```

```python
salt.states.keyboard.xorg(name)
  Set the keyboard layout for XOrg
  layout The keyboard layout to use
```

19.19.124 salt.states.keystone

Management of Keystone users

depends

- keystoneclient Python module

configuration  See `salt.modules.keystone` for setup instructions.

Keystone tenants:
keystone.tenant_present:
  - names:
    - admin
    - demo
    - service

Keystone roles:
keystone.role_present:
  - names:
    - admin
    - Member

admin:
keystone.user_present:
  - password: R00T_4CC3SS
  - email: admin@domain.com
  - roles:
    - admin: # tenants
      - admin  # roles
    - service:
      - admin
      - Member
    - require:
      - keystone: Keystone tenants
- keystone: Keystone roles

**nova:**

```
keystone.user_present:
  - password: 'Sup3rn0v4'
  - email: nova@domain.com
  - tenant: service
  - roles:
    - service:
      - admin
    - require:
      - keystone: Keystone tenants
      - keystone: Keystone roles
```

**demo:**

```
keystone.user_present:
  - password: 'd3m0n$trati0n'
  - email: demo@domain.com
  - tenant: demo
  - roles:
    - demo:
      - Member
    - require:
      - keystone: Keystone tenants
      - keystone: Keystone roles
```

**nova service:**

```
keystone.service_present:
  - name: nova
  - service_type: compute
  - description: OpenStack Compute Service
```

---

**salt.states.keystone.endpoint_absent**(name, region=region, profile=profile, interface=interface, **connection_args)**

Ensure that the endpoint for a service doesn't exist in Keystone catalog.

- **name**: The name of the service whose endpoints should not exist.
- **region** (optional): The region of the endpoint. Defaults to RegionOne.
- **interface**: The interface type, which describes the visibility of the endpoint. (for V3 API)

**salt.states.keystone.endpoint_present**(name, publicurl=publicurl, internalurl=internalurl, adminurl=adminurl, url=url, region=region, profile=profile, url=url, interface=interface, **connection_args)**

Ensure the specified endpoints exists for service.

- **name**: The Service name.
- **publicurl**: The public url of service endpoint (for V2 API).
- **internalurl**: The internal url of service endpoint (for V2 API).
- **adminurl**: The admin url of the service endpoint (for V2 API).
- **region**: The region of the endpoint.
- **url**: The endpoint URL (for V3 API).
- **interface**: The interface type, which describes the visibility of the endpoint. (for V3 API)

**salt.states.keystone.project_absent**(name, profile=profile, **connection_args)**

Ensure that the keystone project is absent. Alias for tenant_absent from V2 API to fulfill V3 API naming convention.

- **name**: The name of the project that should not exist.

New in version 2016.11.0.
delete_nova:
  keystone.project_absent:
    - name: nova

salt.states.keystone.project_present
(name, description=None, enabled=True, profile=None, **connection_args)

Ensures that the keystone project exists Alias for tenant_present from V2 API to fulfill V3 API naming convention.

New in version 2016.11.0.

name The name of the project to manage
description The description to use for this project
default Availability state for this project

```yaml
nova:
  keystone.project_present:
    - enabled: True
    - description: 'Nova Compute Service'
```

salt.states.keystone.role_absent
(name, profile=None, **connection_args)

Ensure that the keystone role is absent.

name The name of the role that should not exist

salt.states.keystone.role_present
(name, profile=None, **connection_args)

Ensures that the keystone role exists

name The name of the role that should be present

salt.states.keystone.service_absent
(name, profile=None, **connection_args)

Ensure that the service doesn't exist in Keystone catalog

name The name of the service that should not exist

salt.states.keystone.service_present
(name, service_type, description=None, profile=None, **connection_args)

Ensure service present in Keystone catalog

name The name of the service
service_type The type of Openstack Service
description (optional) Description of the service

salt.states.keystone.tenant_absent
(name, profile=None, **connection_args)

Ensure that the keystone tenant is absent.

name The name of the tenant that should not exist

salt.states.keystone.tenant_present
(name, description=None, enabled=True, profile=None, **connection_args)

Ensures that the keystone tenant exists

name The name of the tenant to manage
description The description to use for this tenant
default Availability state for this tenant

salt.states.keystone.user_absent
(name, profile=None, **connection_args)

Ensure that the keystone user is absent.

name The name of the user that should not exist

salt.states.keystone.user_present
(name, password, email, tenant=None, enabled=True, roles=None, profile=None, password_reset=True, project=None, **connection_args)

Ensure that the keystone user is present with the specified properties.

name The name of the user to manage
password  The password to use for this user.

*Note:* If the user already exists and a different password was set for the user than the one specified here, the password for the user will be updated. Please set the password_reset option to False if this is not the desired behavior.

password_reset  Whether or not to reset password after initial set. Defaults to True.

email  The email address for this user

tenant  The tenant (name) for this user

project  The project (name) for this user (overrides tenant in api v3)

enabled  Availability state for this user

roles  The roles the user should have under given tenants. Passed as a dictionary mapping tenant names to a list of roles in this tenant, i.e:

```
roles:
  admin:  # tenant
    - admin  # role
  service:
    - admin
    - Member
```

### 19.19.125  salt.states.kmod

**Loading and unloading of kernel modules**

The Kernel modules on a system can be managed cleanly with the kmod state module:

```
add_kvm:
  kmod.present:
    - name: kvm_amd
remove_beep:
  kmod.absent:
    - name: pcspkr
```

Multiple modules can be specified for both kmod.present and kmod.absent.

```
add_sound:
  kmod.present:
    - mods:
      - snd_hda_codec_hdmi
      - snd_hda_codec
      - snd_hwdep
      - snd_hda_core
      - snd_pcm
      - snd_timer
      - snd

salt.states.kmod.absent(name, persist=False, comment=True, mods=None)
Verify that the named kernel module is not loaded

name  The name of the kernel module to verify is not loaded

persist  Remove module from /etc/modules

comment  Comment out module in /etc/modules rather than remove it

mods  A list of modules to verify are unloaded. If this argument is used, the name argument, although still required, is not used, and becomes a placeholder
```
New in version 2016.3.0.

```
salt.states.kmod.presents(name, persist=False, mods=None)
```

Ensure that the specified kernel module is loaded.

- `name`: The name of the kernel module to verify is loaded.
- `persist`: Also add module to `/etc/modules`.
- `mods`: A list of modules to verify are loaded. If this argument is used, the `name` argument, although still required, is not used, and becomes a placeholder.

New in version 2016.3.0.

### 19.19.126 salt.states.kubernetes

Manage Kubernetes resources as salt states.

Note: This module requires the proper pillar values set. See `salt.modules.kubernetes` for more information.

**Warning**: Configuration options will change in Flourine.

The Kubernetes module is used to manage different Kubernetes resources.

```yaml
my-nginx:
  kubernetes.deployment_present:
    - namespace: default
      metadata:
        app: frontend
      spec:
        replicas: 1
        template:
          metadata:
            labels:
              run: my-nginx
          spec:
            containers:
              - name: my-nginx
                image: nginx
                ports:
                  - containerPort: 80

my-mariadb:
  kubernetes.deployment_absent:
    - namespace: default

# Kubernetes deployment as specified inside of
# a file containing the definition of the the
# deployment using the official Kubernetes format
redis-master-deployment:
  kubernetes.deployment_present:
    - name: redis-master
      source: salt://k8s/redis-master-deployment.yml
    require:
      - pip: kubernetes-python-module

# Kubernetes service as specified inside of
# a file containing the definition of the the
```
# service using the official kubernetes format
redis-master-service:
  kubernetes.service_present:
    - name: redis-master
    - source: salt://k8s/redis-master-service.yml
  require:
    - kubernetes.deployment_present: redis-master

# Kubernetes deployment as specified inside of
# a file containing the definition of the the
# deployment using the official kubernetes format
# plus some jinja directives
nginx-source-template:
  kubernetes.deployment_present:
    - source: salt://k8s/nginx.yml.jinja
    - template: jinja
  require:
    - pip: kubernetes-python-module

# Kubernetes secret
k8s-secret:
  kubernetes.secret_present:
    - name: top-secret
    - data:
        key1: value1
        key2: value2
        key3: value3

salt.states.kubernetes.configmap_absent(name, namespace='default', **kwargs)
Ensure that the named configmap is absent from the given namespace.

name The name of the configmap
namespace The name of the namespace

salt.states.kubernetes.configmap_present(name, namespace='default', data=None, source='', template='', **kwargs)
Ensure that the named configmap is present inside of the specified namespace with the given data. If the
configmap exists it will be replaced.

name The name of the configmap.
namespace The namespace holding the configmap. The `default` one is going to be used unless a different
one is specified.
data The dictionary holding the configmaps.
source A file containing the data of the configmap in plain format.
template Template engine to be used to render the source file.

salt.states.kubernetes.deployment_absent(name, namespace='default', **kwargs)
Ensure that the named deployment is absent from the given namespace.

name The name of the deployment
namespace The name of the namespace

salt.states.kubernetes.deployment_present(name, namespace='default', metadata=None, spec=None, source='', template='', **kwargs)
Ensure that the named deployment is present inside of the specified namespace with the given metadata
and spec. If the deployment exists it will be replaced.

name The name of the deployment.
namespace The namespace holding the deployment. The `default` one is going to be used unless a different
one is specified.
metadata  The metadata of the deployment object.
spec  The spec of the deployment object.
source  A file containing the definition of the deployment (metadata and spec) in the official kubernetes format.
template  Template engine to be used to render the source file.

salt.states.kubernetes.namespace_absent(name, **kwargs)
Ensures that the named namespace is absent.
name  The name of the namespace

salt.states.kubernetes.namespace_present(name, **kwargs)
Ensures that the named namespace is present.
name  The name of the deployment.

salt.states.kubernetes.node_label_absent(name, node, **kwargs)
Ensures that the named label is absent from the node.
name  The name of the label
node  The name of the node

salt.states.kubernetes.node_label_folder_absent(name, node, **kwargs)
Ensures the label folder doesn't exist on the specified node.
name  The name of label folder
node  The name of the node

salt.states.kubernetes.node_label_present(name, node, value, **kwargs)
Ensures that the named label is set on the named node with the given value. If the label exists it will be replaced.
name  The name of the label.
value  Value of the label.
node  Node to change.

salt.states.kubernetes.pod_absent(name, namespace='default', **kwargs)
Ensures that the named pod is absent from the given namespace.
name  The name of the pod
namespace  The namespace holding the pod. The `default` one is going to be used unless a different one is specified.

salt.states.kubernetes.pod_present(name, namespace='default', metadata=None, spec=None, source='`, template='`, **kwargs)
Ensures that the named pod is present inside of the specified namespace with the given metadata and spec. If the pod exists it will be replaced.
name  The name of the pod.
namespace  The namespace holding the pod. The `default` one is going to be used unless a different one is specified.
metadata  The metadata of the pod object.
spec  The spec of the pod object.
source  A file containing the definition of the pod (metadata and spec) in the official kubernetes format.
template  Template engine to be used to render the source file.

salt.states.kubernetes.secret_absent(name, namespace='default', **kwargs)
Ensures that the named secret is absent from the given namespace.
name  The name of the secret
namespace  The name of the namespace

salt.states.kubernetes.secret_present(name, namespace='default', data=None, source='`, template='`, **kwargs)
Ensures that the named secret is present inside of the specified namespace with the given data. If the secret exists it will be replaced.
name  The name of the secret.
namespace  The namespace holding the secret. The `default' one is going to be used unless a different one is specified.
data  The dictionary holding the secrets.
source  A file containing the data of the secret in plain format.
template  Template engine to be used to render the source file.
salt.states.kubernetes.service_absent(name, namespace='default', **kwargs)
Ensures that the named service is absent from the given namespace.

name  The name of the service
namespace  The name of the namespace

salt.states.kubernetes.service_present(name, namespace='default', metadata=None,
    spec=None, source='`', template='`', **kwargs)
Ensures that the named service is present inside of the specified namespace with the given metadata and spec. If the deployment exists it will be replaced.

name  The name of the service.
namespace  The namespace holding the service. The `default' one is going to be used unless a different one is specified.
metadata  The metadata of the service object.
spec  The spec of the service object.
source  A file containing the definition of the service (metadata and spec) in the official kubernetes format.
template  Template engine to be used to render the source file.

19.19.127  salt.states.layman

Management of Gentoo Overlays using layman

A state module to manage Gentoo package overlays via layman

sunrise:
  layman.present

salt.states.layman.absent(name)
Verify that the overlay is absent
name  The name of the overlay to delete

salt.states.layman.present(name)
Verify that the overlay is present
name  The name of the overlay to add

19.19.128  salt.states.ldap

Manage entries in an LDAP database

New in version 2016.3.0.
The states.ldap state module allows you to manage LDAP entries and their attributes.
salt.states.ldap.managed(name, entries, connect_spec=None)
Ensure the existence (or not) of LDAP entries and their attributes

Example:

```
ldap:///
  ldap.managed:
    - connect_spec:
```

19.19.  state modules
bind:
  method: sasl

- entries:

  # make sure the entry doesn't exist
  - cn=foo,ou=users,dc=example,dc=com:
    - delete_others: True

  # make sure the entry exists with only the specified
  # attribute values
  - cn=admin,dc=example,dc=com:
    - delete_others: True
    - replace:
      - cn: admin
description:
    - LDAP administrator
objectClass:
    - simpleSecurityObject
    - organizationalRole
userPassword:
    - {{ pillar.ldap_admin_password }}

  # make sure the entry exists, its olcRootDN attribute
  # has only the specified value, the olcRootDN attribute
  # doesn't exist, and all other attributes are ignored
  - 'olcDatabase={1}hdb,cn=config':
    - replace:
      olcRootDN:
        - cn=admin,dc=example,dc=com
      # the admin entry has its own password attribute
      olcRootPW: []

  # note the use of 'default'. also note how you don't
  # have to use list syntax if there is only one attribute
  # value
  - cn=foo,ou=users,dc=example,dc=com:
    - delete_others: True
    - default:
      userPassword: changeme
      shadowLastChange: 0
      # keep sshPublicKey if present, but don't create
      # the attribute if it is missing
      sshPublicKey: []
    - replace:
      cn: foo
      uid: foo
      uidNumber: 1000
      gidNumber: 1000
      gecos: Foo Bar
givenName: Foo
      sn: Bar
      homeDirectory: /home/foo
      loginShell: /bin/bash
      objectClass:
      - inetOrgPerson
      - posixAccount
### Parameters

- **name** -- The URL of the LDAP server. This is ignored if `connect_spec` is either a connection object or a dict with a 'url' entry.
- **entries** -- A description of the desired state of zero or more LDAP entries.

*entries* is an iterable of dicts. Each of these dict's keys are the distinguished names (DNs) of LDAP entries to manage. Each of these dicts is processed in order. A later dict can reference an LDAP entry that was already mentioned in an earlier dict, which makes it possible for later dicts to enhance or alter the desired state of an LDAP entry.

The DNs are mapped to a description of the LDAP entry's desired state. These LDAP entry descriptions are themselves iterables of dicts. Each dict in the iterable is processed in order. They contain directives controlling the entry's state. The key names the directive type and the value is state information for the directive. The specific structure of the state information depends on the directive type.

The structure of *entries* looks like this:

```plaintext
[{{dn1: [{directive1: directive1_state, 
directive2: directive2_state}], 
  {directive3: directive3_state}]}, 
{dn2: [{directive4: directive4_state, 
  directive5: directive5_state}]}, 
{dn3: [{directive6: directive6_state}]]
```

These are the directives:

- **'delete_others'** Boolean indicating whether to delete attributes not mentioned in this dict or any of the other directive dicts for this DN. Defaults to `True`.

  If you don't want to delete an attribute if present, but you also don't want to add it if it is missing or modify it if it is present, you can use either the 'default' directive or the 'add' directive with an empty value list.

- **'default'** A dict mapping an attribute name to an iterable of default values for that attribute. If the attribute already exists, it is left alone. If not, it is created using the given list of values.

  An empty value list is useful when you don't want to create an attribute if it is missing but you do want to preserve it if the 'delete_others' key is `True`.

- **'add'** Attribute values to add to the entry. This is a dict mapping an attribute name to an iterable of values to add.

  An empty value list is useful when you don't want to create an attribute if it is missing but you do want to preserve it if the 'delete_others' key is `True`.

- **'delete'** Attribute values to remove from the entry. This is a dict mapping an attribute name to an iterable of values to delete from the attribute. If the iterable is empty, all of the attribute's values are deleted.

- **'replace'** Attributes to replace. This is a dict mapping an attribute name to an iterable of values. Any existing values for the attribute are deleted, then the given values are added. The iterable may be empty.
In the above directives, the iterables of attribute values may instead be None, in which case an empty list is used, or a scalar such as a string or number, in which case a new list containing the scalar is used.

Note that if all attribute values are removed from an entry, the entire entry is deleted.

- **connect_spec** -- See the description of the connect_spec parameter of the ldap3.connect function in the ldap3 execution module. If this is a dict and the 'url' entry is not specified, the 'url' entry is set to the value of the name parameter.

**Returns**

A dict with the following keys:

- **'name'** This is the same object passed to the name parameter.
- **'changes'** This is a dict describing the changes made (or, in test mode, the changes that would have been attempted). If no changes were made (or no changes would have been attempted), then this dict is empty. Only successful changes are included.

Each key is a DN of an entry that was changed (or would have been changed). Entries that were not changed (or would not have been changed) are not included. The value is a dict with two keys:

  - **'old'** The state of the entry before modification. If the entry did not previously exist, this key maps to None. Otherwise, the value is a dict mapping each of the old entry's attributes to a list of its values before any modifications were made. Unchanged attributes are excluded from this dict.

  - **'new'** The state of the entry after modification. If the entry was deleted, this key maps to None. Otherwise, the value is a dict mapping each of the entry's attributes to a list of its values after the modifications were made. Unchanged attributes are excluded from this dict.

Example 'changes' dict where a new entry was created with a single attribute containing two values:

```
{'dn1': {'old': None,
         'new': {'attr1': ['val1', 'val2']}}}
```

Example 'changes' dict where a new attribute was added to an existing entry:

```
{'dn1': {'old': {},
         'new': {'attr2': ['val3']}}}
```

- **'result'** One of the following values:
  - True if no changes were necessary or if all changes were applied successfully.
  - False if at least one change was unable to be applied.
  - None if changes would be applied but it is in test mode.

### 19.19.129 salt.states.libcloud_dns module

Manage DNS records and zones using libcloud

**codeauthor** Anthony Shaw <anthonyshaw@apache.org>

New in version 2016.11.0.
Create and delete DNS records or zones through Libcloud. Libcloud’s DNS system supports over 20 DNS providers including Amazon, Google, GoDaddy, Softlayer.

This module uses `libcloud`, which can be installed via package, or pip.

**configuration** This module uses a configuration profile for one or multiple DNS providers

```yaml
libcloud_dns:
  profile1:
    driver: godaddy
    key: 2orgk34kgk34g
  profile2:
    driver: route53
    key: blah
    secret: blah
```

Example:

```yaml
webserver:
  libcloud_dns.zone_present:
    name: mywebsite.com
    profile: profile1
  libcloud_dns.record_present:
    name: www
    zone: mywebsite.com
    type: A
    data: 12.34.32.3
    profile: profile1
```

```
depends apache-libcloud
```

`salt.states.libcloud_dns.record_absent(name, zone, type, data, profile)`

Ensures a record is absent.

Parameters

- `name` (str) -- Record name without the domain name (e.g. `www`). Note: If you want to create a record for a base domain name, you should specify empty string ('') for this argument.
- `zone` (str) -- Zone where the requested record is created, the domain name
- `type` (str) -- DNS record type (A, AAAA, ...).
- `data` (str) -- Data for the record (depends on the record type).
- `profile` (str) -- The profile key

`salt.states.libcloud_dns.record_present(name, zone, type, data, profile)`

Ensures a record is present.

Parameters

- `name` (str) -- Record name without the domain name (e.g. `www`). Note: If you want to create a record for a base domain name, you should specify empty string ('') for this argument.
- `zone` (str) -- Zone where the requested record is created, the domain name
- `type` (str) -- DNS record type (A, AAAA, ...).
- `data` (str) -- Data for the record (depends on the record type).
- `profile` (str) -- The profile key

`salt.states.libcloud_dns.state_result(name, result, message)`

`salt.states.libcloud_dns.zone_absent(domain, profile)`

Ensures a zone is absent.

Parameters

- `domain` (str) -- Zone name, i.e. the domain name
• profile (str) -- The profile key

salt.states.libcloud_dns.zone_present(domain, type, profile)
Ensures a record is present.

Parameters
• domain (str) -- Zone name, i.e. the domain name
• type (str) -- Zone type (master / slave), defaults to master
• profile (str) -- The profile key

19.19.130 salt.states.linux_acl

Linux File Access Control Lists

The Linux ACL state module requires the getfacl and setfacl binaries.

Ensure a Linux ACL is present

```
root:
    acl.present:
        - name: /root
        - acl_type: user
        - acl_name: damian
        - perms: rwx
```

Ensure a Linux ACL does not exist

```
root:
    acl.absent:
        - name: /root
        - acl_type: user
        - acl_name: damian
        - perms: rwx
```

salt.states.linux_acl.absent(name, acl_type, acl_name='`, perms='`, recurse=False)
Ensure a Linux ACL does not exist

salt.states.linux_acl.present(name, acl_type, acl_name='`, perms='`, recurse=False)
Ensure a Linux ACL is present

19.19.131 salt.states.locale

Management of languages/locales

Manage the available locales and the system default:

```
us_locale:
    locale.present:
        - name: en_US.UTF-8

default_locale:
    locale.system:
        - name: en_US.UTF-8
        - require:
            - locale: us_locale
```
salt.states.locale.present(name)
  Generate a locale if it is not present
  
  New in version 2014.7.0.
  name  The name of the locale to be present. Some distributions require the charmap to be specified as part of the locale at this point.

salt.states.locale.system(name)
  Set the locale for the system
  name  The name of the locale to use

19.19.132  salt.states.logrotate module

Module for managing logrotate.

New in version 2017.7.0.

salt.states.logrotate.set_(name, key, value, setting=None, conf_file='/etc/logrotate.conf')
  Set a new value for a specific configuration line.

Parameters
  - key (str) -- The command or block to configure.
  - value (str) -- The command value or command of the block specified by the key parameter.
  - setting (str) -- The command value for the command specified by the value parameter.
  - conf_file (str) -- The logrotate configuration file.

Example of usage with only the required arguments:

```
logrotate-rotate:
  logrotate.set:
    - key: rotate
    - value: 2
```

Example of usage specifying all available arguments:

```
logrotate-wtmp-rotate:
  logrotate.set:
    - key: /var/log/wtmp
    - value: rotate
    - setting: 2
    - conf_file: /etc/logrotate.conf
```

19.19.133  salt.states.loop module

Loop state

Allows for looping over execution modules.

New in version 2017.7.0.

```
wait_for_service_to_be_healthy:
  loop.until:
    - name: boto_elb.get_instance_health
    - condition: m_ret[0]["state"] == 'InService'
    - period: 5
    - timeout: 20
```
- m_args:
  - `elb`}
- m_kwargs:
  - keyid: `access_key`}
  - key: `secret_key`}
  - instances: `instance`}

**Warning:** This state allows arbitrary python code to be executed through the condition parameter which is literally evaluated within the state. Please use caution.

```python
salt.states.loop.until(name, m_args=None, m_kwargs=None, condition=None, period=0, timeout=604800)
```

Loop over an execution module until a condition is met.

- **name** The name of the execution module
- **m_args** The execution module's positional arguments
- **m_kwargs** The execution module's keyword arguments
- **condition** The condition which must be met for the loop to break. This should contain `m_ret` which is the return from the execution module.
- **period** The number of seconds to wait between executions
- **timeout** The timeout in seconds

## 19.19.134 salt.states.lvm

Management of Linux logical volumes

A state module to manage LVMs

```python
/dev/sda:
  lvmpv_present

myvg:
  lvmsgpresent:
    - devices: /dev/sda

lvroot:
  lvmpresent:
    - vgname: myvg
    - size: 10G
    - stripes: 5
    - stripenumber: 8K
```

```python
salt.states.lvm.lv_absent(name, vgname=None)
```

Remove a given existing Logical Volume from a named existing volume group

- **name** The Logical Volume to remove
- **vgname** The name of the Volume Group on which the Logical Volume resides

```python
salt.states.lvm.lv_present(name, vgname=None, size=None, extents=None, snapshot=None, pv='', thinvolume=False, thinpool=False, **kwargs)
```

Create a new Logical Volume

- **name** The name of the Logical Volume
- **vgname** The name of the Volume Group on which the Logical Volume resides
- **size** The initial size of the Logical Volume
- **extents** The number of logical extents to allocate
snapshot The name of the snapshot
pv The Physical Volume to use
kwargs Any supported options to lvcreate. See `linux_lvm` for more details.
New in version to_complete.
thinvolume Logical Volume is thinly provisioned
thinpool Logical Volume is a thin pool

`salt.states.lvm.pv_absent(name)`
Ensure that a Physical Device is not being used by lvm
name The device name to initialize.

`salt.states.lvm.pv_present(name, **kwargs)`
Set a Physical Device to be used as an LVM Physical Volume
name The device name to initialize.
kwargs Any supported options to pvcreate. See `linux_lvm` for more details.

`salt.states.lvm.vg_absent(name)`
Remove an LVM volume group
name The volume group to remove

`salt.states.lvm.vg_present(name, devices=None, **kwargs)`
Create an LVM Volume Group
name The Volume Group name to create
devices A list of devices that will be added to the Volume Group
kwargs Any supported options to vgcreate. See `linux_lvm` for more details.

### 19.19.135 `salt.states.lvs_server`

Management of LVS (Linux Virtual Server) Real Server

`salt.states.lvs_server.absent(name, protocol=None, service_address=None, server_address=None)`
Ensure the LVS Real Server in specified service is absent.
name The name of the LVS server.
protocol The service protocol (only support tcp, udp and fwmrk service).
service_address The LVS service address.
server_address The LVS real server address.

`salt.states.lvs_server.present(name, protocol=None, service_address=None, server_address=None, packet_forward_method='dr', weight=1)`
Ensure that the named service is present.
name The LVS server name
protocol The service protocol
service_address The LVS service address
server_address The real server address.
packet_forward_method The LVS packet forwarding method (`dr` for direct routing, `tunnel` for tunneling, `nat` for network access translation).
weight The capacity of a server relative to the others in the pool.

```
lvrs:
  lvs_server.present:
    - protocol: tcp
    - service_address: 1.1.1.1:80
    - server_address: 192.168.0.11:8080
    - packet_forward_method: dr
    - weight: 10
```
19.19.136 salt.states.lvs_service

Management of LVS (Linux Virtual Server) Service

salt.states.lvs_service.absent(name, protocol= None, service_address= None)
Ensure the LVS service is absent.
name The name of the LVS service
protocol The service protocol
service_address The LVS service address

salt.states.lvs_service.present(name, protocol= None, service_address= None, scheduler= 'wlc')
Ensure that the named service is present.
name The LVS service name
protocol The service protocol
service_address The LVS service address
scheduler Algorithm for allocating TCP connections and UDP datagrams to real servers.

```bash
lvstest:
  lvs_service.present:
    - service_address: 1.1.1.1:80
    - protocol: tcp
    - scheduler: rr
```

19.19.137 salt.states.lxc

Manage Linux Containers

salt.states.lxc.absent(name, stop= False, path= None)
Ensure a container is not present, destroying it if present
name Name of the container to destroy
stop stop before destroying default: false
path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.5.2.

Web01:
  lxc.absent

salt.states.lxc.edited_conf(name, lxc_conf= None, lxc_conf_unset= None)

Warning: This state is unsuitable for setting parameters that appear more than once in an LXC config file, or parameters which must appear in a certain order (such as when configuring more than one network interface). It is slated to be replaced, and as of version 2015.5.0 it is deprecated.

Edit LXC configuration options

Deprecated since version 2015.5.0.
path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.
setconf:
  lxc.edited_conf:
    - name: ubuntu
      - lxc_conf:
        - network.ipv4.ip: 10.0.3.6
    - lxc_conf_unset:
      - lxc.utsname

salt.states.lxc.frozen(name, start=True, path=None)
New in version 2015.5.0.

Ensure that a container is frozen

**Note:** This state does not enforce the existence of the named container, it just freezes the container if it is running. To ensure that the named container exists, use `lxc.present`.

- **name** The name of the container
- **path** path to the container parent default: `/var/lib/lxc` (system default)
  New in version 2015.8.0.
- **start** [True] Start container first, if necessary. If `False`, then this state will fail if the container is not running.

```
web01:
lxc.frozen

web02:
lxc.frozen:
  - start: False
```

salt.states.lxc.present(name, running=None, clone_from=None, snapshot=False, profile=None, network_profile=None, template=None, options=None, image=None, config=None, fstype=None, size=None, backing=None, vname=None, lvname=None, thinpool=None, path=None)

Changed in version 2015.8.0: The `lxc.created` state has been renamed to `lxc.present`, and the `lxc.cloned` state has been merged into this state.

Create the named container if it does not exist

- **name** The name of the container to be created
- **path** path to the container parent default: `/var/lib/lxc` (system default)

  New in version 2015.8.0.
- **running** [False]
  - If `True`, ensure that the container is running
  - If `False`, ensure that the container is stopped
  - If `None`, do nothing with regards to the running state of the container

  New in version 2015.8.0.
- **clone_from** Create named container as a clone of the specified container
- **snapshot** [False] Use Copy On Write snapshots (LVM). Only supported with `clone_from`.
- **profile** Profile to use in container creation (see the LXC Tutorial for more information). Values in a profile will be overridden by the parameters listed below.
- **network_profile** Network Profile to use in container creation (see the LXC Tutorial for more information). Values in a profile will be overridden by the parameters listed below.

  New in version 2015.5.2.

**Container Creation Arguments**
template  The template to use. For example, ubuntu or fedora. For a full list of available templates, check out the `lxc.templates` function.
Conflicts with the `image` argument.

**Note:** The `download` template requires the following three parameters to be defined in `options`:
- `dist` - The name of the distribution
- `release` - Release name/version
- `arch` - Architecture of the container
The available images can be listed using the `lxc.images` function.

`options`
New in version 2015.5.0.
Template-specific options to pass to the lxc-create command. These correspond to the long options (ones beginning with two dashes) that the template script accepts. For example:

```yaml
web01:
  lxc.present:
    - template: download
    - options:
      dist: centos
      release: 6
      arch: amd64
```

Remember to double-indent the options, due to how PyYAML works.
For available template options, refer to the lxc template scripts which are usually located under `/usr/share/lxc/templates`, or run `lxc-create -t <template> -h`.

`image`  A tar archive to use as the rootfs for the container. Conflicts with the `template` argument.
`backing`  The type of storage to use. Set to `lvm` to use an LVM group. Defaults to filesystem within `/var/lib/lxc`.
`fstype`  Filesystem type to use on LVM logical volume
`size`  Size of the volume to create. Only applicable if `backing` is set to `lvm`.
`vgname`  [lxc] Name of the LVM volume group in which to create the volume for this container. Only applicable if `backing` is set to `lvm`.
`lvname`  Name of the LVM logical volume in which to create the volume for this container. Only applicable if `backing` is set to `lvm`.
`thinpool`  Name of a pool volume that will be used for thin-provisioning this container. Only applicable if `backing` is set to `lvm`.

`salt.states.lxc.running(name, restart=False, path=None)`
Changed in version 2015.5.0: The `lxc.started` state has been renamed to `lxc.running`
Ensure that a container is running

**Note:** This state does not enforce the existence of the named container, it just starts the container if it is not running. To ensure that the named container exists, use `lxc.present`.

`name`  The name of the container
`path`  path to the container parent default: `/var/lib/lxc` (system default)
New in version 2015.8.0.
`restart`  [False] Restart container if it is already running

```yaml
web01:
  lxc.running
```
salt.states.lxc.set_pass(*name, **kwargs)

Deprecated since version 2015.5.0.

This state function has been disabled, as it did not conform to design guidelines. Specifically, due to the fact that `lxc.set_password` uses `chpasswd(8)` to set the password, there was no method to make this action idempotent (in other words, the password would be changed every time). This makes this state redundant, since the following state will do the same thing:

```python
setpass:
    module.run:
        - name: set_pass
        - m_name: root
        - password: secret
```

salt.states.lxc.stopped(*name, kill=False, path=None)

Ensure that a container is stopped

**Note:** This state does not enforce the existence of the named container, it just stops the container if it running or frozen. To ensure that the named container exists, use `lxc.present`, or use the `lxc.absent` state to ensure that the container does not exist.

- **name** The name of the container
- **path** path to the container parent default: `/var/lib/lxc` (system default)
- **kill** [False] Do not wait for the container to stop, kill all tasks in the container. Older LXC versions will stop containers like this irrespective of this argument.

19.19.138 salt.states.mac_assistive module

Allows you to manage assistive access on macOS minions with 10.9+

Install, enable and disable assistive access on macOS minions

```python
/usr/bin/osascript:
    assistive.installed:
        - enabled: True
```

salt.states.mac_assistive.installed(*name, enabled=True)

Make sure that we have the given bundle ID or path to command installed in the assistive access panel.

- **name** The bundle ID or path to command
- **enable** Should assistive access be enabled on this application?
19.19.139  salt.states.mac_defaults module

Writing/reading defaults from a macOS minion

salt.states.mac_defaults.absent(name, domain, user=None)
    Make sure the defaults value is absent
    name  The key of the given domain to remove
    domain  The name of the domain to remove from
    user  The user to write the defaults to

salt.states.mac_defaults.write(name, domain, value, vtype='string', user=None)
    Write a default to the system
    name  The key of the given domain to write to
    domain  The name of the domain to write to
    value  The value to write to the given key
    vtype  The type of value to be written, valid types are string, data, int[eger], float, bool[ean], date, array,
           array-add, dict, dict-add
    user  The user to write the defaults to

19.19.140  salt.states.mac_keychain module

Installing of certificates to the keychain

Install certificates to the macOS keychain

```
/mnt/test.p12:
    keychain.installed:
    - password: test123
```

salt.states.mac_keychain.default_keychain(name, domain='user', user=None)
    Set the default keychain to use
    name  The chain in which to use as the default
    domain  The domain to use valid values are user|system|common|dynamic, the default is user
    user  The user to run as

salt.states.mac_keychain.installed(name, password, keychain='/Library/Keychains/System.keychain', **kwargs)
    Install a p12 certificate file into the macOS keychain
    name  The certificate to install
    password  The password for the certificate being installed formatted in the way described for openssl command
    in the PASS PHRASE ARGUMENTS section
    keychain  The keychain to install the certificate to, this defaults to /Library/Keychains/System.keychain
    allow_any  Allow any application to access the imported certificate without warning
    keychain_password  If your keychain is likely to be locked pass the password and it will be unlocked before
                       running the import

salt.states.mac_keychain.uninstalled(name, password, keychain='/Library/Keychains/System.keychain', keychain_password=None)
    Uninstall a p12 certificate file from the macOS keychain
    name  The certificate to uninstall, this can be a path for a .p12 or the friendly name
    password  The password for the certificate being installed formatted in the way described for openssl command
    in the PASS PHRASE ARGUMENTS section
    cert_name  The friendly name of the certificate, this can be used instead of giving a certificate
    keychain  The keychain to remove the certificate from, this defaults to /Library/Keychains/System.keychain
keychain_password  If your keychain is likely to be locked pass the password and it will be unlocked before running the import

19.19.141  salt.states.mac_package module

Installing of mac pkg files

Install any kind of pkg, dmg or app file on macOS:

```
/mnt/test.pkg:
  macpackage.installed:
    - store: True
/mnt/test.dmg:
  macpackage.installed:
    - dmg: True
/mnt/xcode.dmg:
  macpackage.installed:
    - dmg: True
    - app: True
    - target: /Applications/Xcode.app
    - version_check: xcodebuild -version=Xcode 7.1
```

```python
salt.states.mac_package.installed(name, target='LocalSystem', dmg=False, store=False, app=False, mpkg=False, user=None, onlyif=None, unless=None, force=False, allow_untrusted=False, version_check=None)
```

Install a Mac OS Package from a pkg or dmg file, if given a dmg file it will first be mounted in a temporary location.

name  The pkg or dmg file to install

target  The location in which to install the package. This can be a path or LocalSystem
dmg  Is the given file a dmg file?
store  Should the pkg be installed as if it was from the Mac OS Store?
app  Is the file a .app? If so then we'll just copy that to /Applications/ or the given target
mpkg  Is the file a .mpkg? If so then we'll check all of the .pkg files found are installed
user  Name of the user performing the unless or onlyif checks
onlyif  A command to run as a check, run the named command only if the command passed to the onlyif option returns true
unless  A command to run as a check, only run the named command if the command passed to the unless option returns false
force  Force the package to be installed even if its already been found installed
allow_untrusted  Allow the installation of untrusted packages
version_check  The command and version that we want to check against, the version number can use regex.

```python
version_check: python --version_check=2.7.[0-9]
```

19.19.142  salt.states.mac_xattr module

Allows you to manage extended attributes on files or directories

Install, enable and disable assistive access on macOS minions
/path/to/file:
  xattr.exists:
    - attributes:
      - com.file.attr=test
      - com.apple.quarantine=0x00001111

salt.states.mac_xattr.delete(name, attributes)
   Make sure the given attributes are deleted from the file/directory
   name  The path to the file/directory
   attributes  The attributes that should be removed from the file/directory, this is accepted as an array.

salt.states.mac_xattr.exists(name, attributes)
   Make sure the given attributes exist on the file/directory
   name  The path to the file/directory
   attributes  The attributes that should exist on the file/directory, this is accepted as an array, with key and value split with an equals sign, if you want to specify a hex value then add 0x to the beginning of the value.

19.19.143 salt.states.makeconf

Management of Gentoo make.conf

A state module to manage Gentoo’s make.conf file

makeopts:
  makeconf.present:
    - value: '-j3'

salt.states.makeconf.absent(name)
   Verify that the variable is not in the make.conf.
   name  The variable name. This will automatically be converted to upper case since variables in make.conf are in upper case

salt.states.makeconf.present(name, value=None, contains=None, excludes=None)
   Verify that the variable is in the make.conf and has the provided settings. If value is set, contains and excludes will be ignored.
   name  The variable name. This will automatically be converted to upper case since variables in make.conf are in upper case
   value  Enforce that the value of the variable is set to the provided value
   contains  Enforce that the value of the variable contains the provided value
   excludes  Enforce that the value of the variable does not contain the provided value.

19.19.144 salt.states.marathon_app module

Configure Marathon apps via a salt proxy.

my_app:
  marathon_app.config:
    - config:
      cmd: "while [ true ]; do echo 'Hello Marathon'; sleep 5; done"
      cpus: 0.1
      mem: 10
      instances: 3
New in version 2015.8.2.

\texttt{salt.states.marathon_app.absent(name)}

Ensure that the marathon app with the given id is not present.

\begin{itemize}
\item \textbf{Parameters} name -- The app name/id
\item \textbf{Returns} A standard Salt changes dictionary
\end{itemize}

\texttt{salt.states.marathon_app.config(name, config)}

Ensure that the marathon app with the given id is present and is configured to match the given config values.

\begin{itemize}
\item \textbf{Parameters}
  \begin{itemize}
  \item name -- The app name/id
  \item config -- The configuration to apply (dict)
  \end{itemize}
\item \textbf{Returns} A standard Salt changes dictionary
\end{itemize}

\texttt{salt.states.marathon_app.running(name, restart=False, force=True)}

Ensure that the marathon app with the given id is present and restart if set.

\begin{itemize}
\item \textbf{Parameters}
  \begin{itemize}
  \item name -- The app name/id
  \item restart -- Restart the app
  \item force -- Override the current deployment
  \end{itemize}
\item \textbf{Returns} A standard Salt changes dictionary
\end{itemize}

\section{19.19.145 \texttt{salt.states.mdadm}}

Managing software RAID with \texttt{mdadm}

\begin{verbatim}
depends \texttt{mdadm}
\end{verbatim}

A state module for creating or destroying software RAID devices.

\begin{verbatim}
/\texttt{dev/md0}:
    raid.present:
    - level: 5
    - devices:
      - \texttt{/dev/xvdd}
      - \texttt{/dev/xvde}
      - \texttt{/dev/xvdf}
    - chunk: 256
    - run: True

/\texttt{dev/md0}:
    raid.absent:
    - raid:
      - absent

/\texttt{dev/md0}:
    raid.present(name, level, devices, **kwargs)

/\texttt{dev/md0}:
    raid.absent(name, level, devices, **kwargs)

\end{verbatim}

\texttt{salt.states.mdadm.absent(name)}

Verify that the raid is absent

\begin{itemize}
\item \textbf{name} The name of raid device to be destroyed
\end{itemize}

\texttt{salt.states.mdadm.present(name, level, devices, **kwargs)}

Verify that the raid is present

\begin{itemize}
\item \textbf{name} The name of raid device to be created
\item \textbf{level} The RAID level to use when creating the raid.
\item \textbf{devices} A list of devices used to build the array.
\item \textbf{kwargs} Optional arguments to be passed to \texttt{mdadm}.
\end{itemize}
Example:

```
/dev/md0:
  raid.present:
    - level: 5
    - devices:
      - /dev/xvdd
      - /dev/xvde
      - /dev/xvdf
    - chunk: 256
    - run: True
```

19.19.146 salt.states.memcached

States for Management of Memcached Keys

New in version 2014.1.0.

salt.states.memcached.absent(name, value=None, host=`127.0.0.1', port=11211, time=0)
Ensure that a memcached key is not present.

- **name** The key
- **value** [None] If specified, only ensure that the key is absent if it matches the specified value.
- **host** The memcached server IP address
- **port** The memcached server port

```
foo:
  memcached.absent

bar:
  memcached.absent:
    - host: 10.0.0.1
```

salt.states.memcached.managed(name, value=None, host=`127.0.0.1', port=11211, time=0, min_compress_len=0)
Manage a memcached key.

- **name** The key to manage
- **value** The value to set for that key
- **host** The memcached server IP address
- **port** The memcached server port

```
foo:
  memcached.managed:
    - value: bar
```

19.19.147 salt.states.modjk

State to control Apache modjk

salt.states.modjk.worker_activated(name, workers=None, profile='default')
Activate all the workers in the modjk load balancer

Example:
loadbalancer:
    modjk.worker_activated:
      - workers:
        - app1
        - app2

salt.states.modjk.modjk_worker
Manage modjk workers
Send commands to a modjk load balancer via the peer system.
This module can be used with the prereq requisite to remove/add the worker from the load balancer before deploying/restarting service.
Mandatory Settings:

- The minion needs to have permission to publish the modjk.* functions (see here for information on configuring peer publishing permissions)
- The modjk load balancer must be configured as stated in the modjk execution module documentation

salt.states.modjk_worker.activate(name, lbn, target, profile='default', tgt_type='glob', expr_form=None)

Changed in version 2017.7.0: The expr_form argument has been renamed to tgt_type, earlier releases
must use `expr_form`.

Activate the named worker from the lbn load balancers at the targeted minions

Example:

```yaml
disable-before-deploy:
  modjk_worker.activate:
    - name: {{ grains['id'] }}
    - lbn: application
    - target: 'roles:balancer'
    - tgt_type: grain

salt.states.modjk_worker.disable(name, lbn, target, profile='default', tgt_type='glob',
  expr_form=None)

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Disable the named worker from the lbn load balancers at the targeted minions. The worker will get traffic only for current sessions and won't get new ones.

Example:

```yaml
disable-before-deploy:
  modjk_worker.disable:
    - name: {{ grains['id'] }}
    - lbn: application
    - target: 'roles:balancer'
    - tgt_type: grain

salt.states.modjk_worker.stop(name, lbn, target, profile='default', tgt_type='glob',
  expr_form=None)

Changed in version 2017.7.0: The `expr_form` argument has been renamed to `tgt_type`, earlier releases must use `expr_form`.

Stop the named worker from the lbn load balancers at the targeted minions. The worker won't get any traffic from the lbn.

Example:

```yaml
disable-before-deploy:
  modjk_worker.stop:
    - name: {{ grains['id'] }}
    - lbn: application
    - target: 'roles:balancer'
    - tgt_type: grain

19.19.149 salt.states.module

Execution of Salt modules from within states

With `module.run` these states allow individual execution module calls to be made via states. To call a single module function use a `module.run` state:

```yaml
mine.send:
  module.run:
    - network.interfaces
```
Note that this example is probably unnecessary to use in practice, since the `mine_functions` and `mine_interval` config parameters can be used to schedule updates for the mine (see [here](#) for more info).

It is sometimes desirable to trigger a function call after a state is executed, for this the `module.wait` state can be used:

```python
fetch_out_of_band:
    module.run:
        - git.fetch:
            - cwd: /path/to/my/repo
            - user: myuser
            - opts: '--all'
```

Another example:

```python
mine.send:
    module.run:
        - network.ip_addrs:
        - interface: eth0
```

And more complex example:

```python
eventsviewer:
    module.run:
        - task.create_task:
            - name: events-viewer
            - user_name: System
            - action_type: Execute
            - cmd: 'c:\netops\scripts\events_viewer.bat'
            - trigger_type: 'Daily'
            - start_date: '2017-1-20'
            - start_time: '11:59PM'
```

Please note, this is a new behaviour of `module.run` function.

With the previous `module.run` there are several differences:

- The need of `name` keyword
- The need of `m_` prefix
- No way to call more than one function at once

For example:

```python
mine.send:
    module.wait:
        - name: network.interfaces
        - watch:
            - file: /etc/network/interfaces
```

All arguments that the `module` state does not consume are passed through to the execution module function being executed:

```python
fetch_out_of_band:
    module.run:
        - name: git.fetch
        - cwd: /path/to/my/repo
        - user: myuser
        - opts: '--all'
```
Due to how the state system works, if a module function accepts an argument called, name, then m_name must be used to specify that argument, to avoid a collision with the name argument.

Here is a list of keywords hidden by the state system, which must be prefixed with m_:

- fun
- name
- names
- state
- saltenv

For example:

```python
define disable_nfs:
    module.run:
    - name: service.disable
    - m_name: nfs
```

Note that some modules read all or some of the arguments from a list of keyword arguments. For example:

```python
define mine.send:
    module.run:
    - func: network.ip_addrs
    - kwargs:
        interface: eth0
```

```python
define cloud.create:
    module.run:
    - func: cloud.create
    - provider: test-provider
    - m_names:
        - test-vlad
    - kwargs:
        ssh_username: 'ubuntu',
        image: 'ami-8d6d9daa',
        securitygroup: 'default',
        size: 'c3.large',
        location: 'ap-northeast-1',
        delvol_on_destroy: 'True'
```

Another example that creates a recurring task that runs a batch file on a Windows system:

```python
define eventsviewer:
    module.run:
    - name: task.create_task
    - m_name: 'events-viewer'
    - user_name: System
    - kwargs:
        action_type: 'Execute',
        cmd: 'c:\netops\scripts\events_viewer.bat',
        trigger_type: 'Daily',
        start_date: '2017-1-20',
        start_time: '11:59PM'
```
Another option is to use the new version of `module.run`. With which you can call one (or more!) functions at once the following way:

```python
call_something:
  module.run:
    - git.fetch:
      - cwd: /path/to/my/repo
      - user: myuser
      - opts: '--all'
```

By default this behaviour is not turned on. In order to do so, please add the following configuration to the minion:

```python
use_superseded:
  - module.run
```

```python
salt.states.module.wait(name, **kwargs)
    Run a single module function only if the watch statement calls it
    name The module function to execute
    **kwargs Pass any arguments needed to execute the function
```

**Note:** Like the `cmd.run` state, this state will return `True` but not actually execute, unless one of the following two things happens:
1. The state has a `watch requisite`, and the state which it is watching changes.
2. Another state has a `watch_in requisite` which references this state, and the state with the `watch_in` changes.

---

### 19.19.150 salt.states.mongodb_database

Management of Mongodb databases

Only deletion is supported, creation doesn't make sense and can be done using `mongodb_user.present`

```python
salt.states.mongodb_database.absent(name, user=None, password=None, host=None, port=None, authdb=None)
    Ensure that the named database is absent
    name The name of the database to remove
    user The user to connect as (must be able to create the user)
    password The password of the user
    host The host to connect to
    port The port to connect to
    authdb The database in which to authenticate
```

### 19.19.151 salt.states.mongodb_user

Management of Mongodb users

**Note:** This module requires PyMongo to be installed.

```python
salt.states.mongodb_user.absent(name, user=None, password=None, host=None, port=None, database='admin', authdb=None)
    Ensure that the named user is absent
    name The name of the user to remove
```
user MongoDB user with sufficient privilege to create the user
password Password for the admin user specified by the user parameter
host The hostname/IP address of the MongoDB server
port The port on which MongoDB is listening
database The database from which to remove the user specified by the name parameter
authdb The database in which to authenticate

salt.states.mongodb_user.present(name, passwd, database='admin', user=None, password=None,
host='localhost', port=27017, authdb=None, roles=None)

Ensure that the user is present with the specified properties
name The name of the user to manage
passwd The password of the user to manage
user MongoDB user with sufficient privilege to create the user
password Password for the admin user specified with the user parameter
host The hostname/IP address of the MongoDB server
port The port on which MongoDB is listening
database The database in which to create the user

Note: If the database doesn't exist, it will be created.

authdb The database in which to authenticate
roles The roles assigned to user specified with the name parameter

Example:

```
mongouser-myapp:
    mongodb_user.present:
    - name: myapp
    - passwd: password-of-myapp
    - database: admin
    # Connect as admin:sekrit
    - user: admin
    - password: sekrit
    - roles:
        - readWrite
        - userAdmin
        - dbOwner
```

### 19.19.152 salt.states.monit

**Monit state**

Manage monit states

monit_enable_service_monitoring:
    monit.monitor:
        • name: service

monit_disable_service_monitoring:
    monit.unmonitor:
        • name: service
**Note:** Use of these states require that the `monit` execution module is available.

```python
salt.states.monit.monitor(name)
Get the summary from module monit and try to see if service is being monitored. If not then monitor the service.

salt.states.monit.unmonitor(name)
Get the summary from module monit and try to see if service is being monitored. If it is then stop monitoring the service.
```

19.19.153  `salt.states.mount`

**Mounting of filesystems**

Mount any type of mountable filesystem with the mounted function:

```text
/mnt/sdb:
mount.mounted:
  - device: /dev/sdb1
  - fstype: ext4
  - mkmnt: True
  - opts:
    - defaults

/srv/bigdata:
mount.mounted:
  - device: UUID=066e0200-2867-4ebe-b9e6-f30026ca2314
  - fstype: xfs
  - opts: nobootwait,noatime,nodiratime,nobarrier,logbufs=8
  - dump: 0
  - pass_num: 2
  - persist: True
  - mkmnt: True
```

```python
salt.states.mount.mod_watch(name, user=None, **kwargs)
The mounted watcher, called to invoke the watch command.
```

**Note:** This state exists to support special handling of the watch `requisite`. It should not be called directly.

Parameters for this function should be set by the state being triggered.

```python
salt.states.mount.mounted(name, device, fstype, mkmnt=False, opts='defaults',
dump=0, pass_num=0, config='/etc/fstab', persist=True,
mount=True, user=None, match_on='auto', device_name_regex=None,
extra_mount_invisible_options=None, extra_mount_invisible_keys=None,
extra_mount_ignore_fs_keys=None, extra_mount_translate_options=None,
hidden_opts=None)
```

Verify that a device is mounted

```text
name  The name of the mount point

device  The device name, typically the device node, such as /dev/sdb1 or UUID=066e0200-2867-4ebe-b9e6-f30026ca2314 or LABEL=DATA
```
fstype

The filesystem type, this will be xfs, ext2/3/4 in the case of classic filesystems, fuse in the case of fuse mounts, and nfs in the case of nfs mounts

mkmnt

If the mount point is not present then the state will fail, set mkmnt: True to create the mount point if it is otherwise not present

opts

A list object of options or a comma delimited list

dump

The dump value to be passed into the fstab, Default is 0

pass_num

The pass value to be passed into the fstab, Default is 0

config

Set an alternative location for the fstab, Default is /etc/fstab

persist

Set if the mount should be saved in the fstab, Default is True

mount

Set if the mount should be mounted immediately, Default is True

user

The account used to execute the mount; this defaults to the user salt is running as on the minion

match_on

A name or list of fstab properties on which this state should be applied. Default is auto, a special value indicating to guess based on fstype. In general, auto matches on name for recognized special devices and device otherwise.

device_name_regex

A list of device exact names or regular expressions which should not force a remount.

For example, glusterfs may be mounted with a comma-separated list of servers in fstab, but the /proc/self/mountinfo will show only the first available server.

```python
{% set glusterfs_ip_list = ['10.0.0.1', '10.0.0.2', '10.0.0.3'] %}

mount glusterfs volume:
  mount.mounted:
    - name: /mnt/glusterfs_mount_point
    - device: {{ glusterfs_ip_list|join(',') }}/volume_name
    - fstype: glusterfs
    - opts: _netdev,rw,defaults,direct-io-mode=disable
    - mkmnt: True
    - persist: True
    - dump: 0
    - pass_num: 0
    - device_name_regex:
      - ({{ glusterfs_ip_list|join('|') }}):/volume_name
```

New in version 2016.11.0.

extra_mount_invisible_options

A list of extra options that are not visible through the /proc/self/mountinfo interface.

If a option is not visible through this interface it will always remount the device. This option extends the builtin mount_invisible_options list.

extra_mount_invisible_keys

A list of extra key options that are not visible through the /proc/self/mountinfo interface.

If a key option is not visible through this interface it will always remount the device. This option extends the builtin mount_invisible_keys list.

A good example for a key option is the password option:

`password=badsecret`

extra_mount_ignore_fs_keys

A dict of filesystem options which should not force a remount. This will update the internal dictionary. The dict should look like this:

```python
{
  'ramfs': ['size']
}
```

extra_mount_translate_options

A dict of mount options that gets translated when mounted. To prevent a remount add additional options to the default dictionary. This will update the internal dictionary. The dictionary should look like this:
hidden_opts A list of mount options that will be ignored when considering a remount as part of the state application

New in version 2015.8.2.

salt.states.mount.swap(name, persist=True, config='/etc/fstab')
Activates a swap device

Note: swap does not currently support LABEL

salt.states.mount.unmounted(name, device=None, config='/etc/fstab', persist=False, user=None)
New in version 0.17.0.

Verify that a device is not mounted
name The path to the location where the device is to be unmounted from
device The device to be unmounted. This is optional because the device could be mounted in multiple places.

New in version 2015.5.0.
config Set an alternative location for the fstab, Default is /etc/fstab
persist Set if the mount should be purged from the fstab, Default is False
user The user to own the mount; this defaults to the user salt is running as on the minion

19.19.154 salt.states.msteams module

Send a message card to Microsoft Teams

This state is useful for sending messages to Teams during state runs.
New in version 2017.7.0.

teams-message:
msteams.post_card:
  - message: 'This state was executed successfully.'
  - hook_url: https://outlook.office.com/webhook/837

The hook_url can be specified in the master or minion configuration like below:

msteams:
  hook_url: https://outlook.office.com/webhook/837

salt.states.msteams.post_card(name, message, hook_url=None, title=None, theme_color=None)
Send a message to a Microsoft Teams channel

send-msteams-message:
msteams.post_card:
  - message: 'This state was executed successfully.'
  - hook_url: https://outlook.office.com/webhook/837
The following parameters are required:
message  The message that is to be sent to the MS Teams channel.
The following parameters are optional:
hook_url  The webhook URL given configured in Teams interface, if not specified in the configuration options of master or minion.
title  The title for the card posted to the channel
theme_color  A hex code for the desired highlight color

19.19.155 salt.states.mysql_database

Management of MySQL databases (schemas)

depends

  • MySQLdb Python module

collection  See salt.modules.mysql for setup instructions.

The mysql_database module is used to create and manage MySQL databases. Databases can be set as either absent or present.

```python
frank:
mysql_database.present
```

salt.states.mysql_database.absent(name, **connection_args)

  Ensure that the named database is absent
name  The name of the database to remove

salt.states.mysql_database.present(name, character_set=None, collate=None, **connection_args)

  Ensure that the named database is present with the specified properties
name  The name of the database to manage

19.19.156 salt.states.mysql_grants

Management of MySQL grants (user permissions)

depends

  • MySQLdb Python module

collection  See salt.modules.mysql for setup instructions.

The mysql_grants module is used to grant and revoke MySQL permissions.

The name you pass in purely symbolic and does not have anything to do with the grant itself.

The database parameter needs to specify a `priv_level' in the same specification as defined in the MySQL documentation:

  • *
  • **
  • db_name.*
  • db_name.tbl_name
  • etc...
This state is not able to set password for the permission from the specified host. See `salt.states.mysql_user` for further instructions.

```yaml
frank_exampledb:
  mysql_grants.present:
    - grant: select, insert, update
    - database: exampledb.*
    - user: frank
    - host: localhost

frank_otherdb:
  mysql_grants.present:
    - grant: all privileges
    - database: otherdb.*
    - user: frank

restricted_single_table:
  mysql_grants.present:
    - grant: select
    - database: somedb.sometable
    - user: joe
```

```
salt.states.mysql_grants.absent(name, grant=None, database=None, user=None, host='localhost',
    grant_option=False, escape=True, **connection_args)

Ensure that the grant is absent

name The name (key) of the grant to add
grant The grant priv_type (i.e. select, insert, update OR all privileges)
database The database priv_level (i.e. db.tbl OR db.*)
user The user to apply the grant to
host The network/host that the grant should apply to
```

```
salt.states.mysql_grants.present(name, grant=None, database=None, user=None,
    host='localhost', grant_option=False, escape=True, revoke_first=False, ssl_option=False, **connection_args)

Ensure that the grant is present with the specified properties

name The name (key) of the grant to add
grant The grant priv_type (i.e. select, insert, update OR all privileges)
database The database priv_level (i.e. db.tbl OR db.*)
user The user to apply the grant to
host The network/host that the grant should apply to
grant_option Adds the WITH GRANT OPTION to the defined grant. Default is False
escape Defines if the database value gets escaped or not. Default is True
revoke_first By default, MySQL will not do anything if you issue a command to grant privileges that are more restrictive than what's already in place. This effectively means that you cannot downgrade permissions without first revoking permissions applied to a db.table/user pair first.

To have Salt forcibly revoke perms before applying a new grant, enable the `revoke_first option.

WARNING: This will remove permissions for a database before attempting to apply new permissions. There is no guarantee that new permissions will be applied correctly which can leave your database security in an unknown and potentially dangerous state. Use with caution!

Default is False
ssl_option Adds the specified ssl options for the connecting user as requirements for this grant. Value is a list of single-element dicts corresponding to the list of ssl options to use.

Possible key/value pairings for the dict in the value:
SSL: True
X509: True
SUBJECT: <subject>
ISSUER: <issuer>
CIPHER: <cipher>

The non-boolean ssl options take a string as their values, which should be an appropriate value as specified by the MySQL documentation for these options.

Default is False (no ssl options will be used)

19.19.157 salt.states.mysql_query

Execution of MySQL queries

New in version 2014.7.0.

depends

- MySQLdb Python module

configuration See salt.modules.mysql for setup instructions.

The mysql_query module is used to execute queries on MySQL databases. Its output may be stored in a file or in a grain.

```python
query_id:
    mysql_query.run
    - database: my_database
    - query: "SELECT * FROM table;"
    - output: "/tmp/query_id.txt"
```

salt.states.mysql_query.run(name, database, query, output=None, grain=None, key=None, overwrite=True, **connection_args)

Execute an arbitrary query on the specified database

name Used only as an ID
database The name of the database to execute the query on
query The query to execute
output grain: output in a grain other: the file to store results None: output to the result comment (default)
grain: grain to store the output (need output=grain)
key: the specified grain will be treated as a dictionary, the result of this state will be stored under the specified key.
overwrite: The file or grain will be overwritten if it already exists (default)

salt.states.mysql_query.run_file(name, database, query_file=None, output=None, grain=None, key=None, overwrite=True, saltenv=None, **connection_args)

Execute an arbitrary query on the specified database

New in version 2017.7.0.

name Used only as an ID
database The name of the database to execute the query_file on
query_file The file of mysql commands to run
output grain: output in a grain other: the file to store results None: output to the result comment (default)
grain: grain to store the output (need output=grain)
key: the specified grain will be treated as a dictionary, the result of this state will be stored under the specified key.
overwrite: The file or grain will be overwritten if it already exists (default)
saltenv: The saltenv to pull the query_file from

19.19.158  salt.states.mysql_user

Management of MySQL users

depends
  • MySQLdb Python module

configuration See salt.modules.mysql for setup instructions.

```
frank:
  mysql_user.present:
    - host: localhost
    - password: bobcat
```

New in version 0.16.2: Authentication overrides have been added.

The MySQL authentication information specified in the minion config file can be overridden in states using the following arguments: connection_host, connection_port, connection_user, connection_pass, connection_db, connection_unix_socket, connection_default_file and connection_charset.

```
frank:
  mysql_user.present:
    - host: localhost
    - password: "bob@cat"
    - connection_user: someuser
    - connection_pass: somepass
    - connection_charset: utf8
    - saltenv:
      - LC_ALL: "en_US.utf8"
```

This state is not able to grant permissions for the user. See salt.states.mysql_grants for further instructions.

```
salt.states.mysql_user.absent(name, host='localhost', **connection_args)
```

Ensure that the named user is absent
name The name of the user to remove

```
salt.states.mysql_user.present(name, host='localhost', password=None, password_hash=None,
                            allow_passwordless=False, unix_socket=False, password_column=None, **connection_args)
```

Ensure that the named user is present with the specified properties. A passwordless user can be configured by omitting password and password_hash, and setting allow_passwordless to True.
name The name of the user to manage
host Host for which this user/password combo applies
password The password to use for this user. Will take precedence over the password_hash option if both are specified.
password_hash The password in hashed form. Be sure to quote the password because YAML doesn't like the *

mysql> SELECT PASSWORD('mypass');
+-------------------------------+
| PASSWORD('mypass')            |
+-------------------------------+
allow_passwordless  If True, then password and password_hash can be omitted to permit a passwordless login.

New in version 0.16.2.

unix_socket  If True and allow_passwordless is True, the unix_socket auth plugin will be used.

19.19.159  salt.states.netacl

Network ACL

Manage the firewall configuration on the network device managed through NAPALM. The firewall configuration is generated by Capirca.

New in version 2017.7.0.

codeauthor  Mircea Ulinic <mircea@cloudflare.com>
maturity  new
depends  capirca, napalm
platform  unix

Dependencies

Capirca

To install Capirca, execute: pip install capirca.

NAPALM

To be able to load configuration on network devices, it requires NAPALM library to be installed: pip install napalm. Please check Installation for complete details.

salt.states.netacl.filter(name, filter_name, filter_options=None, terms=None, prepend=True, pillar_key='acl', pillarenv=None, saltenv=None, merge_pillar=False, only_lower_merge=False, revision_id=None, revision_no=None, revision_date=True, revision_date_format='%Y/%m/%d', test=False, commit=True, debug=False)

Generate and load the configuration of a policy filter.

filter_name  The name of the policy filter.
filter_options  Additional filter options. These options are platform-specific. See the complete list of options.
terms  Dictionary of terms for this policy filter. If not specified or empty, will try to load the configuration from the pillar, unless merge_pillar is set as False.
prepend: True  When merge_pillar is set as True, the final list of terms generated by merging the terms from terms with those defined in the pillar (if any): new terms are prepended at the beginning, while existing ones will preserve the position. To add the new terms at the end of the list, set this argument to False.
pillar_key: acl  The key in the pillar containing the default attributes values. Default: acl.
pillarenv  Query the master to generate fresh pillar data on the fly, specifically from the requested pillar environment.
saltenv Included only for compatibility with pillarenv_from_saltenv, and is otherwise ignored.
merge_pillar: False  Merge terms with the corresponding value from the pillar. Default: False.

Note:  By default this state does not merge, to avoid any unexpected behaviours.
The merge logic depends on the prepend argument.
The terms specified through the terms argument have higher priority than the pillar.

only_lower_merge: False  Specify if it should merge only the terms fields. Otherwise it will try to merge also filters fields. Default: False. This option requires merge_pillar, otherwise it is ignored.
revision_id  Add a comment in the filter config having the description for the changes applied.
revision_no  The revision count.
revision_date: True  Boolean flag: display the date when the filter configuration was generated. Default: True.
revision_date_format: %Y/%m/%d  The date format to be used when generating the perforce data. Default: %Y/%m/%d (<year>/<month>/<day>).
test: False  Dry run? If set as True, will apply the config, discard and return the changes. Default: False and will commit the changes on the device.
debug: False  Debug mode. Will insert a new key under the output dictionary, as loaded_config containing the raw configuration loaded on the device.

CLI Example:
salt 'edge01.flw01' state.sls router.acl test=True

Output Example:

edge01.flw01:

----------
ID: my-filter
Function: netacl.filter
Result: None
Comment: Testing mode: Configuration discarded.
Started: 12:24:40.598232

remark my-other-term
permit tcp any range 5678 5680 any
exit

Summary for edge01.flw01
-------------
Succeeded: 1 (unchanged=1, changed=1)
Failed: 0
-------------
Total states run: 1
Total run time: 2.437 s

Pillar example:

acl:
- my-filter:
  options:
    - inet6
  terms:
    - my-term:
      source_port: [1234, 1235]
      protocol:
        - tcp
        - udp
      source_address: 1.2.3.4
      action: reject
    - my-other-term:
      source_port:
        - [5678, 5680]
      protocol: tcp
      action: accept

State SLS Example:

```
{% set filter_name = 'my-filter' %}
{% set my_filter_cfg = salt.netacl.get_filter_pillar(filter_name, pillar_key='firewall') %}
my_first_filter_state:
  netacl.filter:
    - filter_name: {{ filter_name }}
    - options: {{ my_filter_cfg['options'] | json }}
    - terms: {{ my_filter_cfg['terms'] | json }}
    - revision_date: false
    - revision_no: 5
    - debug: true
```

Or:

```
my_first_filter_state:
  netacl.filter:
    - filter_name: my-filter
    - merge_pillar: true
    - pillar_key: firewall
    - revision_date: false
    - revision_no: 5
    - debug: true
```
In the example above, as `inet6` has been specified in the `filter_options`, the configuration chunk referring to `my-term` has been ignored as it referred to IPv4 only (from `source_address` field).

**Note:** The first method allows the user to eventually apply complex manipulation and / or retrieve the data from external services before passing the data to the state. The second one is more straightforward, for less complex cases when loading the data directly from the pillar is sufficient.

**Note:** When passing retrieved pillar data into the state file, it is strongly recommended to use the json serializer explicitly (`` | json``), instead of relying on the default Python serializer.

salt.states.netacl.managed(name, filters=None, prepend=True, pillar_key='acl', pillarenv=None, saltenv=None, merge_pillar=False, only_lower_merge=False, revision_id=None, revision_no=None, revision_date=True, revision_date_format='%Y/%m/%d', test=False, commit=True, debug=False)

Manage the whole firewall configuration.

**filters** Dictionary of filters for this policy. If not specified or empty, will try to load the configuration from the pillar, unless `merge_pillar` is set as `False`.

**prepend:** *True* When `merge_pillar` is set as `True`, the final list of filters generated by merging the filters from `filters` with those defined in the pillar (if any): new filters are prepended at the beginning, while existing ones will preserve the position. To add the new filters at the end of the list, set this argument to `False`.

**pillar_key:** *acl* The key in the pillar containing the default attributes values. Default: acl.

**pillarenv** Query the master to generate fresh pillar data on the fly, specifically from the requested pillar environment.

**saltenv** Included only for compatibility with `pillarenv_from_saltenv`, and is otherwise ignored.

**merge_pillar:** *False* Merge the filters will the corresponding values from the pillar. Default: `False`.

**only_lower_merge:** *False* Specify if it should merge only the filters and terms fields. Otherwise it will try to merge everything at the policy level. Default: `False`. This option requires `merge_pillar`, otherwise it is ignored.

**test:** *False* Dry run? If set as `True`, will apply the config, discard and return the changes. Default: `False` and will commit the changes on the device.

**revision_id** Add a comment in the policy config having the description for the changes applied. Default: `False`.

**revision_no** The revision count. Default: `True`.

**revision_date:** *True* Boolean flag: display the date when the policy configuration was generated. Default: `True`.

**revision_date_format:** *%Y/%m/%d* The date format to be used when generating the perforce data. Default: `%Y/%m/%d (<year>/<month>/<day>)`.

**commit:** *True* Commit? Default: `True`.

**debug:** *False* Debug mode. Will insert a new key under the output dictionary, as `loaded_config` containing the raw configuration loaded on the device.

CLI Example:

```
salt 'edge01.bjm01' state.sls router.acl test=True
```

Output Example:

Summary for edge01.bjm01
--------------
Succeeded: 1 (unchanged=1, changed=1)
Failed: 0
--------------
Total states run: 1
Total run time: 5.569 s

The policy configuration has been loaded from the pillar, having the following structure:

```
firewall:
  - my-filter:
    terms:
      - my-term:
        source_port: [1234, 1235]
        protocol:
          - tcp
          - udp
        source_address: 1.2.3.4
        action: reject
      - my-other-term:
        source_port:
          - [5678, 5680]
        protocol: tcp
        action: accept
    - block-icmp:
      terms:
        - first-term:
          protocol:
            - icmp
          action: reject
```

Example SLS file:

```
{%- set fw_filters = pillar.get('firewall', {}) -%}
netacl_example:
  netacl.managed:
    - filters: {{ fw_filters | json }}
    - revision_no: 2
    - debug: true
```

Or:

```
netacl_example:
  netacl.managed:
    - pillar_key: firewall
    - merge_pillar: true
    - revision_no: 2
    - debug: true
```

**Note:** The first method allows the user to eventually apply complex manipulation and / or retrieve the data from external services before passing the data to the state. The second one is more straightforward, for less complex cases when loading the data directly from the pillar is sufficient.

**Note:** When passing retrieved pillar data into the state file, it is strongly recommended to use the json
serializer explicitly (`\` | json`), instead of relying on the default Python serializer.

salt.states.netacl.term(name, filter_name, term_name, filter_options=None, pillar_key='acl', pil-

larenv=None, saltenv=None, merge_pillar=False, revision_id=None, re-

vision_no=None, revision_date=True, revision_date_format='%Y/%m/%d',

test=False, commit=True, debug=False, source_service=None, desti-

nation_service=None, **term_fields)

Manage the configuration of a specific policy term.

filter_name The name of the policy filter.
term_name The name of the term.

filter_options Additional filter options. These options are platform-specific. See the complete list of options.
pillar_key: acl The key in the pillar containing the default attributes values. Default: acl.
pillarenv Query the master to generate fresh pillar data on the fly, specifically from the requested pillar

environment.
saltenv Included only for compatibility with pillarenv_from_saltenv, and is otherwise ignored.
merge_pillar: False Merge the CLI variables with the pillar. Default: False.

The properties specified through the state arguments have higher priority than the pillar.
revision_id Add a comment in the term config having the description for the changes applied.
revision_no The revision count.
revision_date: True Boolean flag: display the date when the term configuration was generated. Default: True.
revision_date_format: %Y/%m/%d The date format to be used when generating the perforce data. Default: %Y/%m/%d (%year/%month/%day).
test: False Dry run? If set as True, will apply the config, discard and return the changes. Default: False and will commit the changes on the device.
debug: False Debug mode. Will insert a new key under the output dictionary, as loaded_config con-

taining the raw configuration loaded on the device.

source_service A special service to choose from. This is a helper so the user is able to select a source just

using the name, instead of specifying a source_port and protocol.

As this module is available on Unix platforms only, it reads the IANA port assignment from /etc/services.

If the user requires additional shortcuts to be referenced, they can add entries under /etc/services, which
can be managed using the file state.
destination_service A special service to choose from. This is a helper so the user is able to select a source just using the name, instead of specifying a destination_port and protocol. Allows the same options as

source_service.
term_fields Term attributes. To see what fields are supported, please consult the list of supported keywords. Some platforms have few other optional keywords.

Note: The following fields are accepted:
  • action
  • address
  • address_exclude
  • comment
  • counter
  • expiration
  • destination_address
  • destination_address_exclude
  • destination_port
  • destination_prefix
  • forwarding_class
  • forwarding_class_except
• logging
• log_name
• loss_priority
• option
• policer
• port
• precedence
• principals
• protocol
• protocol_except
• qos
• pan_application
• routing_instance
• source_address
• source_address_exclude
• source_port
• source_prefix
• verbatim
• packet_length
• fragment_offset
• hop_limit
• icmp_type
• ether_type
• traffic_class_count
• traffic_type
• translated
• dscp_set
• dscp_match
• dscp_except
• next_ip
• flexible_match_range
• source_prefix_except
• destination_prefix_except
• vpn
• source_tag
• destination_tag
• source_interface
• destination_interface
• flattened
• flattened_addr
• flattened_saddr
• flattened_daddr
• priority

**Note:** The following fields can be also a single value and a list of values:
• action
• address
• address_exclude
• comment
• destination_address
• destination_address_exclude
• destination_port
**Example:** destination_address can be either defined as:

```
destination_address: 172.17.17.1/24
```

or as a list of destination IP addresses:

```
destination_address:
    - 172.17.17.1/24
    - 172.17.19.1/24
```

or a list of services to be matched:

```
source_service:
    - ntp
    - snmp
    - ldap
    - bgpd
```

**Note:** The port fields source_port and destination_port can be used as above to select either a single value, either a list of values, but also they can select port ranges. Example:

```
source_port:
    - [1000, 2000]
    - [3000, 4000]
```
With the configuration above, the user is able to select the 1000-2000 and 3000-4000 source port ranges.

CLI Example:

```
salt 'edge01.bjm01' state.sls router.acl
```

Output Example:

```
edge01.bjm01:  
-----------

+          }  
+        }  
+      }  
+    }

Summary for edge01.bjm01  
----------  
Succeeded: 1 (unchanged=1, changed=1)  
Failed: 0  
----------  
Total states run: 1  
Total run time: 5.752 s
```

Pillar example:

```
firewall:  
  block-icmp:  
    terms:  
      - first-term:  
        protocol:  
          icmp  
        action: reject
```

State SLS example:
Or directly referencing the pillar keys:

```
update_icmp_first_term:
  netacl.term:
    - filter_name: block-icmp
    - filter_options:
      - not-interface-specific
    - term_name: first-term
    - {{ my_term_cfg | json }}
```

**Note:** The first method allows the user to eventually apply complex manipulation and/or retrieve the data from external services before passing the data to the state. The second one is more straightforward, for less complex cases when loading the data directly from the pillar is sufficient.

**Note:** When passing retrieved pillar data into the state file, it is strongly recommended to use the json serializer explicitly (`` | json``), instead of relying on the default Python serializer.

19.19.160  salt.states.netconfig

**Network Config**

Manage the configuration on a network device given a specific static config or template.

**codeauthor** Mircea Ulinic <mircea@cloudflare.com> & Jerome Fleury <jfi@cloudflare.com>

**maturity** new

**depends** napalm

**platform** unix

**Dependencies**

- NAPALM proxy minion
- Network-related basic features execution module

New in version 2017.7.0.
salt.states.netconfig.managed(name, template_name, template_source=None, template_path=None, template_hash=None, template_hash_name=None, template_user='root', template_group='root', template_mode='755', saltenv=None, template_engine='jinja', skip_verify=False, defaults=None, test=False, commit=True, debug=False, replace=False, **template_vars)

Manages the configuration on network devices.

By default this state will commit the changes on the device. If there are no changes required, it does not commit and the field already_configured from the output dictionary will be set as True to notify that.

To avoid committing the configuration, set the argument test to True (or via the CLI argument test=True) and will discard (dry run).

To preserve the changes, set commit to False (either as CLI argument, either as state parameter). However, this is recommended to be used only in exceptional cases when there are applied few consecutive states and/or configuration changes. Otherwise the user might forget that the config DB is locked and the candidate config buffer is not cleared/merged in the running config.

To replace the config, set replace to True. This option is recommended to be used with caution!

Warning: The support for NAPALM native templates will be dropped beginning with Salt Fluorine. Implicitly, the template_path argument will be deprecated and removed.

template_name Identifies path to the template source. The template can be either stored on the local machine, either remotely. The recommended location is under the file_roots as specified in the master config file. For example, let's suppose the file_roots is configured as:

```
file_roots:
  base:
    - /etc/salt/states
```

Placing the template under /etc/salt/states/templates/example.jinja, it can be used as salt://templates/example.jinja. Alternatively, for local files, the user can specify the absolute path. If remotely, the source can be retrieved via http, https or ftp.

Examples:
- salt://my_template.jinja
- /absolute/path/to/my_template.jinja
- http://example.com/template.cheetah
- https://example.com/template.mako
- ftp://example.com/template.py

template_source: None Inline config template to be rendered and loaded on the device.

template_path: None Required only in case the argument template_name provides only the file basename. E.g.: if template_name is specified as my_template.jinja, in order to find the template, this argument must be provided: template_path: /absolute/path/to/.

template_hash: None Hash of the template file. Format: {hash_type: 'md5', 'hsum': <md5sum>}

template_hash_name: None When template_hash refers to a remote file, this specifies the filename to look for in that file.

template_group: root Owner of file.

template_user: root Group owner of file.

template_user: 755 Permissions of file

saltenv: base Specifies the template environment. This will influence the relative imports inside the templates.

template_engine: jinja The following templates engines are supported:
- cheetah
- genshi
- jinja
- mako
- py
- wempy

skip_verify: False  If True, hash verification of remote file sources (http://, https://, ftp://) will be skipped, and the source_hash argument will be ignored.

Changed in version 2017.7.1.

test: False  Dry run? If set to True, will apply the config, discard and return the changes. Default: False (will commit the changes on the device).

debug: False  Debug mode. Will insert a new key under the output dictionary, as loaded_config containing the raw result after the template was rendered.

**Note:** This argument cannot be used directly on the command line. Instead, it can be passed through the pillar variable when executing either of the state.sls or state.apply (see below for an example).

replace: False  Load and replace the configuration. Default: False (will apply load merge).

defaults: None  Default variables/context passed to the template.

template_vars  Dictionary with the arguments/context to be used when the template is rendered. Do not explicitly specify this argument. This represents any other variable that will be sent to the template rendering system. Please see an example below! In both ntp_peers_example_using_pillar and ntp_peers_example, peers is sent as template variable.

SLS Example (e.g.: under salt://router/config.sls):

```yaml
whole_config_example:
  netconfig.managed:
    - template_name: salt://path/to/complete_config.jinja
    - debug: True
    - replace: True

bgp_config_example:
  netconfig.managed:
    - template_name: /absolute/path/to/bgp_neighbors.mako
    - template_engine: mako

prefix_lists_example:
  netconfig.managed:
    - template_name: prefix_lists.cheetah
    - template_path: /absolute/path/to/
    - debug: True
    - template_engine: cheetah

ntp_peers_example:
  netconfig.managed:
    - template_name: http://bit.ly/2gKOj20
    - skip_verify: False
    - debug: True
    - peers:
      - 192.168.0.1
      - 192.168.0.1

ntp_peers_example_using_pillar:
  netconfig.managed:
    - template_name: http://bit.ly/2gKOj20
    - peers: {{ pillar.get('ntp.peers', []) }}
```

19.19. state modules

2957
Usage examples:

```bash
$ sudo salt 'juniper.device' state.sls router.config test=True
$ sudo salt -N all-routers state.sls router.config pillar="{'debug': True}"
```

`router.config` depends on the location of the SLS file (see above). Running this command, will be executed all five steps from above. These examples above are not meant to be used in a production environment, their sole purpose is to provide usage examples.

Output example:

```
$ sudo salt 'juniper.device' state.sls router.config test=True

juniper.device:
----------
ID: ntp_peers_example_using_pillar
Function: netconfig.managed
Result: None
Comment: Testing mode: Configuration discarded.
Started: 12:01:40.744535
Duration: 8755.788 ms
Changes:
----------
diff:
[edit system ntp]
peer 192.168.0.1 { ... }
+ peer 172.17.17.1;
+ peer 172.17.17.3;

Summary for juniper.device
----------
Succeeded: 1 (unchanged=1, changed=1)
Failed: 0
----------
Total states run: 1
Total run time: 8.756 s
```

Raw output example (useful when the output is reused in other states/execution modules):

```
$ sudo salt --out=pprint 'juniper.device' state.sls router.config test=True

{
    'juniper.device': {
        'netconfig_|-ntp_peers_example_using_pillar_|-ntp_peers_example_using_pillar_|-managed': {
            '__id__': 'ntp_peers_example_using_pillar',
            '__run_num__': 0,
            'already_configured': False,
            'changes': {
                'diff': '[edit system ntp] peer 192.168.0.1 { ... }+ peer 172.17.17.1;
+ peer 172.17.17.3;
}
        },
        'comment': 'Testing mode: Configuration discarded.',
        'duration': 7400.759,
        'loaded_config': 'system { ntp { peer 172.17.17.1; peer 172.17.17.3; }
}
    },
    'name': 'ntp_peers_example_using_pillar',
```
19.19.161  salt.states.netntp

Network NTP

Manage the configuration of NTP peers and servers on the network devices through the NAPALM proxy.

codeauthor  Mircea Ulinic <mircea@cloudflare.com> & Jerome Fleury <jf@cloudflare.com>
maturity new
depends napalm
platform unix

Dependencies

- Requires `netaddr` to be installed: `pip install netaddr` to check if IP Addresses are correctly specified
- Requires `dnspython` to be installed: `pip install dnspython` to resolve the nameserver entities (in case the user does not configure the peers/servers using their IP addresses)

salt.states.netntp.managed(name, peers=None, servers=None)

Manages the configuration of NTP peers and servers on the device, as specified in the state SLS file. NTP entities not specified in these lists will be removed whilst entities not configured on the device will be set.

SLS Example:

```yaml
netntp_example:
  netntp.managed:
    - peers:
      - 192.168.0.1
      - 172.17.17.1
    - servers:
      - 24.124.0.251
      - 138.236.128.36
```

Output example:

```json
{
  'edge01.nrt04': {
    'netntp_|-netntp_example_|-netntp_example_|-managed': {
      'comment': 'NTP servers already configured as needed.',
      'name': 'netntp_example',
      'start_time': '12:45:24.056659',
      'duration': 2938.857,
      'changes': {
        'peers': {
```
'removed': [
    '192.168.0.2',
    '192.168.0.3'
],
'added': [
    '192.168.0.1',
    '172.17.17.1'
]
}
}

19.19.162 salt.states.netsnmp

Network SNMP

Manage the SNMP configuration on network devices.

- codeauthor Mircea Ulinic <mircea@cloudflare.com>
- maturity new
- depends napalm
- platform unix

Dependencies

- napalm snmp management module (salt.modules.napalm_snmp)

salt.states.netsnmp.managed(name, config=None, defaults=None)

Configures the SNMP on the device as specified in the SLS file.

SLS Example:

```python
snmp_example:
    netsnmp.managed:
        - config:
            location: Honolulu, HI, US
        - defaults:
            contact: noc@cloudflare.com
```

Output example (for the SLS above, e.g. called snmp.sls under /router/):

```
$ sudo salt edge01.hnl01 state.sls router.snmp test=True
edge01.hnl01:
---------
ID: snmp_example
Function: netsnmp.managed
Result: None
Comment: Testing mode: configuration was not changed!
Started: 13:29:06.872363
Duration: 920.466 ms
```
Changes:
--------
added:
--------
chassis_id:
None
contact:
noc@cloudflare.com
location:
Honolulu, HI, US

Summary for edge01.hnl01
--------
Succeeded: 1 (unchanged=1, changed=1)
Failed: 0
--------
Total states run: 1
Total run time: 920.466 ms

19.19.163 salt.states.netusers

Network Users

Manage the users configuration on network devices via the NAPALM proxy.

codeauthor Mircea Ulinic <mircea@cloudflare.com>
maturity new
depends napalm
platform unix

Dependencies

- NAPALM proxy minion
- Users configuration management module

New in version 2016.11.0.

salt.states.netusers.managed(name, users=none, defaults=None)

Manages the configuration of the users on the device, as specified in the state SLS file. Users not defined in that file will be removed whilst users not configured on the device, will be added.

SLS Example:

```
netusers_example:
  netusers.managed:
    - users:
      admin:
        level: 15
        password: $1$knmhgPPv$g8745biu4rb.Zf.IT.F/U1
        sshkeys: []
      restricted:
        level: 1
        password: $1$j34j5k4b$4d5SVjTiz1l.Zf.IT.F/K7
```
```
martin:
  level: 15
  password: '
  sshkeys:
    ssh-dss AAAAB3NzaC1kc3MAAACBAK9dP3KariMlM/
    JpQmJYaFqZTnlgi0srGjyifFwPt0DppDwLcGe2M4LXnu3OMqknr54w344zPHP3iFwXhRBrZKtcJo8LhbWCa+

    edb+BAc3awwo1aeWpogjst+We7y2N
```

CLI Example:
salt `edge01.kix01` state.sls router.users

Output example (raw python - can be reused in other modules):

```
{
  'netusers_|-netusers_example_|-netusers_example_|-managed': {
    'comment': 'Configuration updated!
    'name': 'netusers_example',
    'start_time': '10:57:03.678811',
    '__id__': 'netusers_example',
    'duration': 1620.982,
    '__run_num__': 0,
    'changes': {
      'updated': {
        'admin': {
          'level': 15
        },
        'restricted': {
          'level': 1
        },
      },
      'martin': {
        'sshkeys': ['
          ssh-dss AAAAB3NzaC1kc3MAAACBAK9dP3KariMlM/

Total run time: 1.220 s

19.19.164 salt.states.network

Configuration of network interfaces

The network module is used to create and manage network settings, interfaces can be set as either managed or ignored. By default all interfaces are ignored unless specified.

Note: Prior to version 2014.1.0, only RedHat-based systems (RHEL, CentOS, Scientific Linux, etc.) are supported. Support for Debian/Ubuntu is new in 2014.1.0 and should be considered experimental.
Other platforms are not yet supported.

```yaml
system:
  network.system:
    - enabled: True
    - hostname: server1.example.com
    - gateway: 192.168.0.1
    - gatewaydev: eth0
    - nozeroconf: True
    - nisdomain: example.com
    - require_reboot: True

eth0:
  network.managed:
    - enabled: True
    - type: eth
    - proto: none
    - ipaddr: 10.1.0.1
    - netmask: 255.255.255.0
    - dns:
        - 8.8.8.8
        - 8.8.4.4

eth0-range0:
  network.managed:
    - type: eth
    - ipaddr_start: 192.168.1.1
    - ipaddr_end: 192.168.1.10
    - clonenum_start: 10
    - mtu: 9000

bond0-range0:
  network.managed:
    - type: eth
    - ipaddr_start: 192.168.1.1
    - ipaddr_end: 192.168.1.10
    - clonenum_start: 10
    - mtu: 9000

eth1.0-range0:
  network.managed:
    - type: eth
    - ipaddr_start: 192.168.1.1
    - ipaddr_end: 192.168.1.10
    - clonenum_start: 10
    - vlan: True
    - mtu: 9000

bond0.1-range0:
  network.managed:
    - type: eth
    - ipaddr_start: 192.168.1.1
    - ipaddr_end: 192.168.1.10
    - clonenum_start: 10
    - vlan: True
    - mtu: 9000

.. note::
```

19.19. state modules
add support of ranged interfaces (vlan, bond and eth) for redhat system,
Important:type must be eth.

routes:
    network.routes:
        - name: eth0
        - routes:

    - enable_ipv6: true
    - ipaddrs:
      - 127.0.0.1/8
      - 10.1.0.4/32
      - 10.1.0.12/32
    - ipv6addrs:
      - fc00::1/128
      - fc00::100/128

.. note::
  Apply changes to hostname immediately.

.. versionadded:: 2015.5.0

system:
  network.system:
    - hostname: server2.example.com
    - apply_hostname: True
    - retain_settings: True

.. note::
  Use `retain_settings` to retain current network settings that are not otherwise specified in the state. Particularly useful if only setting the hostname. Default behavior is to delete unspecified network settings.

.. versionadded:: 2016.11.0
Note: When managing bridged interfaces on a Debian or Ubuntu based system, the ports argument is required. Red Hat systems will ignore the argument.

```python
salt.states.network.managed(name, type, enabled=True, **kwargs)
```

Ensure that the named interface is configured properly.

- `name`: The name of the interface to manage.
- `type`: Type of interface and configuration.
- `enabled`: Designates the state of this interface.
- `kwargs`: The IP parameters for this interface.

```python
salt.states.network.routes(name, **kwargs)
```

Manage network interface static routes.

- `name`: Interface name to apply the route to.
- `kwargs`: Named routes

```python
salt.states.network.system(name, **kwargs)
```

Ensure that global network settings are configured properly.

- `name`: Custom name to represent this configuration change.
- `kwargs`: The global parameters for the system.

19.19.165 salt.states.netyang

NAPALM YANG state

Manage the configuration of network devices according to the YANG models (OpenConfig/IETF).
New in version 2017.7.0.

Dependencies

- napalm-yang
- pyangbing > 0.5.11

To be able to load configuration on network devices, it requires NAPALM library to be installed: `pip install napalm`. Please check Installation for complete details.

```python
salt.states.netyang.configured(name, data, models, **kwargs)
```

Configure the network device, given the input data structured according to the YANG models.

Note: The main difference between this function and managed is that the later generates and loads the configuration only when there are differences between the existing configuration on the device and the expected configuration. Depending on the platform and hardware capabilities, one could be more optimal than the other. Additionally, the output of the managed is different, in such a way that the pchange field in the output contains structured data, rather than text.

- `data`: YANG structured data.
- `models`: A list of models to be used when generating the config.
- `profiles`: None Use certain profiles to generate the config. If not specified, will use the platform default profile(s).
- `test`: False Dry run? If set as True, will apply the config, discard and return the changes. Default: False and will commit the changes on the device.
commit: **True** Commit? Default: True.
debug: **False** Debug mode. Will insert a new key under the output dictionary, as `loaded_config` containing the raw configuration loaded on the device.
replace: **False** Should replace the config with the new generate one?

State SLS example:

```
{%- set expected_config = pillar.get('openconfig_interfaces_cfg') -%}
interaces_config:
    napalm_yang.configured:
        - data: {{ expected_config | json }}
        - models:
            - models.openconfig_interfaces
        - debug: true
```

Pillar example:

```
openconfig_interfaces_cfg:
    _kwargs:
        filter: true
    interfaces:
        interface:
            Et1:
                config:
                    mtu: 9000
            Et2:
                config:
                    description: "description example"
```

salt.states.netyang.managed

Manage the device configuration given the input data structured according to the YANG models.
data

YANG structured data.
models

A list of models to be used when generating the config.
profiles: None

Use certain profiles to generate the config. If not specified, will use the platform default profile(s).
compliance_report: **False** Return the compliance report in the comment. The compliance report structured object can be found however in the `pchanges` field of the output (not displayed on the CLI).

New in version 2017.7.3.
test: **False** Dry run? If set as True, will apply the config, discard and return the changes. Default: False and will commit the changes on the device.
commit: **True** Commit? Default: True.
debug: **False** Debug mode. Will insert a new key under the output dictionary, as `loaded_config` containing the raw configuration loaded on the device.
replace: **False** Should replace the config with the new generate one?

State SLS example:

```
{%- set expected_config = pillar.get('openconfig_interfaces_cfg') -%}
interaces_config:
    napalm_yang.managed:
        - data: {{ expected_config | json }}
        - models:
            - models.openconfig_interfaces
        - debug: true
```

Pillar example:
openconfig_interfaces_cfg:
  _kwargs:
    filter: true
  interfaces:
    interface:
      Et1:
        config:
          mtu: 9000
        description: "description example"
      Et2:
        config:
  
19.19.166 salt.states.nftables

Management of nftables

This is an nftables-specific module designed to manage Linux firewalls. It is expected that this state module, and other system-specific firewall states, may at some point be deprecated in favor of a more generic firewall state.

httpd:
  nftables.append:
    - table: filter
    - chain: input
    - jump: accept
    - match: state
    - connstate: new
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True

httpd:
  nftables.append:
    - table: filter
    - family: ipv6
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True

httpd:
  nftables.insert:
    - position: 1
    - table: filter
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True
httpd:
  nftables.insert:
    - position: 1
    - table: filter
    - family: ipv6
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True

httpd:
  nftables.delete:
    - table: filter
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True

httpd:
  nftables.delete:
    - position: 1
    - table: filter
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True

httpd:
  nftables.delete:
    - table: filter
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True

salt.states.nftables.append(name, family='ipv4', **kwargs)

New in version 0.17.0.

Append a rule to a chain

name A user-defined name to call this rule by in another part of a state or formula. This should not be an
actual rule.

- **family** Network family, ipv4 or ipv6.
  All other arguments are passed in with the same name as the long option that would normally be used for
  nftables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).

**salt.states.nftables.chain_absent**

```python
(name, table='filter', family='ipv4')
```

New in version 2014.7.0.

Verify the chain is absent.

- **family** Networking family, either ipv4 or ipv6

**salt.states.nftables.chain_present**

```python
(name, table='filter', table_type=None, hook=None, priority=None, family='ipv4')
```

New in version 2014.7.0.

Verify the chain is exist.

- **name** A user-defined chain name.
- **table** The table to own the chain.
- **family** Networking family, either ipv4 or ipv6

**salt.states.nftables.delete**

```python
(name, family='ipv4', **kwargs)
```

New in version 2014.7.0.

Delete a rule to a chain

- **name** A user-defined name to call this rule by in another part of a state or formula. This should not be an
  actual rule.
- **family** Networking family, either ipv4 or ipv6
  All other arguments are passed in with the same name as the long option that would normally be used for
  nftables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).

**salt.states.nftables.flush**

```python
(name, family='ipv4', **kwargs)
```

New in version 2014.7.0.

Flush current nftables state

- **family** Networking family, either ipv4 or ipv6

**salt.states.nftables.insert**

```python
(name, family='ipv4', **kwargs)
```

New in version 2014.7.0.

Insert a rule into a chain

- **name** A user-defined name to call this rule by in another part of a state or formula. This should not be an
  actual rule.
- **family** Networking family, either ipv4 or ipv6
  All other arguments are passed in with the same name as the long option that would normally be used for
  nftables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).

### 19.19.167 salt.states.npm

**Installation of NPM Packages**

These states manage the installed packages for node.js using the Node Package Manager (npm). Note that npm
must be installed for these states to be available, so npm states should include a requisite to a pkg.installed state
for the package which provides npm (simply npm in most cases). Example:

```bash
npm:
    pkg.installed

yml:
```

### 19.19. state modules
salt.states.npm.bootstrap(name, user=None, silent=True)

Bootstraps a node.js application.

Will execute `npm install --json' on the specified directory.

user  The user to run NPM with

  New in version 0.17.0.

salt.states.npm.cache_cleaned(name=None, user=None, force=False)

Ensure that the given package is not cached.

If no package is specified, this ensures the entire cache is cleared.

name  The name of the package to remove from the cache, or None for all packages

user  The user to run NPM with

force  Force cleaning of cache. Required for npm@5 and greater

  New in version 2016.11.6.

salt.states.npm.installed(name, pkgs=None, dir=None, user=None, force_reinstall=False, registry=None, env=None)

Verify that the given package is installed and is at the correct version (if specified).

name  The package to install

  Changed in version 2014.7.2: This parameter is no longer lowercased by salt so that case-sensitive NPM package names will work.

pkgs  A list of packages to install with a single npm invocation; specifying this argument will ignore the name argument

  New in version 2014.7.0.

dir  The target directory in which to install the package, or None for global installation

user  The user to run NPM with

  New in version 0.17.0.

registry  The NPM registry from which to install the package

  New in version 2014.7.0.

e  A list of environment variables to be set prior to execution. The format is the same as the cmd.run. state function.

  New in version 2014.7.0.

force_reinstall  Install the package even if it is already installed

salt.states.npm.removed(name, dir=None, user=None)

Verify that the given package is not installed.

dir  The target directory in which to install the package, or None for global installation

user  The user to run NPM with

  New in version 0.17.0.
19.19.168 salt.states.ntp

Management of NTP servers

New in version 2014.1.0.

This state is used to manage NTP servers. Currently only Windows is supported.

```python
win_ntp:
    ntp.managed:
        - servers:
            - pool.ntp.org
            - us.pool.ntp.org
```

```python
classified
salt.states.ntp.managed(name, servers=None)
    Manage NTP servers
    servers A list of NTP servers
```

19.19.169 salt.states.nxos module

State module for Cisco NX OS Switches Proxy minions

For documentation on setting up the nxos proxy minion look in the documentation for salt.proxy.nxos.

```python
classified
salt.states.nxos.config_absent(name)
    Ensure a specific configuration line does not exist in the running config
    name config line to remove
Examples:
```

```python
add snmp group:
    nxos.config_absent:
        - names:
            - snmp-server community randoSNMPstringHERE group network-operator
            - snmp-server community AnotherRandomSNMPSTRing group network-admin
```

Note: For certain cases extra lines could be removed based on dependencies. In this example, included after the example for config_present, the ACLs would be removed because they depend on the existence of the group.

```python
salt.states.nxos.config_present(name)
    Ensure a specific configuration line exists in the running config
    name config line to set
Examples:
```

```python
add snmp group:
    nxos.config_present:
        - names:
            - snmp-server community randoSNMPstringHERE group network-operator
            - snmp-server community AnotherRandomSNMPSTRing group network-admin
```

```python
add snmp acl:
    nxos.config_present:
        - names:
            - snmp-server community randoSNMPstringHERE use-acl snmp-acl-ro
            - snmp-server community AnotherRandomSNMPSTRing use-acl snmp-acl-rw
```
salt.states.nxos.replace(name, repl, full_match=False)

Replace all instances of a string or full line in the running config

- name String to replace
- repl The replacement text
- full_match Whether name will match the full line or only a subset of the line. Defaults to False. When False, ".*" is added around name for matching in the show run config.

Examples:

replace snmp string:
    nxos.replace:
        - name: randoSNMPstringHERE
        - repl: NEWrandoSNMPstringHERE

replace full snmp string:
    nxos.replace:
        - name: ^snmp-server community randoSNMPstringHERE group network-operator$
        - repl: snmp-server community NEWrandoSNMPstringHERE group network-operator
        - full_match: True

Note: The first example will replace the SNMP string on both the group and the ACL, so you will not lose the ACL setting. Because the second is an exact match of the line, when the group is removed, the ACL is removed, but not readded, because it was not matched.

salt.states.nxos.user_absent(name)

Ensure a user is not present

- name username to remove if it exists

Examples:

delete:
    nxos.user_absent:
        - name: daniel

salt.states.nxos.user_present(name, password=None, roles=None, encrypted=False, crypt_salt=None, algorithm='sha256')

Ensure a user is present with the specified groups

- name Name of user
- password Encrypted or Plain Text password for user
- roles List of roles the user should be assigned. Any roles not in this list will be removed
- encrypted Whether the password is encrypted already or not. Defaults to False
- crypt_salt Salt to use when encrypting the password. Default is None (salt is randomly generated for unhashed passwords)
- algorithm Algorithm to use for hashing password. Defaults to sha256. Accepts md5, blowfish, sha256, sha512

Examples:

create:
    nxos.user_present:
        - name: daniel
        - roles:
            - vdc-admin

set_password:
    nxos.user_present:
        - name: daniel
        - password: admin
        - roles:
19.19.170  salt.states.openstack_config

Manage OpenStack configuration file settings.

   maintainer  Jeffrey C. Ollie <jeff@ocjtech.us>
   maturity   new
   depends
   platform   linux

salt.states.openstack_config.absent(name, filename, section, parameter=None)
Ensure a value is not set in an OpenStack configuration file.
filename The full path to the configuration file
section The section in which the parameter will be set
parameter (optional) The parameter to change. If the parameter is not supplied, the name will be used as
the parameter.

salt.states.openstack_config.present(name, filename, section, value, parameter=None)
Ensure a value is set in an OpenStack configuration file.
filename The full path to the configuration file
section The section in which the parameter will be set
parameter (optional) The parameter to change. If the parameter is not supplied, the name will be used as
the parameter.
value The value to set

19.19.171  salt.states.openvswitch_bridge module

Management of Open vSwitch bridges.

salt.states.openvswitch_bridge.absent(name)
Ensures that the named bridge does not exist, eventually deletes it.
   Parameters  name -- The name of the bridge.

salt.states.openvswitch_bridge.present(name)
Ensures that the named bridge exists, eventually creates it.
   Parameters  name -- The name of the bridge.

19.19.172  salt.states.openvswitch_port module

Management of Open vSwitch ports.

salt.states.openvswitch_port.absent(name, bridge=None)
Ensures that the named port exists on bridge, eventually deletes it. If bridge is not set, port is removed from
whatever bridge contains it.
Parameters

- **name** -- The name of the port.
- **bridge** -- The name of the bridge.

`salt.states.openvswitch_port.present(name, bridge, tunnel_type=None, id=None, remote=None, dst_port=None, internal=False)`

Ensures that the named port exists on bridge, eventually creates it.

Parameters

- **name** -- The name of the port.
- **bridge** -- The name of the bridge.
- **tunnel_type** -- Optional type of interface to create, currently supports: vlan, vxlan and gre.
- **id** -- Optional tunnel's key.
- **remote** -- Remote endpoint's IP address.
- **dst_port** -- Port to use when creating tunnelport in the switch.
- **internal** -- Create an internal port if one does not exist

### 19.19.173 salt.states.pagerduty

Create an Event in PagerDuty

New in version 2014.1.0.

This state is useful for creating events on the PagerDuty service during state runs.

```yaml
server-warning-message: pagerduty.create_event:
- name: 'This is a server warning message'
- details: 'This is a much more detailed message'
- service_key: 9abcd123456789efabcde362783cdbc
- profile: my-pagerduty-account
```

`salt.states.pagerduty.create_event(name, details, service_key, profile)`

Create an event on the PagerDuty service

```yaml
server-warning-message: pagerduty.create_event:
- name: 'This is a server warning message'
- details: 'This is a much more detailed message'
- service_key: 9abcd123456789efabcde362783cdbc
- profile: my-pagerduty-account
```

The following parameters are required:

- **name** This is a short description of the event.
- **details** This can be a more detailed description of the event.
- **service_key** This key can be found by using `pagerduty.list_services`.
- **profile** This refers to the configuration profile to use to connect to the PagerDuty service.

### 19.19.174 salt.states.pagerduty_escalation_policy

Manage PagerDuty escalation policies.

Schedules and users can be referenced by pagerduty ID, or by name, or by email address.

For example:
ensure test escalation policy:

```yaml
    pagerduty_escalation_policy.present:
        - name: bruce test escalation policy
        - escalation_rules:
            - targets:
                - type: schedule
                  id: 'bruce test schedule level1'
                - type: user
                  id: 'Bruce Sherrod'
                  escalation_delay_in_minutes: 15
            - targets:
                - type: schedule
                  id: 'bruce test schedule level2'
                  escalation_delay_in_minutes: 15
                - type: user
                  id: 'Bruce TestUser1'
                  id: 'Bruce TestUser2'
                  id: 'Bruce TestUser3'
                  id: 'bruce+test4@lyft.com'
                  escalation_delay_in_minutes: 15
```

salt.states.pagerduty_escalation_policy.absent(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure that a PagerDuty escalation policy does not exist. Accepts all the arguments that pagerduty_escalation_policy.present accepts; but ignores all arguments except the name.

Name can be the escalation policy id or the escalation policy name.

salt.states.pagerduty_escalation_policy.present(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure that a pagerduty escalation policy exists. Will create or update as needed.

This method accepts as args everything defined in https://developer.pagerduty.com/documentation/rest/escalation_policies/create. In addition, user and schedule id's will be translated from name (or email address) into PagerDuty unique ids. For example:

```yaml
    pagerduty_escalation_policy.present:
        • name: bruce test escalation policy
        • escalation_rules:
            • targets:
                * type: schedule id: `bruce test schedule level1`
                * type: user id: 'Bruce Sherrod'
```

In this example, 'Bruce Sherrod' will be looked up and replaced with the PagerDuty id (usually a 7 digit all-caps string, e.g. PX6GQL7)

19.19.175 salt.states.pagerduty_schedule

Manage PagerDuty schedules.

Example:
ensure test schedule:
  pagerduty_schedule.present:
    - name: 'bruce test schedule level1'
      schedule:
        name: 'bruce test schedule level1'
        time_zone: 'Pacific Time (US & Canada)'
        schedule_layers:
          - name: 'Schedule Layer 1'
            start: '2015-01-01T00:00:00'
            users:
              - user:
                  'id': 'Bruce TestUser1'
                  member_order: 1
              - user:
                  'id': 'Bruce TestUser2'
                  member_order: 2
              - user:
                  'id': 'bruce+test3@lyft.com'
                  member_order: 3
              - user:
                  'id': 'bruce+test4@lyft.com'
                  member_order: 4
          rotation_virtual_start: '2015-01-01T00:00:00'
          priority: 1
          rotation_turn_length_seconds: 604800

salt.states.pagerduty_schedule.absent(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure that a pagerduty schedule does not exist. Name can be pagerduty schedule id or pagerduty schedule name.

salt.states.pagerduty_schedule.present(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure that a pagerduty schedule exists. This method accepts as args everything defined in https://developer.pagerduty.com/documentation/rest/schedules/create. This means that most arguments are in a dict called `schedule`.

User id’s can be pagerduty id, or name, or email address.

19.19.176 salt.states.pagerduty_service

Manage PagerDuty services

Escalation policies can be referenced by pagerduty ID or by namea.

For example:

ensure test service
  pagerduty_service.present:
    - name: 'my service'
    - escalation_policy_id: 'my escalation policy'
    - type: nagios

salt.states.pagerduty_service.absent(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure a pagerduty service does not exist. Name can be the service name or pagerduty service id.
salt.states.pagerduty_service.present(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure pagerduty service exists. This method accepts as arguments everything defined in https://developer.pagerduty.com/documentation/rest/services/create

Note that many arguments are mutually exclusive, depending on the `type` argument.

Examples:

```yaml
# create a PagerDuty email service at test-email@DOMAIN.pagerduty.com
ensure generic email service exists:
pagerduty_service.present:
  - name: my email service
  - service:
      description: "email service controlled by salt"
      escalation_policy_id: "my escalation policy"
      type: "generic_email"
      service_key: "test-email"

# create a pagerduty service using cloudwatch integration
ensure my cloudwatch service exists:
pagerduty_service.present:
  - name: my cloudwatch service
  - service:
      escalation_policy_id: "my escalation policy"
      type: aws_cloudwatch
      description: "my cloudwatch service controlled by salt"
```

19.19.177 salt.states.pagerduty_user

Manage PagerDuty users.

Example

```yaml
ensure bruce test user 1:
pagerduty.user_present:
  • name: 'Bruce TestUser1'
  • email: bruce+test1@lyft.com
  • requester_id: P1GV5NT
```

salt.states.pagerduty_user.absent(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure pagerduty user does not exist. Name can be pagerduty id, email address, or user name.

salt.states.pagerduty_user.present(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

19.19.178 salt.states.pcs module

Management of Pacemaker/Corosync clusters with PCS

A state module to manage Pacemaker/Corosync clusters with the Pacemaker/Corosync configuration system (PCS)

New in version 2016.110.

depends pcs

Requirements: PCS is installed, pcs service is started and the password for the hacluster user is set and known.

Remark on the cibname variable used in the examples: The use of the cibname variable is optional. Use it only if you want to deploy your changes into a cibfile first and then push it. This makes only sense if you want to deploy multiple changes (which require each other) at once to the cluster.

At first the cibfile must be created:

```
mysql_pcs__cib_present_cib_for_galera:
  pcs.cib_present:
  - cibname: cib_for_galera
  - scope: None
  - extra_args: None
```

Then the cibfile can be modified by creating resources (creating only 1 resource for demonstration, see also 7.):

```
mysql_pcs__resource_present_galera:
  pcs.resource_present:
  - resource_id: galera
  - resource_type: "ocf:heartbeat:galera"
  - resource_options:
    - 'wsrep_cluster_address=gcomm://node1.example.org,node2.example.org,node3.example.org'
    - '--master'
  - cibname: cib_for_galera
```

After modifying the cibfile, it can be pushed to the live CIB in the cluster:

```
mysql_pcs__cib_pushed_cib_for_galera:
  pcs.cib_pushed:
  - cibname: cib_for_galera
  - scope: None
  - extra_args: None
```

Create a cluster from scratch:

1. Authorize nodes to each other:

```
pcs_auth__auth:
  pcs.auth:
  - nodes:
    - node1.example.com
    - node2.example.com
  - pcsuser: hacluster
  - pcspassword: hoonetorg
  - extra_args: []
```
2. Do the initial cluster setup:

```yaml
pcs_setup__setup:
  pcs.cluster_setup:
    - nodes:
      - node1.example.com
      - node2.example.com
    - pcsclusternname: pcscluster
    - extra_args:
      - '--start'
      - '--enable'
```

3. Optional: Set cluster properties:

```yaml
pcs_properties__prop_has_value_no-quorum-policy:
  pcs.prop_has_value:
    - prop: no-quorum-policy
    - value: ignore
    - cibname: cib_for_cluster_settings
```

4. Optional: Set resource defaults:

```yaml
pcs_properties__resource_defaults_to_resource-stickiness:
  pcs.resource_defaults_to:
    - default: resource-stickiness
    - value: 100
    - cibname: cib_for_cluster_settings
```

5. Optional: Set resource op defaults:

```yaml
pcs_properties__resource_op_defaults_to_monitor-interval:
  pcs.resource_op_defaults_to:
    - op_default: monitor-interval
    - value: 60s
    - cibname: cib_for_cluster_settings
```

6. Configure Fencing (is often not optional on production ready cluster!):

```yaml
pcs_stonith__created_eps_fence:
  pcs.stonith_present:
    - stonith_id: eps_fence
    - stonith_device_type: fence_eps
    - stonith_device_options:
      - 'pcmk_host_map=node1.example.org:01;node2.example.org:02'
      - 'ipaddr=myepsdevice.example.org'
      - 'power_wait=5'
      - 'verbose=1'
      - 'debug=/var/log/pcsd/eps_fence.log'
      - 'login=hidden'
      - 'passwd=hoonetorg'
    - cibname: cib_for_stonith
```

7. Add resources to your cluster:

```yaml
mysql_pcs__resource_present_galera:
  pcs.resource_present:
    - resource_id: galera
    - resource_type: "ocf:heartbeat:galera"
```
8. Optional: Add constraints (locations, colocations, orders):

```yaml
haproxy_pcs__constraint_present_colocation-vip_galera-haproxy-clone-INFINITY:
  pcs.constraint_present:
    - constraint_id: colocation-vip_galera-haproxy-clone-INFINITY
    - constraint_type: colocation
    - constraint_options:
      - 'add'
      - 'vip_galera'
      - 'with'
      - 'haproxy-clone'
  cibname: cib_for_haproxy
```

New in version 2016.3.0.

**salt.states.pcs.auth** *(name, nodes, pcsuser='hacluster', pcspasswd='hacluster', extra_args=None)*

Ensure all nodes are authorized to the cluster

- **name** Irrelevant, not used (recommended: pcs_auth__auth)
- **nodes** a list of nodes which should be authorized to the cluster
- **pcsuser** user for communication with pcs (default: hacluster)
- **pcspasswd** password for pcsuser (default: hacluster)
- **extra_args** list of extra args for the `pcs cluster auth` command

Example:

```yaml
pcs_auth__auth:
  pcs.auth:
    - nodes:
      - node1.example.com
      - node2.example.com
    - pcsuser: hacluster
    - pcspasswd: hoonetorg
    - extra_args: []
```

**salt.states.pcs.cib_present** *(name, cibname, scope=None, extra_args=None)*

Ensure that a CIB-file with the content of the current live CIB is created

Should be run on one cluster node only (there may be races)

- **name** Irrelevant, not used (recommended: {{formulaname}}__cib_present_{{cibname}})
- **cibname** name/path of the file containing the CIB
- **scope** specific section of the CIB (default: None)
- **extra_args** additional options for creating the CIB-file

Example:

```yaml
mysql_pcs__cib_present_cib_for_galera:
  pcs.cib_present:
    - cibname: cib_for_galera
    - scope: None
    - extra_args: None
```

**salt.states.pcs.cib_pushed** *(name, cibname, scope=None, extra_args=None)*

Ensure that a CIB-file is pushed if it is changed since the creation of it with pcs.cib_present
salt.states.pcs.cluster_node_present(name, node, extra_args=None)
Add a node to the Pacemaker cluster via PCS Should be run on one cluster node only (there may be races)
name Irrelevant, not used (recommended: pcs_setup__node_add_{{node}})
node node that should be added
extra_args list of extra args for the `pcs cluster node add' command
Example:

```
pcs_setup__node_add_node1.example.com:
  pcs.cluster_node_present:
    - node: node1.example.com
    - extra_args:
      - '--start'
      - '--enable'
```

salt.states.pcs.cluster_setup(name, nodes, pcsclustername='pcscluster', extra_args=None)
Setup Pacemaker cluster on nodes. Should be run on one cluster node only (there may be races)
nodes a list of nodes which should be set up
pcsclustername Name of the Pacemaker cluster
extra_args list of extra args for the `pcs cluster setup' command
Example:

```
pcs_setup__setup:
  pcs.cluster_setup:
    - nodes:
      - node1.example.com
      - node2.example.com
    - pcsclustername: pcscluster
    - extra_args:
      - '--start'
      - '--enable'
```
Example:

```
haproxy_pcs___constraint_present_colocation-vip_galera-haproxy-clone-INFINITY:
  pcs.constraint_present:
    - constraint_id: colocation-vip_galera-haproxy-clone-INFINITY
    - constraint_type: colocation
    - constraint_options:
      - 'add'
      - 'vip_galera'
      - 'with'
      - 'haproxy-clone'
    - cibname: cib_for_haproxy
```

**salt.states.pcs.prop_has_value**(*name, prop, value, extra_args=None, cibname=None*)

Ensure that a property in the cluster is set to a given value

Should be run on one cluster node only (there may be races)

- **name** Irrelevant, not used (recommended: pcs_properties__prop_has_value_{{prop}})
- **prop** name of the property
- **value** value of the property
- **extra_args** additional options for the pcs property command
- **cibname** use a cached CIB-file named like cibname instead of the live CIB

Example:

```
pcs_properties___prop_has_value_no-quorum-policy:
  pcs.prop_has_value:
    - prop: no-quorum-policy
    - value: ignore
    - cibname: cib_for_cluster_settings
```

**salt.states.pcs.resource_defaults_to**(*name, default, value, extra_args=None, cibname=None*)

Ensure a resource default in the cluster is set to a given value

Should be run on one cluster node only (there may be races) Can only be run on a node with a functional pacemaker/corosync

- **name** Irrelevant, not used (recommended: pcs_properties__resource_defaults_to_{{default}})
- **default** name of the default resource property
- **value** value of the default resource property
- **extra_args** additional options for the pcs command
- **cibname** use a cached CIB-file named like cibname instead of the live CIB

Example:

```
pcs_properties___resource_defaults_to_resource-stickiness:
  pcs.resource_defaults_to:
    - default: resource-stickiness
    - value: 100
    - cibname: cib_for_cluster_settings
```

**salt.states.pcs.resource_op_defaults_to**(*name, op_default, value, extra_args=None, cibname=None*)

Ensure a resource operation default in the cluster is set to a given value

Should be run on one cluster node only (there may be races) Can only be run on a node with a functional pacemaker/corosync

- **name** Irrelevant, not used (recommended: pcs_properties__resource_op_defaults_to_{{op_default}})
- **op_default** name of the operation default resource property
- **value** value of the operation default resource property
- **extra_args** additional options for the pcs command

Example:
**cibname** use a cached CIB-file named like cibname instead of the live CIB

Example:

```python
pcs_properties__resource_op_defaults_to_monitor-interval:
    pcs.resource_op_defaults_to:
        - op_default: monitor-interval
        - value: 60s
        - cibname: cib_for_cluster_settings
```

**salt.states.pcs.resource_present** *(name, resource_id, resource_type, resource_options=None, cibname=None)*

Ensure that a resource is created

Should be run on one cluster node only (there may be races) Can only be run on a node with a functional pacemaker/corosync

- **name** Irrelevant, not used (recommended: {{formulaname}}__resource_present_{{resource_id}})
- **resource_id** name for the resource
- **resource_type** resource type (f.e. ocf:heartbeat:IPaddr2 or VirtualIP)
- **resource_options** additional options for creating the resource
- **cibname** use a cached CIB-file named like cibname instead of the live CIB

Example:

```python
mysql_pcs__resource_present_galera:
    pcs.resource_present:
        - resource_id: galera
        - resource_type: "ocf:heartbeat:galera"
        - resource_options:
            - 'wsrep_cluster_address=gcomm://node1.example.org,node2.example.org,node3.example.org'
            - '--master'
        - cibname: cib_for_galera
```

**salt.states.pcs.stonith_present** *(name, stonith_id, stonith_device_type, stonith_device_options=None, cibname=None)*

Ensure that a fencing resource is created

Should be run on one cluster node only (there may be races) Can only be run on a node with a functional pacemaker/corosync

- **name** Irrelevant, not used (recommended: pcs_stonith__created_{{stonith_id}})
- **stonith_id** name for the stonith resource
- **stonith_device_type** name of the stonith agent fence_eps, fence_xvm f.e.
- **stonith_device_options** additional options for creating the stonith resource
- **cibname** use a cached CIB-file named like cibname instead of the live CIB

Example:

```python
pcs_stonith__created_eps_fence:
    pcs.stonith_present:
        - stonith_id: eps_fence
        - stonith_device_type: fence_eps
        - stonith_device_options:
            - 'pcmk_host_map=node1.example.org:01;node2.example.org:02'
            - 'ipaddr=myepsdevice.example.org'
            - 'power_wait=5'
            - 'verbose=1'
            - 'debug=/var/log/pcsd/eps_fence.log'
            - 'login=hidden'
            - 'passwd=hoonetorg'
        - cibname: cib_for_stonith
```
19.19.179 salt.states.pecl

Installation of PHP Extensions Using pecl

These states manage the installed pecl extensions. Note that php-pear must be installed for these states to be available, so pecl states should include a requisite to a pkg.installed state for the package which provides pecl (php-pear in most cases). Example:

```yaml
php-pear:
  pkg.installed
mongo:
  pecl.installed:
    - require:
      - pkg: php-pear
```

```python
salt.states.pecl.installed(name, version=None, defaults=False, force=False, preferred_state='stable')
```

New in version 0.17.0.

Make sure that a pecl extension is installed.

- **name** The pecl extension name to install
- **version** The pecl extension version to install. This option may be ignored to install the latest stable version.
- **defaults** Use default answers for extensions such as pecl_http which ask questions before installation. Without this option, the pecl.installed state will hang indefinitely when trying to install these extensions.
- **force** Whether to force the installed version or not
- **preferred_state** The pecl extension state to install

```python
class pdbedit:
    def __init__(self, name):
        self.name = name

    def managed(self):
        pdbedit.managed:
            password: A70C708517B5DD0EDB67714FE25336EB
            password_hashed: True
            drive: 'X:'
            homedir: '\\serenity\mechanic\profile'
```

```python
salt.states.pdbedit.absent(name)
```

Ensure user account is absent

19.19.180 salt.states.pdbedit

Manage accounts in Samba’s passdb using pdbedit

- **maintainer** Jorge Schrauwen <sjorge@blackdot.be>
- **maturity** new
- **depends** pdbedit
- **platform** posix

New in version 2017.7.0.
name [string] username

salt.states.pdbedit.managed(name, **kwargs)
  Manage user account
  login [string] login name
  password [string] password
  password_hashed [boolean] set if password is a nt hash instead of plain text
  domain [string] users domain
  profile [string] profile path
  script [string] logon script
  drive [string] home drive
  homedir [string] home directory
  fullname [string] full name
  account_desc [string] account description
  machine_sid [string] specify the machines new primary group SID or rid
  user_sid [string] specify the users new primary group SID or rid
  account_control [string] specify user account control properties

  **Note:** Only the following can be set: - N: No password required - D: Account disabled - H: Home directory required - L: Automatic Locking - X: Password does not expire

  reset_login_hours [boolean] reset the users allowed logon hours
  reset_bad_password_count [boolean] reset the stored bad login counter

salt.states.pdbedit.present(name, **kwargs)
  Alias for pdbedit.managed

19.19.181 salt.states.pip_state

Installation of Python Packages Using pip

These states manage system installed python packages. Note that pip must be installed for these states to be available, so pip states should include a requisite to a pkg.installed state for the package which provides pip (python-pip in most cases). Example:

```
pip-pip:
  pkg.installed

virtualenvwrapper:
  pip.installed:
    - require:
      - pkg: python-pip
```
salt.states.pip_state.installed(name, pkgs=None, pip_bin=None, requirements=None, bin_env=None, use_wheel=False, no_use_wheel=False, log=None, proxy=None, timeout=None, repo=None, editable=None, find_links=None, index_url=None, extra_index_url=None, no_index=False, mirrors=None, build=None, target=None, download=None, download_cache=None, source=None, upgrade=False, force_reinstall=False, ignore_installed=False, exists_action=None, no_deps=False, no_install=False, no_download=False, install_options=None, global_options=None, user=None, cwd=None, pre_releases=False, cert=None, allow_all_external=False, allow_unverified=None, process_dependency_links=False, env_vars=None, use_vt=False, trusted_host=None, no_cache_dir=False, cache_dir=None, no_binary=None, **kwargs)

Make sure the package is installed

**name** The name of the python package to install. You can also specify version numbers here using the standard operators ==, >=, <=. If requirements is given, this parameter will be ignored.

Example:

```
django:
  pip.installed:
    - name: django >= 1.6, <= 1.7
    - require:
      - pkg: python-pip
```

This will install the latest Django version greater than 1.6 but less than 1.7.

**requirements** Path to a pip requirements file. If the path begins with salt:// the file will be transferred from the master file server.

**user** The user under which to run pip

**use_wheel** [False] Prefer wheel archives (requires pip>=1.4)

**no_use_wheel** [False] Force to not use wheel archives (requires pip>=1.4)

**no_binary** Force to not use binary packages (requires pip >= 7.0.0) Accepts either :all: to disable all binary packages, :none: to empty the set, or a list of one or more packages

Example:

```
django:
  pip.installed:
    - no_binary: ':all:'

flask:
  pip.installed:
    - no_binary:
      - itsdangerous
      - click
```

**log** Log file where a complete (maximum verbosity) record will be kept

**proxy** Specify a proxy in the form user:passwd@proxy.server:port. Note that the user:password@ is optional and required only if you are behind an authenticated proxy. If you provide user@proxy.server:port then you will be prompted for a password.

**timeout** Set the socket timeout (default 15 seconds)

**editable** install something editable (i.e. git+https://github.com/worldcompany/djangoembed.git#egg=djangoembed)

**find_links** URL to look for packages at

**index_url** Base URL of Python Package Index

**extra_index_url** Extra URLs of package indexes to use in addition to index_url
no_index  Ignore package index
mirrors  Specific mirror URL(s) to query (automatically adds --use-mirrors)
build  Unpack packages into build dir
target  Install packages into target dir
download  Download packages into download instead of installing them
download_cache  Cache downloaded packages in download_cache dir
source  Check out editable packages into source dir
upgrade  Upgrade all packages to the newest available version
force_reinstall  When upgrading, reinstall all packages even if they are already up-to-date.
ignore_installed  Ignore the installed packages (reinstalling instead)
exists_action  Default action when a path already exists: (s)witch, (i)gnore, (w)ipe, (b)ackup
no_deps  Ignore package dependencies
no_install  Download and unpack all packages, but don't actually install them
no_cache_dir  Disable the cache.
cwd  Current working directory to run pip from
pre_releases  Include pre-releases in the available versions
cert  Provide a path to an alternate CA bundle
allow_all_external  Allow the installation of all externally hosted files
allow_external  Allow the installation of externally hosted files (comma separated list)
allow_unverified  Allow the installation of insecure and unverifiable files (comma separated list)
process_dependency_links  Enable the processing of dependency links
bin_env  [None] Absolute path to a virtual environment directory or absolute path to a pip executable. The example below assumes a virtual environment has been created at /foo/.virtualenvs/bar.
env_vars  Add or modify environment variables. Useful for tweaking build steps, such as specifying INCLUDE or LIBRARY paths in Makefiles, build scripts or compiler calls. This must be in the form of a dictionary or a mapping.

Example:

```yaml
django:
pip.installed:
    - name: django_app
    - env_vars:
        CUSTOM_PATH: /opt/django_app
        VERBOSE: True
```

use_vt  Use VT terminal emulation (see output while installing)
trusted_host  Mark this host as trusted, even though it does not have valid or any HTTPS.

Example:

```yaml
django:
pip.installed:
    - name: django >= 1.6, <= 1.7
    - bin_env: /foo/.virtualenvs/bar
    - require:
        - pkg: python-pip
```

Or

Example:

```yaml
django:
pip.installed:
    - name: django >= 1.6, <= 1.7
    - bin_env: /foo/.virtualenvs/bar/bin/pip
    - require:
        - pkg: python-pip
```
Attention

The following arguments are deprecated, do not use.

**pip_bin** [None] Deprecated, use `bin_env`

Changed in version 0.17.0: `use_wheel` option added.

**install_options**

Extra arguments to be supplied to the setup.py install command. If you are using an option with a directory path, be sure to use absolute path.

Example:

```yaml
django:
  pip.installed:
    - name: django
    - install_options:
      - --prefix=/blah
    - require:
      - pkg: python-pip
```

global_options

Extra global options to be supplied to the setup.py call before the install command.

New in version 2014.1.3.

Attention

As of Salt 0.17.0 the pip state needs an importable pip module. This usually means having the system's pip package installed or running Salt from an active virtualenv.

The reason for this requirement is because pip already does a pretty good job parsing its own requirements. It makes no sense for Salt to do pip requirements parsing and validation before passing them to the pip library. It's functionality duplication and it's more error prone.

Attention

Please set `reload_modules: True` to have the salt minion import this module after installation.

Example:

```yaml
pyopenssl:
  pip.installed:
    - name: pyOpenSSL
    - reload_modules: True
    - exists_action: i
```

salt.states.pip_state.removed(*name*, *requirements=None*, *bin_env=None*, *log=None*, *proxy=None*, *timeout=None*, *user=None*, *cwd=None*, *use_vt=False*)

Make sure that a package is not installed.

**name** The name of the package to uninstall

**user** The user under which to run pip

**bin_env** [None] the pip executable or virtualenv to use

**use_vt** Use VT terminal emulation (see output while installing)
salt.states.pip_state.uptodate(name, bin_env=None, user=None, cwd=None, use_vt=False)

New in version 2015.5.0.

Verify that the system is completely up to date.

- **name**  The name has no functional value and is only used as a tracking reference
- **user**  The user under which to run pip
- **bin_env**  the pip executable or virtualenv to use
- **use_vt**  Use VT terminal emulation (see output while installing)

### 19.19.182 salt.states.pkg

Installation of packages using OS package managers such as yum or apt-get

Note: On minions running systemd>=205, as of version 2015.8.12, 2016.3.3, and 2016.11.0, systemd-run(1) is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing the package manager commands spawned by Salt, when Salt updates itself (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.use_scope, with a value of False (no quotes).

Salt can manage software packages via the pkg state module, packages can be set up to be installed, latest, removed and purged. Package management declarations are typically rather simple:

```
vim:
  pkg.installed
```

A more involved example involves pulling from a custom repository.

```
base:
  pkgrepo.managed:
    - humanname: Logstash PPA
      - name: ppa:wolfnet/logstash
      - dist: precise
      - file: /etc/apt/sources.list.d/logstash.list
      - keyid: 28B04E4A
      - keyserver: keyserver.ubuntu.com

logstash:
  pkg.installed:
    - fromrepo: ppa:wolfnet/logstash
```

Multiple packages can also be installed with the use of the pkgs state module

```
dotdeb.repo:
  pkgrepo.managed:
    - humanname: Dotdeb
      - name: deb http://packages.dotdeb.org wheezy-php55 all
      - dist: wheezy-php55
      - file: /etc/apt/sources.list.d/dotdeb.list
      - keyid: 89DF5277
      - keyserver: keys.gnupg.net
      - refresh_db: true

php.packages:
  pkg.installed:
    - fromrepo: wheezy-php55
```

### 19.19. state modules
- pkgs:
  - php5-fpm
  - php5-cli
  - php5-curl

**Warning:** Package names are currently case-sensitive. If the minion is using a package manager which is not case-sensitive (such as `pkgng`), then this state will fail if the proper case is not used. This will be addressed in a future release of Salt.

```python
class pkg:
    def downloaded(self, name, version=None, pkgs=None, fromrepo=None, ignore_epoch=None, **kwargs):
        pass
```

New in version 2017.7.0.

Ensure that the package is downloaded, and that it is the correct version (if specified).

Currently supported for the following pkg providers: *yumpkg* and *zypper*

**Parameters**

- **name** *(str)* -- The name of the package to be downloaded. This parameter is ignored if either "pkgs" is used. Additionally, please note that this option can only be used to download packages from a software repository.
- **version** *(str)* -- Download a specific version of a package.

**Important:** As of version 2015.8.7, for distros which use yum/dnf, packages which have a version with a nonzero epoch (that is, versions which start with a number followed by a colon) must have the epoch included when specifying the version number. For example:

```python
vim-enhanced:
    pkg.downloaded:
        - version: 2:7.4.160-1.el7
```

An `ignore_epoch` argument has been added to which causes the epoch to be disregarded when the state checks to see if the desired version was installed.

You can install a specific version when using the `pkgs` argument by including the version after the package:

```python
common_packages:
    pkg.downloaded:
        - pkgs:
            - unzip
            - dos2unix
            - salt-minion: 2015.8.5-1.el6
```

**CLI Example:**

```bash
zsh:
    pkg.downloaded:
        - version: 5.0.5-4.63
        - fromrepo: "myrepository"
```

```python
class pkg:
    def group_installed(self, name, skip=None, include=None, **kwargs):
        pass
```

New in version 2015.8.0.

Changed in version 2016.11.0: Added support in *pacman*
Ensure that an entire package group is installed. This state is currently only supported for the `yum` and `pacman` package managers.

**skip** Packages that would normally be installed by the package group (``default'' packages), which should not be installed.

```python
Load Balancer:
pkg.group_installed:
- skip:
  - piranha
```

**include** Packages which are included in a group, which would not normally be installed by a `yum` groupinstall (``optional'' packages). Note that this will not enforce group membership; if you include packages which are not members of the specified groups, they will still be installed.

```python
Load Balancer:
pkg.group_installed:
- include:
  - haproxy
```

Changed in version 2016.3.0: This option can no longer be passed as a comma-separated list, it must now be passed as a list (as shown in the above example).

---

**Note:** Because this is essentially a wrapper around `pkg.install`, any argument which can be passed to `pkg.install` may also be included here, and it will be passed on to the call to `pkg.install`.

```python
salt.states.pkg.installed(name, version=None, refresh=None, fromrepo=None, skip_verify=False, skip_suggestions=False, pkgs=None, sources=None, allow_updates=False, pkg_verify=False, normalize=True, ignore_epoch=False, reinstall=False, update_holds=False, **kwargs)
```

Ensure that the package is installed, and that it is the correct version (if specified).

**param str name** The name of the package to be installed. This parameter is ignored if either ``pkgs'' or ``sources'' is used. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the ``sources'' option detailed below.

**param str version** Install a specific version of a package. This option is ignored if ``sources'' is used. Currently, this option is supported for the following pkg providers: `apt`, `ebuild`, `pacman`, `win_pkg`, `yumpkg`, and `zypper`. The version number includes the release designation where applicable, to allow Salt to target a specific release of a given version. When in doubt, using the `pkg.latest_version` function for an uninstalled package will tell you the version available.

```python
# salt myminion pkg.latest_version vim-enhanced
myminion:
  2:7.4.160-1.el7
```

**Important:** As of version 2015.8.7, for distros which use yum/dnf, packages which have a version with a nonzero epoch (that is, versions which start with a number followed by a colon like in the `pkg.latest_version` output above) must have the epoch included when specifying the version number. For example:

```python
vim-enhanced:
pkg.installed:
  - version: 2:7.4.160-1.el7
```
In version 2015.8.9, an `ignore_epoch` argument has been added to `pkg.installed, pkg.removed,` and `pkg.purged` states, which causes the epoch to be disregarded when the state checks to see if the desired version was installed.

Also, while this function is not yet implemented for all pkg frontends, `pkg.list_repo_pkgs` will show all versions available in the various repositories for a given package, irrespective of whether or not it is installed.

```
# salt myminion pkg.list_repo_pkgs bash
myminion: #
---------
bash:
   - 4.2.46-21.el7_3
   - 4.2.46-20.el7_2
```

This function was first added for `pkg.list_repo_pkgs` in 2014.1.0, and was expanded to Debian/Ubuntu and Arch Linux-based distros in the 2017.7.0 release.

The version strings returned by either of these functions can be used as version specifiers in pkg states.

You can install a specific version when using the `pkgs` argument by including the version after the package:

```
common_packages:
  pkg.installed:
    - pkgs:
      - unzip
      - dos2unix
      - salt-minion: 2015.8.5-1.el6
```

If the version given is the string `latest`, the latest available package version will be installed à la `pkg.latest`.

**WILDCARD VERSIONS**

As of the 2017.7.0 release, this state now supports wildcards in package versions for SUSE SLES/Leap/Tumbleweed, Debian/Ubuntu, RHEL/CentOS, Arch Linux, and their derivatives. Using wildcards can be useful for packages where the release name is built into the version in some way, such as for RHEL/CentOS which typically has version numbers like `1.2.34-5.el7`. An example of the usage for this would be:

```
mypkg:
  pkg.installed:
    - version: '1.2.34*'
```

Keep in mind that using wildcard versions will result in a slower state run since Salt must gather the available versions of the specified packages and figure out which of them match the specified wildcard expression.

**param bool refresh**  
This parameter controls whether or not the package repo database is updated prior to installing the requested package(s).

If True, the package database will be refreshed (`apt-get update` or equivalent, depending on platform) before installing.
If `False`, the package database will not be refreshed before installing.

If unset, then Salt treats package database refreshes differently depending on whether or not a `pkg` state has been executed already during the current Salt run. Once a refresh has been performed in a `pkg` state, for the remainder of that Salt run no other refreshes will be performed for `pkg` states which do not explicitly set `refresh` to `True`. This prevents needless additional refreshes from slowing down the Salt run.

**param str cache_valid_time**  New in version 2016.11.0.

This parameter sets the value in seconds after which the cache is marked as invalid, and a cache update is necessary. This overwrites the `refresh` parameter's default behavior.

Example:

```
httpd:
  pkg.installed:
    - fromrepo: mycustomrepo
    - skip_verify: True
    - skip_suggestions: True
    - version: 2.0.6-ubuntu3
    - refresh: True
    - cache_valid_time: 300
    - allow_updates: True
    - hold: False
```

In this case, a refresh will not take place for 5 minutes since the last `apt-get update` was executed on the system.

**Note:** This parameter is available only on Debian based distributions and has no effect on the rest.

**param str fromrepo**  Specify a repository from which to install

**Note:** Distros which use APT (Debian, Ubuntu, etc.) do not have a concept of repositories, in the same way as YUM-based distros do. When a source is added, it is assigned to a given release. Consider the following source configuration:

```
deb http://ppa.launchpad.net/saltstack/salt/ubuntu precise
   main
```

The packages provided by this source would be made available via the precise release, therefore `fromrepo` would need to be set to `precise` for Salt to install the package from this source.

Having multiple sources in the same release may result in the default install candidate being newer than what is desired. If this is the case, the desired version must be specified using the `version` parameter.

If the `pkgs` parameter is being used to install multiple packages in the same state, then instead of using `version`, use the method of version specification described in the Multiple Package Installation Options section below.

Running the shell command `apt-cache policy pkgname` on a minion can help elucidate the APT configuration and aid in properly configuring states:
root@saltmaster:~# salt ubuntu01 cmd.run 'apt-cache policyffmpeg'

ubuntu01:
  ffmpeg:
    Installed: (none)
    Candidate: 7:0.10.11-1-precise1
    Version table:
    7:0.10.11-1-precise1 0
    500 http://ppa.launchpad.net/jon-severinsson/ffmpeg/ubuntu/ precise/main amd64 Packages
  → ffmpeg/ubuntu/ precise/main amd64 Packages
  4:0.8.10-0ubuntu0.12.04.1 0
    500 http://us.archive.ubuntu.com/ubuntu/
    → precise-updates/main amd64 Packages
    500 http://security.ubuntu.com/ubuntu/ precise-security/main amd64 Packages
  4:0.8.1-0ubuntu1 0
    500 http://us.archive.ubuntu.com/ubuntu/
    → precise/main amd64 Packages

The release is located directly after the source's URL. The actual release name is the part before the slash, so to install version `4:0.8.10-0ubuntu0.12.04.1` either `precise-updates` or `precise-security` could be used for the `fromrepo` value.

**param bool skip_verify** Skip the GPG verification check for the package to be installed

**param bool skip_suggestions** Force strict package naming. Disables lookup of package alternatives.

New in version 2014.1.1.

**param bool allow_updates** Allow the package to be updated outside Salt's control (e.g. auto updates on Windows). This means a package on the Minion can have a newer version than the latest available in the repository without enforcing a re-installation of the package.

New in version 2014.7.0.

Example:

```python
httpd:
  pkg.installed:
    - fromrepo: mycustomrepo
    - skip_verify: True
    - skip_suggestions: True
    - version: 2.0.6~ubuntu3
    - refresh: True
    - allow_updates: True
    - hold: False
```

**param bool pkg_verify** New in version 2014.7.0.

For requested packages that are already installed and would not be targeted for upgrade or downgrade, use `pkg.verify` to determine if any of the files installed by the package have been altered. If files have been altered, the reinstall option of `pkg.install` is used to force a reinstall. Types to ignore can be passed to `pkg.verify`. Additionally, `verify_options` can be used to modify further the behavior of `pkg.verify`. See examples below. Currently, this option is supported for the following pkg providers: `yumpkg`. 
Examples:

```yaml
httpd:
  pkg.installed:
    - version: 2.2.15-30.el6.centos
    - pkg_verify: True

mypkgs:
  pkg.installed:
    - pkgs:
      - foo
      - bar: 1.2.3-4
      - baz
    - pkg_verify:
      - ignore_types:
        - config
        - doc

mypkgs:
  pkg.installed:
    - pkgs:
      - foo
      - bar: 1.2.3-4
      - baz
    - pkg_verify:
      - ignore_types:
        - config
        - doc
      - verify_options:
        - nodeps
        - nofiledigest
```

**param list ignore_types** List of types to ignore when verifying the package

New in version 2014.7.0.

**param list verify_options** List of additional options to pass when verifying the package. These options will be added to the `rpm -V` command, prepended with `--` (for example, when `nodeps` is passed in this option, `rpm -V` will be run with `--nodeps`).

New in version 2016.11.0.

**param bool normalize** Normalize the package name by removing the architecture, if the architecture of the package is different from the architecture of the operating system. The ability to disable this behavior is useful for poorly-created packages which include the architecture as an actual part of the name, such as kernel modules which match a specific kernel version.

New in version 2014.7.0.

Example:

```yaml
gpfs.gplbin-2.6.32-279.31.1.el6.x86_64:
  pkg.installed:
    - normalize: False
```

**param bool ignore_epoch** When a package version contains a non-zero epoch (e.g. `1:3.14.159-2.el7`), and a specific version of a package is desired, set this option to `True` to ignore the epoch when comparing versions. This allows for the following SLS to be used:
Without this option set to True in the above example, the package would be installed, but the state would report as failed because the actual installed version would be 2:7.4.160-1.el7. Alternatively, this option can be left as False and the full version string (with epoch) can be specified in the SLS file:

```
vim-enhanced:
  pkg.installed:
    - version: 2:7.4.160-1.el7
```

New in version 2015.8.9.

**MULTIPLE PACKAGE INSTALLATION OPTIONS:** (not supported in pkgng)

**param list pkgs** A list of packages to install from a software repository. All packages listed under pkgs will be installed via a single command.

```
mpkgs:
  pkg.installed:
    - pkgs:
        - foo
        - bar
        - baz
        - hold: True
```

**NOTE:** For **apt**, **ebuild**, **pacman**, **winrepo**, **yumpkg**, and **zypper**, version numbers can be specified in the pkgs argument. For example:

```
mpkgs:
  pkg.installed:
    - pkgs:
        - foo
        - bar: 1.2.3-4
        - baz
```

Additionally, **ebuild**, **pacman** and **zypper** support the `<`, `<=`, `>=`, and `>` operators for more control over what versions will be installed. For example:

```
mpkgs:
  pkg.installed:
    - pkgs:
        - foo
        - bar: '>=1.2.3-4'
        - baz
```

**NOTE:** When using comparison operators, the expression must be enclosed in quotes to avoid a YAML render error.
With **ebuild** is also possible to specify a use flag list and/or if the given packages should be in package.accept_keywords file and/or the overlay from which you want the package to be installed. For example:

```
mypkgs:
  pkg.installed:
    - pkgs:
      - foo: '~'
      - bar: '>=1.2:slot::overlay[use,-otheruse]'
    - baz
```

**param list sources** A list of packages to install, along with the source URI or local path from which to install each package. In the example below, foo, bar, baz, etc. refer to the name of the package, as it would appear in the output of the pkg.version or pkg.list_pkgs salt CLI commands.

```
mypkgs:
  pkg.installed:
    - sources:
      - foo: salt://rpms/foo.rpm
      - bar: http://somesite.org/bar.rpm
      - baz: ftp://someothersite.org/baz.rpm
      - qux: /minion/path/to/qux.rpm
```

### PLATFORM-SPECIFIC ARGUMENTS

These are specific to each OS. If it does not apply to the execution module for your OS, it is ignored.

**param bool hold** Force the package to be held at the current installed version. Currently works with YUM/DNF & APT based systems.

New in version 2014.7.0.

**param bool update_holds** If True, and this function would update the package version, any packages which are being held will be temporarily unheld so that they can be updated. Otherwise, if this function attempts to update a held package, the held package(s) will be skipped and the state will fail. By default, this parameter is set to False.

Currently works with YUM/DNF & APT based systems.

New in version 2016.11.0.

**param list names** A list of packages to install from a software repository. Each package will be installed individually by the package manager.

**Warning:** Unlike pkgs, the names parameter cannot specify a version. In addition, it makes a separate call to the package management frontend to install each package, whereas pkgs makes just a single call. It is therefore recommended to use pkgs instead of names to install multiple packages, both for the additional features and the performance improvement that it brings.

**param bool install_recommend** Whether to install the packages marked as recommended. Default is True. Currently only works with APT-based systems.

New in version 2015.5.0.

```
httpd:
  pkg.installed:
```
- install_recommends: False

param bool only_upgrade  Only upgrade the packages, if they are already installed. Default is False. Currently only works with APT-based systems.

New in version 2015.5.0.

httpd:
  pkg.installed:
    - only_upgrade: True

Note: If this parameter is set to True and the package is not already installed, the state will fail.

Parameters report_reboot_exit_codes (bool) --
If the installer exits with a recognized exit code indicating that a reboot is required, the module function

\[\text{win\_system\_set\_reboot\_required\_witnessed}\]

will be called, preserving the knowledge of this event for the remainder of the current boot session. For the time being, 3010 is the only recognized exit code, but this is subject to future refinement. The value of this param defaults to True. This parameter has no effect on non-Windows systems.

New in version 2016.11.0.

ms vcpp installed:
  pkg.installed:
    - name: ms-vcpp
    - version: 10.0.40219
    - report_reboot_exit_codes: False

return A dictionary containing the state of the software installation
rtype dict

Note: The pkg.installed state supports the usage of reload_modules. This functionality allows you to force Salt to reload all modules. In many cases, Salt is clever enough to transparently reload the modules. For example, if you install a package, Salt reloads modules because some other module or state might require the package which was installed. However, there are some edge cases where this may not be the case, which is what reload_modules is meant to resolve.

You should only use reload_modules if your pkg.installed does some sort of installation where if you do not reload the modules future items in your state which rely on the software being installed will fail. Please see the \textit{Reloading Modules} documentation for more information.

\textbf{salt.states.pkg.latest} (name, refresh=None, fromrepo=None, skip_verify=False, pkgs=None, watch_flags=True, **kwargs)

Ensure that the named package is installed and the latest available package. If the package can be updated, this state function will update the package. Generally it is better for the \textit{installed} function to be used, as \textit{latest} will update the package whenever a new package is available.

\textbf{name} The name of the package to maintain at the latest available version. This parameter is ignored if "pkgs" is used.

\textbf{fromrepo} Specify a repository from which to install
skip_verify  Skip the GPG verification check for the package to be installed

refresh  This parameter controls whether or not the package repo database is updated prior to checking for the latest available version of the requested packages.

If True, the package database will be refreshed (apt-get update or equivalent, depending on platform) before checking for the latest available version of the requested packages.

If False, the package database will not be refreshed before checking.

If unset, then Salt treats package database refreshes differently depending on whether or not a pkg state has been executed already during the current Salt run. Once a refresh has been performed in a pkg state, for the remainder of that Salt run no other refreshes will be performed for pkg states which do not explicitly set refresh to True. This prevents needless additional refreshes from slowing down the Salt run.

param str cache_valid_time  New in version 2016.11.0.

This parameter sets the value in seconds after which the cache is marked as invalid, and a cache update is necessary. This overwrites the refresh parameter’s default behavior.

Example:

```yaml
httpd:
  pkg.latest:
    - refresh: True
    - cache_valid_time: 300
```

In this case, a refresh will not take place for 5 minutes since the last apt-get update was executed on the system.

Note: This parameter is available only on Debian based distributions and has no effect on the rest.

Multiple Package Installation Options:

(Not yet supported for: FreeBSD, OpenBSD, MacOS, and Solaris pkgutil)

pkgs  A list of packages to maintain at the latest available version.

```yaml
mypkgs:
  pkg.latest:
    - pkgs:
      - foo
      - bar
      - baz
```

install_recommends  Whether to install the packages marked as recommended. Default is True.

Currently only works with APT-based systems.

New in version 2015.5.0.

```yaml
httpd:
  pkg.latest:
    - install_recommends: False
```

only_upgrade  Only upgrade the packages, if they are already installed. Default is False. Currently only works with APT-based systems.
New in version 2015.5.0.

```yaml
httpd:
  pkg.latest:
    - only_upgrade: True
```

**Note:** If this parameter is set to True and the package is not already installed, the state will fail.

The installer exits with a recognized exit code indicating that a reboot is required, the module function

```
win_system.set_reboot_required
```

will be called, preserving the knowledge of this event for the remainder of the current boot session. For the time being, 3010 is the only recognized exit code, but this is subject to future refinement. The value of this param defaults to True. This parameter has no effect on non-Windows systems.

New in version 2016.11.0.

```yaml
ms vcpp installed:
  pkg.latest:
    - name: ms-vcpp
    - report_reboot_exit_codes: False
```

salt.states.pkg.mod_aggregate(low, chunks, running)

The mod_aggregate function which looks up all packages in the available low chunks and merges them into a single pkgs ref in the present low data

salt.states.pkg.mod_watch(name, **kwargs)

Install/reinstall a package based on a watch requisite

**Note:** This state exists to support special handling of the watch requisite. It should not be called directly. Parameters for this function should be set by the state being triggered.

salt.states.pkg.patch_downloaded(name, advisory_ids=None, **kwargs)

New in version 2017.7.0.

Ensure that packages related to certain advisory ids are downloaded.

Currently supported for the following pkg providers: `yumpkg` and `zypper`

CLI Example:

```yaml
preparing-to-fix-issues:
  pkg.patch_downloaded:
    - advisory_ids:
      - SUSE-SLE-SERVER-12-SP2-2017-185
      - SUSE-SLE-SERVER-12-SP2-2017-150
      - SUSE-SLE-SERVER-12-SP2-2017-120
```

salt.states.pkg.patch_installed(name, advisory_ids=None, downloadonly=None, **kwargs)

New in version 2017.7.0.

Ensure that packages related to certain advisory ids are installed.

Currently supported for the following pkg providers: `yumpkg` and `zypper`

CLI Example:
salt.states.pkg.purged(name, version=None, pkgs=None, normalize=True, ignore_epoch=False, **kwargs)

Verify that a package is not installed, calling pkg.purge if necessary to purge the package. All configuration files are also removed.

name The name of the package to be purged.
version The version of the package that should be removed. Don’t do anything if the package is installed with an unmatching version.

Important: As of version 2015.8.7, for distros which use yum/dnf, packages which have a version with a nonzero epoch (that is, versions which start with a number followed by a colon like in the example above) must have the epoch included when specifying the version number. For example:

```
vim-enhanced:
pkg.purged:
  - version: 2:7.4.160-1.el7
```

In version 2015.8.9, an ignore_epoch argument has been added to pkg.installed, pkg.removed, and pkg.purged states, which causes the epoch to be disregarded when the state checks to see if the desired version was installed. If ignore_epoch was not set to True, and instead of 2:7.4.160-1.el7 a version of 7.4.160-1.el7 were used, this state would report success since the actual installed version includes the epoch, and the specified version would not match.

normalize [True] Normalize the package name by removing the architecture, if the architecture of the package is different from the architecture of the operating system. The ability to disable this behavior is useful for poorly-created packages which include the architecture as an actual part of the name, such as kernel modules which match a specific kernel version.

New in version 2015.8.0.

ignore_epoch [False] When a package version contains a non-zero epoch (e.g. 1:3.14.159-2.el7, and a specific version of a package is desired, set this option to True to ignore the epoch when comparing versions. This allows for the following SLS to be used:

```
# Actual vim-enhanced version: 2:7.4.160-1.el7
vim-enhanced:
pkg.purged:
  - version: 7.4.160-1.el7
  - ignore_epoch: True
```

Without this option set to True in the above example, the state would falsely report success since the actual installed version is 2:7.4.160-1.el7. Alternatively, this option can be left as False and the full version string (with epoch) can be specified in the SLS file:

```
vim-enhanced:
pkg.purged:
  - version: 2:7.4.160-1.el7
```

New in version 2015.8.9.

Multiple Package Options:
pkgs A list of packages to purge. Must be passed as a python list. The name parameter will be ignored if this option is passed. It accepts version numbers as well.
New in version 0.16.0.

salt.states.pkg.removed(name=None, version=None, pkgs=None, normalize=True, ignore_epoch=False, **kwargs)

Verify that a package is not installed, calling pkg.remove if necessary to remove the package.
name The name of the package to be removed.
version The version of the package that should be removed. Don’t do anything if the package is installed with an unmatching version.

**Important:** As of version 2015.8.7, for distros which use yum/dnf, packages which have a version with a nonzero epoch (that is, versions which start with a number followed by a colon like in the example above) must have the epoch included when specifying the version number. For example:

```
vim-enhanced:
  pkg.removed:
    - version: 2:7.4.160-1.el7
```

In version 2015.8.9, an ignore_epoch argument has been added to pkg.installed, pkg.removed, and pkg.purged states, which causes the epoch to be disregarded when the state checks to see if the desired version was installed. If ignore_epoch was not set to True, and instead of 2:7.4.160-1.el7 a version of 7.4.160-1.el7 were used, this state would report success since the actual installed version includes the epoch, and the specified version would not match.

normalize [True] Normalize the package name by removing the architecture, if the architecture of the package is different from the architecture of the operating system. The ability to disable this behavior is useful for poorly-created packages which include the architecture as an actual part of the name, such as kernel modules which match a specific kernel version.

New in version 2015.8.0.

ignore_epoch [False] When a package version contains an non-zero epoch (e.g. 1:3.14.159-2.el7, and a specific version of a package is desired, set this option to True to ignore the epoch when comparing versions. This allows for the following SLS to be used:

```
# Actual vim-enhanced version: 2:7.4.160-1.el7
vim-enhanced:
  pkg.removed:
    - version: 7.4.160-1.el7
    - ignore_epoch: True
```

Without this option set to True in the above example, the state would falsely report success since the actual installed version is 2:7.4.160-1.el7. Alternatively, this option can be left as False and the full version string (with epoch) can be specified in the SLS file:

```
vim-enhanced:
  pkg.removed:
    - version: 2:7.4.160-1.el7
```

New in version 2015.8.9.

Multiple Package Options:

pkgs A list of packages to remove. Must be passed as a python list. The name parameter will be ignored if this option is passed. It accepts version numbers as well.

New in version 0.16.0.
salt.states.pkg.uptodate(name, refresh=False, pkgs=None, **kwargs)

New in version 2014.7.0.

Verify that the system is completely up to date.

name  The name has no functional value and is only used as a tracking reference
refresh  refresh the package database before checking for new upgrades
pkgs  list of packages to upgrade

Parameters  cache_valid_time (str) -- This parameter sets the value in seconds after which
            cache marked as invalid, and cache update is necessary. This overwrite refresh param-
            eter default behavior.

            In this case cache_valid_time is set, refresh will not take place for amount in seconds since
            last apt-get update executed on the system.

            Note:  This parameter available only on Debian based distributions, and have no effect on
            the rest.

kwargs  Any keyword arguments to pass through to pkg.upgrade.

New in version 2015.5.0.

19.19.183 salt.states.pkgbuild

The pkgbuild state is the front of Salt package building backend. It automatically builds DEB and RPM packages
from specified sources

New in version 2015.8.0.

salt_2015.5.2:
    pkgbuild.built:
    - runas: thatch
    - results:
      - salt-2015.5.2-2.el7.centos.noarch.rpm
      - salt-api-2015.5.2-2.el7.centos.noarch.rpm
      - salt-cloud-2015.5.2-2.el7.centos.noarch.rpm
      - salt-master-2015.5.2-2.el7.centos.noarch.rpm
      - salt-minion-2015.5.2-2.el7.centos.noarch.rpm
      - salt-ssh-2015.5.2-2.el7.centos.noarch.rpm
      - salt-syndic-2015.5.2-2.el7.centos.noarch.rpm
    - dest_dir: /tmp/pkg
    - spec: salt://pkg/salt/spec/salt.spec
    - template: jinja
    - deps:
      - salt://pkg/salt/sources/required_dependency.rpm
    - tgt: epel-7-x86_64
    - sources:
      - salt://pkg/salt/sources/logrotate.salt
      - salt://pkg/salt/sources/README.fedora
      - salt://pkg/salt/sources/salt-2015.5.2.tar.gz

      - salt://pkg/salt/sources/salt-minion
      - salt://pkg/salt/sources/salt-minion.service
salt STATES

- salt://pkg/salt/sources/saltpkg.sls
- salt://pkg/salt/sources/salt-syndic
- salt://pkg/salt/sources/salt-syndic.service
- salt://pkg/salt/sources/SaltTesting-2015.5.8.tar.gz

/tmp/pkg:
pkgbuild.repo

salt.states.pkgbuild.built

(name, runas, dest_dir, spec, sources, tgt, template=None,
deps=None, env=None, results=None, force=False, saltenv='base',
log_dir='/var/log/salt/pkgbuild')

Ensure that the named package is built and exists in the named directory

name The name to track the build, the name value is otherwise unused
runas The user to run the build process as
dest_dir The directory on the minion to place the built package(s)
spec The location of the spec file (used for rpms)
sources The list of package sources
tgt The target platform to run the build on
template Run the spec file through a templating engine

Changed in version 2015.8.2: This argument is now optional, allowing for no templating engine to be used if none is desired.
deps Packages required to ensure that the named package is built can be hosted on either the salt master server or on an HTTP or FTP server. Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials

env A dictionary of environment variables to be set prior to execution. Example:

- env:
  DEB_BUILD_OPTIONS: 'nocheck'

Warning: The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

results The names of the expected rpms that will be built
force [False] If True, packages will be built even if they already exist in the dest_dir. This is useful when building a package for continuous or nightly package builds.

New in version 2015.8.2.
saltenv The saltenv to use for files downloaded from the salt filesever
log_dir [/var/log/salt/rpmbuild] Root directory for log files created from the build. Logs will be organized by package name, version, OS release, and CPU architecture under this directory.

New in version 2015.8.2.

salt.staates.pkgbuild.repo

(name, keyid=None, env=None, use_passphrase=False,
gnupghome='/etc/salt/gpgkeys', runas='builder', timeout=15.0)

Make a package repository and optionally sign it and packages present

The name is directory to turn into a repo. This state is best used with onchanges linked to your package building states.

name The directory to find packages that will be in the repository
keyid Changed in version 2016.3.0.

Optional Key ID to use in signing packages and repository. Utilizes Public and Private keys associated with keyid which have been loaded into the minion’s Pillar data.

For example, contents from a Pillar data file with named Public and Private keys as follows:
gpg_pkg_priv_key: |
-----BEGIN PGP PRIVATE KEY BLOCK-----
Version: GnuPG v1

lQO+BFCiIfQBCADAPCtzx7I5Rl32escCMZsPzaEKeW7bIX1em4KCKkBoX47IG54b
w82PCE8V1jF/9Uk2m3RKWhp3YcLcl7Ap3gj6V04ysvVz28UbnhPxsIk0lf2c08qc
 .
 .
Ebe+8JQCTwq5XPRTzXmy/b5WXDeM79CKwvVpXFor76D+ECMRPv/awukEcNptn
R50mgHqvdEn04pWbn8JzQ09YX/Us83MHBVzLC8ei5Z1opzalvX
=JvW8
-----END PGP PRIVATE KEY BLOCK-----

gpg_pkg_priv_keyname: gpg_pkg_key.pem

gpg_pkg_pub_key: |

inNqW9c= 
=s1CX
-----END PGP PUBLIC KEY BLOCK-----

gpg_pkg_pub_keyname: gpg_pkg_key.pub

env
Changed in version 2016.3.0.

A dictionary of environment variables to be utilized in creating the repository. Example:

```
- env:
  OPTIONS: 'ask-passphrase'
```

**Warning:** The above illustrates a common PyYAML pitfall, that `yes`, `no`, `on`, `off`, `true`, and `false` are all loaded as boolean `True` and `False` values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Use of OPTIONS on some platforms, for example: `ask-passphrase`, will require gpg-agent or similar to cache passphrases.

**Note:** This parameter is not used for making yum repositories.

**use_passphrase** [False] New in version 2016.3.0.

Use a passphrase with the signing key presented in keyid. Passphrase is received from Pillar data which could be passed on the command line with `pillar` parameter. For example:

```
pillar='{ "gpg_passphrase" : "my_passphrase" }'
```

**gnupghome** [/etc/salt/gpgkeys] New in version 2016.3.0.

Location where GPG related files are stored, used with `keyid`
runas  [builder] New in version 2016.3.0.
User to create the repository as, and optionally sign packages.

**Note:** Ensure the user has correct permissions to any files and directories which are to be utilized.

timeout  [15.0] New in version 2016.3.4.
Timeout in seconds to wait for the prompt for inputting the passphrase.

## 19.19.184 salt.states.pkgng

**Manage package remote repo using FreeBSD pkgng**

Salt can manage the URL pkgng pulls packages from. ATM the state and module are small so use cases are typically rather simple:

```
pkgng_clients:
  pkgng.update_packaging_site:
    - name: "http://192.168.0.2"
```

```
salt.states.pkgng.update_packaging_site(name)
```

## 19.19.185 salt.states.pkgrepo

**Management of APT/DNF/YUM/Zypper package repos**

States for managing software package repositories on Linux distros. Supported package managers are APT, DNF, YUM and Zypper. Here is some example SLS:

```
base:
  pkgrepo.managed:
    - humanname: CentOS-$releasever - Base
    - mirrorlist: http://mirrorlist.centos.org/?release=$releasever&arch=$basearch&
      repo=os
      comments: [http://mirror.centos.org/centos/$releasever/os/$basearch/]
    - gpgcheck: 1
    - gpgkey: file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-6

base:
  pkgrepo.managed:
    - humanname: Logstash PPA
    - name: deb http://ppa.launchpad.net/wolfnet/logstash/ubuntu precise main
    - dist: precise
    - file: /etc/apt/sources.list.d/logstash.list
    - keyid: 28B04E4A
    - keyserver: keyserver.ubuntu.com
    - require_in:
      - pkg: logstash

pkg.latest:
  - name: logstash
  - refresh: True
```
base:
  pkgrepo.managed:
    - humanname: deb-multimedia
    - name: deb http://www.deb-multimedia.org stable main
    - file: /etc/apt/sources.list.d/deb-multimedia.list
    - key_url: salt://deb-multimedia/files/marillat.pub

base:
  pkgrepo.managed:
    - humanname: Google Chrome
    - name: deb http://dl.google.com/linux/chrome/deb/ stable main
    - dist: stable
    - file: /etc/apt/sources.list.d/chrome-browser.list
    - require_in:
      - pkg: google-chrome-stable
    - gpgcheck: 1
    - key_url: https://dl-ssl.google.com/linux/linux_signing_key.pub

base:
  pkgrepo.managed:
    - ppa: wolfnet/logstash
  pkg.latest:
    - name: logstash
    - refresh: True

---

**Note:** On Ubuntu systems, the `python-software-properties` package should be installed for better support of PPA repositories. To check if this package is installed, run `dpkg -l python-software-properties`. Also, some Ubuntu releases have a bug in their `python-software-properties` package, a missing dependency on pycurl, so `python-pycurl` will need to be manually installed if it is not present once `python-software-properties` is installed.

On Ubuntu & Debian systems, the `python-apt` package is required to be installed. To check if this package is installed, run `dpkg -l python-software-properties`. `python-apt` will need to be manually installed if it is not present.

```
salt.states.pkgrepo.absent(name, **kwargs)
```

This function deletes the specified repo on the system, if it exists. It is essentially a wrapper around `pkg.del_repo`.

**name** The name of the package repo, as it would be referred to when running the regular package manager commands.

**UBUNTU-SPECIFIC OPTIONS**

**ppa** On Ubuntu, you can take advantage of Personal Package Archives on Launchpad simply by specifying the user and archive name.

```yaml
logstash-ppa:
  pkgrepo.absent:
    - ppa: wolfnet/logstash
```

**ppa_auth** For Ubuntu PPAs there can be private PPAs that require authentication to access. For these PPAs the username/password can be specified. This is required for matching if the name format uses the `ppa:` specifier and is private (requires username/password to access, which is encoded in the URI).

```yaml
logstash-ppa:
  pkgrepo.absent:
```

---

19.19. **state modules**
- ppa: wolfnet/logstash
- ppa_auth: username:password

keyid If passed, then the GPG key corresponding to the passed KeyID will also be removed.
keyid_ppa [False] If set to True, the GPG key's ID will be looked up from ppa.launchpad.net and removed, and the keyid argument will be ignored.

Note: This option will be disregarded unless the ppa argument is present.

salt.states.pkgrepo.managed(name, ppa=None, **kwargs)
This state manages software package repositories. Currently, yum, apt, and zypper repositories are supported.

YUM/DNF/ZYPPER-BASED SYSTEMS

Note: One of baseurl or mirrorlist below is required. Additionally, note that this state is not presently capable of managing more than one repo in a single repo file, so each instance of this state will manage a single repo file containing the configuration for a single repo.

name This value will be used in two ways: Firstly, it will be the repo ID, as seen in the entry in square brackets (e.g. [foo]) for a given repo. Secondly, it will be the name of the file as stored in /etc/yum.repos.d (e.g. /etc/yum.repos.d/foo.conf).

enabled [True] Whether or not the repo is enabled. Can be specified as True/False or 1/0.
disabled [False] Included to reduce confusion due to APT's use of the disabled argument. If this is passed for a YUM/DNF/Zypper-based distro, then the reverse will be passed as enabled. For example passing disabled=True will assume enabled=False.

humanname This is used as the `name` value in the repo file in /etc/yum.repos.d/ (or /etc/zypp/repos.d for SUSE distros).

baseurl The URL to a yum repository

mirrorlist A URL which points to a file containing a collection of baseurls

comments Sometimes you want to supply additional information, but not as enabled configuration. Anything supplied for this list will be saved in the repo configuration with a comment marker (#) in front.

gpgautoimport Only valid for Zypper package manager. If set to True, automatically trust and import public GPG key for the repository. The key should be specified with gpgkey parameter. See details below.

Additional configuration values seen in YUM/DNF/Zypper repo files, such as gpgkey or gpgcheck, will be used directly as key-value pairs. For example:

```
foo:
pkgrepo.managed:
  - humanname: Personal repo for foo
  - baseurl: https://mydomain.tld/repo/foo/$releasever/$basearch
  - gpgkey: file:///etc/pki/rpm-gpg/foo-signing-key
  - gpgcheck: 1
```

APT-BASED SYSTEMS

ppa On Ubuntu, you can take advantage of Personal Package Archives on Launchpad simply by specifying the user and archive name. The keyid will be queried from launchpad and everything else is set automatically. You can override any of the below settings by simply setting them as you would normally. For example:

```
logstash-ppa:
pkgrepo.managed:
  - ppa: wolfnet/logstash
```
**ppa_auth** For Ubuntu PPAs there can be private PPAs that require authentication to access. For these PPAs the username/password can be passed as an HTTP Basic style username/password combination.

```
logstash-ppa:
  pkgrepo.managed:
    - ppa: wolfnet/logstash
    - ppa_auth: username:password
```

**name** On apt-based systems this must be the complete entry as it would be seen in the sources.list file. This can have a limited subset of components (i.e. `main`) which can be added/modified with the `comps` option.

```
precise-repo:
  pkgrepo.managed:
    - name: deb http://us.archive.ubuntu.com/ubuntu precise main
```

**Note:** The above example is intended as a more readable way of configuring the SLS, it is equivalent to the following:

```
'deb http://us.archive.ubuntu.com/ubuntu precise main':
  pkgrepo.managed
```

disabled [False] Toggles whether or not the repo is used for resolving dependencies and/or installing packages.

**enabled** [True] Included to reduce confusion due to YUM/DNF/Zypper's use of the `enabled` argument. If this is passed for an APT-based distro, then the reverse will be passed as `disabled`. For example, passing `enabled=False` will assume `disabled=False`.

**architectures** On apt-based systems, architectures can restrict the available architectures that the repository provides (e.g. only amd64). architectures should be a comma-separated list.

**comps** On apt-based systems, comps dictate the types of packages to be installed from the repository (e.g. main, nonfree,...). For purposes of this, comps should be a comma-separated list.

**file** The filename for the .list that the repository is configured in. It is important to include the full-path AND make sure it is in a directory that APT will look in when handling packages

**dist** This dictates the release of the distro the packages should be built for. (e.g. unstable). This option is rarely needed.

**keyid** The KeyID of the GPG key to install. This option also requires the `keyserver` option to be set.

**keyserver** This is the name of the keyserver to retrieve gpg keys from. The keyid option must also be set for this option to work.

**key_url** URL to retrieve a GPG key from. Allows the usage of `http://`, `https://` as well as `salt://`.

**Note:** Use either `keyid/keyserver` or `key_url`, but not both.

**consolidate** If set to true, this will consolidate all sources definitions to the sources.list file, cleanup the now unused files, consolidate components (e.g. main) for the same URI, type, and architecture to a single line, and finally remove comments from the sources.list file. The consolidate will run every time the state is processed. The option only needs to be set on one repo managed by salt to take effect.

**clean_file** If set to true, empty file before config repo, dangerous if use multiple sources in one file.

New in version 2015.8.0.

**refresh_db** If set to false this will skip refreshing the apt package database on debian based systems.

**require_in** Set this to a list of pkg.installed or pkg.latest to trigger the running of apt-get update prior to attempting to install these packages. Setting a require in the pkg will not work for this.
19.19.186  salt.states.portage_config

Management of Portage package configuration on Gentoo

A state module to manage Portage configuration on Gentoo

```
salt:
    portage_config.flags:
        - use:
            - openssl
```

salt.states.portage_config.flags(name, use=None, accept_keywords=None, env=None, license=None, properties=None, unmask=False, mask=False)

Enforce the given flags on the given package or DEPEND atom.

**Warning:** In most cases, the affected package(s) need to be rebuilt in order to apply the changes.

- **name**: The name of the package or its DEPEND atom
- **use**: A list of USE flags
- **accept_keywords**: A list of keywords to accept. ~ARCH means current host arch, and will be translated into a line without keywords
- **env**: A list of environment files
- **license**: A list of accepted licenses
- **properties**: A list of additional properties
- **unmask**: A boolean to unmask the package
- **mask**: A boolean to mask the package

19.19.187  salt.states.ports

Manage software from FreeBSD ports

New in version 2014.1.0.

**Note:** It may be helpful to use a higher timeout when running a `ports.installed` state, since compiling the port may exceed Salt's timeout.

```
salt -t 1200 '*' state.highstate
```

salt.states.ports.installed(name, options=None)

Verify that the desired port is installed, and that it was compiled with the desired options.

- **options**: Make sure that the desired non-default options are set

**Warning:** Any build options not passed here assume the default values for the port, and are not just differences from the existing cached options from a previous `make config`.

Example usage:

```
security/nmap:
    ports.installed:
        - options:
            - IPV6: off
```
19.19.188 salt.states.postgres_cluster module

Management of PostgreSQL clusters

The postgres_cluster state module is used to manage PostgreSQL clusters. Clusters can be set as either absent or present.

```yaml
create cluster 9.3 main:
  postgres_cluster.present:
    - name: 'main'
    - version: '9.3'
```

salt.states.postgres_cluster.absent(version, name)

Ensure that the named cluster is absent

- **version**: Version of the postgresql server of the cluster to remove
- **name**: The name of the cluster to remove

New in version 2015.XX.

salt.states.postgres_cluster.present(version, name, port=None, encoding=None, locale=None, datadir=None)

Ensure that the named cluster is present with the specified properties. For more information about all of these options see man pg_createcluster(1)

- **version**: Version of the postgresql cluster
- **name**: The name of the cluster
- **port**: Cluster port
- **encoding**: The character encoding scheme to be used in this database
- **locale**: Locale with which to create cluster
- **datadir**: Where the cluster is stored

New in version 2015.XX.

19.19.189 salt.states.postgres_database

Management of PostgreSQL databases

The postgres_database module is used to create and manage Postgres databases. Databases can be set as either absent or present.

```yaml
frank:
  postgres_database.present
```

salt.states.postgres_database.absent(name, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named database is absent

- **name**: The name of the database to remove
- **db_user**: database username if different from config or default
- **db_password**: user password if any password for a specified user
- **db_host**: Database host if different from config or default
- **db_port**: Database port if different from config or default
- **user**: System user all operations should be performed on behalf of

New in version 0.17.0.
salt.states.postgres_database.present(name,  
tablespace=None,  
encoding=None,  
lc_collate=None,  
lc_ctype=None,  
owner=None,  
owner_recurse=False,  
template=None,  
user=None,  
maintenance_db=None,  
db_password=None,  
db_host=None,  
db_port=None,  
db_user=None)

Ensure that the named database is present with the specified properties. For more information about all of  
these options see man createdb(1)

**name** The name of the database to manage

**tablespace** Default tablespace for the database

**encoding** The character encoding scheme to be used in this database

**lc_collate** The LC_COLLATE setting to be used in this database

**lc_ctype** The LC_CTYPE setting to be used in this database

**owner** The username of the database owner

**owner_recurse** Recurse owner change to all relations in the database

**template** The template database from which to build this database

**user** System user all operations should be performed on behalf of

**db_user** database username if different from config or default

**db_password** user password if any password for a specified user

**db_host** Database host if different from config or default

**db_port** Database port if different from config or default

New in version 0.17.0.

19.19.190 salt.states.postgres_extension

Management of PostgreSQL extensions

A module used to install and manage PostgreSQL extensions.

```
adminpack:
    postgres_extension.present
```

New in version 2014.7.0.

salt.states.postgres_extension.absent(name,  
if_exists=None,  
restrict=None,  
cascade=None,  
user=None,  
maintenance_db=None,  
db_user=None,  
db_password=None,  
db_host=None,  
db_port=None)

Ensure that the named extension is absent.

**name** Extension name of the extension to remove

**if_exists** Add if exist slug

**restrict** Add restrict slug

**cascade** Drop on cascade

**user** System user all operations should be performed on behalf of

**maintenance_db** Database to act on

**db_user** Database username if different from config or default

**db_password** User password if any password for a specified user

**db_host** Database host if different from config or default

**db_port** Database port if different from config or default

salt.states.postgres_extension.present(name,  
if_not_exists=None,  
schema=None,  
ex_version=None,  
from_version=None,  
user=None,  
maintenance_db=None,  
db_user=None,  
db_password=None,  
db_host=None,  
db_port=None)

Ensure that the named extension is present.
Note: Before you can use the state to load an extension into a database, the extension’s supporting files must be already installed.

For more information about all of these options see CREATE EXTENSION SQL command reference in the PostgreSQL documentation.

- **name**: The name of the extension to be installed
- **if_not_exists**: Add an IF NOT EXISTS parameter to the DDL statement
- **schema**: Schema to install the extension into
- **ext_version**: Version to install
- **from_version**: Old extension version if already installed
- **user**: System user all operations should be performed on behalf of
- **maintenance_db**: Database to act on
- **db_user**: Database username if different from config or default
- **db_password**: User password if any password for a specified user
- **db_host**: Database host if different from config or default
- **db_port**: Database port if different from config or default

19.19.191 salt.states.postgres_group

Management of PostgreSQL groups (roles)

The postgres_group module is used to create and manage Postgres groups.

```python
frank:
    postgres_group.present
```

```
salt.states.postgres_group.absent(name, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)
```

Ensure that the named group is absent

- **name**: The groupname of the group to remove
- **user**: System user all operations should be performed on behalf of

New in version 0.17.0.

- **db_user**: database username if different from config or default
- **db_password**: user password if any password for a specified user
- **db_host**: Database host if different from config or default
- **db_port**: Database port if different from config or default

```
salt.states.postgres_group.present(name, createdb=None, createroles=None, createuser=None, encrypted=None, superuser=None, inherit=None, login=None, replication=None, password=None, refresh_password=None, groups=None, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)
```

Ensure that the named group is present with the specified privileges Please note that the user/group notion in postgresql is just abstract, we have roles, where users can be seen as roles with the LOGIN privilege and groups the others.

- **name**: The name of the group to manage
- **createdb**: Is the group allowed to create databases?
- **createroles**: Is the group allowed to create other roles/users
- **createuser**: Alias to create roles, and history problem, in pgsql normally createuser == superuser
- **encrypted**: Should the password be encrypted in the system catalog?
login Should the group have login perm
inherit Should the group inherit permissions
superuser Should the new group be a `superuser`
replication Should the new group be allowed to initiate streaming replication
password The group’s password It can be either a plain string or a md5 postgresql hashed password:

```
'md5{MD5OF({password}{role})}'
```

If encrypted is None or True, the password will be automatically encrypted to the previous format if it is not already done.
refresh_password Password refresh flag

 Boolean attribute to specify whether to password comparison check should be performed.

 If refresh_password is True, the password will be automatically updated without extra password change check.

 This behaviour makes it possible to execute in environments without superuser access available, e.g. Amazon RDS for PostgreSQL
groups A string of comma separated groups the group should be in
user System user all operations should be performed on behalf of

New in version 0.17.0.
db_user database username if different from config or default
db_password user password if any password for a specified user
db_host Database host if different from config or default
db_port Database port if different from config or default

19.19.192 salt.states.postgres_initdb

Initialization of PostgreSQL data directory

The postgres_initdb module is used to initialize the postgresql data directory.

New in version 2016.3.0.

```
pgsqldata-dir:
postgres_initdb.present:
  - name: /var/lib/pgsql/data
  - auth: password
  - user: postgres
  - password: strong_password
  - encoding: UTF8
  - locale: C
  - runas: postgres
```

salt.states.postgres_initdb.present(name, user=None, password=None, auth='password', encoding='UTF8', locale=None, runas=None)

Initialize the PostgreSQL data directory

 name The name of the directory to initialize
 user The database superuser name
 password The password to set for the postgres user
 auth The default authentication method for local connections
 encoding The default encoding for new databases
 locale The default locale for new databases
 runas The system user the operation should be performed on behalf of
19.19.193 salt.states.postgres_language

Management of PostgreSQL languages

The postgres_language module is used to create and manage Postgres languages. Languages can be set as either absent or present.

New in version 2016.3.0.

```
plpgsql:
  postgres_language.present:
    - maintenance_db: testdb

plpgsql:
  postgres_language.absent:
    - maintenance_db: testdb
```

salt.states.postgres_language.absent(name, maintenance_db, user=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that a named language is absent in the specified database.

- name The name of the language to remove
- maintenance_db The name of the database in which the language is to be installed
- user System user all operations should be performed on behalf of
- db_user database username if different from config or default
- db_password user password if any password for a specified user
- db_host Database host if different from config or default
- db_port Database port if different from config or default

salt.states.postgres_language.present(name, maintenance_db, user=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that a named language is present in the specified database.

- name The name of the language to install
- maintenance_db The name of the database in which the language is to be installed
- user System user all operations should be performed on behalf of
- db_user database username if different from config or default
- db_password user password if any password for a specified user
- db_host Database host if different from config or default
- db_port Database port if different from config or default

19.19.194 salt.states.postgres_privileges

Management of PostgreSQL Privileges

The postgres_privileges module is used to manage Postgres privileges. Privileges can be set as either absent or present.

Privileges can be set on the following database object types:

- database
- schema
- tablespace
- table
• sequence
• language
• group

Setting the grant option is supported as well.

New in version 2016.3.0.

baruwa:

```
postgres_privileges.present:
  - object_name: awl
  - object_type: table
  - privileges:
    - SELECT
    - INSERT
    - DELETE
    - grant_option: False
    - prepend: public
    - maintenance_db: testdb
```

andrew:

```
postgres_privileges.present:
  - object_name: admins
  - object_type: group
  - grant_option: False
  - maintenance_db: testdb
```

baruwa:

```
postgres_privileges.absent:
  - object_name: awl
  - object_type: table
  - privileges:
    - SELECT
    - INSERT
    - DELETE
    - prepend: public
    - maintenance_db: testdb
```

andrew:

```
postgres_privileges.absent:
  - object_name: admins
  - object_type: group
  - maintenance_db: testdb
```

```
salt.states.postgres_privileges.absent(name, object_name, object_type, privileges=None, prepend='public', maintenance_db=None, user=None, db_password=None, db_host=None, db_port=None, db_user=None)
```

Revoke the requested privilege(s) on the specificed object(s)

**name** Name of the role whose privileges should be revoked

**object_name** Name of the object on which the revoke is to be performed

**object_type** The object type, which can be one of the following:
  • table
  • sequence
  • schema
  • tablespace
• language
• database
• group
• function

privileges Comma separated list of privileges to revoke, from the list below:
• INSERT
• CREATE
• TRUNCATE
• CONNECT
• TRIGGER
• SELECT
• USAGE
• TEMPORARY
• UPDATE
• EXECUTE
• REFERENCES
• DELETE
• ALL

note privileges should not be set when revoking group membership

prepend Table and Sequence object types live under a schema so this should be provided if the object is not
under the default public schema

maintenance_db The name of the database in which the language is to be installed

user System user all operations should be performed on behalf of

db_user database username if different from config or default

db_password user password if any password for a specified user

db_host Database host if different from config or default

salt.states.postgres_privileges.present(name, object_name, object_type, privileges=None,
grant_option=None, prepend='public', maintenance_db=None, user=None, db_password=None,
db_host=None, db_port=None, db_user=None)

Grant the requested privilege(s) on the specified object to a role

name Name of the role to which privileges should be granted

object_name Name of the object on which the grant is to be performed. ‘ALL’ may be used for objects of
type ‘table’ or ‘sequence’.

object_type The object type, which can be one of the following:
• table
• sequence
• schema
• tablespace
• language
• database
• group
• function

privileges List of privileges to grant, from the list below:
• INSERT
• CREATE
• TRUNCATE
• CONNECT
• TRIGGER
• SELECT
• USAGE
• TEMPORARY

19.19. state modules 3021
note privileges should not be set when granting group membership
grant_option If grant_option is set to True, the recipient of the privilege can in turn grant it to others
prepend Table and Sequence object types live under a schema so this should be provided if the object is not
under the default public schema
maintenance_db The name of the database in which the language is to be installed
user System user all operations should be performed on behalf of
db_user database username if different from config or default
db_password user password if any password for a specified user
db_host Database host if different from config or default
db_port Database port if different from config or default

19.19.195 salt.states.postgres_schema

Management of PostgreSQL schemas

The postgres_schemas module is used to create and manage Postgres schemas.

```python
public:
    postgres_schema.present 'dbname' 'name'
```

salt.states.postgres_schema.absent(dbname, name, db_user=None, db_password=None, db_host=None, db_port=None)

Ensure that the named schema is absent.

dbname The database's name will work on
name The name of the schema to remove
db_user database username if different from config or default
db_password user password if any password for a specified user
db_host Database host if different from config or default
db_port Database port if different from config or default

salt.states.postgres_schema.present(dbname, name, owner=None, db_user=None, db_password=None, db_host=None, db_port=None)

Ensure that the named schema is present in the database.

dbname The database's name will work on
name The name of the schema to manage
owner The database user that will be the owner of the schema
db_user database username if different from config or default
db_password user password if any password for a specified user
db_host Database host if different from config or default
db_port Database port if different from config or default

19.19.196 salt.states.postgres_tablespace

Management of PostgreSQL tablespace

A module used to create and manage PostgreSQL tablespaces.
ssd-tablespace:

postgres_tablespace.present:
- name: indexes
- directory: /mnt/ssd-data

New in version 2015.8.0.

salt.states.postgres_tablespace.absent(name, user=None, maintenance_db=None, db_user=None, db_password=None, db_host=None, db_port=None)

Ensure that the named tablespace is absent.

name The name of the tablespace to remove
user System user all operations should be performed on behalf of
maintenance_db Database to act on
db_user Database username if different from config or default
db_password User password if any password for a specified user
db_host Database host if different from config or default
db_port Database port if different from config or default

salt.states.postgres_tablespace.present(name, directory, options=None, owner=None, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named tablespace is present with the specified properties. For more information about all of these options run man 7 create_tablespace.

name The name of the tablespace to create/manage.
directory The directory where the tablespace will be located, must already exist
options A dictionary of options to specify for the tablespace. Currently, the only tablespace options supported are seq_page_cost and random_page_cost. Default values are shown in the example below:

my_space:
  postgres_tablespace.present:
    - directory: /srv/my_tablespace
    - options:
      seq_page_cost: 1.0
      random_page_cost: 4.0

owner The database user that will be the owner of the tablespace. Defaults to the user executing the command (i.e. the user option)
user System user all operations should be performed on behalf of
maintenance_db Database to act on
db_user Database username if different from config or default
db_password User password if any password for a specified user
db_host Database host if different from config or default
db_port Database port if different from config or default

19.19.197 salt.states.postgres_user

Management of PostgreSQL users (roles)

The postgres_users module is used to create and manage Postgres users.

frank:
  postgres_user.present
salt.states.postgres_user.absent(name, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named user is absent

name The username of the user to remove
user System user all operations should be performed on behalf of

New in version 0.17.0.

db_user database username if different from config or default
db_password user password if any password for a specified user
db_host Database host if different from config or default
db_port Database port if different from config or default

salt.states.postgres_user.present(name, createdb=None, createroles=None, createuser=None, encrypted=None, superuser=None, replication=None, inherit=None, login=None, password=None, default_password=None, refresh_password=None, groups=None, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named user is present with the specified privileges Please note that the user/group notion in postgresql is just abstract, we have roles, where users can be seen as roles with the LOGIN privilege and groups the others.

name The name of the system user to manage.
createdb Is the user allowed to create databases?
createroles Is the user allowed to create other users?
createuser Alias to create roles
encrypted Should the password be encrypted in the system catalog?
login Should the group have login perm
inherit Should the group inherit permissions
superuser Should the new user be a "superuser"
replication Should the new user be allowed to initiate streaming replication
password The system user's password. It can be either a plain string or a md5 postgresql hashed password:

```
'md5({password}{role})'
```

If encrypted is None or True, the password will be automatically encrypted to the previous format if it is not already done.

default_password The password used only when creating the user, unless password is set.

New in version 2016.3.0.
refresh_password Password refresh flag

Boolean attribute to specify whether to password comparison check should be performed.

If refresh_password is True, the password will be automatically updated without extra password change check.

This behaviour makes it possible to execute in environments without superuser access available, e.g. Amazon RDS for PostgreSQL

groups A string of comma separated groups the user should be in
user System user all operations should be performed on behalf of

New in version 0.17.0.

db_user Postgres database username, if different from config or default.
db_password Postgres user's password, if any password, for a specified db_user.
db_host Postgres database host, if different from config or default.
db_port Postgres database port, if different from config or default.
19.19.198 salt.states.powerpath

Powerpath configuration support

Allows configuration of EMC Powerpath. Currently only addition/deletion of licenses is supported.

```
key:
  powerpath.license_present: []
```

`salt.states.powerpath.license_absent(name)`

Ensures that the specified PowerPath license key is absent on the host.

- `name` - The license key to ensure is absent

`salt.states.powerpath.license_present(name)`

Ensures that the specified PowerPath license key is present on the host.

- `name` - The license key to ensure is present

19.19.199 salt.states.probes

Network Probes

Configure RPM (JunOS)/SLA (Cisco) probes on the device via NAPALM proxy.

- `codeauthor` Mircea Ulinic <mircea@cloudflare.com> & Jerome Fleury <jf@cloudflare.com>
- `maturity` new
- `depends` napalm
- `platform` unix

Dependencies

- `napalm probes management module`

`salt.states.probes.managed(name, probes, defaults=none)`

Ensure the networks device is configured as specified in the state SLS file. Probes not specified will be removed, while probes not configured as expected will trigger config updates.

Parameters

- `probes` -- Defines the probes as expected to be configured on the device. In order to ease the configuration and avoid repeating the same parameters for each probe, the next parameter (defaults) can be used, providing common characteristics.
- `defaults` -- Specifies common parameters for the probes.

SLS Example:

```
rpmprobes:
  probes.managed:
    - probes:
      probe1_name1:
        probe1_test1:
          source: 192.168.0.2
          target: 192.168.0.1
        probe1_test2:
          target: 172.17.17.1
        probe1_test3:
          target: 8.8.8.8
```
In the probes configuration, the only mandatory attribute is target (specified either in probes configuration, either in the defaults dictionary). All the other parameters will use the operating system defaults, if not provided:

- **source** - Specifies the source IP Address to be used during the tests. If not specified will use the IP Address of the logical interface loopback0.
- **target** - Destination IP Address.
- **probe_count** - Total number of probes per test (1..15). System defaults: 1 on both JunOS & Cisco.
- **test_interval** - Delay between tests (0..86400 seconds). System defaults: 3 on JunOS, 5 on Cisco.
- **probe_type** - Probe request type. Available options:
  - `icmp-ping`
  - `tcp-ping`
  - `udp-ping`

Using the example configuration above, after running the state, on the device will be configured 4 probes, with the following properties:

```yaml
probe_name1:
  probe1_test1:
    source: 192.168.0.2
    target: 192.168.0.1
    probe_count: 15
    test_interval: 3
    probe_type: icmp-ping
  probe1_test2:
    target: 172.17.17.1
    probe_count: 15
    test_interval: 3
    probe_type: icmp-ping
  probe1_test3:
    target: 8.8.8.8
    probe_count: 15
    test_interval: 3
    probe_type: http-ping

probe_name2:
  probe2_test1:
    target: 10.10.10.10
    probe_count: 15
    test_interval: 3
    probe_type: icmp-ping
```

19.19.200 *salt.states.process*

**Process Management**

Ensure a process matching a given pattern is absent.
salt.states.process.absent(name, user=None, signal=None)

Ensures that the named command is not running.

- **name**  The pattern to match.
- **user**  The user to which the process belongs
- **signal**  Signal to send to the process(es).

### 19.19.201 salt.states.proxy module

Allows you to manage proxy settings on minions

Setup proxy settings on minions

```
192.168.1.4:
    proxy.managed:
      - port: 3128
      - bypass_domains:
        - localhost
        - 127.0.0.1
```

salt.states.proxy.managed(name, port, services=None, user=None, password=None, bypass_domains=None, network_service='Ethernet')

Manages proxy settings for this minion

- **name**  The proxy server to use
- **port**  The port used by the proxy server
- **services**  A list of the services that should use the given proxy settings, valid services include http, https and ftp. If no service is given all of the valid services will be used.
- **user**  The username to use for the proxy server if required
- **password**  The password to use for the proxy server if required
- **bypass_domains**  An array of the domains that should bypass the proxy
- **network_service**  The network service to apply the changes to, this only necessary on macOS

### 19.19.202 salt.states.pushover

Send a message to PushOver

This state is useful for sending messages to PushOver during state runs.

New in version 2015.5.0.

```
pushover-message:
  pushover.post_message:
    - user: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
    - token: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
    - title: Salt Returner
    - device: phone
    - priority: -1
    - expire: 3600
    - retry: 5
    - message: 'This state was executed successfully.'
```
The api key can be specified in the master or minion configuration like below: .. code-block:: yaml

pushover: token: peWtBiMOS9HrZG15peWtBiMOS9HrZG15

salt.states.pushover.post_message(name, user=None, device=None, message=None, title=None, priority=None, expire=None, retry=None, sound=None, api_version=1, token=None)

Send a message to a PushOver channel.

```
pushover-message:
pusher.post_message:
  - user: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  - token: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  - title: Salt Returner
  - device: phone
  - priority: -1
  - expire: 3600
  - retry: 5
```

The following parameters are required:

- **name**: The unique name for this event.
- **user**: The user or group of users to send the message to. Must be ID of user, not name or email address.
- **message**: The message that is to be sent to the PushOver channel.

The following parameters are optional:

- **title**: The title to use for the message.
- **device**: The device for the user to send the message to.
- **priority**: The priority for the message.
- **expire**: The message should expire after specified amount of seconds.
- **retry**: The message should be resent this many times.
- **token**: The token for PushOver to use for authentication, if not specified in the configuration options of master or minion.

### 19.19.203 salt.states.pyenv

**Managing python installations with pyenv**

This module is used to install and manage python installations with pyenv. Different versions of python can be installed, and uninstalled. pyenv will be installed automatically the first time it is needed and can be updated later. This module will not automatically install packages which pyenv will need to compile the versions of python.

If pyenv is run as the root user then it will be installed to /usr/local/pyenv, otherwise it will be installed to the users ~/.pyenv directory. To make pyenv available in the shell you may need to add the pyenv/shims and pyenv/bin directories to the users PATH. If you are installing as root and want other users to be able to access pyenv then you will need to add pyenv_ROOT to their environment.

This is how a state configuration could look like:

```
pyenv-deps:
pkg.installed:
  - pkgs:
    - make
    - build-essential
    - libssl-dev
    - zlib1g-dev
    - libb2-dev
    - libreadline-dev
    - libsqlite3-dev
```
salt.states.pyenv.absent(name, user=None)
Verify that the specified python is not installed with pyenv. pyenv is installed if necessary.
    name The version of python to uninstall
    user: None The user to run pyenv as.

    New in version 0.17.0.
    New in version 0.16.0.

salt.states.pyenv.install_pyenv(name, user=None)
Install pyenv if not installed. Allows you to require pyenv be installed prior to installing the plugins. Useful if you want to install pyenv plugins via the git or file modules and need them installed before installing any rubies.
    Use the pyenv.root configuration option to set the path for pyenv if you want a system wide install that is not in a user home dir.
    user: None The user to run pyenv as.

salt.states.pyenv.installed(name, default=False, user=None)
Verify that the specified python is installed with pyenv. pyenv is installed if necessary.
    name The version of python to install
    default [False] Whether to make this python the default.
    user: None The user to run pyenv as.

    New in version 0.17.0.
    New in version 0.16.0.

19.19.204 salt.states.pyrax_queues

Manage Rackspace Queues

New in version 2015.5.0.

Create and destroy Rackspace queues. Be aware that this interacts with Rackspace's services, and so may incur charges.

This module uses pyrax, which can be installed via package, or pip. This module is greatly inspired by boto_* modules from SaltStack code source.
myqueue:
  pyrax_queues.present:
    - provider: my-pyrax

myqueue:
  pyrax_queues.absent:
    - provider: my-pyrax

salt.states.pyrax_queues.absent(name, provider)
Ensure the named Rackspace queue is deleted.
name Name of the Rackspace queue.
provider Salt Cloud provider

salt.states.pyrax_queues.present(name, provider)
Ensure the RackSpace queue exists.
name Name of the Rackspace queue.
provider Salt Cloud Provider

19.19.205 salt.states.quota

Management of POSIX Quotas

The quota can be managed for the system:

```
/: 
  quota.mode: 
    mode: off 
    quotatype: user 
```

salt.states.quota.mode(name, mode, quotatype)
Set the quota for the system
name The filesystem to set the quota mode on
mode Whether the quota system is on or off
quotatype Must be user or group

19.19.206 salt.states.rabbitmq_cluster

Manage RabbitMQ Clusters

Example:

```
rabbit@rabbit.example.com:
  rabbitmq_cluster.join: 
    - user: rabbit 
    - host: rabbit.example.com 
```

salt.states.rabbitmq_cluster.join(name, host, user='rabbit', ram_node=None, runas='root')
This function is an alias of joined.
name Irrelevant, not used (recommended: user@host)
user The user of node to join to (default: rabbit)
host The host of node to join to
ram_node Join node as a RAM node
`runas` The user to run the rabbitmq command as

```python
salt.states.rabbitmq_cluster.joined(name, host, user='rabbit', ram_node=None, runas='root')
```

Ensure the current node joined to a cluster with node `user@host`
- `name` Irrelevant, not used (recommended: `user@host`)
- `user` The user of node to join to (default: rabbit)
- `host` The host of node to join to
- `ram_node` Join node as a RAM node
- `runas` The user to run the rabbitmq command as

### 19.19.207 `salt.states.rabbitmq_plugin`

**Manage RabbitMQ Plugins**

New in version 2014.1.0.

Example:

```yaml
some_plugin:
  rabbitmq_plugin.enabled: []
```

```python
salt.states.rabbitmq_plugin.disabled(name, runas=None)
```

Ensure the RabbitMQ plugin is disabled.
- `name` The name of the plugin
- `runas` The user to run the rabbitmq-plugin command as

```python
salt.states.rabbitmq_plugin.enabled(name, runas=None)
```

Ensure the RabbitMQ plugin is enabled.
- `name` The name of the plugin
- `runas` The user to run the rabbitmq-plugin command as

### 19.19.208 `salt.states.rabbitmq_policy`

**Manage RabbitMQ Policies**

- `maintainer` Benn Eichhorn <benn@getlocalmeasure.com>
- `maturity` New
- `platform` All

Example:

```python
rabbit_policy:
  rabbitmq_policy.present:
    - name: HA
    - pattern: '.*'
    - definition: '{"ha-mode": "all"}'
```

```python
salt.states.rabbitmq_policy.absent(name, vhost='/', runas=None)
```

Ensure the named policy is absent

- `name` The name of the policy to remove
- `runas` Name of the user to run the command as
salt.states.rabbitmq_policy.present(name, pattern, definition, priority=0, vhost='/', runas=None)

Ensure the RabbitMQ policy exists.

Reference: http://www.rabbitmq.com/ha.html

name Policy name
pattern A regex of queues to apply the policy to
definition A json dict describing the policy
priority Priority (defaults to 0)
vhost Virtual host to apply to (defaults to '/')
runas Name of the user to run the command as

19.19.209 salt.states.rabbitmq_user

Manage RabbitMQ Users

Example:

```
rabbit_user:
    rabbitmq_user.present:
        - password: password
        - force: True
        - tags:
            - monitoring
            - user
        - perms:
            - '/':
                - '.', '*'
                - '.','x'
                - '.' , '*'
            - runas: rabbitmq
```

salt.states.rabbitmq_user.absent(name, runas=None)

Ensure the named user is absent

name The name of the user to remove
runas User to run the command

salt.states.rabbitmq_user.present(name, password=None, force=False, tags=None, perms=(), runas=None)

Ensure the RabbitMQ user exists.

name User name
password User's password, if one needs to be set
force If user exists, forcibly change the password
tags Optional list of tags for the user
perms A list of dicts with vhost keys and 3-tuple values
runas Name of the user to run the command

19.19.210 salt.states.rabbitmq_vhost

Manage RabbitMQ Virtual Hosts

Example:
salt.states.rabbitmq_vhost.absent(name)
Ensure the RabbitMQ Virtual Host is absent
name  Name of the Virtual Host to remove
runas  User to run the command

Deprecated since version 2015.8.0.

salt.states.rabbitmq_vhost.present(name)
Ensure the RabbitMQ VHost exists.
name  VHost name
user  Initial user permission to set on the VHost, if present

Deprecated since version 2015.8.0.
owner  Initial owner permission to set on the VHost, if present

Deprecated since version 2015.8.0.
conf  Initial conf string to apply to the VHost and user. Defaults to .*

Deprecated since version 2015.8.0.
write  Initial write permissions to apply to the VHost and user. Defaults to .*

Deprecated since version 2015.8.0.
read  Initial read permissions to apply to the VHost and user. Defaults to .*

Deprecated since version 2015.8.0.
runas  Name of the user to run the command

Deprecated since version 2015.8.0.

19.19.211  salt.states.rbac_solaris

Management of Solaris RBAC

maintainer  Jorge Schrauwen <sjorge@blackdot.be>
maturity  new
depends  rbac_solaris,solaris_user
platform  solaris,illumos

New in version 2016.11.0.

sjorge:
rbac.managed:
  - roles:
    - netcfg
  - profiles:
    - System Power
  - authorizations:
    - solaris.audit.*
salt.states.rbac_solaris.managed(name, roles=None, profiles=None, authorizations=None)

Manage RBAC properties for user
name [string] username
roles [list] list of roles for user
profiles [list] list of profiles for user
authorizations [list] list of authorizations for user

**Warning:** All existing roles, profiles and authorizations will be replaced! An empty list will remove everything.
Set the property to `None` to not manage it.

### 19.19.212 salt.states.rbenv

Managing Ruby installations with rbenv

This module is used to install and manage ruby installations with rbenv and the ruby-build plugin. Different versions of ruby can be installed, and uninstalled. Rbenv will be installed automatically the first time it is needed and can be updated later. This module will *not* automatically install packages which rbenv will need to compile the versions of ruby. If your version of ruby fails to install, refer to the ruby-build documentation to verify you are not missing any dependencies: [https://github.com/sstephenson/ruby-build/wiki](https://github.com/sstephenson/ruby-build/wiki)

If rbenv is run as the root user then it will be installed to `/usr/local/rbenv`, otherwise it will be installed to the users `~/.rbenv` directory. To make rbenv available in the shell you may need to add the rbenv/shims and rbenv/bin directories to the users PATH. If you are installing as root and want other users to be able to access rbenv then you will need to add `RBENV_ROOT` to their environment.

The following state configuration demonstrates how to install Ruby 1.9.x and 2.x using rbenv on Ubuntu/Debian:

```
rbenv-deps:
  pkg.installed:
  - names:
    - bash
    - git
    - openssl
    - libssl-dev
    - make
    - curl
    - autoconf
    - bison
    - build-essential
    - libffi-dev
    - libyaml-dev
    - libreadline6-dev
    - zlib1g-dev

ruby-1.9.3-p429:
  rbenv.absent:
  - require:
    - pkg: rbenv-deps

ruby-2.0.0-p598:
  rbenv.installed:
  - default: True
```
- require:
  - pkg: rbenv-deps

salt.states.rbenv.absent(name, user=None)

Verify that the specified ruby is not installed with rbenv. Rbenv is installed if necessary.

name The version of ruby to uninstall
user: None The user to run rbenv as.

New in version 0.17.0.
New in version 0.16.0.

salt.states.rbenv.install_rbenv(name, user=None)

Install rbenv if not installed. Allows you to require rbenv be installed prior to installing the plugins. Useful if you want to install rbenv plugins via the git or file modules and need them installed before installing any rubies.

Use the rbenv.root configuration option to set the path for rbenv if you want a system wide install that is not in a user home dir.
user: None The user to run rbenv as.

salt.states.rbenv.installed(name, default=False, user=None)

Verify that the specified ruby is installed with rbenv. Rbenv is installed if necessary.

name The version of ruby to install
default [False] Whether to make this ruby the default.
user: None The user to run rbenv as.

New in version 0.17.0.
New in version 0.16.0.

19.19.213 salt.states.rdp

Manage RDP Service on Windows servers

salt.states.rdp.disabled(name)

Disable the RDP service

salt.states.rdp.enabled(name)

Enable the RDP service and make sure access to the RDP port is allowed in the firewall configuration

19.19.214 salt.states.redismod

Management of Redis server

New in version 2014.7.0.

depends

- redis Python module

configuration See salt.modules.redis for setup instructions.

key_in_redis:
  redis.string:
    - value: string data

The redis server information specified in the minion config file can be overridden in states using the following arguments: host, post, db, password.
salt.states.redismod.absent(name, keys=None, **connection_args)
Ensure key absent from redis
name Key to ensure absent from redis
keys list of keys to ensure absent, name will be ignored if this is used

salt.states.redismod.slaveof(name, sentinel_host=None, sentinel_port=None, sentinel_password=None, **connection_args)
Set this redis instance as a slave.
name Master to make this a slave of
sentinel_host Ip of the sentinel to check for the master
sentinel_port Port of the sentinel to check for the master

salt.states.redismod.string(name, value, expire=None, expireat=None, **connection_args)
Ensure that the key exists in redis with the value specified
name Redis key to manage
value Data to persist in key
expire Sets time to live for key in seconds
expireat Sets expiration time for key via UNIX timestamp, overrides expire

19.19.215 salt.states.reg
Manage the Windows registry

Many python developers think of registry keys as if they were python keys in a dictionary which is not the case.
The windows registry is broken down into the following components:

Hives

This is the top level of the registry. They all begin with HKEY.
- HKEY_CLASSES_ROOT (HKCR)
- HKEY_CURRENT_USER(HKCU)
- HKEY_LOCAL_MACHINE (HKLM)
- HKEY_USER (HKU)
- HKEY_CURRENT_CONFIG

Keys

Hives contain keys. These are basically the folders beneath the hives. They can contain any number of subkeys.

When passing the hivekey values they must be quoted correctly depending on the backslashes being used (\ vs \\). The way backslashes are handled in the state file is different from the way they are handled when working on the CLI. The following are valid methods of passing the hivekey:
Using single backslashes: HKLMSOFTWAREPython `HKLMSOFTWAREPython`
Using double backslashes: ```HKLMSOFTWAREPython```

Values or Entries

Values or Entries are the name/data pairs beneath the keys and subkeys. All keys have a default name/data pair. It is usually ```(Default)````(value not set)```. The actual value for the name and the date is Null. The registry editor will display ```(Default)``` and ```(value not set)```

Example

The following example is taken from the windows startup portion of the registry:

```
[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Run]
"RTHDVCPL"=""C:\Program Files\Realtek\Audio\HDA\RtkNGUI64.exe" -s"
"NvBackend"=""C:\Program Files (x86)\NVIDIA Corporation\Update Core\NvBackend.exe"
"BTMTrayAgent"="rundll32.exe "C:\Program Files (x86)\Intel\Bluetooth\btmshellex.dll",TrayApp"
```

In this example these are the values for each:

Hive: **HKEY_LOCAL_MACHINE**

Key and subkeys: **SOFTWARE\Microsoft\Windows\CurrentVersion\Run**

Value:

- There are 3 value names: *RTHDVCPL*, *NvBackend*, and *BTMTrayAgent*
- Each value name has a corresponding value

**salt.states.reg.absent**(name, vname=None, use_32bit_registry=False)

Ensure a registry value is removed. To remove a key use key_absent.

**Parameters**

- name *(str)* -- A string value representing the full path of the key to include the Hive, Key, and all Subkeys. For example:
  
  HKEY_LOCAL_MACHINE\SOFTWARE\Salt
  HKLM\SOFTWARE\Salt

  Valid hive values include:
  - HKEY_CURRENT_USER or HKCU
  - HKEY_LOCAL_MACHINE or HKLM
  - HKEY_USERS or HKU

- vname *(str)* -- The name of the value you'd like to create beneath the Key. If this parameter is not passed it will assume you want to set the (Default) value

- use_32bit_registry *(bool)* -- Use the 32bit portion of the registry. Applies only to 64bit Windows. 32bit Windows will ignore this parameter. Default is False

**Returns**

A dictionary showing the results of the registry operation

**Return type** *dict*

**CLI Example:**

```
'HKEY_CURRENT_USER\SOFTWARE\Salt':
  reg.absent
  " vname: version
```
In the above example the value named `version` will be removed from the SOFTWARE\Salt key in the HKEY_CURRENT_USER hive. If `vname` was not passed, the (Default) value would be deleted.

```python
salt.states.reg.key_absent(name, use_32bit_registry=False)
```

New in version 2015.5.4.

Ensure a registry key is removed. This will remove a key and all value entries it contains. It will fail if the key contains subkeys.

Parameters

- `name (str)` -- A string representing the full path to the key to be removed to include the hive and the keypath. The hive can be any of the following:
  - HKEY_LOCAL_MACHINE or HKLM
  - HKEY_CURRENT_USER or HKCU
  - HKEY_USER or HKU

- `use_32bit_registry (bool)` -- Use the 32bit portion of the registry. Applies only to 64bit Windows. 32bit Windows will ignore this parameter. Default is False

Returns A dictionary showing the results of the registry operation

Return type dict

The following example will delete the SOFTWARE\Salt key and all subkeys under the HKEY_CURRENT_USER hive.

Example:

```python
'HKEY_CURRENT_USER\SOFTWARE\Salt':
    reg.key_absent:
        - force: True
```

In the above example the path is interpreted as follows:

- HKEY_CURRENT_USER is the hive
- SOFTWARE\Salt is the key

```python
salt.states.reg.present(name, vname=None, vdata=None, vtype='REG_SZ', use_32bit_registry=False)
```

Ensure a registry key or value is present.

Parameters

- `name (str)` -- A string value representing the full path of the key to include the HIVE, Key, and all Subkeys. For example:
  
  HKEY_LOCAL_MACHINE\SOFTWARE\Salt HKLM\SOFTWARE\Salt

  Valid hive values include:
  - HKEY_CURRENT_USER or HKCU
  - HKEY_LOCAL_MACHINE or HKLM
  - HKEY_USERS or HKU

- `vname (str)` -- The name of the value you'd like to create beneath the Key. If this parameter is not passed it will assume you want to set the (Default) value

- `vdata (str)` -- The value you'd like to set. If a value name (vname) is passed, this will be the data for that value name. If not, this will be the (Default) value for the key.

  The type for the (Default) value is always REG_SZ and cannot be changed. This parameter is optional. If not passed, the Key will be created with no associated item/value pairs.

- `vtype (str)` -- The value type for the data you wish to store in the registry. Valid values are:
  - REG_BINARY
  - REG_DWORD
  - REG_EXPAND_SZ
- REG_MULTI_SZ
- REG_SZ (Default)

- **use_32bit_registry** *(bool)* -- Use the 32bit portion of the registry. Applies only to 64bit windows. 32bit Windows will ignore this parameter. Default is False

**Returns** Returns a dictionary showing the results of the registry operation

**Return type** dict

The following example will set the (Default) value for the SOFTWARE\Salt key in the HKEY_CURRENT_USER hive to 2016.3.1:

Example:

```
"HKEY_CURRENT_USER\SOFTWARE\Salt":
  reg.present:
    - vdata: 2016.3.1
```

The following example will set the value for the version entry under the SOFTWARE\Salt key in the HKEY_CURRENT_USER hive to 2016.3.1. The value will be reflected in Wow6432Node:

Example:

```
HKEY_CURRENT_USER\SOFTWARE\Salt:
  reg.present:
    - vname: version
    - vdata: 2016.3.1
```

In the above example the path is interpreted as follows: - HKEY_CURRENT_USER is the hive - SOFTWARE\Salt is the key - vname is the value name (`version`) that will be created under the key - vdata is the data that will be assigned to `version`

### 19.19.216 state.modules.rsync

State to synchronize files and directories with rsync.

New in version 2016.3.0.

```
/opt/user-backups:
  rsync.synchronized:
    - source: /home
    - force: True
```

**salt.states.rsync**.synchronized *(name, source, delete=False, force=False, update=False, passwordfile=None, exclude=None, excludefrom=None, prepare=False, dryrun=False)*

Guarantees that the source directory is always copied to the target.

**name** Name of the target directory.

**source** Source directory.

**prepare** Create destination directory if it does not exists.

**delete** Delete extraneous files from the destination dirs (True or False)

**force** Force deletion of dirs even if not empty

**update** Skip files that are newer on the receiver (True or False)

**passwordfile** Read daemon-access password from the file (path)

**exclude** Exclude files, that matches pattern.

**excludefrom** Read exclude patterns from the file (path)

**dryrun** Perform a trial run with no changes made. Is the same as doing test=True

New in version 2016.3.1.
19.19.217 salt.states.rvm

Managing Ruby installations and gemsets with Ruby Version Manager (RVM)

This module is used to install and manage ruby installations and gemsets with RVM, the Ruby Version Manager. Different versions of ruby can be installed and gemsets created. RVM itself will be installed automatically if it's not present. This module will not automatically install packages that RVM depends on or ones that are needed to build ruby. If you want to run RVM as an unprivileged user (recommended) you will have to create this user yourself. This is how a state configuration could look like:

```yaml
rvm:
  group.present: []
  user.present:
    - gid: rvm
    - home: /home/rvm
    - require:
      - group: rvm

rvm-deps:
  pkg.installed:
    - pkgs:
      - bash
      - coreutils
      - gzip
      - bzip2
      - gawk
      - sed
      - curl
      - git-core
      - subversion

mri-deps:
  pkg.installed:
    - pkgs:
      - build-essential
      - openssl
      - libreadline6
      - libreadline6-dev
      - curl
      - git-core
      - zlib1g
      - zlib1g-dev
      - libssl-dev
      - libyaml-dev
      - libsqlite3-0
      - libsqlite3-dev
      - sqlite3
      - libxml2-dev
      - libxslt1-dev
      - autoconf
      - libc6-dev
      - libncurses5-dev
      - automake
      - libtool
      - bison
      - subversion
      - ruby
```
jruby-deps:
pkg.installed:
  - pkgs:
    - curl
    - g++
    - openjdk-6-jre-headless

ruby-1.9.2:
  rvm.installed:
    - default: True
    - user: rvm
    - require:
      - pkg: rvm-deps
      - pkg: mri-deps
      - user: rvm

jruby:
  rvm.installed:
    - user: rvm
    - require:
      - pkg: rvm-deps
      - pkg: jruby-deps
      - user: rvm

gemset:
  rvm.gemset_present:
    - ruby: jruby
    - user: rvm
    - require:
      - rvm: jruby

mygemset:
  rvm.gemset_present:
    - ruby: ruby-1.9.2
    - user: rvm
    - require:
      - rvm: ruby-1.9.2

salt.states.rvm.gemset_present(name, ruby='default', user=None)
    Verify that the gemset is present.
    name  The name of the gemset.
    ruby: default The ruby version this gemset belongs to.
    user: None  The user to run rvm as.

    New in version 0.17.0.

salt.states.rvm.installed(name, default=False, user=None)
    Verify that the specified ruby is installed with RVM. RVM is installed when necessary.
    name   The version of ruby to install
    default [False] Whether to make this ruby the default.
    user: None  The user to run rvm as.

    New in version 0.17.0.

19.19.218  salt.states.salt_proxy module

Salt proxy state
New in version 2015.8.2.

State to deploy and run salt-proxy processes on a minion.

Set up pillar data for your proxies per the documentation.

Run the state as below

.. code-block:: yaml

    salt-proxy-configure:
        salt_proxy.configure_proxy:
            • proxynmae: p8000
            • start: True

This state will configure the salt proxy settings within /etc/salt/proxy (if /etc/salt/proxy doesn't exists) and start the salt-proxy process (default true), if it isn't already running.

```
salt.states.salt_proxy.configure_proxy(name, proxynmae='p8000', start=True)
```

Create the salt proxy file and start the proxy process if required

Parameters

• **name** -- The name of this state
• **proxynmae** -- Name to be used for this proxy (should match entries in pillar)
• **start** -- Boolean indicating if the process should be started

Example:

.. code-block:: yaml

    salt-proxy-configure:
        salt_proxy.configure_proxy:
            • proxynmae: p8000
            • start: True

19.19.219 salt.states.saltmod

Control the Salt command interface

This state is intended for use from the Salt Master. It provides access to sending commands down to minions as well as access to executing master-side modules. These state functions wrap Salt's Python API.

Support for masterless minions was added to the salt.state function, so they can run orchestration sls files. This is particularly useful when the rendering of a state is dependent on the execution of another state. Orchestration will render and execute each orchestration block independently, while honoring requisites to ensure the states are applied in the correct order.

See also:

More Orchestrate documentation

• Full Orchestrate Tutorial
• The Orchestrate runner

```
salt.states.saltmod.function(name, tgt, ssh=False, tgt_type='glob', expr_form=None, ret='',
    expect_minions=False, fail_minions=None, fail_function=None,
    arg=None, kwarg=None, timeout=None, batch=None, subset=None)
```

Execute a single module function on a remote minion via salt or salt-ssh

**name** The name of the function to run, aka cmd.run or pkg.install
**tgt** The target specification, aka '*' for all minions
tgt_type  The target type, defaults to **glob**

expr_form  Deprecated since version 2017.7.0: Use tgt_type instead

arg  The list of arguments to pass into the function

kwarg  The dict (not a list) of keyword arguments to pass into the function

ret  Optionally set a single or a list of returners to use

expect_minions  An optional boolean for failing if some minions do not respond

fail_minions  An optional list of targeted minions where failure is an option

fail_function  An optional string that points to a salt module that returns True or False based on the returned data dict for individual minions

ssh  Set to True to use the ssh client instead of the standard salt client

batch  Execute the command in batches. E.g.: 10%.

subset  Number of minions from the targeted set to randomly use

New in version 2017.7.0.

salt.states.saltmod.runner(name, **kwargs)

Execute a runner module on the master

New in version 2014.7.0.

name  The name of the function to run

kwargs  Any keyword arguments to pass to the runner function

run-manage-up:
salt.runner:
   - name: manage.up

salt.states.saltmod.state(name, tgt=True, tgt_type='glob', expr_form=None, ret=None, highstate=None, sls=None, top=None, saltenv=None, test=False, pillar=None, pillarenv=None, expect_minions=True, fail_minions=None, allow_fail=0, concurrent=False, timeout=None, batch=False, queue=False, subset=None, orchestration_jid=None)

Invoke a state run on a given target

name  An arbitrary name used to track the state execution

tgt  The target specification for the state run.

  Masterless support: When running on a masterless minion, the tgt is ignored and will always be the local minion.

tgt_type  The target type to resolve, defaults to **glob**

expr_form  Deprecated since version 2017.7.0: Use tgt_type instead

ret  Optionally set a single or a list of returners to use

highstate  Defaults to None, if set to True the target systems will ignore any sls references specified in the sls option and call state.highstate on the targeted minions

top  Should be the name of a top file. If set state.top is called with this top file instead of state.sls.

sls  A group of sls files to execute. This can be defined as a single string containing a single sls file, or a list of sls files

test  Pass test=true through to the state function

pillar  Pass the pillar kwarg through to the state function

pillarenv  The pillar environment to grab pillars from

New in version 2017.7.0.

saltenv  The default salt environment to pull sls files from

ssh  Set to True to use the ssh client instead of the standard salt client

roster  In the event of using salt-ssh, a roster system can be set

expect_minions  An optional boolean for failing if some minions do not respond

fail_minions  An optional list of targeted minions where failure is an option

allow_fail  Pass in the number of minions to allow for failure before setting the result of the execution to False

concurrent  Allow multiple state runs to occur at once.
WARNING: This flag is potentially dangerous. It is designed for use when multiple state runs can safely be run at the same Do not use this flag for performance optimization.

**queue**  Pass `queue=true` through to the state function

**batch**  Execute the command *in batches*. E.g.: 10%.

New in version 2016.3.0.

**subset**  Number of minions from the targeted set to randomly use

New in version 2017.7.0.

Examples:

Run a list of sls files via `state.sls` on target minions:

```
webservers:
  salt.state:
    - tgt: 'web*' 
    - sls: 
      - apache
      - django
      - core
    - saltenv: prod
```

Run a full `state.highstate` on target minions.

```
databases:
  salt.state:
    - tgt: role:database 
    - tgt_type: grain
    - highstate: True
```

```
salt.states.saltmod.wait_for_event(name, id_list, event_id='id', timeout=300, node='master')
```

Watch Salt's event bus and block until a condition is met

New in version 2014.7.0.

**name**  An event tag to watch for; supports Reactor-style globbing.

**id_list**  A list of event identifiers to watch for -- usually the minion ID. Each time an event tag is matched the event data is inspected for `event_id`, if found it is removed from `id_list`. When `id_list` is empty this function returns success.

**event_id**  [id] The name of a key in the event data. Default is `id` for the minion ID, another common value is `name` for use with orchestrating salt-cloud events.

**timeout**  [300] The maximum time in seconds to wait before failing.

The following example blocks until all the listed minions complete a restart and reconnect to the Salt master:

```
reboot_all_minions:
  salt.function:
    - name: system.reboot
    - tgt: '
''

wait_for_reboots:
  salt.wait_for_event:
    - name: salt/minion/*/start
    - id_list:
      - jerry
      - stuart
      - dave
      - phil
      - kevin
      - mike
```
- require:
  - salt: reboot_all_minions

```
salt.states.saltmod.wheel(name, **kwargs)

Execute a wheel module on the master

New in version 2014.7.0.
name  The name of the function to run
kwargs Any keyword arguments to pass to the wheel function
```

```
accept_minion_key:
salt.wheel:
  - name: key.accept
  - match: frank
```

**19.19.220  salt.states.schedule**

Management of the Salt scheduler

```
job3:
schedule.present:
  - function: test.ping
  - seconds: 3600
  - splay: 10

This will schedule the command: test.ping every 3600 seconds
(every hour) splaying the time between 0 and 10 seconds
```

```
job2:
schedule.present:
  - function: test.ping
  - seconds: 15
  - splay:
    start: 10
    end: 20

This will schedule the command: test.ping every 15 seconds
splaying the time between 10 and 20 seconds
```

```
job1:
schedule.present:
  - function: state.sls
  - job_args:
    - httpd
  - job_kwargs:
    test: True
  - when:
    - Monday 5:00pm
    - Tuesday 3:00pm
    - Wednesday 5:00pm
    - Thursday 3:00pm
    - Friday 5:00pm

This will schedule the command: state.sls httpd test=True at 5pm on Monday,
Wednesday and Friday, and 3pm on Tuesday and Thursday. Requires that
python-dateutil is installed on the minion.
```
Scheduled jobs can also be specified using the format used by cron. This will schedule the command: state.sls httpd test=True to run every 5 minutes. Requires that python-croniter is installed on the minion.

This will schedule the command: state.sls httpd test=True at 5pm on Monday, Wednesday and Friday, and 3pm on Tuesday and Thursday. Using the xmpp returner to return the results of the scheduled job, with the alternative configuration options found in the xmpp_state_run section.

ensure a job is absent from the schedule

Ensure a job is disabled in the schedule

Ensure a job is enabled in the schedule

Ensure a job is present in the schedule

seconds The scheduled job will be executed after the specified number of seconds have passed.

minutes The scheduled job will be executed after the specified number of minutes have passed.

hours The scheduled job will be executed after the specified number of hours have passed.
days  The scheduled job will be executed after the specified number of days have passed.
when  This will schedule the job at the specified time(s). The when parameter must be a single value or a
dictionary with the date string(s) using the dateutil format. Requires python-dateutil.
cron  This will schedule the job at the specified time(s) using the crontab format. Requires python-croniter.
run_on_start  Whether the job will run when Salt minion start. Value should be a boolean.
function  The function that should be executed by the scheduled job.
job_args  The arguments that will be used by the scheduled job.
job_kwargs  The keyword arguments that will be used by the scheduled job.
maxrunning  Ensure that there are no more than N copies of a particular job running.
jid_include  Include the job into the job cache.
splay  The amount of time in seconds to splay a scheduled job. Can be specified as a single value in seconds
or as a dictionary range with `start' and `end' values.
range  This will schedule the command within the range specified. The range parameter must be a dictionary
with the date strings using the dateutil format. Requires python-dateutil.
once  This will schedule a job to run once on the specified date.
once_fmt  The default date format is ISO 8601 but can be overridden by also specifying the once_fmt option.
enabled  Whether the job should be enabled or disabled. Value should be a boolean.
return_job  Whether to return information to the Salt master upon job completion.
metadata  Using the metadata parameter special values can be associated with a scheduled job. These values
are not used in the execution of the job, but can be used to search for specific jobs later if combined
with the return_job parameter. The metadata parameter must be specified as a dictionary, otherwise it
will be ignored.
returner  The returner to use to return the results of the scheduled job.
return_config  The alternative configuration to use for returner configuration options.
return_kwargs  Any individual returner configuration items to override. Should be passed as a dictionary.
persist  Whether the job should persist between minion restarts, defaults to True.

19.19.221  salt.states.selinux

Management of SELinux rules

If SELinux is available for the running system, the mode can be managed and booleans can be set.

enforcing:
    selinux.mode

samba_create_home_dirs:
    selinux.boolean:
        - value: True
        - persist: True

nginx:
    selinux.module:
        - enabled: False

Note:  Use of these states require that the selinux execution module is available.

salt.states.selinux.boolean(name, value, persist=False)
Set up an SELinux boolean
name  The name of the boolean to set
value  The value to set on the boolean
persist  Defaults to False, set persist to true to make the boolean apply on a reboot
salt.states.selinux.fcontext_policy_absent(name, filetype='a', sel_type=None, sel_user=None, sel_level=None)

New in version 2017.7.0.

Makes sure an SELinux file context policy for a given filespec (name), filetype and SELinux context type is absent.

name filespec of the file or directory. Regex syntax is allowed.
filetype The SELinux filetype specification. Use one of [a, f, d, c, b, s, l, p]. See also man semanage-fcontext.
Defaults to `a' (all files).
sel_type The SELinux context type. There are many.
sel_user The SELinux user.
sel_level The SELinux MLS range.

salt.states.selinux.fcontext_policy_applied(name, recursive=False)

New in version 2017.7.0.

Checks and makes sure the SELinux policies for a given filespec are applied.

salt.states.selinux.fcontext_policy_present(name, sel_type, filetype='a', sel_user=None, sel_level=None)

New in version 2017.7.0.

Makes sure a SELinux policy for a given filespec (name), filetype and SELinux context type is present.

name filespec of the file or directory. Regex syntax is allowed.
sel_type SELinux context type. There are many.
filetype The SELinux filetype specification. Use one of [a, f, d, c, b, s, l, p]. See also man semanage-fcontext.
Defaults to `a' (all files).
sel_user The SELinux user.
sel_level The SELinux MLS range.

salt.states.selinux.mode(name)

Verifies the mode SELinux is running in, can be set to enforcing, permissive, or disabled

Note: A change to or from disabled mode requires a system reboot. You will need to perform this yourself.

ame The mode to run SELinux in, permissive, enforcing, or disabled.

salt.states.selinux.module(name, module_state='Enabled', version='any', **opts)

Enable/Disable and optionally force a specific version for an SELinux module

name The name of the module to control
module_state Should the module be enabled or disabled?
version Defaults to no preference, set to a specified value if required. Currently can only alert if the version is incorrect.
install Setting to True installs module
source Points to module source file, used only when install is True
remove Setting to True removes module
New in version 2016.3.0.

salt.states.selinux.module_install(name)

Installs custom SELinux module from given file

name Path to file with module to install
New in version 2016.11.6.

salt.states.selinux.module_remove(name)

Removes SELinux module

name The name of the module to remove
New in version 2016.11.6.
Monitor Server with Server Density

New in version 2014.7.0.

Server Density is a hosted monitoring service.

**Warning:** This state module is beta. It might be changed later to include more or less automation.

**Note:** This state module requires a pillar for authentication with Server Density. To install a v1 agent:

```yaml
serverdensity:
  api_token: "b97da80a41c4f61bff05975ee51eb1aa"
  account_url: "https://your-account.serverdensity.io"
```

To install a v2 agent:

```yaml
serverdensity:
  api_token: "b97da80a41c4f61bff05975ee51eb1aa"
  account_name: "your-account"
```

**Note:** Although Server Density allows duplicate device names in its database, this module will raise an exception if you try monitoring devices with the same name.

Example:

```yaml
'server_name':
  serverdensity_device.monitored
```

```python
salt.states.serverdensity_device.monitored(name, group=None, salt_name=True, salt_params=True, agent_version=1, **params)
```

Device is monitored with Server Density.

- **name** Device name in Server Density.
- **salt_name** If True (default), takes the name from the id grain. If False, the provided name is used.
- **group** Group name under with device will appear in Server Density dashboard. Default - None.
- **agent_version** The agent version you want to use. Valid values are 1 or 2. Default - 1.
- **salt_params** If True (default), needed config parameters will be sourced from grains and from `status.all_status`.
- **params** Add parameters that you want to appear in the Server Density dashboard. Will overwrite the `salt_params` parameters. For more info, see the API docs.

Usage example:

```yaml
'server_name':
  serverdensity_device.monitored
```

```yaml
'server_name':
  serverdensity_device.monitored:
    - group: web-servers
```
19.19.223 salt.states.service

Starting or restarting of services and daemons

Services are defined as system daemons and are typically launched using system init or rc scripts. This service state uses whichever service module is loaded on the minion with the virtualname of service. Services can be defined as either running or dead.

If you need to know if your init system is supported, see the list of supported service modules for your desired init system (systemd, sysvinit, launchctl, etc.).

Note that Salt’s service execution module, and therefore this service state, uses OS grains to ascertain which service module should be loaded and used to execute service functions. As existing distributions change init systems or new distributions are created, OS detection can sometimes be incomplete. If your service states are running into trouble with init system detection, please see the Overriding Virtual Module Providers section of Salt’s module documentation to work around possible errors.

Note: The current status of a service is determined by the return code of the init/rc script status command. A status return code of 0 it is considered running. Any other return code is considered dead.

httpd:
    service.running: []

The service can also be set to start at runtime via the enable option:

openvpn:
    service.running:
      - enable: True

By default if a service is triggered to refresh due to a watch statement the service is restarted. If the desired behavior is to reload the service, then set the reload value to True:

redis:
    service.running:
      - enable: True
      - reload: True
      - watch:
        - pkg: redis

Note: More details regarding watch can be found in the Requisites documentation.
enable Set the service to be enabled at boot time, True sets the service to be enabled, False sets the named service to be disabled. The default is None, which does not enable or disable anything.
sig The string to search for when looking for the service process with ps
init_delay Add a sleep command (in seconds) before the check to make sure service is killed.

New in version 2017.7.0.
no_block [False] For systemd minions only. Stops the service using --no-block.

New in version 2017.7.0.
salt.states.service.disabled(name, **kwargs)
Ensure that the service is disabled on boot, only use this state if you don't want to manage the running process, remember that if you want to disable a service to use the enable: False option for the running or dead function.
name The name of the init or rc script used to manage the service

salt.states.service.enabled(name, **kwargs)
Ensure that the service is enabled on boot, only use this state if you don't want to manage the running process, remember that if you want to enable a running service to use the enable: True option for the running or dead function.
name The name of the init or rc script used to manage the service

salt.states.service.masked(name, runtime=False)
New in version 2017.7.0.

Note: This state is only available on minions which use systemd.

Ensures that the named service is masked (i.e. prevented from being started).
name Name of the service to mask
runtime [False] By default, this state will manage an indefinite mask for the named service. Set this argument to True to runtime mask the service.

Note: It is possible for a service to have both indefinite and runtime masks set for it. Therefore, this state will manage a runtime or indefinite mask independently of each other. This means that if the service is already indefinitely masked, running this state with runtime set to True will not remove the indefinite mask before setting a runtime mask. In these cases, if it is desirable to ensure that the service is runtime masked and not indefinitely masked, pair this state with a service.unmasked state, like so:

```
mask_runtime_foo:
service.masked:
  - name: foo
  - runtime: True

unmask_indefinite_foo:
service.unmasked:
  - name: foo
  - runtime: False
```

salt.states.service.mod_watch(name, sfun=None, sig=None, reload=False, full_restart=False, init_delay=None, force=False, **kwargs)
The service watcher, called to invoke the watch command. When called, it will restart or reload the named service.

Note: This state exists to support special handling of the watch requisite. It should not be called directly.
Parameters for this function should be set by the watching service. (i.e. service.running)

- **name**  The name of the init or rc script used to manage the service
- **sfun**  The original function which triggered the mod_watch call (service.running, for example).
- **sig**  The string to search for when looking for the service process with ps
- **reload**  When set, reload the service instead of restarting it. (i.e. service nginx reload)
- **full_restart**  Perform a full stop/start of a service by passing --full-restart. This option is ignored if reload is set and is supported by only a few service modules.
- **force**  Use service.force_reload instead of reload (needs reload to be set to True)
- **init_delay**  Add a sleep command (in seconds) before the service is restarted/reloaded

```python
salt.states.service.running(name, enable=None, sig=None, init_delay=None, no_block=False, unmask=False, unmask_runtime=False, **kwargs)
```

Ensures that the service is running

- **name**  The name of the init or rc script used to manage the service
- **enable**  Set the service to be enabled at boot time, True sets the service to be enabled, False sets the named service to be disabled. The default is None, which does not enable or disable anything.
- **sig**  The string to search for when looking for the service process with ps
- **init_delay**  Some services may not be truly available for a short period after their startup script indicates to the system that they are. Provide an `init_delay` to specify that this state should wait an additional given number of seconds after a service has started before returning. Useful for requisite states wherein a dependent state might assume a service has started but is not yet fully initialized.

- **no_block**  [False] **For systemd minions only.** Starts the service using --no-block.

  New in version 2017.7.0.

- **unmask**  [False] **For systemd minions only.** Set to True to remove an indefinite mask before attempting to start the service.

  New in version 2017.7.0: In previous releases, Salt would simply unmask a service before making any changes. This behavior is no longer the default.

- **unmask_runtime**  [False] **For systemd minions only.** Set to True to remove a runtime mask before attempting to start the service.

  New in version 2017.7.0: In previous releases, Salt would simply unmask a service before making any changes. This behavior is no longer the default.

**Note:**  
`watch` can be used with service.running to restart a service when another state changes (example: a file.managed state that creates the service’s config file). More details regarding `watch` can be found in the Requisites documentation.

```python
salt.states.service.unmasked(name, runtime=False)
```

New in version 2017.7.0.

**Note:**  This state is only available on minions which use systemd.

Ensures that the named service is unmasked

- **name**  Name of the service to unmask
- **runtime**  [False] By default, this state will manage an indefinite mask for the named service. Set this argument to True to ensure that the service is runtime masked.

**Note:**  It is possible for a service to have both indefinite and runtime masks set for it. Therefore, this state will manage a runtime or indefinite mask independently of each other. This means that if the service is indefinitely
masked, running this state with runtime set to True will _not_ remove the indefinite mask.

19.19.224 salt.states.slack

Send a message to Slack

This state is useful for sending messages to Slack during state runs.

New in version 2015.5.0.

```
salt.states.slack.slack-message:
    slack.post_message:
    - channel: '#general'
    - from_name: SuperAdmin
    - message: 'This state was executed successfully.'
    - api_key: peWcBiM0S9HrZHg15peWcBiM0S9HrZHg15
```

The api key can be specified in the master or minion configuration like below:

```
salt:
    api_key: peWcBiM0S9HrZHg15peWcBiM0S9HrZHg15
```

salt.states.slack.post_message(name, channel, from_name, message, api_key=None, icon=None)

Send a message to a Slack channel.

```
salt.states.slack.slack-message:
    slack.post_message:
    - channel: '#general'
    - from_name: SuperAdmin
    - message: 'This state was executed successfully.'
    - api_key: peWcBiM0S9HrZHg15peWcBiM0S9HrZHg15
```

The following parameters are required:

- **name** The unique name for this event.
- **channel** The channel to send the message to. Can either be the ID or the name.
- **from_name** The name of that is to be shown in the "from" field.
- **message** The message that is to be sent to the Slack channel.

The following parameters are optional:

- **api_key** The api key for Slack to use for authentication, if not specified in the configuration options of master or minion.
- **icon** URL to an image to use as the icon for this message.

19.19.225 salt.states.smartos

Management of SmartOS Standalone Compute Nodes

- **maintainer** Jorge Schrauwen <sjorge@blackdot.be>
- **maturity** new
- **depends** vmadm, imgadm
- **platform** smartos

New in version 2016.3.0.
vmtest.example.org:
  smartos.vm_present:
    - config:
      reprovision: true
    - vmconfig:
      image_uuid: c02a2044-c1bd-11e4-bd8c-dfc1db8b0182
      brand: joyent
      alias: vmtest
      quota: 5
      max_physical_memory: 512
      tags:
        label: 'test vm'
        owner: 'sjorge'
      nics:
        "82:1b:8e:49:e9:12"
          nic_tag: trunk
          mtu: 1500
          ips:
            - 172.16.1.123/16
            - 192.168.2.123/24
          vlan_id: 10
        "82:1b:8e:49:e9:13"
          nic_tag: trunk
          mtu: 1500
          ips:
            - dhcp
          vlan_id: 30
    filesystems:
      "/bigdata"
      source: "/bulk/data"
      type: lofs
      options:
        - ro
        - nodevices

kvmtest.example.org:
  smartos.vm_present:
    - vmconfig:
      brand: kvm
      alias: kvmtest
      cpu_type: host
      ram: 512
      vnc_port: 9
    tags:
      label: 'test kvm'
      owner: 'sjorge'
    disks:
      disk0
        size: 2048
        model: virtio
        compression: lz4
        boot: true
    nics:
      "82:1b:8e:49:e9:15"
        nic_tag: trunk
        mtu: 1500
        ips:
          - dhcp
Note: Keep in mind that when removing properties from vmconfig they will not get removed from the vm's current configuration, except for nics, disk, tags, ... they get removed via add_, set_, update_, and remove_. Properties must be manually reset to their default value. The same behavior as when using `vmadm update`.

```
salt.states.smartos.config_absent(name)
   Ensure configuration property is absent in /usbkey/config
   name [string] name of property

salt.states.smartos.config_present(name, value)
   Ensure configuration property is set to value in /usbkey/config
   name [string] name of property
   value [string] value of property

salt.states.smartos.image_absent(name)
   Ensure image is absent on the computenode
   name [string] uuid of image

   Note: computenode.image_absent will only remove the image if it is not used by a vm.

salt.states.smartos.image_present(name)
   Ensure image is present on the computenode
   name [string] uuid of image

salt.states.smartos.image_vacuum(name)
   Delete images not in use or installed via image_present

salt.states.smartos.vm_absent(name, archive=False)
   Ensure vm is absent on the computenode
   name [string] hostname of vm
   archive [boolean] toggle archiving of vm on removal

   Note: State ID is used as hostname. Hostnames must be unique.

salt.states.smartos.vm_present(name, vmconfig, config=None)
   Ensure vm is present on the computenode
   name [string] hostname of vm
   vmconfig [dict] options to set for the vm
   config [dict] fine grain control over vm_present

   Note:
   The following configuration properties can be toggled in the config parameter.
   - kvm_reboot (true) - reboots of kvm zones if needed for a config update
   - auto_import (false) - automatic importing of missing images
   - reprovision (false) - reprovision on image_uuid changes
   - enforce_customer_metadata (true) - false = add metadata only, true = add, update, and remove metadata
   - enforce_tags (true) - false = add tags only, true = add, update, and remove tags

19.19. state modules 3055
**Note:** State ID is used as hostname. Hostnames must be unique.

**Note:** If hostname is provided in vmconfig this will take president over the State ID. This allows multiple states to be applied to the same vm.

**Note:** The following instances should have a unique ID.
- nic : mac
- filesystem: target
- disk : path or diskN for zvols

e.g. disk0 will be the first disk added, disk1 the 2nd,...

```python
salt.states.smartos.vm_running(name)
Ensure vm is in the running state on the computenode
name [string] hostname of vm

**Note:** State ID is used as hostname. Hostnames must be unique.
```

```python
salt.states.smartos.vm_stopped(name)
Ensure vm is in the stopped state on the computenode
name [string] hostname of vm

**Note:** State ID is used as hostname. Hostnames must be unique.
```

### 19.19.226 salt.states.smtp

**Sending Messages via SMTP**

New in version 2014.7.0.

This state is useful for firing messages during state runs, using the SMTP protocol

```python
server-warning-message:
smtplib.send_msg:
    - name: 'This is a server warning message'
    - profile: my-smtp-account
    - recipient: admins@example.com

salt.states.smtp.send_msg(name, recipient, subject, sender=None, profile=None, use_ssl='True')
Send a message via SMTP
```

```python
server-warning-message:
smtplib.send_msg:
    - name: 'This is a server warning message'
    - profile: my-smtp-account
    - subject: 'Message from Salt'
    - recipient: admin@example.com
    - sender: admin@example.com
    - use_ssl: True
```
name The message to send via SMTP

19.19.227 salt.states.snapper module

Managing implicit state and baselines using snapshots

New in version 2016.11.0.

Salt can manage state against explicitly defined state, for example if your minion state is defined by:

```yaml
/etc/config_file:
  file.managed:
    - source: salt://configs/myconfig
```

If someone modifies this file, the next application of the highstate will allow the admin to correct this deviation and the file will be corrected.

Now, what happens if somebody creates a file `/etc/new_config_file` and deletes `/etc/important_config_file`? Unless you have a explicit rule, this change will go unnoticed.

The snapper state module allows you to manage state implicitly, in addition to explicit rules, in order to define a baseline and iterate with explicit rules as they show that they work in production.

The workflow is: once you have a working and audited system, you would create your baseline snapshot (eg. with `salt tgt snapper.create_snapshot`) and define in your state this baseline using the identifier of the snapshot (in this case: 20):

```yaml
my_baseline:
    snapper.baseline_snapshot:
      - number: 20
      - include_diff: False
      - ignore:
          - /var/log
          - /var/cache
```

Baseline snapshots can be also referenced by tag. Most recent baseline snapshot is used in case of multiple snapshots with the same tag:

```yaml
my_baseline_external_storage:
    snapper.baseline_snapshot:
      - tag: my_custom_baseline_tag
      - config: external
      - ignore: - /mnt/tmp_files/
```

If you have this state, and you haven't done changes to the system since the snapshot, and you add a user, the state will show you the changes (including full diffs) to `/etc/passwd`, `/etc/shadow`, etc if you call it with `test=True` and will undo all changes if you call it without.

This allows you to add more explicit state knowing that you are starting from a very well defined state, and that you can audit any change that is not part of your explicit configuration.

So after you made this your state, you decided to introduce a change in your configuration:
my_baseline:
  snapper.baseline_snapshot:
    - number: 20
    - ignore:
        - /var/log
        - /var/cache

hosts_entry:
  file.blockreplace:
    - name: /etc/hosts
    - content: "First line of content"
    - append_if_not_found: True

The change in /etc/hosts will be done after any other change that deviates from the specified snapshot are reverted. This could be for example, modifications to the /etc/passwd file or changes in the /etc/hosts that could render your the hosts_entry rule void or dangerous.

Once you take a new snapshot and you update the baseline snapshot number to include the change in /etc/hosts the hosts_entry rule will basically do nothing. You are free to leave it there for documentation, to ensure that the change is made in case the snapshot is wrong, but if you remove anything that comes after the snapper.baseline_snapshot as it will have no effect; by the moment the state is evaluated, the baseline state was already applied and include this change.

**Warning:** Make sure you specify the baseline state before other rules, otherwise the baseline state will revert all changes if they are not present in the snapshot.

**Warning:** Do not specify more than one baseline rule as only the last one will affect the result.

**codeauthor** Duncan Mac-Vicar P. <dmacvicar@suse.de>

**codeauthor** Pablo Suárez Hernández <psuarezhernandez@suse.de>

**maturity** new

**platform** Linux

salt.states.snapper.baseline_snapshot(name, number=None, tag=None, include_diff=True, config='root', ignore=None)

Enforces that no file is modified comparing against a previously defined snapshot identified by number.

- **number** Number of selected baseline snapshot.
- **tag** Tag of the selected baseline snapshot. Most recent baseline baseline snapshot is used in case of multiple snapshots with the same tag. (tag and number cannot be used at the same time)
- **include_diff** Include a diff in the response (Default: True)
- **config** Snapper config name (Default: root)
- **ignore** List of files to ignore. (Default: None)

**19.19.228 salt.states.solrcloud module**

States for solrcloud alias and collection configuration

New in version 2017.7.0.

salt.states.solrcloud.alias(name, collections, **kwargs)

Create alias and enforce collection list.
Use the solrcloud module to get alias members and set them.

You can pass additional arguments that will be forwarded to http.query

```python
name The collection name
collections list of collections to include in the alias
```

```python
salt.states.solrcloud.collection(name, options=None, **kwargs)
```

Create collection and enforce options.

Use the solrcloud module to get collection parameters.

You can pass additional arguments that will be forwarded to http.query

```python
name The collection name
collection options ([{}]) options to ensure
```

### 19.19.229 salt.states.splunk

Splunk User State Module

New in version 2016.3.0.

This state is used to ensure presence of users in splunk.

```python
ensure example test user 1:
splunk.present:
- name: 'Example TestUser1'
- email: example@domain.com
```

```python
salt.states.splunk.absent(email, profile='splunk', **kwargs)
```

Ensure a splunk user is absent

```python
ensure example test user 1:
splunk.absent:
- email: 'example@domain.com'
- name: 'exampleuser'
```

The following parameters are required:

- **email** This is the email of the user in splunk
- **name** This is the splunk username used to identify the user.

```python
salt.states.splunk.present(email, profile='splunk', **kwargs)
```

Ensure a user is present

```python
ensure example test user 1:
splunk.user_present:
- realname: 'Example TestUser1'
- name: 'exampleuser'
- email: 'example@domain.com'
- roles: ['user']
```

The following parameters are required:

- **email** This is the email of the user in splunk

### 19.19.230 salt.states.splunk_search

Splunk Search State Module

New in version 2015.5.0.
This state is used to ensure presence of splunk searches.

```yaml
server-warning-message:
  splunk_search.present:
    - name: This is the splunk search name
    - search: index=main sourcetype=
```

salt.states.splunk_search.absent(name, profile='splunk')
Ensure a search is absent

```yaml
API Error Search:
splunk_search.absent
```

The following parameters are required:
name This is the name of the search in splunk

salt.states.splunk_search.present(name, profile='splunk', **kwargs)
Ensure a search is present

```yaml
API Error Search:
splunk_search.present:
  - search: index=main sourcetype=blah
template: alert_5min
```

The following parameters are required:
name This is the name of the search in splunk

19.19.231 salt.states.sqlite3

Management of SQLite3 databases

New in version 2016.3.0.

```
depends
  • SQLite3 Python Module
```

configuration See `salt.modules.sqlite3` for setup instructions

The sqlite3 module is used to create and manage sqlite3 databases and execute queries

Here is an example of creating a table using sql statements:

```yaml
users:
  sqlite3.table_present:
    - db: /var/www/data/app.sqlite
    - schema: CREATE TABLE `users` (`username` TEXT COLLATE NOCASE UNIQUE NOT NULL, `password` BLOB NOT NULL, `salt` BLOB NOT NULL, `last_login` INT)
```

Here is an example of creating a table using yaml/jinja instead of sql:

```yaml
users:
  sqlite3.table_present:
    - db: /var/www/app.sqlite
    - schema:
      - email TEXT COLLATE NOCASE UNIQUE NOT NULL
      - firstname TEXT NOT NULL
      - lastname TEXT NOT NULL
      - company TEXT NOT NULL
```
Here is an example of making sure a table is absent:

```yaml
badServers:
  sqlite3.table_absent:
    - db: /var/www/data/users.sqlite
```

Sometimes you would to have specific data in tables to be used by other services Here is an example of making sure rows with specific data exist:

```yaml
user_john_doe_xyz:
  sqlite3.row_present:
    - db: /var/www/app.sqlite
    - table: users
    - where_sql: email='john.doe@companyxyz.com'
    - data:
      email: john.doe@companyxyz.com
      lastname: doe
      firstname: john
      company: companyxyz.com
      password: abcdef012934125
      salt: abcdef012934125
    - require:
      - sqlite3: users
```

Here is an example of removing a row from a table:

```yaml
user_john_doe_abc:
  sqlite3.row_absent:
    - db: /var/www/app.sqlite
    - table: users
    - where_sql: email="john.doe@companyabc.com"
    - require:
      - sqlite3: users
```

Note that there is no explicit state to perform random queries, however, this can be approximated with sqlite3's module functions and module.run:

```yaml
zone-delete:
  module.run:
    - name: sqlite3.modify
    - db: {{ db }}
    - sql: "DELETE FROM records WHERE id > {{ count[0] }} AND domain_id = {{ domain_id }}"
  watch:
    - sqlite3: zone-insert-12
```

salt.states.sqlite3.row_absent(name, db, table, where_sql, where_args=None)

Makes sure the specified row is absent in db. If multiple rows match where_sql, then the state will fail.
name Only used as the unique ID
db The database file name
table The table name to check
where_sql The sql to select the row to check
where_args The list parameters to substitute in where_sql
salt.states.sqlite3.row_present(name, db, table, data, where_sql, where_args=None, update=False)

Checks to make sure the given row exists. If row exists and update is True then row will be updated with data. Otherwise it will leave existing row unmodified and check it against data. If the existing data doesn't match data_check the state will fail. If the row doesn't exist then it will insert data into the table. If more than one row matches, then the state will fail.

- **name** Only used as the unique ID
- **db** The database file name
- **table** The table name to check the data
- **data** The dictionary of key/value pairs to check against if row exists, insert into the table if it doesn’t
- **where_sql** The sql to select the row to check
- **where_args** The list parameters to substitute in where_sql
- **update** True will replace the existing row with data When False and the row exists and data does not equal the row data then the state will fail

salt.states.sqlite3.table_absent(name, db)

Make sure the specified table does not exist

- **name** The name of the table
- **db** The name of the database file

salt.states.sqlite3.table_present(name, db, schema, force=False)

Make sure the specified table exists with the specified schema

- **name** The name of the table
- **db** The name of the database file
- **schema** The dictionary containing the schema information
- **force** If the name of the table exists and force is set to False, the state will fail. If force is set to True, the existing table will be replaced with the new table

## 19.19.232 salt.states.ssh_auth

**Control of entries in SSH authorized_key files**

The information stored in a user's SSH authorized_key file can be easily controlled via the ssh_auth state. Defaults can be set by the enc, options, and comment keys. These defaults can be overridden by including them in the name.

Since the YAML specification limits the length of simple keys to 1024 characters, and since SSH keys are often longer than that, you may have to use a YAML 'explicit key', as demonstrated in the second example below.

```
AAAAAB3NzaC1kc3MAAACCBAL0sQ9fJ5bYTEyY==:
  ssh_auth.present:
    - user: root
    - enc: ssh-dss

AAAAB3NzaC1kc3MAAACCBAL0sQ9fJ5bYTEyY=
  : ssh_auth.present:
    - user: root
    - enc: ssh-dss
thatch:
  ssh_auth.present:
    - user: root
    - source: salt://ssh_keys/thatch.id_rsa.pub
    - config: '%h/.ssh/authorized_keys'
```

**sshkeys:**
Salt Documentation, Release 2017.7.8

```
ssh_auth.present:
  - user: root
  - enc: ssh-rsa
  - options:
    - option1="value1"
    - option2="value2 flag2"
  - comment: myuser
  - names:
    - AAAAB3NzaC1kc3MAAABCAL0sQ9fJ5bYTEyY==
    - ssh-dss AAAAB3NzaCL0sQ9fJ5bYTEyY== user@domain
    - option3="value3" ssh-dss AAAAB3NzaC1kcQ9fJFF435bYTEyY== other@testdomain
    - AAAAB3NzaC1kcQ9fJFF435bYTEyY== newcomment

salt.states.ssh_auth.absent(name, user, enc='ssh-rsa', comment='`', source='`', options=None, config='.ssh/authorized_keys', fingerprint_hash_type=None)

Verifies that the specified SSH key is absent

name  The SSH key to manage
user  The user who owns the SSH authorized keys file to modify
enc  Defines what type of key is being used; can be ed25519, ecdsa, ssh-rsa or ssh-dss
comment  The comment to be placed with the SSH public key
options  The options passed to the key, pass a list object
source  The source file for the key(s). Can contain any number of public keys, in standard ``authorized_keys`` format. If this is set, comment, enc and options will be ignored.

New in version 2015.8.0.
config  The location of the authorized keys file relative to the user's home directory, defaults to ``.ssh/authorized_keys``. Token expansion %u and %h for username and home path supported.
fingerprint_hash_type  The public key fingerprint hash type that the public key fingerprint was originally hashed with. This defaults to md5 if not specified.

New in version 2016.11.7.

Note:  The default value of the fingerprint_hash_type will change to sha256 in Salt 2017.7.0.

salt.states.ssh_auth.present(name, user, enc='ssh-rsa', comment='`', source='`', options=None, config='.ssh/authorized_keys', fingerprint_hash_type=None, **kwargs)

Verifies that the specified SSH key is present for the specified user

name  The SSH key to manage
user  The user who owns the SSH authorized keys file to modify
enc  Defines what type of key is being used; can be ed25519, ecdsa, ssh-rsa or ssh-dss
comment  The comment to be placed with the SSH public key
source  The source file for the key(s). Can contain any number of public keys, in standard ``authorized_keys`` format. If this is set, comment and enc will be ignored.

Note:  The source file must contain keys in the format <enc> <key> <comment>. If you have generated a keypair using PuTTYgen, then you will need to do the following to retrieve an OpenSSH-compatible public key.

1. In PuTTYgen, click Load, and select the private key file (not the public key), and click Open.
2. Copy the public key from the box labeled Public key for pasting into OpenSSH authorized_keys file.
3. Paste it into a new file.

options  The options passed to the key, pass a list object
config  The location of the authorized keys file relative to the user's home directory, defaults to

19.19. state modules
fingerprint_hash_type  The public key fingerprint hash type that the public key fingerprint was originally hashed with. This defaults to md5 if not specified.

New in version 2016.11.7.

Note: The default value of the fingerprint_hash_type will change to sha256 in Salt 2017.7.0.

19.19.233  salt.states.ssh_known_hosts

Control of SSH known_hosts entries

Manage the information stored in the known_hosts files.

<table>
<thead>
<tr>
<th>github.com:</th>
</tr>
</thead>
<tbody>
<tr>
<td>ssh_known_hosts:</td>
</tr>
<tr>
<td>- present</td>
</tr>
<tr>
<td>- user: root</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>example.com:</th>
</tr>
</thead>
<tbody>
<tr>
<td>ssh_known_hosts:</td>
</tr>
<tr>
<td>- absent</td>
</tr>
<tr>
<td>- user: root</td>
</tr>
</tbody>
</table>

salt.states.ssh_known_hosts.absent(name, user=None, config=None)

Verifies that the specified host is not known by the given user

name  The host name
user  The user who owns the ssh authorized keys file to modify
config  The location of the authorized keys file relative to the user's home directory, defaults to ".ssh/known_hosts". If no user is specified, defaults to `~/etc/ssh/ssh_known_hosts`. If present, must be an absolute path when a user is not specified.

salt.states.ssh_known_hosts.present(name, user=None, fingerprint=None, key=None, port=None, enc=None, config=None, hash_known_hosts=True, timeout=5, fingerprint_hash_type=None)

Verifies that the specified host is known by the specified user

On many systems, specifically those running with openssh 4 or older, the enc option must be set, only openssh 5 and above can detect the key type.

name  The name of the remote host (e.g. `github.com`)
user  The user who owns the ssh authorized keys file to modify
fingerprint  The fingerprint of the key which must be present in the known_hosts file (optional if key specified)
key  The public key which must be present in the known_hosts file (optional if fingerprint specified)
port  optional parameter, port which will be used to when requesting the public key from the remote host, defaults to port 22.
enc  Defines what type of key is being used, can be ed25519, ecdsa ssh-rsa or ssh-dss
config  The location of the authorized keys file relative to the user's home directory, defaults to ".ssh/known_hosts". If no user is specified, defaults to `~/etc/ssh/ssh_known_hosts`. If present, must be an absolute path when a user is not specified.
hash_known_hosts  [True] Hash all hostnames and addresses in the known hosts file.
timeout  [int]  Set the timeout for connection attempts. If timeout seconds have elapsed since a connection was initiated to a host or since the last time anything was read from that host, then the connection is closed and the host in question considered unavailable. Default is 5 seconds.

New in version 2016.3.0.

fingerprint_hash_type  The public key fingerprint hash type that the public key fingerprint was originally hashed with. This defaults to sha256 if not specified.

New in version 2016.11.4.

Changed in version 2017.7.0:: default changed from md5 to sha256

19.19.234  salt.states.stateconf

Stateconf System

The stateconf system is intended for use only with the stateconf renderer. This State module presents the set function. This function does not execute any functionality, but is used to interact with the stateconf renderer.

salt.states.stateconf.context(name, **kwargs)
    No-op state to support state config via the stateconf renderer.

salt.states.stateconf.set(name, **kwargs)
    No-op state to support state config via the stateconf renderer.

19.19.235  salt.states.status

Minion status monitoring

Maps to the status execution module.

salt.states.status.loadavg(name, maximum=None, minimum=None)
    Return the current load average for the specified minion. Available values for name are 1-min, 5-min and 15-min. minimum and maximum values should be passed in as strings.

salt.states.status.process(name)
    Return whether the specified signature is found in the process tree. This differs slightly from the services states, in that it may refer to a process that is not managed via the init system.

19.19.236  salt.states.statuspage

StatusPage

Manage the StatusPage configuration.

In the minion configuration file, the following block is required:

```
statuspage:
    api_key: <API_KEY>
    page_id: <PAGE_ID>
```

New in version 2017.7.0.

salt.states.statuspage.create(name, endpoint=u'incidents', api_url=None, page_id=None, api_key=None, api_version=None, **kwargs)
    Insert a new entry under a specific endpoint.

    endpoint: incidents  Insert under this specific endpoint.
page_id  Page ID. Can also be specified in the config file.
api_key  API key. Can also be specified in the config file.
api_version: 1  API version. Can also be specified in the config file.
api_url  Custom API URL in case the user has a StatusPage service running in a custom environment.
kwarg  Other params.
SLS Example:

```
create-my-component:
    statuspage.create:
        - endpoint: components
        - name: my component
        - group_id: 993vgplshj12
```

```
salt.states.statuspage.delete(name, endpoint='incidents', id=None, api_url=None, page_id=None, api_key=None, api_version=None)
```
Remove an entry from an endpoint.

```
endpoint: incidents  Request a specific endpoint.
page_id  Page ID. Can also be specified in the config file.
api_key  API key. Can also be specified in the config file.
api_version: 1  API version. Can also be specified in the config file.
api_url  Custom API URL in case the user has a StatusPage service running in a custom environment.
SLS Example:

```
delete-my-component:
    statuspage.delete:
        - endpoint: components
        - id: ftgks5isfs2d
```

```
salt.states.statuspage.managed(name, config, api_url=None, page_id=None, api_key=None, api_version=None, pace=1, allow_empty=False)
```
Manage the StatusPage configuration.

```
cfg  Dictionary with the expected configuration of the StatusPage. The main level keys of this dictionary represent the endpoint name. If a certain endpoint does not exist in this structure, it will be ignored / not configured.
page_id  Page ID. Can also be specified in the config file.
api_key  API key. Can also be specified in the config file.
api_version: 1  API version. Can also be specified in the config file.
api_url  Custom API URL in case the user has a StatusPage service running in a custom environment.
pace: 1  Max requests per second allowed by the API.
allow_empty: False  Allow empty config.
SLS example:

```
my-statuspage-config:
    statuspage.managed:
        - config:
            components:
                name: component1
                group_id: uy4g37rf
                name: component2
                group_id: 3n4uyu4gf
            incidents:
                name: incident1
                status: resolved
                impact: major
                backfilled: false
                name: incident2
                status: investigating
```

**salt.states.statuspage.update**

```python
salt.states.statuspage.update(name, endpoint='incidents', id=None, api_url=None, page_id=None, api_key=None, api_version=None, **kwargs)
```

Update attribute(s) of a specific endpoint.

- **id**: The unique ID of the endpoint entry.
- **endpoint**: incidents (Endpoint name).
- **page_id**: Page ID. Can also be specified in the config file.
- **api_key**: API key. Can also be specified in the config file.
- **api_version**: 1 (API version. Can also be specified in the config file).
- **api_url**: Custom API URL in case the user has a StatusPage service running in a custom environment.

**SL5 Example:**

```python
update-my-incident:
    statuspage.update:
        - id: dz959yz2nd4l
        - status: resolved
```

---

19.19.237  **salt.states.stormpath_account**

Support for Stormpath.

New in version 2015.8.0.

**salt.states.stormpath_account.absent**

Ensure that an account associated with the given email address is absent. Will search all directories for the account, unless a **directory_id** is specified.

- **name**: The email address of the account to delete.
- **directory_id**: Optional. The ID of the directory that the account is expected to belong to. If not specified, then a list of directories will be retrieved, and each will be scanned for the account. Specifying a directory_id will therefore cut down on the number of requests to Stormpath, and increase performance of this state.

**salt.states.stormpath_account.present**

Ensure that an account is present and properly configured

- **name**: The email address associated with the Stormpath account
- **directory_id**: The ID of a directory which the account belongs to. Required.
- **password**: Required when creating a new account. If specified, it is advisable to reference the password in another database using an sdb:// URL. Will NOT update the password if an account already exists.
- **givenName**: Required when creating a new account.
- **surname**: Required when creating a new account.
- **username**: Optional. Must be unique across the owning directory. If not specified, the username will default to the email field.
- **middleName**: Optional.
- **status**: enabled accounts are able to login to their assigned applications, disabled accounts may not login to applications, unverified accounts are disabled and have not verified their email address.
- **customData**: Optional. Must be specified as a dict.

19.19.238  **salt.states.supervisord**

Interaction with the Supervisor daemon

```python
wsgi_server:
    supervisord.running:
```

---

19.19  **state modules**
salt.states.supervisord.dead(name, user=None, conf_file=None, bin_env=None, **kwargs)

Ensure the named service is dead (not running).

Parameters:
- **name** - Service name as defined in the supervisor configuration file
- **user** - Name of the user to run the supervisorctl command

New in version 0.17.0.

salt.states.supervisord.mod_watch(name, restart=True, update=False, user=None, conf_file=None, bin_env=None, **kwargs)

The supervisord watcher, called to invoke the watch command. Always restart on watch.

**Note:** This state exists to support special handling of the watch requisite. It should not be called directly. Parameters for this function should be set by the state being triggered.

salt.states.supervisord.running(name, restart=False, update=False, user=None, conf_file=None, bin_env=None, **kwargs)

Ensure the named service is running.

Parameters:
- **name** - Service name as defined in the supervisor configuration file
- **restart** - Whether to force a restart
- **update** - Whether to update the supervisor configuration.
- **user** - Name of the user to run the supervisorctl command

New in version 0.17.0.

salt.states.svn

Manage SVN repositories

Manage repository checkouts via the svn vcs system. Note that subversion must be installed for these states to be available, so svn states should include a requisite to a pkg.installed state for the package which provides subversion (subversion in most cases). Example:

```
subversion:
  pkg.installed

http://unladen-swallow.googlecode.com/svn/trunk/:
  svn.latest:
    - target: /tmp/swallow
```

salt.states.svn.dirty(name, target, user=None, username=None, password=None, ignore_unversioned=False)

Determine if the working directory has been changed.

salt.states.svn.export(name, target=None, rev=None, user=None, username=None, password=None, force=False, overwrite=False, externals=True, trust=False)

Export a file or directory from an SVN repository
name  Address and path to the file or directory to be exported.
target Name of the target directory where the checkout will put the working directory
rev  [None] The name revision number to checkout. Enable ``force'' if the directory already exists.
user  [None] Name of the user performing repository management operations
username  [None] The user to access the name repository with. The svn default is the current user
password  Connect to the Subversion server with this password

    New in version 0.17.0.
force  [False] Continue if conflicts are encountered
overwrite  [False] Overwrite existing target
externals  [True] Change to False to not checkout or update externals
trust  [False] Automatically trust the remote server. SVN’s --trust-server-cert

salt.states.svn.latest(name, target=None, rev=None, user=None, username=None, password=None,
                        force=False, externals=True, trust=False)
    Checkout or update the working directory to the latest revision from the remote repository.
name  Address of the name repository as passed to ``svn checkout”
target Name of the target directory where the checkout will put the working directory
rev  [None] The name revision number to checkout. Enable ``force'' if the directory already exists.
user  [None] Name of the user performing repository management operations
username  [None] The user to access the name repository with. The svn default is the current user
password  Connect to the Subversion server with this password

    New in version 0.17.0.
force  [False] Continue if conflicts are encountered
externals  [True] Change to False to not checkout or update externals
trust  [False] Automatically trust the remote server. SVN’s --trust-server-cert

19.19.240  salt.states.sysctl

Configuration of the Linux kernel using sysctl

Control the kernel sysctl system.

```
vm.swappiness:
    sysctl.present:
        - value: 20
```

salt.states.sysctl.present(name, value, config=None)
    Ensure that the named sysctl value is set in memory and persisted to the named configuration file. The default
    sysctl configuration file is /etc/sysctl.conf
name  The name of the sysctl value to edit
value  The sysctl value to apply
config  The location of the sysctl configuration file. If not specified, the proper location will be detected based
    on platform.

19.19.241  salt.states.syslog_ng

State module for syslog_ng

    maintainer  Tibor Benke <btibi@sch.bme.hu>
maturity  new
depends  cmd, ps, syslog_ng
Users can generate syslog-ng configuration files from YAML format or use plain ones and reload, start, or stop their syslog-ng by using this module.

Details

The service module is not available on all system, so this module includes `syslog_ng.reloaded`, `syslog_ng.stopped`, and `syslog_ng.started` functions. If the service module is available on the computers, users should use that.

Users can generate syslog-ng configuration with `syslog_ng.config` function. For more information see `syslog-ng state usage`.

Syslog-ng configuration file format

The syntax of a configuration snippet in syslog-ng.conf:

    object_type object_id {<options>};

These constructions are also called statements. There are options inside of them:

    option(parameter1, parameter2); option2(parameter1, parameter2);

**salt.states.syslog_ng.config**(name, config, write=True)

Builds syslog-ng configuration.

    name : the id of the Salt document
    config : the parsed YAML code
    write : if True, it writes the config into the configuration file, otherwise just returns it

**salt.states.syslog_ng.reloaded**(name)

Reloads syslog-ng.

**salt.states.syslog_ng.started**(name=None, user=None, group=None, chroot=None, caps=None, no_caps=False, pidfile=None, enable_core=False, fd_limit=None, verbose=False, debug=False, trace=False, yydebug=False, persist_file=None, control=None, worker_threads=None, **kwargs)

Ensures, that syslog-ng is started via the given parameters.

Users shouldn't use this function, if the service module is available on their system.

**salt.states.syslog_ng.stopped**(name=None)

Kills syslog-ng.

19.19.242  **salt.states.sysrc**

**salt.states.sysrc.absent**(name, **kwargs)

Ensure a sysrc variable is absent.

    name  The variable name to set
    file  (optional) The rc file to add the variable to.
    jail  (option) the name or JID of the jail to set the value in.
salt.states.sysrc.managed(name, value, **kwargs)
   Ensure a sysrc variable is set to a specific value.
   name  The variable name to set
   value Value to set the variable to
   file (optional) The rc file to add the variable to.
   jail (option) the name or JID of the jail to set the value in.
Example:

```
syslogd:
sysrc.managed:
   - name: syslogd_flags
   - value: -ss
```

19.19.243 salt.states.telemetry_alert

New in version 2016.3.0..

Manage Telemetry alert configurations

Create, Update and destroy Mongo Telemetry alert configurations.

This module uses requests, which can be installed via package, or pip.

This module accepts explicit credential (telemetry api key) or can also read api key credentials from a pillar. Example:

```
ensure telemetry alert X is defined on deployment Y:
telemetry_alert.present:
   deployment_id: "rs-XXXXXX"
   metric_name: "testMetric"
   alert_config:
      max: 1
      filter:  SERVER_ROLE_MONGOD_PRIMARY
      escalate_to: "example@pagerduty.com"
      - name: "**MANAGED BY ORCA DO NOT EDIT BY HAND** manages alarm on testMetric"
```

salt.states.telemetry_alert.absent(name, deployment_id, metric_name, api_key=None, profile='telemetry')

Ensure the telemetry alert config is deleted

name  An optional description of the alarms (not currently supported by telemetry API)
deployment_id Specifies the ID of the root deployment resource (replica set cluster or sharded cluster) to which this alert definition is attached
metric_name Specifies the unique ID of the metric to whose values these thresholds will be applied
api_key   Telemetry api key for the user
profile A dict with telemetry config data. If present, will be used instead of api_key.

salt.states.telemetry_alert.present(name, deployment_id, metric_name, alert_config, api_key=None, profile='telemetry')

Ensure the telemetry alert exists.

name  An optional description of the alarm (not currently supported by telemetry API)
deployment_id Specifies the ID of the root deployment resource (replica set cluster or sharded cluster) to which this alert definition is attached
metric_name Specifies the unique ID of the metric to whose values these thresholds will be applied
alert_config: Is a list of dictionaries where each dict contains the following fields:
   filter By default the alert will apply to the deployment and all its constituent resources. If the alert only applies to a subset of those resources, a filter may be specified to narrow this scope.
min  the smallest ‘ok’ value the metric may take on; if missing or null, no minimum is enforced.
max  the largest ‘ok’ value the metric may take on; if missing or null, no maximum is enforced.
notify_all  Used to indicate if you want to alert both onCallEngineer and apiNotifications
api_key  Telemetry api key for the user
profile  A dict of telemetry config information. If present, will be used instead of api_key.

19.19.244 salt.states.test

Test States

Provide test case states that enable easy testing of things to do with state calls, e.g. running, calling, logging, output filtering etc.

always-passes-with-any-kwarg:
  test.nop:
    - name: foo
    - something: else
    - foo: bar

always-passes:
  test.succeed_without_changes:
    - name: foo

always-fails:
  test.fail_without_changes:
    - name: foo

always-changes-and-succeeds:
  test.succeed_with_changes:
    - name: foo

always-changes-and-fails:
  test.fail_with_changes:
    - name: foo

my-custom-combo:
  test.configurable_test_state:
    - name: foo
    - changes: True
    - result: False
    - comment: bar.baz

is-pillar-foo-present-and-bar-is-int:
  test.check_pillar:
    - present:
      - foo
    - integer:
      - bar

salt.states.test.check_pillar(name, present=None, boolean=None, integer=None, string=None, listing=None, dictionary=None, verbose=False)

Checks the presence and, optionally, the type of given keys in Pillar. Supported kwargs for types are: boolean (bool) - integer (int) - string (str) - listing (list) - dictionary (dict)

Checking for None type pillars is not implemented yet.
salt.states.test.configurable_test_state(name, changes=True, result=True, comment='')
A configurable test state which determines its output based on the inputs.

New in version 2014.7.0.
name: A unique string.
changes: Do we return anything in the changes field? Accepts True, False, and 'Random' Default is True
result: Do we return successfully or not? Accepts True, False, and 'Random' Default is True If test is True
and changes is True, this will be None. If test is True and and changes is False, this will be True.
comment: String to fill the comment field with. Default is ''

salt.states.test.fail_with_changes(name)
Returns failure and changes is not empty.

New in version 2014.7.0.
name: A unique string.

salt.states.test.fail_without_changes(name)
Returns failure.

New in version 2014.7.0.
name: A unique string.

salt.states.test.mod_watch(name, sfun=None, **kwargs)
Call this function via a watch statement

New in version 2014.7.0.
Any parameters in the state return dictionary can be customized by adding the keywords result, comment,
and changes.

this_state_will_return_changes:
  test.succeed_with_changes

this_state_will_NOT_return_changes:
  test.succeed_without_changes

this_state_is_watching_another_state:
  test.succeed_without_changes:
    - comment: 'This is a custom comment'
    - watch:
      - test: this_state_will_return_changes
      - test: this_state_will_NOT_return_changes

this_state_is_also_watching_another_state:
  test.succeed_without_changes:
    - watch:
      - test: this_state_will_NOT_return_changes

salt.states.test.nop(name, **kwargs)
A no-op state that does nothing. Useful in conjunction with the use requisite, or in templates which could
otherwise be empty due to jinja rendering

salt.states.test.show_notification(name, text=None, **kwargs)
Simple notification using text argument.
    New in version 2015.8.0.
    name A unique string.
    text Text to return in the comment.
salt.states.test.succeed_with_changes(name)
Returns successful and changes is not empty
    New in version 2014.7.0.
    name A unique string.
salt.states.test.succeed_without_changes(name)
Returns successful.
    New in version 2014.7.0.
    name A unique string.

19.19.245 salt.states.testinfra mod ule

19.19.246 salt.states.timezone

Management of timezones

The timezone can be managed for the system:

<table>
<thead>
<tr>
<th>America/Denver:</th>
</tr>
</thead>
<tbody>
<tr>
<td>timezone.system</td>
</tr>
</tbody>
</table>

The system and the hardware clock are not necessarily set to the same time. By default, the hardware clock is set to localtime, meaning it is set to the same time as the system clock. If utc is set to True, then the hardware clock will be set to UTC, and the system clock will be an offset of that.

<table>
<thead>
<tr>
<th>America/Denver:</th>
</tr>
</thead>
<tbody>
<tr>
<td>timezone.system:</td>
</tr>
<tr>
<td>- utc: True</td>
</tr>
</tbody>
</table>

The Ubuntu community documentation contains an explanation of this setting, as it applies to systems that dual-boot with Windows. This is explained in greater detail here.

salt.states.timezone.system(name, utc=True)
Set the timezone for the system.
    name The name of the timezone to use (e.g.: America/Denver)
    utc Whether or not to set the hardware clock to UTC (default is True)

19.19.247 salt.states.tls

Enforce state for SSL/TLS

salt.states.tls.valid_certificate(name, weeks=0, days=0, hours=0, minutes=0, seconds=0)
Verify that a TLS certificate is valid now and (optionally) will be valid for the time specified through weeks, days, hours, minutes, and seconds.
19.19.248  salt.states.tomcat

Manage Apache Tomcat web applications

Note: This state requires the Tomcat Manager webapp to be installed and running.

The following grains/pillars must be set for communication with Tomcat Manager to work:

```
tomcat-manager:
    user: 'tomcat-manager'
    passwd: 'Passw0rd'
```

Configuring Tomcat Manager

To manage webapps via the Tomcat Manager, you'll need to configure a valid user in the file `conf/tomcat-users.xml`.

Listing 19.1: conf/tomcat-users.xml

```
<?xml version='1.0' encoding='utf-8'?>
<tomcat-users>
    <role rolename="manager-script"/>
    <user username="tomcat-manager" password="Passw0rd" roles="manager-script"/>
</tomcat-users>
```

Notes

- Using multiple versions (aka. parallel deployments) on the same context path is not supported.
- If you use only this module for deployments you might want to restrict access to the manager so it's only accessible via localhost. For more info: http://tomcat.apache.org/tomcat-7.0-doc/manager-howto.html#Configuring_Manager_Application_Access
- Last tested on:
  - Tomcat Version: Apache Tomcat/7.0.54
  - JVM Vendor: Oracle Corporation
  - JVM Version: 1.8.0_101-b13
  - OS Architecture: amd64
  - OS Name: Linux
  - OS Version: 3.10.0-327.22.2.el7.x86_64

```
salt.states.tomcat.mod_watch(name, url='http://localhost:8080/manager', timeout=180)
```

The tomcat watcher, called to invoke the watch command. When called, it will reload the webapp in question

Note: This state exists to support special handling of the watch requisite. It should not be called directly.
Parameters for this function should be set by the state being triggered.

```python
salt.states.tomcat.undeployed(name, url='http://localhost:8080/manager', timeout=180)
```

Enforce that the WAR will be undeployed from the server.

- **name** The context path to undeploy.
- **url** [http://localhost:8080/manager] The URL of the server with the Tomcat Manager webapp.
- **timeout** [180] Timeout for HTTP request to the Tomcat Manager.

Example:

```yaml
jenkins:
  tomcat.undeployed:
    - name: /ran
    - require:
      - service: application-service
```

```python
salt.states.tomcat.wait(name, url='http://localhost:8080/manager', timeout=180)
```

Wait for the Tomcat Manager to load.

Notice that if tomcat is not running we won't wait for it start and the state will fail. This state can be required in the tomcat.war_deployed state to make sure tomcat is running and that the manager is running as well and ready for deployment.

- **url** [http://localhost:8080/manager] The URL of the server with the Tomcat Manager webapp.
- **timeout** [180] Timeout for HTTP request to the Tomcat Manager.

Example:

```yaml
tomcat-service:
  service.running:
    - name: tomcat
    - enable: True

wait-for-tomcatmanager:
  tomcat.wait:
    - timeout: 300
    - require:
      - service: tomcat-service

jenkins:
  tomcat.war_deployed:
    - name: /ran
    - war: salt://jenkins-1.2.4.war
    - require:
      - tomcat: wait-for-tomcatmanager
```

```python
salt.states.tomcat.war_deployed(name, war, force=False, url='http://localhost:8080/manager', timeout=180, temp_war_location=None, version=True)
```

Enforce that the WAR will be deployed and started in the context path, while making use of WAR versions in the filename.

**Note:** For more info about Tomcats file paths and context naming, please see [http://tomcat.apache.org/tomcat-7.0-doc/config/context.html#Naming](http://tomcat.apache.org/tomcat-7.0-doc/config/context.html#Naming)

- **name** The context path to deploy (incl. forward slash) the WAR to.
- **war** Absolute path to WAR file (should be accessible by the user running Tomcat) or a path supported by the `salt.modules.cp.get_url` function.
- **force** [False] Force deployment even if the version strings are the same. Disabled by default.

timeout [180] Timeout for HTTP requests to the Tomcat Manager.

temp_war_location [None] Use another location to temporarily copy the WAR file to. By default the system’s temp directory is used.

version [''] Specify the WAR version. If this argument is provided, it overrides the version encoded in the WAR file name, if one is present.

Use False or blank value to prevent guessing the version and keeping it blank.

New in version 2016.11.0.

Example:

```
jenkins:
    tomcat.war_deployed:
        - name: /salt-powered-jenkins
        - war: salt://jenkins-1.2.4.war
        - require:
            - service: application-service
```

**Note:** Be aware that in the above example the WAR `jenkins-1.2.4.war` will be deployed to the context path `salt-powered-jenkins##1.2.4`. To avoid this either specify a version yourself, or set version to False.

### 19.19.249 salt.states.trafficserver

**Control Apache Traffic Server**

New in version 2015.8.0.

salt.states.trafficserver.bounce_cluster(name)

```
bounce_ats_cluster:
    trafficserver.bounce_cluster
```

salt.states.trafficserver.bounce_local(name, drain=False)

This option modifies the behavior of `traffic_line -b` and `traffic_line -L` such that `traffic_server` is not shut down until the number of active client connections drops to the number given by the `proxy.config.restart.active_client_threshold` configuration variable.

```
bounce_ats_local:
    trafficserver.bounce_local

bounce_ats_local:
    trafficserver.bounce_local
    - drain: True
```

salt.states.trafficserver.clear_cluster(name)

Clears accumulated statistics on all nodes in the cluster.
clear_ats_cluster:
    trafficserver.clear_cluster

clear_ats_node:
    trafficserver.clear_node

salt.states.trafficserver.clear_node(name)
Clears accumulated statistics on the local node.

clear_ats_node:
    trafficserver.clear_node

salt.states.trafficserver.config(name, value)
Set Traffic Server configuration variable values.

proxy.config.proxy_name:
    trafficserver.config:
        - value: cdn.site.domain.tld

OR

traffic_server_setting:
    trafficserver.config:
        - name: proxy.config.proxy_name
        - value: cdn.site.domain.tld

salt.states.trafficserver.offline(name, path)
Mark a cache storage device as offline. The storage is identified by a path which must match exactly a path specified in storage.config. This removes the storage from the cache and redirects requests that would have used this storage to other storage. This has exactly the same effect as a disk failure for that storage. This does not persist across restarts of the traffic_server process.

offline_ats_path:
    trafficserver.offline:
        - path: /path/to/cache

salt.states.trafficserver.refresh(name)
Initiate a Traffic Server configuration file reread. Use this command to update the running configuration after any configuration file modification.

    The timestamp of the last reconfiguration event (in seconds since epoch) is published in the proxy.node.config.reconfigure_time metric.

refresh_ats:
    trafficserver.refresh

salt.states.trafficserver.restart_cluster(name)
Restart the traffic_manager process and the traffic_server process on all the nodes in a cluster.

restart_ats_cluster:
    trafficserver.restart_cluster

salt.states.trafficserver.restart_local(name, drain=False)
Restart the traffic_manager and traffic_server processes on the local node.

    This option modifies the behavior of traffic_line -b and traffic_line -L such that traffic_server is not shut down until the number of active client connections drops to the number given by the proxy.config.restart.active_client_threshold configuration variable.
salt.states.trafficserver.set_var(name, value)
Set Traffic Server configuration variable values.

Deprecated since version Fluorine: Use trafficserver.config instead.

proxy.config.proxy_name:
  trafficserver.set_var:
    - value: cdn.site.domain.tld

OR

traffic_server_setting:
  trafficserver.set_var:
    - name: proxy.config.proxy_name
    - value: cdn.site.domain.tld

salt.states.trafficserver.shutdown(name)
Shut down Traffic Server on the local node.

shutdown_ats:
  trafficserver.shutdown

salt.states.trafficserver.startup(name)
Start Traffic Server on the local node.

startup_ats:
  trafficserver.startup

salt.states.trafficserver.zero_cluster(name)
Reset performance statistics to zero across the cluster.

zero_ats_cluster:
  trafficserver.zero_cluster

salt.states.trafficserver.zero_node(name)
Reset performance statistics to zero on the local node.

zero_ats_node:
  trafficserver.zero_node

19.19.250  salt.states.tuned
Interface to Red Hat tuned-adm module

  maintainer  Syed Ali <alicsyed@gmail.com>
  maturity  new
  depends  cmd.run
  platform  Linux
salt.states.tuned.off(name=None)
   Turns `tuned' off. Example tuned.sls file for turning tuned off:
   tuned: tuned.off: []
   To see a valid list of states call execution module: tuned.list

salt.states.tuned.profile(name)
   This state module allows you to modify system tuned parameters
   Example tuned.sls file to set profile to virtual-guest
   tuned:
      • profile
      • name: virtual-guest
   name tuned profile name to set the system to
   To see a valid list of states call execution module: tuned.list

19.19.251 salt.states.uptime

Monitor Web Server with Uptime

Uptime is an open source remote monitoring application using Node.js, MongoDB, and Twitter Bootstrap.

**Warning:** This state module is beta. It might be changed later to include more or less automation.

**Note:** This state module requires a pillar to specify the location of your uptime install

```yaml
uptime:
   application_url: "http://uptime-url.example.org"
```

Example:

```yaml
url:
   uptime.monitored
url/sitemap.xml:
   uptime.monitored:
      polling: 600 # every hour
```

salt.states.uptime.monitored(name, **params)
   Makes sure an URL is monitored by uptime. Checks if URL is already monitored, and if not, adds it.

19.19.252 salt.states.user

Management of user accounts

The user module is used to create and manage user settings, users can be set as either absent or present

```yaml
fred:
   user.present:
      - fullname: Fred Jones
      - shell: /bin/zsh
      - home: /home/fred
```
- uid: 4000
- gid: 4000
- groups:
  - wheel
  - storage
  - games

testuser:
  user.absent

salt.states.user.absent(name, purge=False, force=False)

Ensure that the named user is absent

ame
The name of the user to remove

purge
Set purge to True to delete all of the user's files as well as the user, Default is False.

force
If the user is logged in, the absent state will fail. Set the force option to True to remove the user even if they are logged in. Not supported in FreeBSD and Solaris, Default is False.
	salt.states.user.present(name, uid=None, gid=None, gid_from_name=False, groups=None, optional_groups=None, remove_groups=True, home=None, createhome=True, password=None, hash_password=False, enforce_password=True, empty_password=False, shell=None, unique=True, system=False, full_name=None, room_number=None, workphone=None, home_phone=None, login_class=None, date=None, mindays=None, maxdays=None, inactdays=None, warn_days=None, expire=None, win_homedrive=None, win_profile=None, win_logonscript=None, win_description=None, nologinit=False)

Ensure that the named user is present with the specified properties

ame
The name of the user to manage

uid
The user id to assign, if left empty then the next available user id will be assigned

gid
The default group id. Also accepts group name.

gid_from_name
If True, the default group id will be set to the id of the group with the same name as the user. If the group does not exist the state will fail. Default is False.

groups
A list of groups to assign the user to, pass a list object. If a group specified here does not exist on the minion, the state will fail. If set to the empty list, the user will be removed from all groups except the default group. If unset, salt will assume current groups are still wanted (see issue #28706).

optional_groups
A list of groups to assign the user to, pass a list object. If a group specified here does not exist on the minion, the state will silently ignore it.

NOTE: If the same group is specified in both `groups` and `optional_groups`, then it will be assumed to be required and not optional.

remove_groups
Remove groups that the user is a member of that weren't specified in the state, Default is True.

home
The custom login directory of user. Uses default value of underlying system if not set. Notice that this directory does not have to exist. This also the location of the home directory to create if createhome is set to True.

createhome
[True] If set to False, the home directory will not be created if it doesn't already exist.

**Warning:** Not supported on Windows or Mac OS.

Additionally, parent directories will not be created. The parent directory for home must already exist.

nologinit
[False] If set to True, it will not add the user to lastlog and faillog databases.
Note: Not supported on Windows or Mac OS.

**password** A password hash to set for the user. This field is only supported on Linux, FreeBSD, NetBSD, OpenBSD, and Solaris. If the `empty_password` argument is set to `True` then `password` is ignored. For Windows this is the plain text password. For Linux, the hash can be generated with `openssl passwd -1`.

Changed in version 0.16.0: BSD support added.

**hash_password** Set to True to hash the clear text password. Default is `False`.

**enforce_password** Set to False to keep the password from being changed if it has already been set and the password hash differs from what is specified in the "password" field. This option will be ignored if `password` is not specified. Default is `True`.

**empty_password** Set to True to enable password-less login for user. Default is `False`.

**shell** The login shell, defaults to the system default shell

**unique** Require a unique UID, Default is `True`.

**system** Choose UID in the range of FIRST_SYSTEM_UID and LAST_SYSTEM_UID, Default is `False`.

**loginclass** The login class, defaults to empty (BSD only)

User comment field (GECOS) support (currently Linux, BSD, and MacOS only):

The below values should be specified as strings to avoid ambiguities when the values are loaded. (Especially the phone and room number fields which are likely to contain numeric data)

**fullname** The user's full name

**roomnumber** The user's room number (not supported in MacOS)

**workphone** The user's work phone number (not supported in MacOS)

**homephone** The user's home phone number (not supported in MacOS) If GECOS field contains more than 3 commas, this field will have the rest of them

Changed in version 2014.7.0: Shadow attribute support added.

Shadow attributes support (currently Linux only):

The below values should be specified as integers.

**date** Date of last change of password, represented in days since epoch (January 1, 1970).

**mindays** The minimum number of days between password changes.

**maxdays** The maximum number of days between password changes.

**inactdays** The number of days after a password expires before an account is locked.

**warnays** Number of days prior to maxdays to warn users.

**expire** Date that account expires, represented in days since epoch (January 1, 1970).

The below parameters apply to windows only:

**win_homedrive** (Windows Only) The drive letter to use for the home directory. If not specified the home directory will be a unc path. Otherwise the home directory will be mapped to the specified drive. Must be a letter followed by a colon. Because of the colon, the value must be surrounded by single quotes. ie: `- win_homedrive: `U:

Changed in version 2015.8.0.

**win_profile** (Windows Only) The custom profile directory of the user. Uses default value of underlying system if not set.

Changed in version 2015.8.0.

**win_logonscript** (Windows Only) The full path to the logon script to run when the user logs in.

Changed in version 2015.8.0.

**win_description** (Windows Only) A brief description of the purpose of the users account.

Changed in version 2015.8.0.
19.19.253 salt.states.vault module

maintainer SaltStack
maturity new
platform all

New in version 2017.7.0.

States for managing Hashicorp Vault. Currently handles policies. Configuration instructions are documented in the execution module docs.

`salt.states.vault.policy_present(name, rules)`

Ensure a Vault policy with the given name and rules is present.

- **name**  The name of the policy
- **rules**  Rules formatted as in-line HCL

```hcl
# demo-policy:
demo-policy:
  vault.policy_present:
    - name: foo/bar
    - rules:
      path "secret/top-secret/*" {
        policy = "deny"
      }
      path "secret/not-very-secret/*" {
        policy = "write"
      }
```

19.19.254 salt.states.vbox_guest

VirtualBox Guest Additions installer state

`salt.states.vbox_guest.additions_installed(name, reboot=False, upgrade_os=False)`

Ensure that the VirtualBox Guest Additions are installed. Uses the CD, connected by VirtualBox.

- **name**  The name has no functional value and is only used as a tracking reference.
- **reboot** [False] Restart OS to complete installation.
- **upgrade_os** [False] Upgrade OS (to ensure the latests version of kernel and developer tools installed).

`salt.states.vbox_guest.additions_removed(name, force=False)`

Ensure that the VirtualBox Guest Additions are removed. Uses the CD, connected by VirtualBox.

To connect VirtualBox Guest Additions via VirtualBox graphical interface press `Host+D` (`Host` is usually `Right Ctrl`).

- **name**  The name has no functional value and is only used as a tracking reference.
- **force** Force VirtualBox Guest Additions removing.

`salt.states.vbox_guest.grant_access_to_shared_folders_to(name, users=None)`

Grant access to auto-mounted shared folders to the users.

- **name**  Name of the user to grant access to auto-mounted shared folders to.
- **users** List of names of users to grant access to auto-mounted shared folders to. If specified, `name` will not be taken into account.
19.19.255  salt.states.victorops

Create an Event in VictorOps

New in version 2015.8.0.

This state is useful for creating events on the VictorOps service during state runs.

```python
webserver-warning-message:
victorops.create_event:
- message_type: 'CRITICAL'
- entity_id: 'webserver/diskspace'
- state_message: 'Webserver diskspace is low.'

database-server-warning-message:
victorops.create_event:
- message_type: 'WARNING'
- entity_id: 'db_server/load'
- state_message: 'Database Server load is high.'

salt.states.victorops.create_event(name, message_type, routing_key='everyone', **kwargs)
```

Create an event on the VictorOps service

The following parameters are required:
- name  This is a short description of the event.
- message_type  One of the following values: INFO, WARNING, ACKNOWLEDGEMENT, CRITICAL, RECOVERY.

The following parameters are optional:
- routing_key  The key for where messages should be routed. By default, sent to `everyone` route.
- entity_id  The name of alerting entity. If not provided, a random name will be assigned.
- timestamp  Timestamp of the alert in seconds since epoch. Defaults to the time the alert is received at VictorOps.
- timestamp_fmt  The date format for the timestamp parameter. Defaults to `'%Y-%m-%dT%H:%M:%S'`.
- state_start_time  The time this entity entered its current state (seconds since epoch). Defaults to the time alert is received.
- state_start_time_fmt  The date format for the timestamp parameter. Defaults to `'%Y-%m-%dT%H:%M:%S'`.
- state_message  Any additional status information from the alert item.
- entity_is_host  Used within VictorOps to select the appropriate display format for the incident.
- entity_display_name  Used within VictorOps to display a human-readable name for the entity.
- ack_message  A user entered comment for the acknowledgment.
- ack_author  The user that acknowledged the incident.
19.19.256  salt.states.virt module

Manage virt

For the key certificate this state uses the external pillar in the master to call for the generation and signing of
certificates for systems running libvirt:

```python
libvirt_keys:
    virt.keys

salt.states.virt.keys(name, basepath='/etc/pki')
  Manage libvirt keys.
    name  The name variable used to track the execution
    basepath  Defaults to /etc/pki, this is the root location used for libvirt keys on the hypervisor

salt.states.virt.powered_off(name)
  Stops a VM by power off.
    New in version 2016.3.0.

    domain_name:
        virt.stopped

salt.states.virt.rebooted(name)
  Reboots VMs
    New in version 2016.3.0.
    Parameters
      name --
    Returns

salt.states.virt.reverted(name, snapshot=None, cleanup=False)
  Deprecates since version 2016.3.0.
  Reverts to the particular snapshot.
    New in version 2016.3.0.

    domain_name:
        virt.reverted:
            - cleanup: True
    domain_name_1:
        virt.reverted:
            - snapshot: snapshot_name
            - cleanup: False

salt.states.virt.running(name, **kwargs)
  Starts an existing guest, or defines and starts a new VM with specified arguments.
    New in version 2016.3.0.

    domain_name:
        virt.running

    domain_name:
        virt.running:
            - cpu: 2
            - mem: 2048
            - eth0_mac: 00:00:6a:53:00:e3
```
salt.states.virt.saved\((name, suffix=None)\)

Deprecated since version 2016.3.0: Use snapshot() instead.

Takes a snapshot of a particular VM or by a UNIX-style wildcard.

New in version 2016.3.0.

```yaml
domain_name:
  virt.saved:
    - suffix: periodic

domain*:
  virt.saved:
    - suffix: periodic
```

salt.states.virt.snapshot\((name, suffix=None)\)

Takes a snapshot of a particular VM or by a UNIX-style wildcard.

New in version 2016.3.0.

```yaml
domain_name:
  virt.snapshot:
    - suffix: periodic

domain*:
  virt.snapshot:
    - suffix: periodic
```

salt.states.virt.stopped\((name)\)

Stops a VM by shutting it down nicely.

New in version 2016.3.0.

```yaml
domain_name:
  virt.stopped
```

salt.states.virt.unpowered\((name)\)

Deprecated since version 2016.3.0: Use powered_off() instead.

Stops a VM by power off.

New in version 2016.3.0.

```yaml
domain_name:
  virt.stopped
```

19.19.257  salt.states.virtualenv

Setup of Python virtualenv sandboxes.

New in version 0.17.0.
Create a virtualenv and optionally manage it with pip

name Path to the virtualenv.

requirements: None Path to a pip requirements file. If the path begins with salt:// the file will be transferred from the master file server.

use_wheel: False Prefer wheel archives (requires pip >= 1.4).

python [None] Python executable used to build the virtualenv

user: None The user under which to run virtualenv and pip.

cwd: None Path to the working directory where pip install is executed.

no_deps: False Pass --no-deps to pip install.

pip_exists_action: None Default action of pip when a path already exists: (s)witch, (i)gnore, (w)ipe, (b)ackup.

proxy: None Proxy address which is passed to pip install.

env_vars: None Set environment variables that some builds will depend on. For example, a Python C-module may have a Makefile that needs INCLUDE_PATH set to pick up a header file while compiling.

no_use_wheel: False Force to not use wheel archives (requires pip>1.4)

no_binary Force to not use binary packages (requires pip >= 7.0.0) Accepts either :all: to disable all binary packages, :none: to empty the set, or a list of one or more packages

pip_upgrade: False Pass --upgrade to pip install.

pip_pkgs: None As an alternative to requirements, pass a list of pip packages that should be installed.

process_dependency_links: False Run pip install with the --process_dependency_links flag.

New in version 2017.7.0.

Also accepts any kwargs that the virtualenv module will. However, some kwargs, such as the pip option, require --distribute: True.

```
/var/www/myvirtualenv.com:
virtualenv.managed:
  - system_site_packages: False
  - requirements: salt://REQUIREMENTS.txt
  - env_vars:
    PATH_VAR: '/usr/local/bin/'
```

19.19.258 salt.states.win_certutil module

Installing of certificates to the Windows Certificate Manager

Install certificates to the Windows Certificate Manager

```
salt://certs/cert.cer:
certutil.add_store:
  - store: TrustedPublisher
```

salt.states.win_certutil.add_store(name, store, saltenv='base')
Store a certificate to the given store

**name**  The certificate to store, this can use local paths or salt:// paths

**store**  The store to add the certificate to

**saltenv**  The salt environment to use, this is ignored if a local path is specified

```python
salt.states.win_certutil.del_store(name, store, saltenv='base')
```

Remove a certificate in the given store

**name**  The certificate to remove, this can use local paths or salt:// paths

**store**  The store to remove the certificate from

**saltenv**  The salt environment to use, this is ignored if a local path is specified

19.19.259  salt.states.win_dacl

Windows Object Access Control Lists

Ensure an ACL is present

**parameters:**  name - the path of the object
objectType - Registry/File/Directory
user - user account or SID
for the ace
permission - permission for the ace (see module win_acl for available permissions for each
objectType)
acetype - Allow/Deny
propagation - how the ACL should apply to child objects (see module
win_acl for available propagation types)

```python
addAcl:
    win_dacl.present:
    - name: HKEY_LOCAL_MACHINE\SOFTWARE\mykey
    - objectType: Registry
    - user: FakeUser
    - permission: FullControl
    - acetype: ALLOW
    - propagation: KEY&SUBKEYS
```

Ensure an ACL does not exist

**parameters:**  name - the path of the object
objectType - Registry/File/Directory
user - user account or SID
for the ace
permission - permission for the ace (see module win_acl for available permissions for each
objectType)
acetype - Allow/Deny
propagation - how the ACL should apply to child objects (see module
win_acl for available propagation types)

```python
removeAcl:
    win_dacl.absent:
    - name: HKEY_LOCAL_MACHINE\SOFTWARE\mykey
    - objectType: Registry
    - user: FakeUser
    - permission: FullControl
    - acetype: ALLOW
    - propagation: KEY&SUBKEYS
```

Ensure an object is inheriting permissions

**parameters:**  name - the path of the object
objectType - Registry/File/Directory
clear_existing_acl - True/False
- when inheritance is enabled, should the existing ACL be kept or cleared out

```python
eInherit:
    win_dacl.enableinheritance:
    - name: HKEY_LOCAL_MACHINE\SOFTWARE\mykey
    - objectType: Registry
    - clear_existing_acl: True
```
Ensure an object is not inheriting permissions

```python
parameters: name - the path of the object objectType - Registry/File/Directory copy_inherited_acl -
    True/False - if inheritance is enabled, should the inherited permissions be copied to the ACL when inheritance is disabled

dInherit:
    win_dacl.disableinheritance:
        - name: HKEY_LOCAL_MACHINE\SOFTWARE\mykey
        - objectType: Registry
        - copy_inherited_acl: False
```

```python
salt.states.win_dacl.absent(name, objectType, user, permission, acetype, propagation)
Ensure an ACL does not exist
```

```python
salt.states.win_dacl.disinherit(name, objectType, copy_inherited_acl=True)
Ensure an object is not inheriting ACLs from its parent
```

```python
salt.states.win_dacl.inherit(name, objectType, clearExisting_acl=False)
Ensure an object is inheriting ACLs from its parent
```

```python
salt.states.win_dacl.present(name, objectType, user, permission, acetype, propagation)
Ensure an ACE is present
```

### 19.19.260 salt.states.win_dism module

**Installing of Windows features using DISM**

Install windows features/capabilities with DISM

```python
Language.Basic~~~en-US~0.0.1.0:
    dism.capability_installed

NetFx3:
    dism.feature_installed
```

```python
salt.states.win_dism.capability_installed(name, source=None, limit_access=False, image=None, restart=False)
Install a DISM capability
```

**Parameters**

- `name` *(str)* -- The capability to install
- `source` *(str)* -- The optional source of the capability
- `limit_access` *(bool)* -- Prevent DISM from contacting Windows Update for online images
- `image` *(Optional[str])* -- The path to the root directory of an offline Windows image. If `None` is passed, the running operating system is targeted. Default is None.
- `restart` *(Optional[bool])* -- Reboot the machine if required by the install

**Example**

Run `dism.available_capabilities` to get a list of available capabilities. This will help you get the proper name to use.

```python
install_dotnet35:
    dism.capability_installed:
        - name: NetFX3~~~
```
salt.states.win_dism.capability_removed(name, image=None, restart=False)
Uninstall a DISM capability
Parameters
- **name (str)** -- The capability to uninstall
- **image (Optional[str])** -- The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None.
- **restart (Optional[bool])** -- Reboot the machine if required by the install

Example

Run dism.installed_capabilities to get a list of installed capabilities. This will help you get the proper name to use.

```py
remove_dotnet35:
    dism.capability_removed:
        - name: NetFX3
```

salt.states.win_dism.feature_installed(name, package=None, source=None, limit_access=False, enable_parent=False, image=None, restart=False)
Install a DISM feature
Parameters
- **name (str)** -- The feature in which to install
- **package (Optional[str])** -- The parent package for the feature. You do not have to specify the package if it is the Windows Foundation Package. Otherwise, use package to specify the parent package of the feature
- **source (str)** -- The optional source of the feature
- **limit_access (bool)** -- Prevent DISM from contacting Windows Update for online images
- **enable_parent (Optional[bool])** -- True will enable all parent features of the specified feature
- **image (Optional[str])** -- The path to the root directory of an offline Windows image. If None is passed, the running operating system is targeted. Default is None.
- **restart (Optional[bool])** -- Reboot the machine if required by the install

Example

Run dism.available_features to get a list of available features. This will help you get the proper name to use.

```py
install_telnet_client:
    dism.feature_installed:
        - name: TelnetClient
```

salt.states.win_dism.feature_removed(name, remove_payload=False, image=None, restart=False)
Disables a feature.
Parameters
- **name (str)** -- The feature to disable
- **remove_payload (Optional[bool])** -- Remove the feature's payload. Must supply source when enabling in the future.
- **image** (*Optional*[str]) -- The path to the root directory of an offline Windows image. If *None* is passed, the running operating system is targeted. Default is *None*.

- **restart** (*Optional*[bool]) -- Reboot the machine if required by the install

### Example

Run `dism.installed_features` to get a list of installed features. This will help you get the proper name to use.

```python
remove_telnet_client:
  dism.feature_removed:
    - name: TelnetClient
    - remove_payload: True
```

#### `salt.states.win_dism.package_installed`(*name*, *ignore_check=False*, *prevent_pending=False*, *image=None*, *restart=False*)

Install a package.

**Parameters**

- **name** (*str*) -- The package to install. Can be a .cab file, a .msu file, or a folder
- **ignore_check** (*Optional*[bool]) -- Skip installation of the package if the applicability checks fail
- **prevent_pending** (*Optional*[bool]) -- Skip the installation of the package if there are pending online actions
- **image** (*Optional*[str]) -- The path to the root directory of an offline Windows image. If *None* is passed, the running operating system is targeted. Default is *None*.
- **restart** (*Optional*[bool]) -- Reboot the machine if required by the install

### Example

```python
install_KB123123123:
  dism.package_installed:
    - name: C:\Packages\KB123123123.cab
```

#### `salt.states.win_dism.package_removed`(*name*, *image=None*, *restart=False*)

Uninstall a package

**Parameters**

- **name** (*str*) -- The full path to the package. Can be either a .cab file or a folder. Should point to the original source of the package, not to where the file is installed. This can also be the name of a package as listed in `dism.installed_packages`
- **image** (*Optional*[str]) -- The path to the root directory of an offline Windows image. If *None* is passed, the running operating system is targeted. Default is *None*.
- **restart** (*Optional*[bool]) -- Reboot the machine if required by the install

### Example

```python
# Example using source
remove_KB1231231:
  dism.package_installed:
    - name: C:\Packages\KB123123123.cab

# Example using name from `dism.installed_packages`
remove_KB1231231:
```
19.19.261 salt.states.win_dns_client

Module for configuring DNS Client on Windows systems

salt.states.win_dns_client.dns_dhcp(name, interface='Local Area Connection')  
Configure the DNS server list from DHCP Server

salt.states.win_dns_client.dns_exists(name, servers=None, interface='Local Area Connection', replace=False)  
Configure the DNS server list in the specified interface

Example:

```
cfg_dns_servers:
  win_dns_client.dns_exists:
    - replace: True  #remove any servers not in the "servers" list, default is False
    - servers:
      - 8.8.8.8
      - 8.8.8.9
```

salt.states.win_dns_client.primary_suffix(name, suffix=None, updates=False)  
New in version 2014.7.0.

Configure the global primary DNS suffix of a DHCP client.

- **suffix** [None] The suffix which is advertised for this client when acquiring a DHCP lease. When none is set, the explicitly configured DNS suffix will be removed.
- **updates** [False] Allow syncing the DNS suffix with the AD domain when the client’s AD domain membership changes

```
pprimary_dns_suffix:
  win_dns_client.primary_suffix:
    - suffix: sub.domain.tld
    - updates: True
```

19.19.262 salt.states.win_firewall

State for configuring Windows Firewall

salt.states.win_firewall.add_rule(name, localport, protocol='tcp', action='allow', dir='in', remoteip='any')  
Add a new inbound or outbound rule to the firewall policy

Parameters

- **name** (str) -- The name of the rule. Must be unique and cannot be `all`. Required.
- **localport** (int) -- The port the rule applies to. Must be a number between 0 and 65535. Can be a range. Can specify multiple ports separated by commas. Required.
- **protocol** (Optional[str]) -- The protocol. Can be any of the following:
  - A number between 0 and 255
  - icmpv4
  - icmpv6
  - tcp
  - udp
  - any
- **action** (*Optional*[str]) -- The action the rule performs. Can be any of the following:
  - allow
  - block
  - bypass
- **dir** (*Optional*[str]) -- The direction. Can be in or out.
- **remoteip** (*Optional*[str]) -- The remote IP. Can be any of the following:
  - any
  - localsubnet
  - dns
  - dhcp
  - wins
  - defaultgateway
  - Any valid IPv4 address (192.168.0.12)
  - Any valid subnet (192.168.1.0/24)
  - Any valid range of IP addresses (192.168.0.1-192.168.0.12)
  - A list of valid IP addresses
Can be combinations of the above separated by commas.

New in version 2016.11.6.

Example:

```python
open_smb_port:
  win_firewall.add_rule:
    - name: SMB (445)
    - localport: 445
    - protocol: tcp
    - action: allow
```

salt.states.win_firewall.disabled(name='allprofiles')

Disable all the firewall profiles (Windows only)

**Parameters**

- **profile** (*Optional*[str]) -- The name of the profile to disable. Default is all-profiles. Valid options are:
  - allprofiles
  - domainprofile
  - privateprofile
  - publicprofile

Example:

```python
# To disable the domain profile
disable_domain:
  win_firewall.disabled:
    - name: domainprofile

# To disable all profiles
disable_all:
  win_firewall.disabled:
    - name: allprofiles
```

salt.states.win_firewall.enabled(name='allprofiles')

Enable all the firewall profiles (Windows only)

**Parameters**

- **profile** (*Optional*[str]) -- The name of the profile to enable. Default is all-profiles. Valid options are:
  - allprofiles
  - domainprofile

19.19. state modules
• privateprofile
• publicprofile

Example:

```yaml
# To enable the domain profile
enable_domain:
  win_firewall.enabled:
    - name: domainprofile

# To enable all profiles
enable_all:
  win_firewall.enabled:
    - name: allprofiles
```

19.19.263 salt.states.win_iis module

Microsoft IIS site management

This module provides the ability to add/remove websites and application pools from Microsoft IIS.

New in version 2016.3.0.

salt.states.win_iis.container_setting(name, container, settings=None)

Set the value of the setting for an IIS container.

Parameters

• name (str) -- The name of the IIS container.
• container (str) -- The type of IIS container. The container types are: AppPools, Sites, SslBindings
• settings (str) -- A dictionary of the setting names and their values. Example of usage for the AppPools container:

```yaml
site0-apppool-setting:
  win_iis.container_setting:
    - name: site0
    - container: AppPools
    - settings:
      managedPipelineMode: Integrated
      processModel.maxProcesses: 1
      processModel.userName: TestUser
      processModel.password: TestPassword
      processModel.identityType: SpecificUser
```

Example of usage for the Sites container:

```yaml
site0-site-setting:
  win_iis.container_setting:
    - name: site0
    - container: Sites
    - settings:
      logFile.logFormat: W3C
      logFile.period: Daily
      limits.maxUrlSegments: 32
```

salt.states.win_iis.create_app(name, site, sourcepath, apppool=None)

Create an IIS application.

Parameters

• name (str) -- The IIS application.
• **site** *(str)* -- The IIS site name.
• **sourcepath** *(str)* -- The physical path.
• **apppool** *(str)* -- The name of the IIS application pool.

Example of usage with only the required arguments:

```python
site0-v1-app:
    win_iis.create_app:
        - name: v1
        - site: site0
        - sourcepath: C:\inetpub\site0\v1
```

Example of usage specifying all available arguments:

```python
site0-v1-app:
    win_iis.create_app:
        - name: v1
        - site: site0
        - sourcepath: C:\inetpub\site0\v1
        - apppool: site0
```

```python
salt.states.win_iis.create_apppool(name)
Create an IIS application pool.

Parameters
• **name** *(str)* -- The name of the IIS application pool.

Usage:

```python
site0-apppool:
    win_iis.create_apppool:
        - name: site0
```

```python
salt.states.win_iis.create_binding(name, site, hostheader='`, ipaddress='`, port=80, protocol='http', sslflags=0)
Create an IIS binding.

Parameters
• **site** *(str)* -- The IIS site name.
• **hostheader** *(str)* -- The host header of the binding.
• **ipaddress** *(str)* -- The IP address of the binding.
• **port** *(str)* -- The TCP port of the binding.
• **protocol** *(str)* -- The application protocol of the binding.
• **sslflags** *(str)* -- The flags representing certificate type and storage of the binding.

Usage:

```python
site0-https-binding:
    win_iis.create_binding:
        - site: site0
        - hostheader: site0.local
        - ipaddress: '*`
        - port: 443
        - protocol: https
        - sslflags: 0
```

```
19.19. state modules 3095
```
salt.states.win_iis.create_cert_binding(name, site, hostheader='', ipaddress='*', port=443, sslflags=0)

Assign a certificate to an IIS binding.

Parameters
- **name** *(str)* -- The thumbprint of the certificate.
- **site** *(str)* -- The IIS site name.
- **hostheader** *(str)* -- The host header of the binding.
- **ipaddress** *(str)* -- The IP address of the binding.
- **port** *(str)* -- The TCP port of the binding.
- **sslflags** *(str)* -- Flags representing certificate type and certificate storage of the binding.

Example of usage with only the required arguments:

```yaml
site0-cert-binding:
  win_iis.create_cert_binding:
    - name: 9988776655443322111000AAABBBCCCDDEEEFFFF
    - site: site0
```

Example of usage specifying all available arguments:

```yaml
site0-cert-binding:
  win_iis.create_cert_binding:
    - name: 9988776655443322111000AAABBBCCCDDEEEFFFF
    - site: site0
    - hostheader: site0.local
    - ipaddress: 192.168.1.199
    - port: 443
    - sslflags: 1
```

New in version 2016.11.0.

salt.states.win_iis.create_vdir(name, site, sourcepath, app='/')

Create an IIS virtual directory.

Parameters
- **name** *(str)* -- The virtual directory name.
- **site** *(str)* -- The IIS site name.
- **sourcepath** *(str)* -- The physical path.
- **app** *(str)* -- The IIS application.

Example of usage with only the required arguments:

```yaml
site0-foo-vdir:
  win_iis.create_vdir:
    - name: foo
    - site: site0
    - sourcepath: C:\inetpub\vdirs\foo
```

Example of usage specifying all available arguments:

```yaml
site0-foo-vdir:
  win_iis.create_vdir:
    - name: foo
    - site: site0
    - sourcepath: C:\inetpub\vdirs\foo
    - app: v1
```

salt.states.win_iis.deployed(name, sourcepath, apppool='", hostheader='", ipaddress='", port=80, protocol='http')

Ensure the website has been deployed.
Parameters

- **name** (str) -- The IIS site name.
- **sourcepath** (str) -- The physical path of the IIS site.
- **apppool** (str) -- The name of the IIS application pool.
- **hostheader** (str) -- The host header of the binding.
- **ipaddress** (str) -- The IP address of the binding.
- **port** (str) -- The TCP port of the binding.
- **protocol** (str) -- The application protocol of the binding.

Example of usage with only the required arguments. This will default to using the default application pool assigned by IIS:

```yaml
site0-deployed:
  win_iis.deployed:
    - name: site0
    - sourcepath: C:\inetpub\site0
```

Example of usage specifying all available arguments:

```yaml
site0-deployed:
  win_iis.deployed:
    - name: site0
    - sourcepath: C:\inetpub\site0
    - apppool: site0
    - hostheader: site0.local
    - ipaddress: '*'
    - port: 443
    - protocol: https
```

**salt.states.win_iis.remove_app(name, site)**

Remove an IIS application.

Parameters

- **name** (str) -- The application name.
- **site** (str) -- The IIS site name.

Usage:

```yaml
site0-v1-app-remove:
  win_iis.remove_app:
    - name: v1
    - site: site0
```

**salt.states.win_iis.remove_apppool(name)**

Remove an IIS application pool.

Parameters **name** (str) -- The name of the IIS application pool.

Usage:

```yaml
defaultapppool-remove:
  win_iis.remove_apppool:
    - name: DefaultAppPool
```

**salt.states.win_iis.remove_binding(name, site, hostheader='', ipaddress='*', port=80)**

Remove an IIS binding.

Parameters

- **site** (str) -- The IIS site name.
- **hostheader** (str) -- The host header of the binding.
- **ipaddress** (str) -- The IP address of the binding.
- **port** (str) -- The TCP port of the binding.
Example of usage with only the required arguments:

```yaml
site0-https-binding-remove:
    win_iis.remove_binding:
        - site: site0
```

Example of usage specifying all available arguments:

```yaml
site0-https-binding-remove:
    win_iis.remove_binding:
        - site: site0
        - hostheader: site0.local
        - ipaddress: '*'
        - port: 443
```

```python
salt.states.win_iis.remove_cert_binding(name, site, hostheader='*', ipaddress='*', port=443)
```

Remove a certificate from an IIS binding.

**Parameters**

- `name (str)` -- The thumbprint of the certificate.
- `site (str)` -- The IIS site name.
- `hostheader (str)` -- The host header of the binding.
- `ipaddress (str)` -- The IP address of the binding.
- `port (str)` -- The TCP port of the binding.

Example of usage with only the required arguments:

```yaml
site0-cert-binding-remove:
    win_iis.remove_cert_binding:
        - name: 9988776655443322111000AAABBBCCCDDDEEEFFF
        - site: site0
```

Example of usage specifying all available arguments:

```yaml
site0-cert-binding-remove:
    win_iis.remove_cert_binding:
        - name: 9988776655443322111000AAABBBCCCDDDEEEFFF
        - site: site0
        - hostheader: site0.local
        - ipaddress: 192.168.1.199
        - port: 443
```

New in version 2016.11.0.

```python
salt.states.win_iis.remove_site(name)
```

Delete a website from IIS.

**Parameters**

- `name (str)` -- The IIS site name.

Usage:

```yaml
defaultwebsite-remove:
    win_iis.remove_site:
        - name: Default Web Site
```

```python
salt.states.win_iis.remove_vdir(name, site, app='/')
```

Remove an IIS virtual directory.

**Parameters**

- `name (str)` -- The virtual directory name.
- `site (str)` -- The IIS site name.
- `app (str)` -- The IIS application.
Example of usage with only the required arguments:

```
site0-foo-vdir-remove:
    win_iis.remove_vdir:
    - name: foo
    - site: site0
```

Example of usage specifying all available arguments:

```
site0-foo-vdir-remove:
    win_iis.remove_vdir:
    - name: foo
    - site: site0
    - app: v1
```

```
salt.states.win_iis.set_app(name, site, settings=None)
```

New in version 2017.7.0.
Set the value of the setting for an IIS web application.

**Note:** This function only configures existing app. Params are case sensitive.

**Parameters**
- **name (str)** -- The IIS application.
- **site (str)** -- The IIS site name.
- **settings (str)** -- A dictionary of the setting names and their values.

**Available settings:**
- `physicalPath` - The physical path of the webapp
- `applicationPool` - The application pool for the webapp
- `userName` "connectAs" user
- `password` "connectAs" password for user

**Return type** bool

Example of usage:

```
site0-webapp-setting:
    win_iis.set_app:
    - name: app0
    - site: Default Web Site
    - settings:
        userName: domain\user
        password: pass
        physicalPath: c:\inetpub\wwwroot
        applicationPool: appPool0
```

**19.19.264 salt.states.win_lgpo module**

**Manage Windows Local Group Policy**

New in version 2016.11.0.
This state allows configuring local Windows Group Policy
The state can be used to ensure the setting of a single policy or multiple policies in one pass.
Single policies must specify the policy name, the setting, and the policy class (Machine/User/Both)

Example single policy configuration

```
Ensure Account Lockout Duration:
  lgpo.set:
    - name: Account lockout duration
    - setting: 90
    - policy_class: Machine

Account lockout duration:
  gpo.set:
    - setting: 120
    - policy_class: Machine
```

Multiple policy configuration

```
Company Local Group Policy:
  lgpo.set:
    - computer_policy:
      Deny logon locally: Guest
      Account lockout duration: 120
      Account lockout threshold: 10
      Reset account lockout counter after: 1440
      Enforce password history: 24
      Maximum password age: 60
      Minimum password age: 1
      Minimum password length: 14
      Password must meet complexity requirements: Enabled
      Store passwords using reversible encryption: Disabled
      Configure Automatic Updates:
        Configure automatic updating: 4 - Auto download and schedule the install
        Scheduled install day: 7 - Every Saturday
        Scheduled install time: 17:00
      Specify intranet Microsoft update service location:
        Set the intranet update service for detecting updates: http://mywsus
        Set the intranet statistics server: http://mywsus
    - user_policy:
      Do not process the legacy run list: Enabled

server_policy:
  lgpo.set:
    - computer_policy:
      Maximum password age: 60
      Minimum password age: 1
      Minimum password length: 14
      Account lockout duration: 1440
      Account lockout threshold: 10
      Reset account lockout counter after: 1440
      Manage auditing and security log:
        - "BUILTIN\Administrators"
      Replace a process level token:
        - "NT AUTHORITY\NETWORK SERVICE"
        - "NT AUTHORITY\LOCAL SERVICE"
      "Accounts: Guest account status": Disabled
      "Accounts: Rename guest account": Not_4_U
      "Audit: Audit the use of Backup and Restore privilege": Enabled
      "Interactive logon: Do not display last user name": Enabled
```
"Network\DNS Client\Dynamic update": Disabled
"System\Logon\Do not display the Getting Started welcome screen at logon": Enabled
"Windows Components\Remote Desktop Services\Remote Desktop Session\Host\Connections\Select RDP transport protocols": "Select Transport Type": "Use both UDP and TCP"
"Windows Components\Windows Update\Allow Automatic Updates immediate installation": Enabled
"Windows Components\Windows Update\Allow non-administrators to receive update notifications": Disabled
"Windows Components\Windows Update\Always automatically restart at the scheduled time": "The restart timer will give users this much time to save their work": 15
"Windows Components\Windows Update\Automatic Updates detection frequency": "Check for updates at the following interval (hours)": 1
"Windows Components\Windows Update\Configure Automatic Updates": "Configure automatic updating": 4 - Auto download and schedule the install
"Install during automatic maintenance": False
"Scheduled install day": 7 - Every Saturday
"Scheduled install time": "17:00"
"Windows Components\Windows Update\Delay Restart for scheduled installations": "Wait the following period before proceeding with a scheduled restart": 1
"Windows Components\Windows Update\No auto-restart with logged on users for scheduled installations": Disabled
"Windows Components\Windows Update\Re-prompt for restart with scheduled installations": "Wait the following period before prompting again with a scheduled restart": 30
"Windows Components\Windows Update\Reschedule Automatic Updates scheduled installations": Disabled
"Windows Components\Windows Update\Specify intranet Microsoft update service location": "Set the intranet update service for detecting updates": http://mywsus
"Set the intranet statistics server": http://mywsus
- cumulative_rights_assignments: True

salt.states.win_lgpo.set_(name, setting=NoSuch, policy_class=NoSuch, computer_policy=NoSuch, user_policy=NoSuch, cumulative_rights_assignments=True, admil_language='en-US')

Ensure the specified policy is set
name the name of a single policy to configure
setting the configuration setting for the single named policy if this argument is used the computer_policy/user_policy arguments will be ignored
policy_class the policy class of the single named policy to configure this can `machine`, `user`, or `both`
computer_policy a dict of policymame: value pairs of a set of computer policies to configure if this argument is used, the name/setting/policy_class arguments will be ignored
user_policy a dict of policymame: value pairs of a set of user policies to configure if this argument is used, the name/setting/policy_class arguments will be ignored
cumulative_rights_assignments determine if any user right assignment policies specified will be cumulative or explicit
admil_language the admil language to use for AMDX policy data/display conversions
19.19.265 salt.states.win_license module

Installation and activation of windows licenses

Install and activate windows licenses

```
XXXXX-XXXXX-XXXXX-XXXXX-XXXXX:
    license.activate
```

salt.states.win_license.activate(name)

  Install and activate the given product key

  name  The 5x5 product key given to you by Microsoft

19.19.266 salt.states.win_network

Configuration of network interfaces on Windows hosts

New in version 2014.1.0.

This module provides the network state(s) on Windows hosts. DNS servers, IP addresses and default gateways can currently be managed. Below is an example of the configuration for an interface that uses DHCP for both DNS servers and IP addresses:

```
Local Area Connection #2:
    network.managed:
        - dns_proto: dhcp
        - ip_proto: dhcp
```

**Note:** Both the dns_proto and ip_proto arguments are required.

Static DNS and IP addresses can be configured like so:

```
Local Area Connection #2:
    network.managed:
        - dns_proto: static
        - dns_servers:
            - 8.8.8.8
            - 8.8.4.4
        - ip_proto: static
        - ip_addrs:
            - 10.2.3.4/24
```

**Note:** IP addresses are specified using the format `<ip-address>/<subnet-length>`. Salt provides a convenience function called `ip.get_subnet_length` to calculate the subnet length from a netmask.

Optionally, if you are setting a static IP address, you can also specify the default gateway using the gateway parameter:
salt.states.win_network.managed(name, dns_proto=None, dns_servers=None, ip_proto=None, ip_addrs=None, gateway=None, enabled=True, **kwargs)

Ensure that the named interface is configured properly.

Parameters

• name (str) -- The name of the interface to manage
• dns_proto (str) -- None Set to static and use the dns_servers parameter to provide a list of DNS nameservers. set to dhcp to use DHCP to get the DNS servers.
• dns_servers (list) -- None A list of static DNS servers. To clear the list of DNS servers pass an empty list ([]). None will make no changes.
• ip_proto (str) -- None Set to static and use the ip_addrs and (optionally) gateway parameters to provide a list of static IP addresses and the default gateway. Set to dhcp to use DHCP.
• ip_addrs (list) -- None A list of static IP addresses with netmask flag, ie: 192.168.0.100/24
• gateway (str) -- None The gateway to set for the interface
• enabled (bool) -- True Set to False to ensure that this interface is disabled.

Returns
A dictionary of old and new settings

Example:

Ethernet1:
network.managed:
  - dns_proto: static
  - dns_servers:
    - 8.8.8.8
    - 8.8.4.4
  - ip_proto: static
  - ip_addrs:
    - 192.168.0.100/24
  - gateway: None
  - enabled: True

Clear DNS entries example:

Ethernet1:
network.managed:
  - dns_proto: static
  - dns_servers:
  - 8.8.8.8
  - 8.8.4.4
  - ip_proto: static
  - ip_addrs:
  - 192.168.0.100/24
  - gateway: None
  - enabled: False

19.19.267 salt.states.win_path

Manage the Windows System PATH

salt.states.win_path.absent(name)
Remove the directory from the SYSTEM path

index: where the directory should be placed in the PATH (default: 0)

Example:
salt.states.win_path.exists(name, index=None)

Add the directory to the system PATH at index location

index: where the directory should be placed in the PATH (default: None). This is 0-indexed, so 0 means to
prepend at the very start of the PATH. [Note: Providing no index will append directory to PATH and will not
enforce its location within the PATH.]

Example:

'C:\python27':
    win_path.exists

'C:\sysinternals':
    win_path.exists:
        - index: 0

19.19.268 salt.states.win_pki module

Microsoft certificate management via the Pki PowerShell module.

    platform  Windows
New in version 2016.11.0.

salt.states.win_pki.import_cert(name, cert_format='cer', context='LocalMachine', store='My', exportable=True, password='`, saltenv='base')

Import the certificate file into the given certificate store.

Parameters
    • name (str) -- The path of the certificate file to import.
    • cert_format (str) -- The certificate format. Specify 'cer' for X.509, or 'pfx' for
      PKCS #12.
    • context (str) -- The name of the certificate store location context.
    • store (str) -- The name of the certificate store.
    • exportable (bool) -- Mark the certificate as exportable. Only applicable to pfx
      format.
    • password (str) -- The password of the certificate. Only applicable to pfx format.
    • saltenv (str) -- The environment the file resides in.

Example of usage with only the required arguments:

site0-cert-imported:
    win_pki.import_cert:
        - name: salt://win/webserver/certs/site0.cer

Example of usage specifying all available arguments:

site0-cert-imported:
    win_pki.import_cert:
        - name: salt://win/webserver/certs/site0.pfx
        - cert_format: pfx
        - context: LocalMachine
        - store: My
        - exportable: True
        - password: TestPassword
        - saltenv: base
**salt.states.win_pki.remove_cert** *(name, thumbprint, context='LocalMachine', store='My')*

Remove the certificate from the given certificate store.

**Parameters**

- **thumbprint** *(str)* -- The thumbprint value of the target certificate.
- **context** *(str)* -- The name of the certificate store location context.
- **store** *(str)* -- The name of the certificate store.

**Example of usage with only the required arguments:**

```yaml
site0-cert-removed:
  win_pki.remove_cert:
    - thumbprint: 988776655443322111000AAABBBCCDDDEEEFFF
```

**Example of usage specifying all available arguments:**

```yaml
site0-cert-removed:
  win_pki.remove_cert:
    - thumbprint: 988776655443322111000AAABBBCCDDDEEEFFF
    - context: LocalMachine
    - store: My
```

### 19.19.269 salt.states.win_powercfg

This module allows you to control the power settings of a windows minion via powercfg.

New in version 2015.8.0.

```yaml
# Set timeout to 30 minutes on battery power
monitor:
  powercfg.set_timeout:
    - value: 30
    - power: dc
```

**salt.states.win_powercfg.set_timeout** *(name, value, power='ac', scheme=None)*

Set the sleep timeouts of specific items such as disk, monitor, etc.

**Parameters**

- **name** *(str)* -- The setting to change, can be one of the following:
  - monitor
  - disk
  - standby
  - hibernate
- **value** *(int)* -- The amount of time in minutes before the item will timeout
- **power** *(str)* -- Set the value for AC or DC power. Default is ac. Valid options are:
  - ac (AC Power)
  - dc (Battery)
- **scheme** *(str)* -- The scheme to use, leave as None to use the current. Default is None. This can be the GUID or the Alias for the Scheme. Known Aliases are:
  - SCHEME_BALANCED - Balanced
  - SCHEME_MAX - Power saver
  - SCHEME_MIN - High performance

**CLI Example:**

```yaml
# Set monitor timeout to 30 minutes on Battery
monitor:
  powercfg.set_timeout:
    - value: 30
```
- power: dc

# Set disk timeout to 10 minutes on AC Power
disk:
    powercfg.set_timeout:
        - value: 10
        - power: ac

19.19.270 salt.states.win_servermanager

Manage Windows features via the ServerManager powershell module

salt.states.win_servermanager.installed(name, recurse=False, force=False, restart=False, 
source=None, exclude=None)

Install the windows feature

Parameters

- **name** (str) -- Short name of the feature (the right column in win_servermanager.list_available)
- **recurse** (Optional[bool]) -- install all sub-features as well
- **force** (Optional[bool]) -- if the feature is installed but one of its sub-features are not installed set this to True to force the installation of the sub-features
- **source** (Optional[str]) -- Path to the source files if missing from the target system. None means that the system will use windows update services to find the required files. Default is None
- **restart** (Optional[bool]) -- Restarts the computer when installation is complete, if required by the role/feature installed. Default is False
- **exclude** (Optional[str]) -- The name of the feature to exclude when installing the named feature.

**restart**: Restarts the computer when installation is complete, if restarting is required by the role feature installed.

**Note**: Some features require reboot after un/installation. If so, until the server is restarted other features can not be installed!

Example

Run `salt MinionName win_servermanager.list_available` to get a list of available roles and features. Use the name in the right column. Do not use the role or feature names mentioned in the PKGMGR documentation. In this example for IIS-WebServerRole the name to be used is Web-Server.

**ISWebserverRole:**

```yaml
win_servermanager.installed:
    - force: True
    - recurse: True
    - name: Web-Server
```

salt.states.win_servermanager.removed(name, remove_payload=False, restart=False)

Remove the windows feature

Parameters

- **name** (str) -- Short name of the feature (the right column in win_servermanager.list_available)
- **remove_payload** (*Optional*[bool]) -- True will cause the feature to be removed from the side-by-side store
- **restart** (*Optional*[bool]) -- Restarts the computer when uninstall is complete, if required by the role/feature removed. Default is False

**Note:** Some features require a reboot after uninstallation. If so the feature will not be completely uninstalled until the server is restarted.

### Example

Run `salt MinionName win_servermanager.list_installed` to get a list of all features installed. Use the top name listed for each feature, not the indented one. Do not use the role or feature names mentioned in the PKGMGR documentation.

```yaml
ISWebserverRole:
  win_servermanager.removed:
    - name: Web-Server
```

### 19.19.271 salt.states.win_smtp_server module

Module for managing IIS SMTP server configuration on Windows servers.

**salt.states.win_smtp_server.active_log_format**(*name*, *log_format*, *server=*'SmtpSvc/1'*)

Manage the active log format for the SMTP server.

**Parameters**
- **log_format** (*str*) -- The log format name.
- **server** (*str*) -- The SMTP server name.

Example of usage:

```yaml
smtp-log-format:
  win_smtp_server.active_log_format:
    - log_format: Microsoft IIS Log File Format
```

**salt.states.win_smtp_server.connection_ip_list**(*name*, *addresses*=None, *grant_by_default*=False, *server=*'SmtpSvc/1'*)

Manage IP list for SMTP connections.

**Parameters**
- **addresses** (*str*) -- A dictionary of IP + subnet pairs.
- **grant_by_default** (*bool*) -- Whether the addresses should be a blacklist or whitelist.
- **server** (*str*) -- The SMTP server name.

Example of usage for creating a whitelist:

```yaml
smtp-connection-whitelist:
  win_smtp_server.connection_ip_list:
    - addresses:
        127.0.0.1: 255.255.255.255
        172.16.1.98: 255.255.255.255
        172.16.1.99: 255.255.255.255
    - grant_by_default: False
```

Example of usage for creating a blacklist:
smtp-connection-blacklist:
  win_smtp_server.connection_ip_list:
    - addresses:
      172.16.1.100: 255.255.255.255
      172.16.1.101: 255.255.255.255
    - grant_by_default: True

Example of usage for allowing any source to connect:

smtp-connection-blacklist:
  win_smtp_server.connection_ip_list:
    - addresses: {}
    - grant_by_default: True

salt.states.win_smtp_server.relay_ip_list(name, addresses=None, server='SmtpSvc/1')
Manage IP list for SMTP relay connections.

Due to the unusual way that Windows stores the relay IPs, it is advisable to retrieve the existing list you wish
to set from a pre-configured server.

For example, setting \\
'127.0.0.1' as an allowed relay IP through the GUI would generate an actual relay IP list
similar to the following:

\[['24.0.0.128', '32.0.0.128', '60.0.0.128', '68.0.0.128', '1.0.0.0', '76.0.0.0',
  '0.0.0.0', '0.0.0.0', '1.0.0.0', '1.0.0.0', '2.0.0.0', '2.0.0.0', '4.0.0.0',
  '0.0.0.0', '76.0.0.128', '0.0.0.0', '0.0.0.0', '0.0.0.0', '0.0.0.0',
  '76.255.255.255', '127.0.0.1']\]

Note: Setting the list to None corresponds to the restrictive \\
'Only the list below' GUI parameter with an
empty access list configured, and setting an empty list/tuple corresponds to the more permissive \\
'All except
the list below' GUI parameter.

Parameters
  • addresses (str) -- A list of the relay IPs. The order of the list is important.
  • server (str) -- The SMTP server name.

Example of usage:

smtp-relay-list:
  win_smtp_server.relay_ip_list:
    - addresses:
      - 24.0.0.128
      - 32.0.0.128
      - 60.0.0.128
      - 1.0.0.0
      - 76.0.0.0
      - 0.0.0.0
      - 0.0.0.0
      - 1.0.0.0
      - 1.0.0.0
      - 2.0.0.0
      - 2.0.0.0
      - 4.0.0.0
      - 0.0.0.0
      - 76.0.0.128
      - 0.0.0.0
Example of usage for disabling relaying:

```yaml
smtp-relay-list:
  win_smtp_server.relay_ip_list:
    addresses: None
```

Example of usage for allowing relaying from any source:

```yaml
smtp-relay-list:
  win_smtp_server.relay_ip_list:
    addresses: []
```

`salt.states.win_smtp_server.server_setting(name, settings=None, server='SmtpSvc/1')`

Ensure the value is set for the specified setting.

**Note:** The setting names are case-sensitive.

**Parameters**

- `settings (str)` -- A dictionary of the setting names and their values.
- `server (str)` -- The SMTP server name.

Example of usage:

```yaml
smtp-settings:
  win_smtp_server.server_setting:
    settings:
      LogType: 1
      LogFilePeriod: 1
      MaxMessageSize: 16777216
      MaxRecipients: 10000
      MaxSessionSize: 16777216
```

### 19.19.272 `salt.states.win_snmp` module

Module for managing SNMP service settings on Windows servers.

`salt.states.win_snmp.agent_settings(name, contact, location, services=None)`

Manage the SNMP sysContact, sysLocation, and sysServices settings.

**Parameters**

- `contact (str)` -- The SNMP contact.
- `location (str)` -- The SNMP location.
- `services (str)` -- A list of selected services.

Example of usage:

```yaml
snmp-agent-settings:
  win_snmp.agent_settings:
    contact: Test Contact
    location: Test Location
    services:
```
salt.states.win_snmp.auth_traps_enabled(name, status=True)
Manage the sending of authentication traps.
Parameters status (bool) -- The enabled status.
Example of usage:
```python
snmp-auth-traps:
    win_snmp.auth_traps_enabled:
        - status: True
```

salt.states.win_snmp.community_names(name, communities=None)
Manage the SNMP accepted community names and their permissions.
Parameters communities (str) -- A dictionary of SNMP communities and permissions.
Example of usage:
```python
snmp-community-names:
    win_snmp.community_names:
        - communities:
            TestCommunity: Read Only
            OtherCommunity: Read Write
```

19.19.273 salt.states.win_system

Management of Windows system information

New in version 2014.1.0.
This state is used to manage system information such as the computer name and description.
```
ERIK-WORKSTATION:
    system.computer_name: []
This is Erik's computer, don't touch!:
    system.computer_desc: []
```

salt.states.win_system.computer_desc(name)
Manage the computer's description field
name The desired computer description
salt.states.win_system.computer_name(name)
Manage the computer's name
name The desired computer name
salt.states.win_system.hostname(name)
New in version 2016.3.0.
Manage the hostname of the computer
name The hostname to set
salt.states.win_system.join_domain(name, username=None, password=None, account_ou=None, account_exists=False, restart=False)
Checks if a computer is joined to the Domain. If the computer is not in the Domain, it will be joined.
Parameters
  • name (str) -- The name of the Domain.
• **username** *(str)* -- Username of an account which is authorized to join computers to the specified domain. Need to be either fully qualified like `user@domain.tld` or simply `user`.

• **password** *(str)* -- Password of the account to add the computer to the Domain.

• **account_ou** *(str)* -- The DN of the OU below which the account for this computer should be created when joining the domain, e.g. `ou=computers,ou=department,dc=my-company,dc=com`.

• **account_exists** *(bool)* -- Needs to be set to `True` to allow re-using an existing computer account.

• **restart** *(bool)* -- Needs to be set to `True` to restart the computer after a successful join.

Example:

```python
def join_to_domain():
    system.join_domain:
        - name: mydomain.local.com
        - username: myaccount@mydomain.local.com
        - password: mysecretpassword
        - restart: True
```

### `salt.states.win_system.reboot` *(name, message=\_\_\_\_\_\_, timeout=5, force_close=True, in_seconds=False, only_on_pending_reboot=True)*

Reboot the computer

**Parameters**

• **message** *(str)* -- An optional message to display to users. It will also be used as a comment in the event log entry.

  The default value is `None`.

• **timeout** *(int)* -- The number of minutes or seconds before a reboot will occur. Whether this number represents minutes or seconds depends on the value of `in_seconds`.

  The default value is `5`.

• **in_seconds** *(bool)* -- If this is `True`, the value of `timeout` will be treated as a number of seconds. If this is `False`, the value of `timeout` will be treated as a number of minutes.

  The default value is `False`.

• **force_close** *(bool)* -- If this is `True`, running applications will be forced to close without warning. If this is `False`, running applications will not get the opportunity to prompt users about unsaved data.

  The default value is `True`.

• **only_on_pending_reboot** *(bool)* -- If this is `True`, the reboot will only occur if the system reports a pending reboot. If this is `False`, the reboot will always occur.

  The default value is `True`.

### `salt.states.win_system.shutdown` *(name, message=\_\_\_\_\_\_, timeout=5, force_close=True, reboot=False, in_seconds=False, only_on_pending_reboot=False)*

Shutdown the computer

**Parameters**

• **message** *(str)* -- An optional message to display to users. It will also be used as a comment in the event log entry.

  The default value is `None`.

• **timeout** *(int)* -- The number of minutes or seconds before a shutdown will occur. Whether this number represents minutes or seconds depends on the value of `in_seconds`.

  The default value is `5`.

• **in_seconds** *(bool)* -- If this is `True`, the value of `timeout` will be treated as a number of seconds. If this is `False`, the value of `timeout` will be treated as a number of minutes.

  The default value is `False`.

• **force_close** *(bool)* -- If this is `True`, running applications will be forced to close without warning. If this is `False`, running applications will not get the opportunity to prompt users about unsaved data.

  The default value is `True`.

• **only_on_pending_reboot** *(bool)* -- If this is `True`, the shutdown will only occur if the system reports a pending shutdown. If this is `False`, the shutdown will always occur.

  The default value is `False`.

19.19. state modules
in_seconds.

The default value is 5.

- **in_seconds (bool)** -- If this is True, the value of timeout will be treated as a number of seconds. If this is False, the value of timeout will be treated as a number of minutes.

The default value is False.

- **force_close (bool)** -- If this is True, running applications will be forced to close without warning. If this is False, running applications will not get the opportunity to prompt users about unsaved data.

The default value is True.

- **reboot (bool)** -- If this is True, the computer will restart immediately after shutting down. If False the system flushes all caches to disk and safely powers down the system.

The default value is False.

- **only_on_pending_reboot (bool)** -- If this is True, the shutdown will only occur if the system reports a pending reboot. If this is False, the shutdown will always occur.

The default value is False.

### 19.19.274 salt.states.win_update

Management of the windows update agent

This module is being deprecated and will be removed in Salt Fluorine. Please use the `win_wua` state module instead.

New in version 2014.7.0.

Set windows updates to run by category. Default behavior is to install all updates that do not require user interaction to complete.

Optionally set category to a category of your choice to only install certain updates. Default is to set to install all available updates.

The following example will install all Security and Critical Updates, and download but not install standard updates.

```yaml
updates:
  win_update.installed:
    categories:
      - Critical Updates
      - Security Updates
    skips:
      - downloaded
  win_update.downloaded:
    categories:
      - Updates
    skips:
      - downloaded
```

You can also specify a number of features about the update to have a fine grain approach to specific types of updates. These are the following features/states of updates available for configuring:

- **'UI'** - User interaction required, skipped by default
- **'downloaded'** - Already downloaded, included by default
- **'present'** - Present on computer, skipped by default
'installed' - Already installed, skipped by default
'reboot' - Reboot required, included by default
'hidden' - Skip updates that have been hidden, skipped by default
'software' - Software updates, included by default
'driver' - driver updates, included by default

The following example installs all driver updates that don't require a reboot: .. code-block:: yaml

```yaml
gr fing dor:
  win_update.installed:
    • skips: - driver: True - software: False - reboot: False
```

To just update your windows machine, add this your sIs:

```yaml
updates:
  win_update.installed
```

class salt.states.win_update.PyWinUpdater(categories=None, skipUI=True, skipDownloaded=False, skipInstalled=True, skipReboot=False, skipPresent=False, skipSoftwareUpdates=False, skipDriverUpdates=False, skipHidden=True)

- AutoSearch()
- Download()
- GetAvailableCategories()
- GetCategories()
- GetDownloadResults()
- GetInstallationResults()
- Install()
- Search(searchString)
- SetCategories(categories)
- SetSkip(skip, state)
- SetSkips(skips)

class salt.states.win_update.downloaded(name, categories=None, skips=None, retries=10)

Cache updates for later install.

- name: if categories is left empty, it will be assumed that you are passing the category option through the name. These are separate because you can only have one name, but can have multiple categories.
- categories: the list of categories to be downloaded. These are simply strings in the update's information, so there is no enumeration of the categories available. Some known categories:

```text
Updates
Windows 7
Critical Updates
Security Updates
Update Rollups
```
- skips: a list of features of the updates to cull by. Available features:
retries  Number of retries to make before giving up. This is total, not per step.

salt.states.win_updateinstalled(name, categories=None, skips=None, retries=10)
Install specified windows updates.
name: if categories is left empty, it will be assumed that you are passing the category option through the
name. These are separate because you can only have one name, but can have multiple categories.
categories: the list of categories to be downloaded. These are simply strings in the update's information, so
there is no enumeration of the categories available. Some known categories:

<table>
<thead>
<tr>
<th>Updates</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows 7</td>
</tr>
<tr>
<td>Critical Updates</td>
</tr>
<tr>
<td>Security Updates</td>
</tr>
<tr>
<td>Update Rollups</td>
</tr>
</tbody>
</table>

skips: a list of features of the updates to cull by. Available features:

retries  Number of retries to make before giving up. This is total, not per step.

19.19.275  salt.states.win_wua module

Installation of Windows Updates using the Windows Update Agent

New in version 2017.7.0.

Salt can manage Windows updates via the ``wua'' state module. Updates can be installed and removed. Update
management declarations are as follows:

For installation:

# Install a single update using the KB
KB3194343:
  wua.installed

# Install a single update using the name parameter
install_update:
  wua.installed:
    - name: KB3194343

# Install multiple updates using the updates parameter and a combination of
# KB number and GUID
install_updates:
  wua.installed:
  - updates:
    - KB3194343
    - bb1db26-3fb6-45fd-bb05-e3c8e379195c

For removal:

# Remove a single update using the KB
KB3194343:
  wua.removed

# Remove a single update using the name parameter
remove_update:
  wua.removed:
    - name: KB3194343

# Remove multiple updates using the updates parameter and a combination of
# KB number and GUID
remove_updates:
  wua.removed:
    - updates:
      - KB3194343
      - bb1db26-3fb6-45fd-bb05-e3c8e379195c

salt.states.win_wua.installed(name, updates=None)

Ensure Microsoft Updates are installed. Updates will be downloaded if needed.

Parameters
   • name (str) -- The identifier of a single update to install.
   • updates (list) -- A list of identifiers for updates to be installed.
   • name. Default is None. (Overrides)

Note: Identifiers can be the GUID, the KB number, or any part of the Title of the Microsoft update. GUIDs and KBs are the preferred method to ensure you're installing the correct update.

Warning: Using a partial KB number or a partial Title could result in more than one update being installed.

Returns A dictionary containing the results of the update
Return type dict

CLI Example:

# using a GUID
install_update:
  wua.installed:
    - name: 28cf1b09-2b1a-458c-9bd1-971d1b26b211

# using a KB
install_update:
  wua.installed:
    - name: KB3194343

# using the full Title
install_update:
Salt Documentation, Release 2017.7.8

```python
wua.installed:
    - name: Security Update for Adobe Flash Player for Windows 10 Version 1607 (for x64-based Systems) (KB3194343)

# Install multiple updates
install_updates:
    wua.installed:
        - name:
            - KB3194343
            - 28cf1b09-2b1a-458c-9bd1-971d1b26b211

salt.states.win_wua.removed(name, updates=None)
Ensure Microsoft Updates are uninstalled.
Parameters
- name (str) -- The identifier of a single update to uninstall.
- updates (list) -- A list of identifiers for updates to be removed.
- name. Default is None. (Overrides)

Note: Identifiers can be the GUID, the KB number, or any part of the Title of the Microsoft update. GUIDs and KBs are the preferred method to ensure you’re uninstalling the correct update.

Warning: Using a partial KB number or a partial Title could result in more than one update being removed.

Returns A dictionary containing the results of the removal
Return type dict

CLI Example:

# using a GUID
uninstall_update:
    wua.removed:
        - name: 28cf1b09-2b1a-458c-9bd1-971d1b26b211

# using a KB
uninstall_update:
    wua.removed:
        - name: KB3194343

# using the full Title
uninstall_update:
    wua.removed:
        - name: Security Update for Adobe Flash Player for Windows 10 Version 1607 (for x64-based Systems) (KB3194343)

# Install multiple updates
uninstall_updates:
    wua.removed:
        - updates:
            - KB3194343
            - 28cf1b09-2b1a-458c-9bd1-971d1b26b211
```

Chapter 19. Salt Module Reference
19.19.276 salt.states.winrepo

Manage Windows Package Repository

salt.states.winrepo.genrepo(name, force=False, allow_empty=False)

Refresh the winrepo.p file of the repository (salt-run winrepo.genrepo)

If force is True no checks will be made and the repository will be generated if allow_empty is True
then the state will not return an error if there are 0 packages,

**Note:** This state only loads on minions that have the roles: salt-master grain set.

Example:

```
winrepo:
  winrepo.genrepo
```

19.19.277 salt.states.x509

Manage X509 Certificates

New in version 2015.8.0.

**depends** M2Crypto

This module can enable managing a complete PKI infrastructure including creating private keys, CA's, certificates and CRLs. It includes the ability to generate a private key on a server, and have the corresponding public key sent to a remote CA to create a CA signed certificate. This can be done in a secure manner, where private keys are always generated locally and never moved across the network.

Here is a simple example scenario. In this example ca is the ca server, and www is a web server that needs a certificate signed by ca.

For remote signing, peers must be permitted to remotely call the *sign_remote_certificate* function.

/etc/salt/master.d/peer.conf

```
peer:
  .*:
    - x509.sign_remote_certificate
```

/srv/salt/top.sls

```
base:
  '*':
    - cert
  'ca':
    - ca
  'www':
    - www
```

This state creates the CA key, certificate and signing policy. It also publishes the certificate to the mine where it can be easily retrieved by other minions.

/srv/salt/ca.sls
The signing policy defines properties that override any property requested or included in a CRL. It also can define a restricted list of minions which are allowed to remotely invoke this signing policy.

/xsrv/salt/signing_policies.conf

x509_signing_policies:
  www:
    - minions: 'www'
    - signing_private_key: /etc/pki/ca.key
    - signing_cert: /etc/pki/ca.crt
    - C: US
    - ST: Utah
    - L: Salt Lake City

The signing policy defines properties that override any property requested or included in a CRL. It also can define a restricted list of minions which are allowed to remotely invoke this signing policy.
- basicConstraints: "critical CA:False"
- keyUsage: "critical keyEncipherment"
- subjectKeyIdentifier: hash
- authorityKeyIdentifier: keyid,issuer:always
- days_valid: 90
- copypath: /etc/pki/issued_certs/

This state will instruct all minions to trust certificates signed by our new CA. Using jinja to strip newlines from the text avoids dealing with newlines in the rendered yaml, and the sign_remote_certificate state will handle properly formatting the text before writing the output.

/srv/salt/cert.sls

/usr/local/share/ca-certificates:
  file.directory

/usr/local/share/ca-certificates/intca.crt:
  x509.pem_managed:
    - text:
        {{ salt['mine.get']("ca", 'x509.get_pem_entries')['ca']["/etc/pki/ca.crt"] | replace(\'\n', \'\' ) }}

This state creates a private key then requests a certificate signed by ca according to the www policy.

/srv/salt/www.sls

/etc/pki/www.crt:
  x509.certificate_managed:
    - ca_server: ca
    - signing_policy: www
    - public_key: /etc/pki/www.key
    - CN: www.example.com
    - days_remaining: 30
    - backup: True
    - managed_private_key:
      name: /etc/pki/www.key
      bits: 4096
      backup: True

salt.states.x509.certificate_managed(name, days_remaining=90, managed_private_key=None, append_certs=None, **kwargs)

Manage a Certificate

name Path to the certificate
days_remaining [90] The minimum number of days remaining when the certificate should be recreated. A value of 0 disables automatic renewal.
managed_private_key Manages the private key corresponding to the certificate. All of the arguments supported by x509.private_key_managed are supported. If name is not specified or is the same as the name of the certificate, the private key and certificate will be written together in the same file.
append_certs: A list of certificates to be appended to the managed file.
kwarg: Any arguments supported by x509.create_certificate or file.managed are supported. Examples:

/etc/pki/ca.crt:
  x509.certificate_managed:
    - signing_private_key: /etc/pki/ca.key
    - CN: ca.example.com
    - C: US
    - ST: Utah
    - L: Salt Lake City

19.19. state modules
salt.states.x509.crl_managed(name, signing_private_key, signing_private_key_passphrase=None, signing_cert=None, revoked=None, days_valid=100, digest='', days_remaining=30, include_expired=False, **kwargs)

Manage a Certificate Revocation List

name Path to the certificate

signing_private_key The private key that will be used to sign this crl. This is usually your CA's private key.

signing_private_key_passphrase Passphrase to decrypt the private key.

signing_cert The certificate of the authority that will be used to sign this crl. This is usually your CA's certificate.

revoked A list of certificates to revoke. Must include either a serial number or a the certificate itself. Can optionally include the revocation date and notAfter date from the certificate. See example below for details.

days_valid [100] The number of days the certificate should be valid for.

digest The digest to use for signing the CRL. This has no effect on versions of pyOpenSSL less than 0.14.

days_remaining [30] The crl should be automatically recreated if there are less than days_remaining days until the crl expires. Set to 0 to disable automatic renewal.

include_expired [False] If True, include expired certificates in the CRL.

kwargs Any arguments supported by file.managed are supported.

Example:

salt.states.x509.csr_managed(name, **kwargs)

Manage a Certificate Signing Request

name Path to the CSR
**properties:** The properties to be added to the certificate request, including items like subject, extensions and public key. See above for valid properties.

**kwargs:** Any arguments supported by `file.managed` are supported.

Example:

```bash
/etc/pki/mycert.csr:
x509.csr_managed:
  - private_key: /etc/pki/mycert.key
  - CN: www.example.com
  - C: US
  - ST: Utah
  - L: Salt Lake City
  - keyUsage: 'critical dataEncipherment'
```

**salt.states.x509.pem_managed(name, text, backup=False, **kwargs)**

Manage the contents of a PEM file directly with the content in text, ensuring correct formatting.

- **name:** The path to the file to manage
- **text:** The PEM formatted text to write.
- **kwargs:** Any arguments supported by `file.managed` are supported.

**salt.states.x509.private_key_managed(name, bits=2048, passphrase=None, cipher='aes_128_cbc', new=False, overwrite=False, verbose=True, **kwargs)**

Manage a private key's existence.

- **name:** Path to the private key
- **bits:** Key length in bits. Default 2048.
- **passphrase:** Passphrase for encrypting the private key.
- **cipher:** Cipher for encrypting the private key.
- **new:** Always create a new key. Defaults to False. Combining new with `prereq`, or when used as part of a `managed_private_key` can allow key rotation whenever a new certificate is generated.
- **overwrite:** Overwrite an existing private key if the provided passphrase cannot decrypt it.
- **verbose:** Provide visual feedback on stdout, dots while key is generated. Default is True.

New in version 2016.11.0.

- **kwargs:** Any kwargs supported by file.managed are supported.

Example:

```bash
The jinja templating in this example ensures a private key is generated if the file doesn't exist and that a new private key is generated whenever the certificate that uses it is to be renewed.
```

```
/etc/pki/www.key:
x509.private_key_managed:
  - bits: 4096
  - new: True
  {% if salt['file.file_exists']('/etc/pki/ca.key') -%}
  - prereq:
    - x509: /etc/pki/www.crt
  {%- endif %}
```

### 19.19.278 salt.states.xmpp

**Sending Messages over XMPP**

New in version 2014.1.0.

This state is useful for firing messages during state runs, using the XMPP protocol.
server-warning-message:
xmpp.send_msg:
  - name: 'This is a server warning message'
  - profile: my-xmpp-account
  - recipient: admins@xmpp.example.com/salt

salt.states.xmpp.send_msg(name, recipient, profile)
Send a message to an XMPP user

server-warning-message:
xmpp.send_msg:
  - name: 'This is a server warning message'
  - profile: my-xmpp-account
  - recipient: admins@xmpp.example.com/salt

name The message to send to the XMPP user

salt.states.xmpp.send_msg_multi(name, profile, recipients=none, rooms=none)
Send a message to a list of recipients or rooms

server-warning-message:
xmpp.send_msg:
  - name: 'This is a server warning message'
  - profile: my-xmpp-account
  - recipients:
    - admins@xmpp.example.com/salt
  - rooms:
    - qa@conference.xmpp.example.com

name The message to send to the XMPP user

19.19.279 salt.states.zabbix_host module
Management of Zabbix hosts.

codeauthor Jiri Kotlin <jiri.kotlin@ultimum.io>
salt.states.zabbix_host.absent(name, **kwargs)
Ensures that the host does not exists, eventually deletes host.
New in version 2016.3.0.

Param name: technical name of the host
Parameters
  - _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
  - _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
  - _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

TestHostWithInterfaces:
zabbix_host.absent

salt.states.zabbix_host.assign_templates(host, templates, **kwargs)
Ensures that templates are assigned to the host.
New in version 2017.7.0.
Parameters

- **host** -- technical name of the host
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

```python
add_zabbix_templates_to_host:
    zabbix_host.assign_templates:
    - host: TestHost
      templates:
        - "Template OS Linux"
        - "Template App MySQL"
```

salt.states.zabbix_host.present(host, groups, interfaces, **kwargs)

Ensures that the host exists, eventually creates new host. NOTE: please use argument visible_name instead of name to not mess with name from salt sls. This function accepts all standard host properties: keyword argument names differ depending on your zabbix version, see: https://www.zabbix.com/documentation/2.4/manual/api/reference/host/object#host

New in version 2016.3.0.

Parameters

- **host** -- technical name of the host
- **groups** -- groupids of host groups to add the host to
- **interfaces** -- interfaces to be created for the host
- **proxy_host** -- Optional proxy name or proxyid to monitor host
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)
- **visible_name** -- Optional - string with visible name of the host, use `visible_name` instead of `name` parameter to not mess with value supplied from Salt sls file.

```python
create_test_host:
    zabbix_host.present:
    - host: TestHostWithInterfaces
      - proxy_host: 12345
      - groups:
        - 5
        - 6
        - 7
      - interfaces:
        - test1.example.com:
          - ip: '192.168.1.8'
          - type: 'Agent'
          - port: 92
        - testing2_create:
          - ip: '192.168.1.9'
          - dns: 'test2.example.com'
          - type: 'agent'
          - main: false
        - testovaci1_ipmi:
          - ip: '192.168.100.111'
```

19.19. state modules
19.19.280 salt.states.zabbix_hostgroup module

Management of Zabbix host groups.

codeauthor Jiri Kotlin <jiri.kotlin@ultimum.io>

salt.states.zabbix_hostgroup.absent(name, **kwargs)
Ensures that the host group does not exist, eventually delete host group.
New in version 2016.3.0.

Parameters
- name -- name of the host group
- _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- _connection_url -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

```
delete_testing_host_group:
    zabbix_hostgroup.absent:
        - name: 'My hostgroup name'
```

can use the zabbix_hostgroup.present module:

```
create_testing_host_group:
    zabbix_hostgroup.present:
        - name: 'My hostgroup name'
```

19.19.281 salt.states.zabbix_mediatype module

Management of Zabbix mediatypes.

codeauthor Raymond Kuiper <qix@the-wired.net>

salt.states.zabbix_mediatype.absent(name, **kwargs)
Ensures that the mediatype does not exist, eventually deletes the mediatype.

Parameters
- name -- name of the mediatype
- _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
delete_mediatype:
  zabbix_mediatype.absent:
    - name: 'Email'

salt.states.zabbix_mediatype.present(name, mediatype, **kwargs)
  Creates new mediatype. NOTE: This function accepts all standard mediatype properties: keyword argument names differ depending on your zabbix version, see: https://www.zabbix.com/documentation/3.0/manual/api/reference/host/object#host_inventory

Parameters
  • name -- name of the mediatype
  • _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
  • _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
  • _connection_url -- Optional - url of zabbix frontend (can also be set in opts or pillar, see module's docstring)

make_new_mediatype:
  zabbix_mediatype.present:
    - name: 'Email'
    - mediatype: 0
    - smtp_server: smtp.example.com
    - smtp_hello: zabbix.example.com
    - smtp_email: zabbix@example.com

19.19.282 salt.states.zabbix_user module

Management of Zabbix users.

codeauthor Jiri Kotlin <jiri.kotlin@ultimum.io>

salt.states.zabbix_user.absent(name, **kwargs)
  Ensures that the user does not exist, eventually delete user.

Parameters
  • name -- user alias
  • _connection_user -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
  • _connection_password -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
  • _connection_url -- Optional - url of zabbix frontend (can also be set in opts or pillar, see module's docstring)

George:
  zabbix_user.absent

salt.states.zabbix_user.present(alias, passwd, usgrps, medias, password_reset=False, **kwargs)
  Ensures that the user exists, eventually creates new user. NOTE: use argument firstname instead of name to not mess values with name from salt sls.
New in version 2016.3.0.

Parameters

- **alias** -- user alias
- **passwd** -- user's password
- **usrgrps** -- user groups to add the user to
- **medias** -- user's medias to create
- **password_reset** -- whether or not to reset password at update
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
- **_connection_password** -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
- **_connection_url** -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)
- **firstname** -- string with firstname of the user, use 'firstname' instead of 'name' parameter to not mess with value supplied from Salt sls file.

```yaml
code
make_user:
    zabbix_user.present:
        - alias: George
        - passwd: donottellanyonE@456x
        - password_reset: True
        - usrgrps:
            - 13
            - 7
        - medias:
            - me@example.com:
                - mediatype: mail
                - period: '1-7,00:00-24:00'
                - severity: NIWAHD
            - make_jabber:
                - active: true
                - mediatype: jabber
                - period: '1-5,08:00-19:00'
                - sendto: jabbera@example.com
            - text_me_morning_disabled:
                - active: false
                - mediatype: sms
                - period: '1-5,09:30-10:00'
                - severity: D
                - sendto: '+42032132588568'
```

19.19.283 `salt.states.zabbix_usergroup module`

Management of Zabbix user groups.

**codeauthor** Jiri Kotlin <jiri.kotlin@ultimum.io>

salt.states.zabbix_usergroup.absent(name, **kwargs)

Ensures that the user group does not exist, eventually delete user group.

New in version 2016.3.0.

Parameters

- **name** -- name of the user group
- **_connection_user** -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
• `_connection_password` -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
• `_connection_url` -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

```
delete_thai_monks_usrgp:
    zabbix_usergroup.absent:
        - name: 'Thai monks'
```

```
salt.states.zabbix_usergroup.present(name, **kwargs)
    Creates new user group. NOTE: This function accepts all standard user group properties: keyword argument names differ depending on your zabbix version, see: https://www.zabbix.com/documentation/2.0/manual/appendix/api/usergroup/definitions#user_group

    New in version 2016.3.0.
    Parameters
    • `name` -- name of the user group
    • `_connection_user` -- Optional - zabbix user (can also be set in opts or pillar, see module's docstring)
    • `_connection_password` -- Optional - zabbix password (can also be set in opts or pillar, see module's docstring)
    • `_connection_url` -- Optional - url of zabbix frontend (can also be set in opts, pillar, see module's docstring)

```
make_new_thai_monks_usergroup:
    zabbix_usergroup.present:
        - name: 'Thai monks'
        - gui_access: 1
        - debug_mode: 0
        - users_status: 0
```

19.19.284 `salt.states.zcbuildout`

**Management of zc.buildout**

This module is inspired from minitage's buildout maker (https://github.com/minitage/minitage/blob/master/src/minitage/core/makers/buildout.py)

New in version 2016.3.0.

**Note:** This state module is beta; the API is subject to change and no promise as to performance or functionality is yet present

**Available Functions**

• `built`

```
installed1
    buildout.installed:
        - name: /path/to/buildout

installed2
