### 28.2.8 Salt 2018.3.3 Release Notes

Version 2018.3.3 is a security and bugfix release for 2018.3.0.

**Statistics**

- Total Merges: 548
- Total Issue References: 69
- Total PR References: 341
- **Contributors**: 55 (Ch3LL, FedericoCeratto, KaiSforza, L4rS6, Lutseslav, The-Loeki, Vaelatern, admid, aepseito91, asenci, astorath, azelezni, babs, bbczeuz, bbinet, brejoc, cro, daa, dmcrypto18, dubb-b, dwoz, eliasp, ezh, garethgreenaway, gtnanfred, ishm, jeduardo, kt97679, kuetrzi, linopl, lomere, lusche, mateiw, maxarnold, max-im-sermin, meaksh, mmulqueen, morganwillcock, mtorromeo, nullify005, paulcollinsiii, pritambaral, rallytime, rares-pop, rmarchei, rosscdh, sizgiyaev, sjorge, t0fik, terminalmage, travispaull, twangboy, vinian, weshet, zerthimon)

**Warning**: If you are using Jinja to dump lists or dictionaries in your SLS files, this will now cause errors in Python 2 since Jinja does not produce YAML-compatible output when strings in the data structures contain unicode types. The dictionary must be passed through a Jinja filter to produce YAML-compatible strings.

The below is an example of invalid SLS:

```yaml
/etc/foo.conf:
  file.managed:
    - source: salt://foo.conf
    - template: jinja
    - defaults: {{ mydict }}
```

### 28.2. Previous Releases
To make it valid, use either one of Salt's own `json` or `yaml` filters. Another option would be to use Jinja’s `tojson` filter.

```
/etc/foo.conf:
  file.mangaged:
    - source: salt://foo.conf
    - template: jinja
    - defaults: {{ mydict | tojson }}
```

Security Fix

CVE-2018-15751 Remote command execution and incorrect access control when using salt-api.

CVE-2018-15750 Directory traversal vulnerability when using salt-api. Allows an attacker to determine what files exist on a server when querying /run or /events.

Changes to win_timezone

Improves timezone detection by using the pytz module.

```
timezone.get_offset and timezone.get_zonecode now work properly.
```

Adds `timezone.list` to list supported timezones in either Windows or Unix format.

New Jinja Filter

The `tojson` filter (from Jinja 2.9 and later) has been ported to Salt, and will be used when this filter is not available. This allows older LTS releases such as CentOS 7 and Ubuntu 14.04 to use this filter.

You can use this filter any time you wish to dump a list or dictionary into an SLS file, to ensure that the result is able to be loaded by the YAML renderer. For example:

```
foo:
  bar.baz:
    - some_arg: {{ mydict | tojson }}
```

MacOSX escape characters with runas

You are now required to escape quotes when using the runas argument with the cmd module on macosx.

Example:

```
cmd.run 'echo "h="baz""\""' runas=macuser
```

    * 8a1285239a Merge pull request #48426 from garethgreen-away/46689_fixing_pkg_held_when_package_is_installed
      – 9b0f5dd212 Fixing indentation, removing some unnecessary conditionals.
      – 727964ab55 One last cleanup.
      – 11cbb86e6eb General cleanup in pkg state, reducing duplicate code. Fixing the requires_salt_modules decorator, sys.doc was returning too much information for the event to handle. This change specifically calls sys.doc with the module name.
      – 16fb6ae635 Make sure pkg.hold and pkg.unhold are available before running the test.
      – 998651102d Fixing a situation when a package is already installed via salt or manually and a state attempts to set that package to be held. Previously the holding/unholding logic was only being run against packages that were being installed. This change moves the holding...
logic outside and runs it against all desired packages. Adding a new test to test holding logic.

### 28.2.9 Salt 2018.3.4 Release Notes

Version 2018.3.4 is a bugfix release for 2018.3.0.

#### State Changes

- The `host.present` state can now remove the specified hostname from IPs not specified in the state. This can be done by setting the newly-added `clean` argument to `True`.

      - a289e3c Merge branch '2017.7' into zmqpubserv
    - 6679242 Merge pull request #50590 from garethgreenaway/bp-50333
      - 1f5a4b pkg.installed currently fails when sources is used along with hold: True. This was due to a change in #48426 that swapped out sending the pkgs variable for the desired variable instead. This caused problems with pkg.hold because desired and sources are always populated, and pkg.hold can only include one or the other. This change just includes desired in the call to pkg.hold since desired has the same value for sources.
      - 39e811b Add issue url to tests

  - d9179b Merge pull request #50333 from garethgreenaway/50311_pkg_installed_fails_sources_hold
  - 7bc9b3d Merge branch '2018.3' into 50311_pkg_installed_fails_sources_hold
  - 6e96728 pkg.installed currently fails when sources is used along with hold: True. This was due to a change in #48426 that swapped out sending the pkgs variable for the desired variable instead. This caused problems with pkg.hold because desired and sources are always populated, and pkg.hold can only include one or the other. This change just includes desired in the call to pkg.hold since desired has the same value for sources.

28.2.10 Salt 2018.3.5 Release Notes

Version 2018.3.5 is a CVE-fix release for 2018.3.0.

Security Fix

CVE-2019-17361

With the Salt NetAPI enabled in addition to having a SSH roster defined, unauthenticated access is possible when specifying the client as SSH. Additionally, when the raw_shell option is specified any arbitrary command may be run on the Salt master when specifying SSH options.
28.2.11 Salt 2017.7.0 Release Notes - Codename Nitrogen

28.2.12 Python 3

The 2017.7 Salt Release adds initial Python 3 support.
The default Python version of Salt will remain Python 2, although Python 3 packages will be supplied for users who want to help test this new feature.

28.2.13 Python 2.6 Deprecation

Salt will no longer support Python 2.6. We will provide python2.7 packages on our repo for RedHat and CentOS 6 to ensure users can still run Salt on these platforms.

As this will impact the installation of additional dependencies for salt modules please use pip packages if there is not a package available in a repository. You will need to install the python27-pip package to get access to the correct pip27 executable: `yum install python27-pip`

28.2.14 Known Issues

The following salt-cloud drivers have known issues running with Python 3. These drivers will not work with Python 3, and Python 2.7 should be used instead:

- Joyent

- When running under Python 3, users who require Unicode support should ensure that a locale is set on their machines. Users using the C locale are advised to switch to a UTF-aware locale to ensure proper functionality with Salt with Python 3.

Remember to update the Salt Master first

Salt’s policy has always been that when upgrading, the minion should never be on a newer version than the master. Specifically with this update, because of changes in the fileclient, the 2017.7 minion requires a 2017.7 master.

Backwards compatibility is still maintained, so older minions can still be used.

More information can be found in the Salt FAQ

States Added for Management of systemd Unit Masking

The `service.masked` and `service.umasked` states have been added to allow Salt to manage masking of systemd units.

Additionally, the following functions in the `systemd` execution module have changed to accommodate the fact that indefinite and runtime masks can co-exist for the same unit:

- `service.masked` - The return from this function has changed from previous releases. Before, `False` would be returned if the unit was not masked, and the output of `systemctl is-enabled <unit name>` would be returned if the unit was masked. However, since indefinite and runtime masks can exist for the same unit at the same time, this function has been altered to accept a `runtime` argument. If `True`, the minion will be checked for a runtime mask assigned to the named unit. If `False`, then the minion will be checked for an indefinite mask. If one is found, `True` will be returned. If not, then `False` will be returned.
• `service.masked` - This function used to just run `systemctl is-enabled <unit name>` and based on the return from this function the corresponding mask type would be removed. However, if both runtime and indefinite masks are set for the same unit, then `systemctl is-enabled <unit name>` would show just the indefinite mask. The indefinite mask would be removed, but the runtime mask would remain. The function has been modified to accept a `runtime` argument, and will attempt to remove a runtime mask if that argument is set to `True`. If set to `False`, it will attempt to remove an indefinite mask.

These new `runtime` arguments default to `False`.

**Pillar Encryption**

Beginning in 2016.3.0 the CLI pillar data passed to several functions could conditionally be passed through a renderer to be decrypted. This functionality has now been extended to pillar SLS files as well. See [here](#) for detailed documentation on this feature.

**Grains Changes**

• The `osmajorrelease` grain has been changed from a string to an integer. State files, especially those using a templating language like Jinja, may need to be adjusted to account for this change.

• Add ability to specify disk backing mode in the VMWare salt cloud profile.

**State Module Changes**

• The `service.running` and `service.dead` states now support a `no_block` argument which, when set to `True` on systemd minions, will start/stop the service using the `--no-block` flag in the `systemctl` command. On non-systemd minions, a warning will be issued.

• The `module.run` state has dropped its previous syntax with `m_` prefix for reserved keywords. Additionally, it allows running several functions in a batch.

---

Note: It is necessary to explicitly turn on the new behavior (see below)

```bash
# Before
run_something:
  module.run:
    - name: mymodule.something
    - m_name: 'some name'
    - kwargs: {
      first_arg: 'one',
      second_arg: 'two',
      do_stuff: 'True'
    }

# After
run_something:
  module.run:
    - mymodule.something:
      name: some name
      first_arg: one
      second_arg: two
      do_stuff: True
```
Since a lot of users are already using `module.run` states, this new behavior must currently be explicitly turned on, to allow users to take their time updating their SLS files. However, please keep in mind that the new syntax will take effect in the next feature release of Salt (Oxygen) and the old usage will no longer be supported at that time.

Another feature of the new `module.run` is that it allows calling many functions in a single batch, such as:

```plaintext
run_something:
  module.run:
    - mymodule.function_without_parameters:
    - mymodule.another_function:
      myparam
      my_other_param
```

In a rare case that you have a function that needs to be called several times but with the different parameters, an additional feature of "tagging" is to the rescue. In order to tag a function, use a colon delimiter. For example:

```plaintext
run_something:
  module.run:
    - mymodule.same_function:1:
    - mymodule.same_function:2:
      myparam
      my_other_param
    - mymodule.same_function:3:
      foo: bar
```

The example above will run `mymodule.same_function` three times with the different parameters.

To enable the new behavior for `module.run`, add the following to the minion config file:

```plaintext
use_superseded:
  module.run
```

- The default for the `fingerprint_hash_type` option used in the `present` function in the `ssh` state changed from `md5` to `sha256`.

**Execution Module Changes**

- Several functions in the `systemd` execution module have gained a `no_block` argument, which when set to `True` will use `--no-block` in the `systemctl` command.

- In the `solarisips pkg` module, the default value for the `refresh` argument to the `list_upgrades` function has been changed from `False` to `True`. This makes the function more consistent with all of the other `pkg` modules (The other `pkg.list_upgrades` functions all defaulted to `True`).

- The functions which handle masking in the `systemd` module have changed. These changes are described above alongside the information on the new states which have been added to manage masking of systemd units.

- The `pkg.list_repo_pkgs` function for yum/dnf-based distros has had its default output format changed. In prior releases, results would be organized by repository. Now, the default for each package will be a simple list of versions. To get the old behavior, pass `byrepo=True` to the function.

- A `pkg.list_repo_pkgs` function has been added for both `Debian/Ubuntu` and `Arch Linux`-based distros.

- The `system` module changed its return format from "HH:MM AM/PM" to "HH:MM:SS AM/PM" for `get_system_time`.
• The default for the fingerprint_hash_type option used in the ssh execution module changed from md5 to sha256.

Proxy Module Changes

The proxy_merge_grains_in_module configuration variable introduced in 2016.3, has been changed, defaulting to True.

The connection with the remote device is kept alive by default, when the module implements the alive function and proxy_keep_alive is set to True. The polling interval is set using the proxy_keep_alive_interval option which defaults to 1 minute.

The developers are also able to use the proxy_always_alive, when designing a proxy module flexible enough to open the connection with the remote device only when required.

Wildcard Versions in pkg.installed States

• The pkg.installed state now supports wildcards in package versions, for the following platforms:
  – SUSE/openSUSE Leap/Thumbleweed
  – Debian/Ubuntu
  – RHEL/CentOS
  – Arch Linux

This support also extends to any derivatives of these distros, which use the aptpkg, yumpkg, or pacman providers for the pkg virtual module.

Using wildcards can be useful for packages where the release name is built into the version in some way, such as for RHEL/CentOS which typically has version numbers like 1.2.34-5.el7. An example of the usage for this would be:

```yaml
mypkg:
  pkg.installed:
    - version: '1.2.34*'
```

Master Configuration Additions

• syndic_forward_all_events - Option on multi-syndic or single when connected to multiple masters to be able to send events to all connected masters.

• eauth_acl_module - In case external auth is enabled master can get authenticate and get the authorization list from different auth modules.

• keep_acl_in_token - Option that allows master to build ACL once for each user being authenticated and keep it in the token.

Minion Configuration Additions

• pillarenv_from_saltenv - When set to True (default is False), the pillarenv option will take the same value as the effective saltenv when running states. This would allow a user to run salt '*' state.apply mysls saltenv=dev, and the SLS for both the state and pillar data would be sourced from the dev environment, essentially the equivalent of running salt '*' state.apply mysls saltenv=dev
pillarenv=dev. Note that if pillarenv is set in the minion config file, or if pillarenv is provided on the CLI, it will override this option.

salt-api Changes

The rest_cherrypy netapi module has received a few minor improvements:

- A CORS bugfix.
- A new /token convenience endpoint to generate Salt eauth tokens.
- A proof-of-concept JavaScript single-page application intended to demonstrate how to use the Server-Sent Events stream in an application. It is available in a default install by visiting the /app URL in a browser.

Python API Changes

expr_form Deprecation

The LocalClient’s expr_form argument has been deprecated and renamed to tgt_type. This change was made due to numerous reports of confusion among community members, since the targeting method is published to minions as tgt_type, and appears as tgt_type in the job cache as well.

While expr_form will continue to be supported until the 2019.2.0 release cycle (two major releases after this one), those who are using the LocalClient (either directly, or implicitly via a netapi module) are encouraged to update their code to use tgt_type.

full_return Argument in LocalClient and RunnerClient

An full_return argument has been added to the cmd and cmd_sync methods in LocalClient and RunnerClient which causes the return data structure to include job meta data such as retcode.

This is useful at the Python API:

```
>>> import salt.client
>>> client = salt.client.LocalClient()
>>> client.cmd('*', 'cmd.run', ['return 1'], full_return=True)
{'jerry': {'jid': '20170520151213898053', 'ret': '', 'retcode': 1}}
```

As well as from salt-api:

```
% curl -b /tmp/cookies.txt -sS http://localhost:8000 \
   -H 'Content-type: application/json' \
   -d '[[
   "client": "local",
   "tgt": "*",
   "fun": "cmd.run",
   "arg": ["return 1"],
   "full_return": true
   ]]

{"return": [["jerry": {"jid": "20170520151213898053", "retcode": 1, "ret": ""}]}}
```
Jinja

Logs

Another new feature - although not limited to Jinja only - is being able to log debug messages directly from the template:

```python
{% do salt.log.error('logging from jinja') -%}
```

See the logs paragraph.

Network Automation

NAPALM

Introduced in 2016.11, the modules for cross-vendor network automation have been improved, enhanced and widened in scope:
• Manage network devices like servers: the NAPALM modules have been transformed so they can run in both proxy and regular minions. That means, if the operating system allows, the salt-minion package can be installed directly on the network gear. Examples of such devices (also covered by NAPALM) include: Arista, Cumulus, Cisco IOS-XR or Cisco Nexus.

• Not always alive: in certain less dynamic environments, maintaining the remote connection permanently open with the network device is not always beneficial. In those particular cases, the user can select to initialize the connection only when needed, by specifying the field `always_alive: false` in the `proxy configuration` or using the `proxy_always_alive` option.

• Proxy keepalive: due to external factors, the connection with the remote device can be dropped, e.g.: packet loss, idle time (no commands issued within a couple of minutes or seconds), or simply the device decides to kill the process. In 2017.7.0 we have introduced the functionality to re-establish the connection. One can disable this feature through the `proxy_keep_alive` option and adjust the polling frequency specifying a custom value for `proxy_keep_alive_interval`, in minutes.

New modules:

• **Netconfig state module** - Manage the configuration of network devices using arbitrary templates and the Salt-specific advanced templating methodologies.

• **Network ACL execution module** - Generate and load ACL (firewall) configuration on network devices.

• **Network ACL state** - Manage the firewall configuration. It only requires writing the pillar structure correctly!

• **NAPALM YANG execution module** - Parse, generate and load native device configuration in a standard way, using the OpenConfig/IETF models. This module contains also helpers for the states.

• **NAPALM YANG state module** - Manage the network device configuration according to the YANG models (OpenConfig or IETF).

• **NET finder** - Runner to find details easily and fast. It’s smart enough to know what you are looking for. It will search in the details of the network interfaces, IP addresses, MAC address tables, ARP tables and LLDP neighbors.

• **BGP finder** - Runner to search BGP neighbors details.

• **NAPALM syslog** - Engine to import events from the napalm-logs library into the Salt event bus. The events are based on the syslog messages from the network devices and structured following the OpenConfig/IETF YANG models.

• **NAPALM Helpers** - Generic helpers for NAPALM-related operations. For example, the Compliance report function can be used inside the state modules to compare the expected and the existing configuration.

New functions:

• **Configuration getter** - Return the whole configuration of the network device.

• **Optics getter** - Fetches the power usage on the various transceivers installed on the network device (in dBm).

New grains: Host, Host DNS, Username and Optional args.

**Custom Refspecs in GitFS / git_pillar / winrepo**

It is now possible to specify the refspecs to use when fetching from remote repositories for GitFS, git_pillar, and winrepo. More information on how this feature works can be found here in the GitFS Walkthrough. The git_pillar and winrepo versions of this feature work the same as their GitFS counterpart.
git_pillar "mountpoints" Feature Added

See *here* for detailed documentation.

Big Improvements to Docker Support

The old `docker` state and execution modules have been moved to `salt-contrib`. The `dockerng` execution module has been renamed to `docker` and now serves as Salt’s official Docker execution module.

The old `dockerng` state module has been split into 4 state modules:

- `docker_container` - States to manage Docker containers
- `docker_image` - States to manage Docker images
- `docker_volume` - States to manage Docker volumes
- `docker_network` - States to manage Docker networks

The reason for this change was to make states and requisites more clear. For example, imagine this SLS:

```yaml
myuser/appimage:
  docker.image_present:
    - sls: docker.images.appimage

myapp:
  docker.running:
    - image: myuser/appimage
    - require:
      - docker: myuser/appimage
```

The new syntax would be:

```yaml
myuser/appimage:
  docker_image.present:
    - sls: docker.images.appimage

myapp:
  docker_container.running:
    - image: myuser/appimage
    - require:
      - docker_image: myuser/appimage
```

This is similar to how Salt handles MySQL, MongoDB, Zabbix, and other cases where the same execution module is used to manage several different kinds of objects (users, databases, roles, etc.).

**Note:** With the Moby announcement coming at this year’s DockerCon, Salt’s `docker` execution module (as well as the state modules) work interchangeably when `docker` is replaced with `moby` (e.g. `moby_container.running`, `moby_image.present`, `moby.inspect_container`, etc.)

The old syntax will continue to work until the 2019.2.0 release of Salt. The old `dockerng` naming will also continue to work until that release, so no immediate changes need to be made to your SLS files (unless you were still using the old docker states that have been moved to `salt-contrib`).

The `docker_container.running` state has undergone a significant change in how it determines whether or not a container needs to be replaced. Rather than comparing individual arguments to their corresponding values in the named container, a temporary container is created (but not started) using the passed arguments. The two containers
are then compared to each other to determine whether or not there are changes, and if so, the old container is stopped and destroyed, and the temporary container is renamed and started.

Salt still needs to translate arguments into the format which docker-py expects, but if it does not properly do so, the `skip_translate` argument can be used to skip input translation on an argument-by-argument basis, and you can then format your SLS file to pass the data in the format that the docker-py expects. This allows you to work around any changes in Docker’s API or issues with the input translation, and continue to manage your Docker containers using Salt. Read the documentation for `skip_translate` for more information.

Note: When running the `docker_container.running` state for the first time after upgrading to 2017.7.0, your container(s) may be replaced. The changes may show diffs for certain parameters which say that the old value was an empty string, and the new value is `None`. This is due to the fact that in prior releases Salt was passing empty strings for these values when creating the container if they were undefined in the SLS file, where now Salt simply does not pass any arguments not explicitly defined in the SLS file. Subsequent runs of the state should not replace the container if the configuration remains unchanged.

New SSH Cache Roster

The SSH cache Roster has been rewritten from scratch to increase its usefulness. The new roster supports all minion matchers, so it is now possible to target minions identically through `salt` and `salt-ssh`.

Using the new `roster_order` configuration syntax it’s now possible to compose a roster out of any combination of grains, pillar and mine data and even Salt SDB URLs. The new release is also fully IPv4 and IPv6 enabled and even has support for CIDR ranges.

Salt-SSH Default Options

Defaults for rosters can now be set, so that they don’t have to be set on every entry in a roster or specified from the commandline.

The new option is `roster_defaults` and is specified in the master config file:

```
roster_defaults:
  user: daniel
  sudo: True
  priv: /root/.ssh/id_rsa
  tty: True
```

Blacklist or Whitelist Extmod Sync

The modules that are synced to minions can now be limited.

The following configuration options have been added for the master:

- `extmod_whitelist`
- `extmod_blacklist`

and for the minion:

- `extmod_whitelist`
- `extmod_blacklist`
Additional Features

- The `mine.update` function has a new optional argument `mine_functions` that can be used to refresh mine functions at a more specific interval than scheduled using the `mine_interval` option. However, this argument can be used by explicit schedule. For example, if we need the mines for `net.lldp` to be refreshed every 12 hours:

```yaml
schedule:
  lldp_mine_update:
    function: mine.update
    kwargs:
      mine_functions:
        net.lldp: []
    hours: 12
```

- The `salt` runner has a new function: `salt.execute`. It is mainly a shortcut to facilitate the execution of various functions from other runners, e.g.:

```python
ret1 = __salt__['salt.execute']('*', 'mod.fun')
```

**Deprecations**

**General Deprecations**

- Removed support for aliasing `cmd.run` to `cmd.shell`.
- Removed support for Dulwich from `GitFS`.
- Beacon configurations should be lists instead of dictionaries.
- The `PidfileMixin` has been removed. Please use `DaemonMixIn` instead.
- The `use_pending` argument was removed from the `salt.utils.event.get_event` function.
- The `pending_tags` argument was removed from the `salt.utils.event.get_event` function.

**Configuration Option Deprecations**

- The `client_acl` configuration option has been removed. Please use `publisher_acl` instead.
- The `client_acl_blacklist` configuration option has been removed. Please use `publisher_acl_blacklist` instead.
- The `win_gitrepos` configuration option has been removed. Please use the `winrepo_remotes` option instead.
- The `win_repo` configuration option has been removed. Please use `winrepo_dir` instead.
- The `win_repo_mastercachefile` configuration option has been removed. Please use the `winrepo_cachefile` option instead.

**Module Deprecations**

The `git` execution module had the following changes:

- The `fmt` argument was removed from the `archive` function. Please use `format` instead.
- The `repository` argument was removed from the `clone` function. Please use `url` instead.
- The `is_global` argument was removed from the `config_set` function. Please use `global` instead.
- The `branch` argument was removed from the `merge` function. Please use `rev` instead.
• The branch argument was removed from the `push` function. Please use `rev` instead.

The `glusterfs` execution module had the following functions removed:
• `create`: Please use `create_volume` instead.
• `delete`: Please use `delete_volume` instead.
• `list_peers`: Please use `peer_status` instead.

The `htpasswd` execution module had the following function removed:
• `useradd_all`: Please use `useradd` instead.

The `img` execution module has been removed. All of its associated functions were marked for removal in the 2017.7.0 release. The functions removed in this module are mapped as follows:
• `mount_image/mnt_image`: Please use `mount.mount` instead.
• `umount_image`: Please use `mount.umount` instead.
• `bootstrap`: Please use `genesis.bootstrap` instead.

The `smartos_virt` execution module had the following functions removed:
• `create`: Please use `start` instead.
• `destroy` Please use `stop` instead.
• `list_vms`: Please use `list_domains` instead.

The `virt` execution module had the following functions removed:
• `create`: Please use `start` instead.
• `destroy` Please use `stop` instead.
• `list_vms`: Please use `list_domains` instead.

The `virtualenv_mod` execution module had the following changes:
• The `package_or_requirement` argument was removed from both the `get_resource_path` and the `get_resource_content` functions. Please use `package` instead.
• The `resource_name` argument was removed from both the `get_resource_path` and `get_resource_content` functions. Please use `resource` instead.

The `win_repo` execution module had the following changes:
• The `win_repo_source_dir` option was removed from the `win_repo` module. Please use `winrepo_source_dir` instead.

The `xapi` execution module had the following functions removed:
• `create`: Please use `start` instead.
• `destroy`: Please use `stop` instead.
• `list_vms`: Please use `list_domains` instead.

The `zypper` execution module had the following function removed:
• `info`: Please use `info_available` instead.
Pillar Deprecations

- Support for the `raw_data` argument for the `file_tree` ext_pillar has been removed. Please use `keep_newline` instead.
- SQLite3 database connection configuration previously had keys under pillar. This legacy compatibility has been removed.

Proxy Minion Deprecations

- The `proxy_merge_grains_in_module` default has been switched from `False` to `True`.

Salt-API Deprecations

- The `SaltAPI.run()` function has been removed. Please use the `SaltAPI.start()` function instead.

Salt-Cloud Deprecations

- Support for using the keyword `provider` in salt-cloud provider config files has been removed. Please use `driver` instead. The `provider` keyword should now only be used in cloud profile config files.

Salt-SSH Deprecations

- The `wipe_ssh` option for `salt-ssh` has been removed. Please use the `ssh_wipe` option instead.

State Deprecations

The `apache_conf` state had the following functions removed:
- `disable`: Please use `disabled` instead.
- `enable`: Please use `enabled` instead.

The `apache_module` state had the following functions removed:
- `disable`: Please use `disabled` instead.
- `enable`: Please use `enabled` instead.

The `apache_site` state had the following functions removed:
- `disable`: Please use `disabled` instead.
- `enable`: Please use `enabled` instead.

The `chocolatey` state had the following functions removed:
- `install`: Please use `installed` instead.
- `uninstall`: Please use `uninstalled` instead.

The `git` state had the following changes:
- The `config` function was removed. Please use `config_set` instead.
- The `is_global` option was removed from the `config_set` function. Please use `global` instead.
• The `always_fetch` option was removed from the `latest` function, as it no longer has any effect. Please see the 2015.8.0 release notes for more information.
• The `force` option was removed from the `latest` function. Please use `force_clone` instead.
• The `remote_name` option was removed from the `latest` function. Please use `remote` instead.

The `glusterfs` state had the following function removed:
• `created`: Please use `volume_present` instead.

The `openvswitch_port` state had the following change:
• The `type` option was removed from the `present` function. Please use `tunnel_type` instead.

Security Fix

CVE-2017-12791 Maliciously crafted minion IDs can cause unwanted directory traversals on the Salt-master

Correct a flaw in minion id validation which could allow certain minions to authenticate to a master despite not having the correct credentials. To exploit the vulnerability, an attacker must create a salt-minion with an ID containing characters that will cause a directory traversal. Credit for discovering the security flaw goes to: Vernhk@qq.com

Windows Changes

pkg Execution Module

Significante changes (PR #43708 & #45390, damon-atkins) have been made to the pkg execution module. Users should test this release against their existing package sls definition files.

• pkg.list_available no longer defaults to refreshing the winrepo meta database.
- `pkg.install` without a `version` parameter no longer upgrades software if the software is already installed. Use `pkg.install version=latest` (or simply use a `pkg.latest` state) to get the old behavior.

- `pkg.list_pkgs` now returns multiple versions if software installed more than once.

- `pkg.list_pkgs` now returns `Not Found` when the version is not found instead of `(value not set)` which matches the contents of the sls definitions.

- `pkg.remove` will wait up to 3 seconds (normally about a second) to detect changes in the registry after removing software, improving reporting of version changes.

- `pkg.remove` can remove `latest` software, if `latest` is defined in sls definition.

- Documentation was update for the execution module to match the style in new versions, some corrections as well.

- All install/remove commands are prefix with cmd.exe shell and cmdmod is called with a command line string instead of a list. Some sls files in saltstack/salt-winrepo-ng expected the commands to be prefixed with cmd.exe (i.e. the use of &).

- Some execution module functions results, now behave more like their Unix/Linux versions.

**cmd Execution Module**

Due to a difference in how Python's `subprocess.Popen()` spawns processes on Windows, passing the command as a list of arguments can result in problems. This is because Windows' `CreateProcess` requires the command to be passed as a single string. Therefore, `subprocess` will attempt to re-assemble the list of arguments into a string. Some escaped characters and quotes can cause the resulting string to be incorrectly-assembled, resulting in a failure to execute the command.

Salt now deals with these cases by joining the list of arguments correctly and ensuring that the command is passed to `subprocess.Popen()` as a string.

  - 494835c3f2 I backported develop and applied a long list of fixes to 2016.11 this brings these fixes into 2017.7 - Software was not always being removed, general if & was in the string or msi was downloaded to uninstall the software - pkg.list_upgrades failed. Added support for 'latest' and 'Not Found' for version_cmp() to fix this. - output fixes - pkg.list_available no longer forces a pkg.refresh_db this is no longer required, as by default it will update if older than 6 hours - cmd /s /c is prefixed for all commands i.e. installs and removes. - cmd are now strings, instead of a list when using cmd.run. As windows only supports strings. And the " were being broken

Changes to file.blockreplace State

The append_newline argument was added to this state. Additionally, to improve idempotence, if the string represented by marker_end is found in the middle of the line, the content preceding the marker will be removed when the block is replaced. This allows one to remove append_newline: False from the SLS and have the block properly replaced if the end of the content block is immediately followed by the marker_end (i.e. no newline before the marker).

Note: This will require changes to your SLS if your marker_end does not include the very beginning of the content you want to keep.

See the file.blockreplace state documentation for further information.

**Tornado 5.0 Support for Python 2 Only**

Tornado 5.0 moves to using asyncio for all python3 versions. Because of this and changes in asyncio between python 3.4 and 3.5 to only be able to use one ioloop, which requires some rearchitecting, support for tornado 5.0 and python3 versions of salt has been delayed to a later release.

For now, to use tornado 5.0, the python 2 version of salt must be used.

Option to Return to Previous Pillar Include Behavior

Prior to version 2017.7.3, keys from pillar includes would be merged on top of the pillar SLS. Since 2017.7.3, the includes are merged together and then the pillar SLS is merged on top of that.

The pillar_includes_override_sls option has been added allow users to switch back to the pre-2017.7.3 behavior.

  - f038ec3c452 Merge pull request #46571 from garethgreenaway/46552_onfail_and_require
  - 152c43e843 Accounting for a case when multiple onfails are used along with requires. Previously if you have multiple states using 'onfail' and two of those states using a 'require' against the first one state, the last two will run even if the 'onfail' isn’t met because the ‘require’ is met because the first state returns true even though it didn’t execute. This change adds an additional hidden variable that is used when checking requisities to determine if the state actually ran.

### 28.2.21 Salt 2017.7.7 Release Notes

Version 2017.7.7 is a bugfix release for 2017.7.0.

The 2017.7.7 release contains only a small number of fixes, which are detailed below.

This release fixes two critical issues.

The first is Issue #48038, which is a critical bug that occurs in a multi-syndic setup where the same job is run multiple times on a minion.

The second issue is #48130. This bug appears in certain setups where the Master reports a Minion time-out, even though the job is still running on the Minion.
Both of these issues have been fixed with this release.

Security Fix

CVE-2018-15751 Remote command execution and incorrect access control when using salt-api.
CVE-2018-15750 Directory traversal vulnerability when using salt-api. Allows an attacker to determine what files exist on a server when querying /run or /events.

New win_snmp behavior

- win_snmp.get_community_names now returns the SNMP settings actually in effect on the box. If settings are managed via GroupPolicy, those settings will be returned. Otherwise, normal settings are returned.
- win_snmp.set_community_names now raises an error when SNMP settings are being managed by GroupPolicy.

Option Added to Disable Docker Mine Updates

When a docker container is added, removed, started, stopped, etc., the results of a docker.ps verbose=True all=True host=True are sent to the mine, to be used by mine.get_docker.

A new config option (docker.update_mine) has been added. When set to False, Salt will not send this information to the mine. This is useful in cases where sensitive information is stored in the container’s environment.

• **ISSUE #46689:** (mxork) pkg.installed: hold: True not applied to a package which is already installed. (refs: #48426)

• **PR #48426:** (garethgreenaway) [2017.7] fixes to states/pkg.py @ 2018-07-31 20:18:05 UTC
  – 8a1285239a Merge pull request #48426 from garethgreenaway/46689_fixing_pkg_held_when_package_is_installed
  – 9b0f5dd212 Fixing indentation, removing some unnecessary conditionals.
  – 727964ab55 One last cleanup.
  – 11cb86e6eb General cleanup in pkg state, reducing duplicate code. Fixing the requires_salt_modules decorator, sys.doc was returning too much information for the event to handle. This change specifically calls sys.doc with the module name.
  – 16fb6ae635 Make sure pkg.hold and pkg.unhold are available before running the test.
  – 998651102d Fixing a situation when a package is already installed via salt or manually and a state attempts to set that package to be held. Previously the holding/unholding logic was only being run against packages that were being installed. This change moves the holding logic outside and runs it against all desired packages. Adding a new test to test holding logic.

• **PR #48388**: (garethgreenaway) [2017.7] reset file_roots for renderers after compile_pillar @ 2018-07-11 13:13:45 UTC
  - ad5a959ab9 Merge pull request #48388 from garethgreenaway/48277_2017_7_file_roots_wrong
  - 6f11da35a7 Fixing a few things in the new test.
  - cf747b14ec Fixing lint issue
  - 16d36c79c8 When pillar items are compiled a new render is instantiated but the file_roots is the pillar_roots. This change forces the __opts__['file_roots'] to be set to what is set in actual_file_roots for all renderers once compile_pillar has finished. Adding a test when this situation is run via an orchestration runner.

28.2.23 In Progress: Salt 2017.7.9 Release Notes

Version 2017.7.9 is an unreleased bugfix release for 2017.7.0. This release is still in progress and has not been released yet.

Salt Cloud Features

GCE Driver

The GCE salt cloud driver can now be used with GCE instance credentials by setting the configuration parameters service_account_private_key and service_account_private_email to an empty string.

28.2.24 Salt 2016.11.0 Release Notes - Codename Carbon

New Features

Docker Introspection and Configuration

Major additions have been made to the Docker support in 2016.11.0. The new addition allows Salt to be executed within a Docker container without a minion running or installed in the container. This allows states to be run inside a container, but also all of Salt’s remote execution commands to be run inside docker containers as well. This makes container introspection simple and powerful. See the tutorial on using this new feature here:

See Salt in Docker Containers.
Advanced Ceph Control

Our friends over at SUSE have delivered a powerful new tool to make the deployment of Ceph storage systems using Salt very easy. These new Ceph tools allow for a storage system to be easily defined using the new `ceph.quorum` state.

Thorium Additions and Improvements

The Thorium advanced reactor has undergone extensive testing and updates. These updates include many more Thorium states, a system for automating key management, the ability to use Thorium to easily replace old reactors and a great deal of stability and bug fixes.

State Rollback Using Snapper

Rollback has been one of the most prevalent requests for Salt. We have researched it extensively and concluded that the only way to accomplish truly reliable rollback would be to execute it at the filesystem layer. To accomplish this we have introduced Snapper integration into Salt States.

Snapper is a tool which allows for simple and reliable snapshots of the filesystem to be made. With the new `snapper_states` option set to `True` in the minion config a snapshot will be made before and after every Salt State run.

These snapshots can be viewed, managed and rolled back to via the `snapper` execution module.

Preserve File Perms in File States

This feature has been requested for years, the ability to set a flag and use the same file permissions for files deployed to a minion as the permissions set to the file on the master. Just set the `keep_mode` option on any file management state to `True`.

Ponies!

We all agreed that cowsay was just not good enough, install the `ponysay` command and the new `pony` outputter will work. Fun for the whole family!

Additional Features

- Minions can run in stand-alone mode to use beacons and engines without having to connect to a master. (Thanks @adelcast!)
- Added a `salt` runner to allow running salt modules via `salt-run`.

```
salt-run salt.cmd test.ping
  # call functions with arguments and keyword arguments
salt-run salt.cmd test.arg 1 2 3 a=1
```

- Added SSL support to Cassandra CQL returner. SSL can be enabled by setting `ssl_options` for the returner. Also added support for specifying `protocol_version` when establishing cluster connection.
- The `mode` parameter in the `file.managed` state, and the `file_mode` parameter in the `file.recurse` state, can both now be set to `keep` and the minion will keep the mode of the file from the Salt fileserver. This
works only with files coming from sources prefixed with `salt://`, or files local to the minion (i.e. those which are absolute paths, or are prefixed with `file://`). For example:

```
/etc/myapp/myapp.conf:
  file.managed:
    - source: salt://conf/myapp/myapp.conf
    - mode: keep
/var/www/myapp:
  file.recurse:
    - source: salt://path/to/myapp
    - dir_mode: 755
    - file_mode: keep
```

• The `junos` state module is now available. It has all the functions that are present in the `junos` execution module.

• The `junos` state module is now available. It has all the functions that are present in the `junos` execution module.

• The minion data cache is a pluggable data store now. It’s configurable with `cache` option. Default is `localfs`.

• User names in `client_acl` support glob matching now.

**New Top File Merging Strategy for States**

A new strategy called `merge_all` has been added to provide a new way of merging top file matches when executing a `highstate`. See the `top_file_merging_strategy` documentation for further information.

In addition, the same merging strategy was not functioning as documented. This has now been corrected. While this is technically a bugfix, we decided to hold a change in top file merging until a feature release to minimize user impact.

**Improved Archive Extraction Support**

The `archive.extracted` state has been overhauled. Notable changes include the following:

• When enforcing ownership (with the `user` and/or `group` arguments), the `if_missing` argument no longer has any connection to which path(s) have ownership enforced. Instead, the paths are determined using the either the newly-added `archive.list` function, or the newly-added `enforce_ownership_on` argument.

• `if_missing` also is no longer required to skip extraction, as Salt is now able to tell which paths would be present if the archive were extracted. It should, in most cases, only be necessary in cases where a semaphore file is used to conditionally skip extraction of the archive.

• Password-protected ZIP archives are now detected before extraction, and the state fails without attempting to extract the archive if no password was specified.

• By default, a single top-level directory is enforced, to guard against ‘tar-bombs’. This enforcement can be disabled by setting `enforce_toplevel` to `False`.

• The `tar_options` and `zip_options` arguments have been deprecated in favor of a single `options` argument.

• The `archive_format` argument is now optional. The ending of the `source` argument is used to guess whether it is a tar, zip or rar file. If the `archive_format` cannot be guessed, then it will need to be specified, but in many cases it can now be omitted.
Ownership enforcement is now performed irrespective of whether or not the archive needed to be extracted. This means that the state can be re-run after the archive has been fully extracted to repair changes to ownership.

A number of new arguments were also added. See the docs for the archive.extracted state for more information.

Additionally, the following changes have been made to the **archive** execution module:

- A new function (**archive.list** has been added. This function lists the files/directories in an archive file, and supports a **verbose** argument that gives a more detailed breakdown of which paths are files, which are directories, and which paths are at the top level of the archive.
- A new function (**archive.is_encrypted**) has been added. This function will return **True** if the archive is a password-protected ZIP file, **False** if not. If the archive is not a ZIP file, an error will be raised.
- **archive.cmd_unzip** now supports passing a password, bringing it to feature parity with **archive.unzip**. Note that this is still not considered to be secure, and **archive.unzip** is recommended for dealing with password-protected ZIP archives.
- The default value for the **extract_perms** argument to **archive.unzip** has been changed to **True**.

### Improved Checksum Handling in **file.managed, archive.extracted** States

When the **source_hash** argument for these states refers to a file containing checksums, Salt now looks for checksums matching the name of the source URI, as well as the file being managed. Prior releases only looked for checksums matching the filename being managed. Additionally, a new argument (**source_hash_name**) has been added, which allows the user to disambiguate ambiguous matches when more than one matching checksum is found in the **source_hash** file.

A more detailed explanation of this functionality can be found in the **file.managed** documentation, in the section for the new **source_hash_name** argument.

**Note:** This improved functionality is also available in the 2016.3 (Boron) release cycle, starting with the 2016.3.5 release.

### Config Changes

The following default config values were changed:

- **gitfs_ssl_verify**: Changed from **False** to **True**
- **git_pillar_ssl_verify**: Changed from **False** to **True**
- **winrepo_ssl_verify**: Changed from **False** to **True**

### Grains Changes

- All core grains containing **VMWare** have been changed to **VMware**, which is the **official** capitalization. Additionally, all references to **VMWare** in the documentation have been changed to **VMware** issue #30807. Environments using versions of Salt before and after Salt 2016.11.0 should employ case-insensitive grain matching on these grains.

```python
{% set on_vmware = grains['virtual'].lower() == 'vmware' %}
```
On Windows the `cpu_model` grain has been changed to provide the actual cpu model name and not the cpu family.

Old behavior:

```bash
root@master:~# salt 'testwin200' grains.item cpu_model
testwin200:  
____________
cpu_model:  
Intel64 Family 6 Model 58 Stepping 9, GenuineIntel
```

New behavior:

```bash
root@master:~# salt 'testwin200' grains.item cpu_model
testwin200:  
____________
cpu_model:  
Intel(R) Core(TM) i7-3520M CPU @ 2.90GHz
```

**Beacons Changes**

- The `loadavg` beacon now outputs averages as integers instead of strings. (Via issue #31124.)

**Runner Changes**

- Runners can now call out to *utility modules* via `__utils__`.
- ref:`Utility modules <writing-utility-modules>` (placed in `salt://_utils/`) are now able to be synced to the master, making it easier to use them in custom runners. A `saltutil.sync_utils` function has been added to the `saltutil runner` to facilitate the syncing of utility modules to the master.

**Pillar Changes**

- Thanks to the new `saltutil.sync_utils` runner, it is now easier to get ref:`utility modules <writing-utility-modules>` synced to the correct location on the Master so that they are available in execution modules called from Pillar SLS files.

**Junos Module Changes**

- The following new functionalities were added to the junos module
  - facts - Displays the facts gathered during the connection.
  - shutdown - Shut down or reboot a device running Junos OS.
  - install_config - Modify the configuration of a Junos device.
  - install_os - Install Junos OS software package.
  - zeroize - Remove all configuration information on the Routing Engines and reset all key values on a device.
  - file_copy - Copy file from proxy to the Junos device.
Network Automation: NAPALM

Beginning with 2016.11.0, network automation is included by default in the core of Salt. It is based on the NAPALM library and provides facilities to manage the configuration and retrieve data from network devices running widely used operating systems such as JunOS, IOS-XR, eOS, IOS, NX-OS etc.

- see the complete list of supported devices.

The connection is established via the NAPALM proxy.

In the current release, the following modules were included:

- **NAPALM grains** - Select network devices based on their characteristics
- **NET execution module** - Networking basic features
- **NTP execution module**
- **BGP execution module**
- **Routes execution module**
- **SNMP execution module**
- **Users execution module**
- **Probes execution module**
- **NTP peers management state**
- **SNMP configuration management state**
- **Users management state**

Cisco NXOS Proxy Minion

Beginning with 2016.11.0, there is a proxy minion that can be used to configure nxos cisco devices over ssh.

- **Proxy Minion**
- **Execution Module**
- **State Module**

Cisco Network Services Orchestrator Proxy Minion

Beginning with 2016.11.0, there is a proxy minion to use the Cisco Network Services Orchestrator as a proxy minion.

- **Proxy Minion**
- **Execution Module**
- **State Module**

Junos Module Changes

- The following new functionalities were added to the junos module
  - facts - Displays the facts gathered during the connection.
  - shutdown - Shut down or reboot a device running Junos OS.
  - install_config - Modify the configuration of a Junos device.
– install_os - Install Junos OS software package.
– zeroize - Remove all configuration information on the Routing Engines and reset all key values on a device.
– file_copy - Copy file from proxy to the Junos device.

**Returner Changes**

- Any returner which implements a save_load function is now required to accept a minions keyword argument. All returners which ship with Salt have been modified to do so.

**Renderer Changes**

Added the ability to restrict allowed renderers. Two new config parameters, renderer_whitelist and renderer_blacklist are introduced for this purpose.

**eAuth Changes**

- External auth modules' auth method can return an ACL list for the given username instead of True. This list should be in the same format as described in the eAuth documentation. It will be used for the user instead of one set in master config.

Example of the auth method return that allows a user to execute functions in the test and network modules on the minions that match the web* target and allow access to wheel and runner modules:

```
[{
    'web*': ['test.*',
             'network.*'],
    '@wheel',
    '@runner']
```

- External auth is supported by salt-run and salt-key now. Note that master must be started to use them with eAuth.

**External Module Packaging**

Modules may now be packaged via entry-points in setuptools. See external module packaging tutorial for more information.

**Functionality Changes**

- The onfail requisite now uses OR logic instead of AND logic. issue #22370
- The consul external pillar now strips leading and trailing whitespace. issue #31165
- The win_system.py state is now case sensitive for computer names. Previously computer names set with a state were converted to all caps. If you have a state setting computer names with lower case letters in the name that has been applied, the computer name will be changed again to apply the case sensitive name.
- The mac_user.list_groups function in the mac_user execution module now lists all groups for the specified user, including groups beginning with an underscore. In previous releases, groups beginning with an underscore were excluded from the list of groups.
- The junos.call_rpc function in the junos execution module can now be used to call any valid rpc. Earlier it used to call only "get_software_information".
• A new option for minions called `master_tries` has been added. This specifies the number of times a minion should attempt to contact a master to attempt a connection. This allows better handling of occasional master downtime in a multi-master topology.

• The default `hash_type` is now `sha256` instead of `md5`. You will need to make sure both your master and minion share the same `hash_type`.

• Nodegroups consisting of a simple list of minion IDs can now also be declared as a yaml list. The below two examples are equivalent:

```yaml
# Traditional way
nodegroups:
  - group1: L@host1,host2,host3

# New way (optional)
nodegroups:
  - group1:
    - host1
    - host2
    - host3
```

**New Azure ARM Cloud Driver**

A new cloud driver has been added for Azure ARM, aka, the Azure Resource Manager. The older Azure driver is still required to work with the older Azure API. This new driver works with the newer ARM API, which is managed via the newer Azure Portal website.

**New Modules**

**Beacons**

• `salt.beacons.avahi_announce`
• `salt.beacons.bonjour_announce`
• `salt.beacons.haproxy`
• `salt.beacons.status`

**Clouds**

• `salt.cloud.clouds.azurearm`

**Engines**

• `salt.engines.hipchat`
• `salt.engines.http_logstash`

**Modules**

• `salt.modules.boto_cloudwatch_event`
- `salt.modules.celery`
- `salt.modules.ceph`
- `salt.modules.influx08`
- `salt.modules.inspectlib.entities`
- `salt.modules.inspectlib.fsdb`
- `salt.modules.inspectlib.kiwiproc`
- `salt.modules.inspector`
- `salt.modules.libcloud_dns`
- `salt.modules.openstack_mng`
- `salt.modules.servicenow`
- `salt.modules.testinframod`
- `salt.modules.win_lgpo`
- `salt.modules.win_pki`
- `salt.modules.win_psget`
- `salt.modules.win_snmp`
- `salt.modules.xbpspkg`

**Outputters**

- `salt.output.pony`

**Pillar**

- `salt.pillar.csvpillar`
- `salt.pillar.http_json`
- `salt.pillar.makostack`

**Returners**

- `salt.returners.zabbix_return`

**Runners**

- `salt.runners.auth`
- `salt.runners.event`
- `salt.runners.smartos_vmadm`
- `salt.runners.vistara`
SDB

- `salt.sdb.env`

States

- `salt.states.boto_cloudwatch_event`
- `salt.states.csf`
- `salt.states.ethtool`
- `salt.states.influxdb08_database`
- `salt.states.influxdb08_user`
- `salt.states.libcloud_dns`
- `salt.states.snapper`
- `salt.states.testinframod`
- `salt.states.win_lgpo`
- `salt.states.win_pki`
- `salt.states.win_snmp`

Thorium

- `salt.thorium.calc`
- `salt.thorium.key`
- `salt.thorium.runner`
- `salt.thorium.status`
- `salt.thorium.wheel`

Deprecations

General Deprecations

- `env` to `saltenv`

All occurrences of `env` and some occurrences of `__env__` marked for deprecation in Salt 2016.11.0 have been removed. The new way to use the salt environment setting is with a variable called `saltenv`:

```python
def fcn(msg='', env='base', refresh=True, saltenv='base', **kwargs):
```

has been changed to

```python
def fcn(msg='', refresh=True, saltenv='base', **kwargs):
```

- If `env` (or `__env__`) is supplied as a keyword argument to a function that also accepts arbitrary keyword arguments, then a new warning informs the user that `env` is no longer used if it is found. This new warning will be removed in Salt 2017.7.0.
```
def fcn(msg='', refresh=True, saltenv='base', **kwargs):
    # will result in a warning log message
    fcn(msg='add more salt', env='prod', refresh=False)
```

- If env (or __env__) is supplied as a keyword argument to a function that does not accept arbitrary keyword arguments, then python will issue an error.

```
def fcn(msg='', refresh=True, saltenv='base'):
    # will result in a python TypeError
    fcn(msg='add more salt', env='prod', refresh=False)
```

- If env (or __env__) is supplied as a positional argument to a function, then undefined behavior will occur, as the removal of env and __env__ from the function’s argument list changes the function’s signature.

```
def fcn(msg='', refresh=True, saltenv='base'):
    # will result in refresh evaluating to True and saltenv likely not being a
    # string at all
    fcn('add more salt', 'prod', False)
```

- Deprecations in minion.py:
  - The salt.minion.parse_args_and_kwargs function has been removed. Please use the salt.minion.load_args_and_kwargs function instead.

Cloud Deprecations

- The vsphere cloud driver has been removed. Please use the vmware cloud driver instead.
- The private_ip option in the linode cloud driver is deprecated and has been removed. Use the assign_private_ip option instead.
- The create_dns_record and delete_dns_record functions are deprecated and have been removed from the digital_ocean driver. Use the post_dns_record function instead.

Execution Module Deprecations

- The blockdev execution module had four functions removed:
  - dump
  - tune
  - resize2fs
  - wipe
  The disk module should be used instead with the same function names.
- The boto_vpc execution module had two functions removed, boto_vpc.associate_new_dhcp_options_to_vpc and boto_vpc.associate_new_network_acl_to_subnet in favor of more concise function names, boto_vpc.create_dhcp_options and boto_vpc.create_network_acl, respectively.
• The data execution module had `getval` and `getvals` functions removed in favor of one function, `get`, which combines the functionality of the removed functions.

• File module deprecations:
  – The `contains_regex_multiline` function was removed. Use `file.search` instead.
  – Additional command line options for `file.grep` should be passed one at a time. Please do not pass more than one in a single argument.

• The `lxc` execution module has the following changes:
  – The `run_cmd` function was removed. Use `lxc.run` instead.
  – The `nic` argument was removed from the `lxc.init` function. Use `network_profile` instead.
  – The `clone` argument was removed from the `lxc.init` function. Use `clone_from` instead.
  – Passwords passed to the `lxc.init` function will be assumed to be hashed, unless `password_encrypted=False`.
  – The `restart` argument for `lxc.start` was removed. Use `lxc.restart` instead.
  – The old style of defining LXC containers has been removed. Please use keys under which LXC profiles should be configured such as `lxc.container_profile.profile_name`.

• The `env` and `activate` keyword arguments have been removed from the `install` function in the `pip` execution module. The use of `bin_env` replaces both of these options.

• The `reg` execution module

  Functions in the `reg` execution module had misleading and confusing names for dealing with the Windows registry. They failed to clearly differentiate between hives, keys, and name/value pairs. Keys were treated like value names. There was no way to delete a key.

  New functions were added in 2015.5 to properly work with the registry. They also made it possible to edit key default values as well as delete an entire key tree recursively. With the new functions in place, the following functions have been deprecated:
  – `read_key`
  – `set_key`
  – `create_key`
  – `delete_key`

  Use the following functions instead:
  – `for read_key use read_value`
  – `for set_key use set_value`
  – `for create_key use set_value with no vname and no vdata`.
  – `for delete_key use delete_key_recursive`. To delete a value, use `delete_value`.

• The `hash_hostname` option was removed from the `salt.modules.ssh` execution module. The `hash_known_hosts` option should be used instead.

• The `human_readable` option was removed from the `uptime` function in the `status` execution module. The function was also updated in 2015.8.9 to return a more complete offering of uptime information, formatted as an easy-to-read dictionary. This updated function replaces the need for the `human_readable` option.

• The `persist` kwarg was removed from the `win_useradd` execution module. This option is no longer supported for Windows. `persist` is only supported as part of user management in UNIX/Linux.
• The `zpool_list` function in the `zpool` execution module was removed. Use `list` instead.

**Outputter Module Deprecations**

• The `compact` outputter has been removed. Set `state_verbose` to `False` instead.

**Runner Module Deprecations**

• The `grains.cache` runner no longer accepts `outputter` or `minion` as keyword arguments. Users will need to specify an outputter using the `--out` option. `tgt` is replacing the `minion` kwarg.

• The `fileserv er` runner no longer accepts the `outputter` keyword argument. Users will need to specify an outputter using the `--out` option.

• The `jobs` runner no longer accepts the `outputter` keyword argument. Users will need to specify an outputter using the `--out` option.

• `virt` runner module:
  – The `hyper` kwarg was removed from the `init`, `list`, and `query` functions. Use the `host` option instead.
  – The `next_hyper` function was removed. Use the `next_host` function instead.
  – The `hyper_info` function was removed. Use the `host_info` function instead.

**State Module Deprecations**

• The `env` and `activate` keyword arguments were removed from the `installed` function in the `pip` state module. The use of `bin_env` replaces both of these options.

• `reg` state module

  The `reg` state module was modified to work with the new functions in the execution module. Some logic was left in the `reg.present` and `reg.absent` functions to handle existing state files that used the final key in the name as the value name. That logic has been removed so you now must specify value name (`vname`) and, if needed, value data (`vdata`).

  For example, a state file that adds the version value/data pair to the `Software\Salt` key in the `HKEY_LOCAL_MACHINE` hive used to look like this:
  ```
  HKEY_LOCAL_MACHINE\Software\Salt\version:
  reg.present:
  - value: 2016.3.1
  ```

  Now it should look like this:
  ```
  HKEY_LOCAL_MACHINE\Software\Salt
  reg.present:
  - vname: version
  - vdata: 2016.3.1
  ```

  A state file for removing the same value added above would have looked like this:
  ```
  HKEY_LOCAL_MACHINE\Software\Salt\version:
  reg.absent:
  ```
Now it should look like this:

```yaml
HKEY_LOCAL_MACHINE\Software\Salt
  reg.absent:
    - vname: version
```

This new structure is important as it allows salt to deal with key default values which was not possible before. If vname is not passed, salt will work with the default value for that hivekey.

Additionally, since you could only delete a value from a the state module, a new function (key_absent) has been added to allow you to delete a registry key and all subkeys and name/value pairs recursively. It uses the new delete_key_recursive function.

For additional information see the documentation for the reg execution and state modules.

- **lxc state module:** The following functions were removed from the lxc state module:
  - created: replaced by the present state.
  - started: replaced by the running state.
  - cloned: replaced by the present state. Use the clone_from argument to set the name of the clone source.

- The hash_hostname option was removed from the salt.states.ssh_known_hosts state. The hash_known_hosts option should be used instead.

- The always kwarg used in the built function of the pkgbuild state module was removed. Use force instead.

### Utils Module Deprecations

- The use of jid_dir and jid_load were removed from the salt.utils.jid.jid_dir functionality for job_cache management was moved to the local_cache returner. jid_load data is now retrieved from the master_job_cache.

- ip_in_subnet function in salt.utils.network.py has been removed. Use the in_subnet function instead.

- The iam utils module had two functions removed: salt.utils.iam.get_iam_region and salt.utils.iam.get_iam_metadata in favor of the aws utils functions salt.utils.aws.get_region_from_metadata and salt.utils.aws.creds, respectively.

## 28.2.25 Salt 2016.11.1 Release Notes

Version 2016.11.1 is a bugfix release for 2016.11.0.

28.2.26 Salt 2016.11.10 Release Notes

Version 2016.11.10 is a security release for 2016.11.0.

Changes for v2016.11.9..v2016.11.10

Security Fix

CVE-2018-15751 Remote command execution and incorrect access control when using salt-api.

CVE-2018-15750 Directory traversal vulnerability when using salt-api. Allows an attacker to determine what files exist on a server when querying /run or /events.

Credit and thanks for discovery and responsible disclosure: nullbr4in, xcuter, koredge, loupos, blackcon, Naver Business Platform

28.2.27 Salt 2016.11.2 Release Notes

Version 2016.11.2 is a bugfix release for 2016.11.0.

Security Fixes

CVE-2017-5192 local_batch client external authentication not respected

The LocalClient.cmd_batch() method client does not accept external_auth credentials and so access to it from salt-api has been removed for now. This vulnerability allows code execution for already-authenticated users and is only in effect when running salt-api as the root user.

CVE-2017-5200 Salt-api allows arbitrary command execution on a salt-master via Salt’s ssh_client

Users of Salt-API and salt-ssh could execute a command on the salt master via a hole when both systems were enabled.

We recommend everyone upgrade to 2016.11.2 as soon as possible.

• **PR #39153** (nicholasmhughes) Fix selinux.mode state config file handling @ 2017-02-06 18:37:34 UTC
  - 30455079fe Merge pull request #39153 from nicholasmhughes/fix-selinux.mode-config-predictability
  - 8d8ba9c7d2 added the new getconfig function to the test
  - a6a24e1a1b Addressed edge case when attempting to set the config file to 'Disabled'. The state should only check the file, since the in-memory setting won't disappear until after reboot.
  - 6858658cc2 The selinux.mode state only checked the current status of SELinux in memory (getenforce) when determining if changes needed to be made. The /etc/selinux/config file could have a different value, and it would not be changed. This commit enhances idempotency of the state in regards to both the in-memory and configuration file enforcement of SELinux.

AIX Support Expanded

AIX support has been added for the following execution modules:

- user
- group
- network
- status
- timezone

Additionally, AIX is now supported in the `disk.iostat` remote-execution function, and the `status` beacon is now supported.

Minion Data Cache Enhancement

Memcache is now supported as a data store for the minion data cache.

Memcache is an additional cache layer that keeps a limited amount of data fetched from the minion data cache for a limited period of time in memory that makes cache operations faster. It doesn’t make much sense for the localfs cache driver but helps for more complex drivers like consul.

For more details see `memcache_expire_seconds` and other memcache_* options in the master config reference.

Docker Fixes

- Docker authentication has been re-organized. Instead of attempting a login for each push/pull (which was unnecessary), a new function called `dockerng.login` has been added, which authenticates to the registry and adds the credential token to the `~/.docker/config.json`. After upgrading, if you have not already performed a docker login on the minion using the docker CLI, you will need to run `dockerng.login` to login. This only needs to be done once.

- A bug in resolving the tag name for images in a custom registry (where a colon can appear in the image name, e.g. `myregistry.com:5000/image:tagname`) has been fixed. In previous releases, Salt would use the colon to separate the tag name from the image name, and if there was no colon, the default tag name of `latest` would be assumed. However, this caused custom registry images to be misidentified when no explicit tag name was passed (e.g. `myregistry.com:5000/image`). To work around this in earlier releases, simply specify the tag name.
Salt-Cloud Fixes

2016.11.0 added support for templating userdata files for the ec2 driver, using the renderer option from the master config file. However, as the default renderer first evaluates jinja templating, followed by loading the data as a YAML dictionary, this results in unpredictable results when userdata files are comprised of non-YAML data (which they generally are).

2016.11.4 fixes this by only templating the userdata_file when it is explicitly configured to do so. This is done by adding a new optional parameter to the cloud profile called userdata_template. This option is used in the same way as the template argument in file.managed states, it is simply set to the desired templating renderer:

```yaml
my-ec2-config:
  # Pass userdata to the instance to be created
  userdata_file: /etc/salt/my-userdata-file
  userdata_template: jinja
```

If no userdata_template option is set in the cloud profile, then salt-cloud will check for the presence of the master configuration parameter userdata_renderer. If this is also not set, then no templating will be performed on the userdata_file.

In addition, the other cloud drivers which support setting a userdata_file (azurearm, nova, and openstack) have had templating support added to bring them to feature parity with the ec2 driver’s implementation of the userdata_file option.

Patched Packages

Due to the critical nature of issue issue #41230 we have decided to patch the 2016.11.5 packages with PR #41244. This issue affects all calls to a salt-minion if there is an ipv6 nameserver set on the minion’s host. The patched packages on repo.saltstack.com will divert from the v2016.11.5 tag and pypi packages due to the patches applied to the packages.

  - d9546c6283 Merge pull request #41599 from garethgreenaway/41540 Fixes to_archive_module
  - 66a136e6d8 Fixing issues raised in #41540 when a zip file is created on a Windows system. The issue has two parts, first directories that end up in the archive end up in the results of archive.list twice as they show up as both files and directories because of the logic to handle the fact that Windows doesn’t mark them as directories. This issue shows up when an extraction is run a second time since the module verified the file types and the subdirectory is not a file. The second issue is related to permissions, if Salt is told to extract permissions (which is the default) then the directory and files end up being unreadable since the permissions are not available. This change sets the permissions to what the default umask for the user running Salt is.

### 28.2.32 Salt 2016.11.7 Release Notes

Version 2016.11.7 is a bugfix release for 2016.11.0.

**Security Fix**

**CVE-2017-12791** Maliciously crafted minion IDs can cause unwanted directory traversals on the Salt-master

This release corrects a flaw in minion ID validation which could allow certain minions to authenticate to a master despite not having the correct credentials. To exploit the vulnerability, an attacker must create a salt-minion with an ID containing characters that will cause a directory traversal. Credit for discovering the security flaw goes to: Vernhk@qq.com

### 28.2.33 Salt 2016.11.8 Release Notes

Version 2016.11.8 is a bugfix release for 2016.11.0.

**Statistics**

Security Fix

CVE-2017-14695 Directory traversal vulnerability in minion id validation in SaltStack. Allows remote minions with incorrect credentials to authenticate to a master via a crafted minion ID. Credit for discovering the security flaw goes to: Julian Brost (julian@0x4a42.net)

CVE-2017-14696 Remote Denial of Service with a specially crafted authentication request. Credit for discovering the security flaw goes to: Julian Brost (julian@0x4a42.net)

Anonymous Binds and LDAP/Active Directory

When auth.ldap.anonymous is set to False, the bind password can no longer be empty.

Windows Changes

pkg Execution Module

Significant changes (PR #43708 & #45390, damon-atkins) have been made to the pkg execution module. Users should test this release against their existing package sls definition files.

- pkg.list_available no longer defaults to refreshing the winrepo meta database.
- pkg.install without a version parameter no longer upgrades software if the software is already installed. Use pkg.install version=latest (or simply use a pkg.latest state to get the old behavior.
- pkg.list_pkgs now returns multiple versions if software installed more than once.
- pkg.list_pkgs now returns Not Found when the version is not found instead of (value not set) which matches the contents of the sls definitions.
- pkg.remove will wait up to 3 seconds (normally about a second) to detect changes in the registry after removing software, improving reporting of version changes.
- pkg.remove can remove latest software, if latest is defined in sls definition.
- Documentation was update for the execution module to match the style in new versions, some corrections as well.
- All install/remove commands are prefix with cmd.exe shell and cmdmod is called with a command line string instead of a list. Some sls files in saltstack/salt-winrepo-ng expected the commands to be prefixed with cmd.exe (i.e. the use of &).
- Some execution module functions results, now behave more like their Unix/Linux versions.
cmd Execution Module

Due to a difference in how Python’s `subprocess.Popen()` spawns processes on Windows, passing the command as a list of arguments can result in problems. This is because Windows’ `CreateProcess` requires the command to be passed as a single string. Therefore, `subprocess` will attempt to re-assemble the list of arguments into a string. Some escaped characters and quotes can cause the resulting string to be incorrectly-assembled, resulting in a failure to execute the command.

Salt now deals with these cases by joining the list of arguments correctly and ensuring that the command is passed to `subprocess.Popen()` as a string.

28.2.35 Salt 2016.3.0 Release Notes - Codename Boron

Known Issues

Warning: Some Salt Masters may need to apply a patch for Default Job Cache to prevent a possible crash

An issue exists that prevents the Salt master from cleaning the default job cache. This issue can cause an over-consumption of resources resulting in a crash. 2016.3.0 Salt masters should apply the patch in PR #33555. This issue will be addressed in 2016.3.1.

- issue #33516: When upgrading from 2015.8.10 to 2016.3.0 on centos7/redhat7 salt-minion must be restarted twice.
- issue #33517: SPM does not work on amazon linux 2015 in 2016.3.0.

Backwards-incompatible Changes

- The default path for the extension_modules master config option has been changed. Prior to this release, the location was a directory named extmods in the Salt cachedir. On most platforms, this would put the extension_modules directory in /var/cache/salt/extmods. It has been moved one directory down, into the master cachedir. On most platforms, this is /var/cache/salt/master/extmods. Most users won’t have to worry about this, but those who have been manually placing custom runners into /var/cache/salt/extmods/runners, or outputters into /var/cache/salt/extmods/output, etc. will be affected by this. To transition, it is recommended not to simply move the extmods directory into /var/cache/salt/master, but to copy the custom modules into the salt files server under salt://_runners, salt://_output, etc. and sync them using the functions in the new saltutil runner.
- The pkg.check_db function has been removed for yum/dnf.

Core Changes

- The onchanges requisite now fires if any watched state changes. issue #19592.
- The ext_pillar functions must now accept a minion ID as the first argument. This stops the deprecation path started in Salt 0.17.x. Before this minion ID first argument was introduced, the minion ID could be retrieved accessing __opts__['id'] losing the reference to the master ID initially set in opts. This is no longer the case, __opts__['id'] will be kept as the master ID.
- Custom types can now be synced to the master using the new saltutil runner. Before, these needed to manually be placed under the extension_modules directory. This allows custom modules to easily be synced to the master to make them available when compiling Pillar data. Just place custom runners into salt://_runners, custom outputters into salt://_output, etc. and use the functions from the saltutil runner to sync them.
- The client_acl configuration options were renamed to publisher_acl.
- Added a new --config-dump option (issue #26639).
- TCP Transport presence events were updated to work with a NAT (PR #30629).

28.2. Previous Releases
• A `minion_pillar_cache` setting was added to save rendered pillar data to cachedir for later use when file_client is set to local (PR #30428).

• Added the ability for binary data (such as a license key) to be distributed via pillar using the `file.managed` (issue #9569).

• Scheduled jobs now include `success` and `retcode` (issue #24237).

• The `saltversioninfo` grain was changed from a string to a list to enable reading values by index. (PR #30082).

• A `pillar_merge_lists` option was added to enable recursively merging pillar lists by aggregating them instead of replacing them (PR #30062).

• Grain values reported by Debian 8 (jessie) when lsb-release is installed were updated for consistency (PR #28649).

• A new option for minions called master_tries has been added. This specifies the number of times a minion should attempt to contact a master to attempt a connection. This allows better handling of occasional master downtime in a multi-master topology.

• The default directory for deploying the salt-thin tarball has changed for salt-ssh. It is now `/var/tmp` instead of `/tmp`. Users may also wish to delete any directories in `/tmp` ending with `_salt/`. (issue #32771)

**External Module Packaging**

Modules may now be packaged via entry-points in setuptools. See *external module packaging* tutorial for more information.

**Cloud Changes**

• Refactored the OpenNebula driver and added numerous `--function` and `--action` commands to enhance Salt support for image, template, security group, virtual network and virtual machine management in OpenNebula.

• Added execution/state modules to support the deployment of AWS cognito identity pools (PR #31094).

• Added ability to set tags and listener policies on a AWS ELB (PR #27552).

**Platform Changes**

• Renamed modules related to macOS. The following module filenames were changed. The virtual name remained unchanged.

  • PR ##30558: renamed osxdesktop.py to mac_desktop.py
  • PR ##30557: renamed macports.py to mac_ports.py
  • PR ##30556: renamed darwin_sysctl.py to mac_sysctl.py
  • PR ##30555: renamed brew.py to mac_brew.py
  • PR ##30552: renamed darwin_pkgutil.py to mac_pkgutil.py
Package Support

- Ubuntu Xenial: Packages for Ubuntu Xenial (16.04) are available for 2016.3.0 and onwards. See repo.saltstack.com for more information. Note that Xenial comes with Debian’s packaged version of Salt 2015.8.8 and official repo.saltstack.com packages are available for 2015.8 releases beginning with Salt 2015.8.11.

Proxy Minion Changes

The deprecated config option enumerate_proxy_minions has been removed.

As mentioned in earlier documentation, the add_proxymodule_to_opts configuration variable defaults to False in this release. This means if you have proxymodules or other code looking in __opts__['proxymodule'] you will need to set this variable in your /etc/salt/proxy file, or modify your code to use the __proxy__ injected variable.

The __proxyenabled__ directive now only applies to grains and proxy modules themselves. Standard execution modules and state modules are not prevented from loading for proxy minions.

Support has been added to Salt’s loader allowing custom proxymodules to be placed in salt://_proxy. Proxy minions that need these modules will need to be restarted to pick up any changes. A corresponding utility function, saltutil.sync_proxymodules, has been added to sync these modules to minions.

Enhancements in grains processing have made the __proxyenabled__ directive somewhat redundant in dynamic grains code. It is still required, but best practices for the __virtual__ function in grains files have changed. It is now recommended that the __virtual__ functions check to make sure they are being loaded for the correct proxytype, example below:

```python
def __virtual__(self):
    '''
    Only work on proxy
    '''
    try:
        if salt.utils.is_proxy() and __opts__['proxymodule'] == 'ssh_sample':
            return __virtualname__
    except KeyError:
        pass
    return False
```

Note: salt.utils.is_proxy() has been renamed to salt.utils.platform.is_proxy as of the Oxygen release.

The try/except block above exists because grains are processed very early in the proxy minion startup process, sometimes earlier than the proxy key in the __opts__ dictionary is populated.

Grains are loaded so early in startup that no dunder dictionaries are present, so __proxy__, __salt__, etc. are not available. Custom grains located in /srv/salt/_grains and in the salt install grains directory can now take a single argument, proxy, that is identical to __proxy__. This enables patterns like

```python
def get_ip(proxy):
    '''
    Ask the remote device what IP it has
    '''
    return {'ip':proxy['proxymodule.get_ip']}()
```
Then the grain ip will contain the result of calling the get_ip() function in the proxymodule called proxymodulename.

Proxy modules now benefit from including a function called initialized(). This function should return True if the proxy’s init() function has been successfully called. This is needed to make grains processing easier.

Finally, if there is a function called grains in the proxymodule, it will be executed on proxy-minion startup and its contents will be merged with the rest of the proxy’s grains. Since older proxy-minions might have used other methods to call such a function and add its results to grains, this is config-gated by a new proxy configuration option called proxy_merge_grains_in_module. This defaults to False in this release. It will default to True in the release after next. The next release is codenamed Carbon, the following is Nitrogen.

The example proxy minions rest_sample and ssh_sample have been updated to reflect these changes.

Syndic Updates

A major performance and management issue was found and fixed in the syndic. This makes the Salt Syndic substantially more reliable and performant. Please make sure that the syndic and the master of masters which syndics attach to are updated, otherwise the syndic fixes alone can cause minor performance issues with older master of masters. Please update masters first, then syndics. Minions do not need to be updated for this fix to work.

Module Changes

- **file execution module:** show_diff is deprecated in favor of show_changes. (PR #30988)
- **reg execution module:**
  - Removed the following deprecated functions from the reg module (PR #30956):
    * read_key
    * set_key
    * create_key
    * delete_key
  - Removed force parameter from reg state module
  - Fixed virtual function in state
  - Improved error information for reg.delete_value function
- **jboss7 execution module:** deployed function was decoupled from Artifactory by removing Artifactory-specific functionality. Note that the changes in some of the function arguments break existing state files, see issue #30515 and PR #3080 for details.
- **pkg state module:** The wait function was removed, the functionality was replaced with the onchanges requisite (PR #30297).
- **firewalld state module:** A permanent argument was added add_port. Note that permanent defaults to True, which changes previous behavior (PR #30275). A bind function was also added that allows binding zones to interfaces and sources (PR #29497).
- **journald beacon module:** The event string was updated to include a tag. Note this might impact existing reactors based on this beacon. (PR #30116).
- **postgres_privileges state module:** The default value of the prepend argument was changed from None to public.
- **zenoss execution module:** The add_device function was updated with a default value of 1000 for prod_state to match the documentation (PR #28924).
• The etcd execution module, state module, returner module, and util module were refactor (PR #28599). This refactor changes error returns for several functions (primarily edge cases):
  – get: Used to return " on key-not-found. Now returns None.
  – set: Used to return " on issues setting keys. Now returns None.
  – ls: Used to return [path: {}] on key-not-found. Now returns None.
  – Tree: Used to return {} on key-not-found. Now returns None.
• smartos_virt execution module: Updated to use most of the new smartos_vmadm (PR #28284).
• apache_conf state module, apache_module state module, and apache_site state module: the enable and disable functions were renamed to enabled and disabled, respectively. In PR #33562, these functions were readded and properly deprecated and will be removed in Salt 2017.7.0. This fix will be available in 2016.3.1. As a workaround, try
  ```python
  apache_module.enable{{ 'd' if grains.saltversioninfo == [2016, 3, 0] else '' }}
  ```

### New Features

**Thorium - Provisional New Reactor**

The 2016.3 release introduces the new Thorium Reactor. This reactor is an experimental new feature that implements a flow programming interface using the salt state system as the engine. This means that the Thorium reactor uses a classic state tree approach to create a reactor that can aggregate event data from multiple sources and make aggregate decisions about executing reactions.

This feature is both experimental and provisional, it may be removed and APIs may be changed. This system should be considered as ambitious as the Salt State System in that the scope of adding a programmable logic engine of this scale into the event systems is non trivial.

See [Thorium Complex Reactor](#).

**Improved Mac OS Support**

**Improved Solaris Support**

A lot of work was done to improve support for SmartOS. This work also resulted in improvements for Solaris and illumos as SmartOS.

• rewrite of vmadm module (SmartOS)
• rewrite of imgadm module (SmartOS)
• depreciation of virt module in favor of vmadm (SmartOS)
• implemented smartos state (SmartOS)
• improved zpool module add SmartOS, illumos and Solaris support
• improved zfs module add SmartOS, illumos and Solaris support
• implemented zpool state
• implemented zfs state implemented solaris_system system module to provide better Solaris support (PR #30519)
• other minor fixes to grains, localmod, ...
Tornado Transport

**Important:** The Tornado Transport wire protocol was changed in 2016.3, making it incompatible with 2015.8 (PR #29339).

Windows DSC Integration (Experimental)

Dimension Data Cloud Support

A SaltStack Cloud driver for Dimension Data Public Cloud, provides the driver functionality to service automation for any of the Dimension Data Public Cloud locations:

- Deploy new virtual machines
- List and query virtual machine images
- Destroy and query virtual machines

Documentation of the Dimension Data SaltStack integration is found on developer.dimensiondata.com

Minion Blackout

During a blackout, minions will not execute any remote execution commands, except for `saltutil.refresh_pillar`. Blackouts are enabled using a special pillar key, `minion_blackout` set to `True`. See Minion Blackout.

Splunk Returner

A Splunk Returner that uses HTTP Event Collector is now available (PR #30718).

SQLCipher Pillar Module

Support was added for retrieving pillar data via queries to SQLCipher databases (PR #29782).

Final Release of Debian 7 Packages

Regular security support for Debian 7 ended on April 25th, 2016. As a result, 2016.3.1 and 2015.8.10 will be the last Salt releases for which Debian 7 packages are created.

- Total PR References: 115
- Contributors: 36 (The-Loeki, abednarik, cachedout, cro, deniszh, dkruger, dmurphy18, eliasp, farcaller, galet, gtmanfred, hu-dabao, isbm, jacobhammons, jacobweinstock, jfindlay, justinta, kstreee, lubyou, markuskramerlgitt, meaksh, miihael, mzupan, nishigori, rallytime, s0undt3ch, skizunov, tankywoo, terminalmage, thatch45, theredcat, ticosax, tonybaloney, twangboy, vutny, whiteinge)

Known Issues

issue #36055: Salt Cloud events (salt/cloud) are not generated on the master event bus when provisioning cloud systems.

Bootstrap Issue #973: python-futures is not installed when installing from a git tag on RedHat-based distributions. Python futures is needed when running Salt with the TCP transport. This is fixed on the develop branch of the salt-bootstrap repo and the fix will be included in the upcoming release of salt-bootstrap, but is a bug in the bootstrap release that ships with this version of Salt. Please see the salt-bootstrap repo for more information on how to update your bootstrap version.

Known Issues

The Salt Minion does not clean up files in /tmp when rendering templates. This potentially results in either running out of disk space or running out of inodes. Please see issue #37541 for more information. This bug was fixed with PR #37540, which will be available in the 2016.3.5 release of Salt.

The release of the bootstrap-salt.sh script that is included with 2016.3.4 release has a bug in it that fails to install salt correctly for git installs using tags in the 2015.5 branch. This bug has not been fixed in the salt-bootstrap repository yet, but the previous bootstrap release (v2016.08.16) does not contain this bug.

Changes

- The `disk.wipe` execution module function has been modified so that it correctly wipes a disk.
- Add ability to clone from a snapshot to the VMWare salt-cloud driver.
- Add ability to specify disk backing mode in the VMWare salt cloud profile.

#### Security Fixes

- **CVE-2017-5192** local_batch client external authentication not respected
  The `LocalClient.cmd_batch()` method client does not accept `external_auth` credentials and so access to it from salt-api has been removed for now. This vulnerability allows code execution for already-authenticated users and is only in effect when running salt-api as the root user.

- **CVE-2017-5200** Salt-api allows arbitrary command execution on a salt-master via Salt’s ssh_client
  Users of Salt-API and salt-ssh could execute a command on the salt master via a hole when both systems were enabled.

  We recommend everyone on the 2016.3 branch upgrade to a patched release as soon as possible.

#### Improved Checksum Handling in `file.managed`, `archive.extracted` States

When the `source_hash` argument for these states refers to a file containing checksums, Salt now looks for checksums matching the name of the source URI, as well as the file being managed. Prior releases only looked for checksums matching the filename being managed. Additionally, a new argument (`source_hash_name`) has been added, which allows the user to disambiguate ambiguous matches when more than one matching checksum is found in the `source_hash` file.
A more detailed explanation of this functionality can be found in the file.managed documentation, in the section for the new source_hash_name argument.

28.2.42 Salt 2016.3.7 Release Notes

Version 2016.3.7 is a bugfix release for 2016.3.0.

Security Fix

CVE-2017-12791 Maliciously crafted minion IDs can cause unwanted directory traversals on the Salt-master

This release corrects a flaw in minion ID validation which could allow certain minions to authenticate to a master despite not having the correct credentials. To exploit the vulnerability, an attacker must create a salt-minion with an ID containing characters that will cause a directory traversal. Credit for discovering the security flaw goes to: Vernhk@qq.com

- 11d176ff1b Add release notes for 2016.3.7 release
- dc649ded51 Add clean_id function to salt.utils.verify.py

28.2.43 Salt 2016.3.8 Release Notes

Version 2016.3.8 is a bugfix release for 2016.3.0.

Security Fix

CVE-2017-14695 Directory traversal vulnerability in minion id validation in SaltStack. Allows remote minions with incorrect credentials to authenticate to a master via a crafted minion ID. Credit for discovering the security flaw goes to: Julian Brost (julian@0x4a42.net)

CVE-2017-14696 Remote Denial of Service with a specially crafted authentication request. Credit for discovering the security flaw goes to: Julian Brost (julian@0x4a42.net)

- 0425defe84 Do not allow IDs with null bytes in decoded payloads
- 31b38f50eb Don’t allow path separators in minion ID

28.2.44 Salt 2016.3.9 Release Notes

Version 2016.3.9 is a bugfix release for 2016.3.0.

Master Changes

The following options have been added to the master config file:

- **allow_minion_key_revoke** - This option controls whether a minion can request that the master revoke its key. When **True**, a minion can request a key revocation and the master will comply. If it is **False**, the key will not be revoked by the master.
- **require_minion_sign_messages** - This requires that minions cryptographically sign the messages they publish to the master. If minions are not signing, then log this information at loglevel **INFO** and drop the message without acting on it.
- **drop_messages_signature_fail** - Drop messages from minions when their signatures do not validate. Note that when this option is **False** but **require_minion_sign_messages** is **True**, minions MUST sign their messages, but the validity of their signatures is ignored.
- **minion_sign_messages** - Causes the minion to cryptographically sign the payload of messages it places on the event bus for the master. The payloads are signed with the minion’s private key so the master can verify the signature with its public key.

The 2015.8.0 feature release of Salt contains several major new features. As usual the release notes are not exhaustive and primarily include the most notable additions and improvements. Hundreds of bugs have been fixed and many modules have been substantially updated and added.

**New SaltStack Installation Repositories**

SaltStack now provides installation repositories for several platforms, with more to come. See the following links for instructions:

- Red Hat / CentOS 5, 6, 7
- Debian 8
- Windows

**Send Event on State Completion**

A `fire_event` global state keyword argument was added that allows any state to send an event upon completion. Useful for custom progress bars and checking in on long state runs. See `fire_event`.

**ZeroMQ socket monitoring**

If `zmq_monitor` is enabled, log all ZMQ events for socket monitoring purposes. Verbose, but useful.

**SPM (Salt Package Manager)**

Allows Salt formulas to be packaged for ease of deployment. See `spm`.

**Note:** The `spm` executable was not included in the Debian or Ubuntu packages for the 2015.8.0 or the 2015.8.1 releases. This executable will be included in an upcoming release. As a workaround, copy the SPM script from the salt library installation into `/usr/local/bin` or your local equivalent.
Specify a Single Environment for Top Files

A new `default_top` option was added to load the state top file from a single, specific environment, rather than merging top data across all environments. Additionally, new `top_file_merge_strategy` and `env_order` options were added for more control over top file merging. See `The Top File`.

Tornado TCP Transport

Implemented a pure-TCP transport, in addition to ZeroMQ and RAET. The new transport uses Tornado, which allows Salt to use a standardized set of libraries for asynchronous behavior, which should greatly improve reliability and performance.

Note: Tornado is considered expiermental in this release. The following known issues were being investigated at the time of release:

- TCP tests show performance degradation over time (issue #26051)
- TCP transport stacktrace on windows minion: Future exception was never retrieved (issue #25718)
- [freebsd] TCP transport not working in 2015.8.0rc3 (issue #26364)

Proxy Minion Enhancements

Proxy Minions have undergone a significant overhaul in 2015.8, see Proxy Minion Enhancements.

Engines

Salt engines are long-running, external processes that leverage Salt. See `Salt Engines`.

Core Changes

- Add system version info to `versions_report`, which appears in both `salt --versions-report` and `salt '*' test.versions_report`. Also added is an alias `test.versions` to `test.versions_report`. (issue #21906)
- Add colorized console logging support. This is activated by using `%(colorlevel)s`, `%(colorname)s`, `%(colorprocess)s`, and `%(colormsg)s` in `log_fmt_console` in the config file for any of `salt-master`, `salt-minion`, and `salt-cloud`.

Git Pillar

The git external pillar has been rewritten to bring it up to feature parity with `gitfs`. Support for `pygit2` has been added, bringing with it the ability to access authenticated repositories.

Using the new features will require updates to the git ext_pillar configuration, further details can be found in the `pillar.git_pillar` docs.
Salt Cloud Improvements

- Pricing data from several cloud providers (GCE, DigitalOcean, SoftLayer_HW, EC2)
- All cloud providers now use standardized bootstrapping code.
- Modified the Linode Salt Cloud driver to use Linode’s native API instead of depending on apache-libcloud or linode-python.

Salt Cloud Changes

- Changed the default behavior of rename_on_destroy to be set to True in the EC2 and AWS drivers.
- Changed the default behavior of the EC2 and AWS drivers to always check for duplicate names of VMs before trying to create a new VM. Will now throw an error similarly to other salt-cloud drivers when trying to create a VM of the same name, even if the VM is in the terminated state.
- When querying for VMs in digital_ocean.py, the number of VMs to include in a page was changed from 20 (default) to 200 to reduce the number of API calls to Digital Ocean.Ocean.

State and Execution Module Improvements

- New and improved Docker state and execution modules (state and execution module).

Git State and Execution Modules Rewritten

The git state and execution modules have gone through an extensive overhaul.

Changes in the git.latest State

- The branch argument has been added, allowing for a custom branch name to be used in the local checkout maintained by the git.latest state. This can be helpful in avoiding ambiguous refs in the local checkout when a tag is used as the rev argument. If no branch is specified, then the state uses the value of rev as the branch name.
- The always_fetch argument no longer has any effect, and will be removed in a future release. The state now detects whether or not a fetch is needed based on comparisons made between the local and remote repositories.
- The force_fetch argument has been added to force a fetch if the fetch is not a fast-forward (for instance, if someone has done a reset and force-pushed to the remote repository).
- The remote_name argument has been deprecated and renamed to remote.
- The force argument has been deprecated and renamed to force_clone to reduce ambiguity with the other "force" arguments.
- Using SHA1 hashes (full or shortened) in the rev argument is now properly supported.
- Non-fast-forward merges are now detected before the repository is updated, and the state will not update the repository if the change is not a fast-forward. Non-fast-forward updates must be overridden with the force_reset argument. If force_reset is set to True, the state will only reset the repository if it cannot be fast-forwarded. This is in contrast to the earlier behavior, in which a hard-reset would be performed every time the state was run if force_reset was set to True.
- A git pull is no longer performed by this state, dropped in favor of a fetch-and-merge (or fetch-and-reset) workflow.
**git.config_unset state added**

This state allows for configuration values (or entire keys) to be unset. See [here](#) for more information and example SLS.

**git.config State Renamed to git.config_set**

To reduce confusion after the addition of `git.config_unset`, the `git.config` state has been renamed to `git.config_set`. The old `config.get` name will still work for a couple releases, allowing time for SLS files to be updated. In addition, this state now supports managing multivar git configuration values. See [here](#) for more information and example SLS.

**Initial Support for Git Worktrees in Execution Module**

Several functions have been added to the execution module to manage worktrees (a feature new to Git 2.5.0). State support does not exist yet, but will follow soon.

**New Functions in Git Execution Module**

- `git.config_get_regexp`
- `git.config_unset`
- `git.is_worktree`
- `git.list_branches`
- `git.list_tags`
- `git.list_worktrees`
- `git.merge_base`
- `git.merge_tree`
- `git.rev_parse`
- `git.version`
- `git.worktree_rm`
- `git.worktree_add`
- `git.worktree_prune`

**Changes to Functions in Git Execution Module**

**git.add**

- `--verbose` is now implied when running the `git add` command, to provide a list of the files added in the return data.
git.archive

- Now returns True when the git archive command was successful, and otherwise raises an error.
- The overwrite argument has been added to prevent an existing archive from being overwritten by this function.
- The fmt argument has been deprecated and renamed to format.
- Trailing slash no longer implied in prefix argument, must be included if this argument is passed.

git.checkout

- The rev argument is now optional when using -b or -B in opts, allowing for a branch to be created (or reset) using HEAD as the starting point.

git.clone

- The name argument has been added to specify the name of the directory in which to clone the repository. If this option is specified, then the clone will be made within the directory specified by the cwd, instead of at that location.
- The repository argument has been deprecated and renamed to url.

git.config_get

- The setting_name argument has been deprecated and renamed to key.
- The global argument has been added, to query the global git configuration
- The all argument has been added to return a list of all values for the specified key, allowing for all values in a multivar to be returned.
- The cwd argument is now optional if global is set to True

git.config_set

- The value(s) of the key being set are now returned
- The setting_name argument has been deprecated and renamed to key.
- The setting_value argument has been deprecated and renamed to value.
- The is_global argument has been deprecated and renamed to global.
- The multivar argument has been added to specify a list of values to set for the specified key. The value argument is not compatible with multivar.
- The add argument has been added to add a value to a key (this essentially just adds an --add to the git config command that is run to set the value).
**git.fetch**

- The `force` argument has been added to force the fetch when it is not a fast-forward. This could have been achieved in previous Salt versions by including `--force` in the `opts` argument, this argument is just for convenience and to match the usage of other functions with `force` arguments.
- The `refspecs` argument has been added to allow for one or more refsdspecs to be provided which override the one(s) specified by the `remote.remote_name.fetch` git configuration option.

**git.ls_remote**

- The `repository` argument has been deprecated and renamed to `remote`.
- The `branch` argument has been deprecated and renamed to `ref`.
- The `opts` argument has been added to allow for additional CLI options to be passed to the `git ls-remote` command.

**git.merge**

- The `branch` argument has been deprecated and renamed to `rev`.

**git.status**

- Return data has been changed from a list of lists to a dictionary containing lists of files in the modified, added, deleted, and untracked states.

**git.submodule**

- Added the `command` argument to allow for operations other than `update` to be run on submodules, and deprecated the `init` argument. To do a submodule update with `init=True` moving forward, use `command=update opts='--init'`.
- OpenStack Glance API V2 execution module
- Amazon VPC state module
- RallyDev execution module
- BambooHR execution module
- Stormpath execution, state modules
- Remove unused argument `timeout` in `jboss7.status`.
- Deprecate `enabled` argument in `pkgrepo.managed` in favor of `disabled`.
- Archive module changes: In the `archive.tar` and `archive.cmd_unzip` module functions, remove the arbitrary prefixing of the options string with `-`. An options string beginning with a `--long-option`, would have uncharacteristically needed its first `-` removed under the former scheme. Also, tar will parse its options differently if short options are used with or without a preceding `-`, so it is better to not confuse the user into thinking they're using the non-`-` format, when really they are using the with-`-` format.
- Added `__states__` to state modules, for cross-calling states. This enables using existing states when writing custom states. See `cross calling states`. 
Windows Improvements

- Enhanced the windows minion silent installation with command line parameters to configure the salt master and minion name. See Silent Installer Options.
- Improved user management with additional capabilities in the user module for Windows.
- Improved patch management with a new module for managing windows updates (win_wua).
- Turned on multi-processing by default for windows in minion configuration.

Windows Software Repo Changes

A next-generation (ng) windows software repo is available for 2015.8.0 and later minions. When using this new repository, the repo cache is compiled on the Salt Minion, which enables pillar, grains and other things to be available during compilation time.

See the Windows Software Repository documentation for more information.

Changes to legacy Windows repository

If you have pre 2015.8 Windows minions connecting to your 2015.8 Salt master, you can continue to use the legacy Windows repository for these Salt minions.

If you were previously using this repository and have customized settings, be aware that several config options have been renamed to make their naming more consistent.

See the Windows Software Repository documentation for more information.

Win System Module

The unit of the timeout parameter in the system.halt, system.poweroff, system.reboot, and system.shutdown functions has been changed from seconds to minutes in order to be consistent with the linux timeout setting. (issue #24411) Optionally, the unit can be reverted to seconds by specifying in_seconds=True.

Other Improvements

- Sanitize sensitive fields in http.query
- Allow authorization to be read from Django and eauth
- Add templating to SMTP returner
- New REST module for SDB
- Added rest_timeout config option and timeout argument to jobs api call
- Provide config options for Raet lane and road buffer count. (Useful for BSD kernels)
- Implemented ZeroMQ socket monitor for master and minion
- Add end time to master job cache for jobs (optional, off by default)
- Tornado is now the default backend for http.request
- Support pillarenv selection as it’s done for saltenv
- salt was updated to use python-crypto version 2.6.1, which removes the dependency on python-m2crypto.
Deprecations

- The `digital_ocean.py` Salt Cloud driver was removed in favor of the `digital_ocean_v2.py` driver as DigitalOcean has removed support for APIv1. The `digital_ocean_v2.py` was renamed to `digital_ocean.py` and supports DigitalOcean's APIv2.
- The `vsphere.py` Salt Cloud driver has been deprecated in favor of the `vmware.py` driver.
- The `openstack.py` Salt Cloud driver has been deprecated in favor of the `nova.py` driver.
- The use of `provider` in Salt Cloud provider files to define cloud drivers has been deprecated in favor of using `driver`. Both terms will work until the 2017.7.0 release of Salt. Example provider file:

```yaml
my-ec2-cloud-config:
  id: 'HJGRYCILJLKJYG'
  key: 'kdjgfsgm;woormgl/aserigksjdhasdfgn'
  private_key: /etc/salt/my_test_key.pem
  keyname: my_test_key
  securitygroup: default
  driver: ec2
```

- The use of `lock` has been deprecated and from `salt.utils.fopen`, `salt.utils.flopen` should be used instead.
- The following args have been deprecated from the `rabbitmq_vhost.present` state: `user`, `owner`, `conf`, `write`, `read`, and `runas`.
- The use of `runas` has been deprecated from the `rabbitmq_vhost.absent` state.
- Support for `output` in `mine.get` was removed. `--out` should be used instead.
- The use of `delim` was removed from the following functions in the match execution module: `pillar_pcre`, `pillar`, `grain_pcre`,

Security Fixes

CVE-2015-6918 - Git modules leaking HTTPS auth credentials to debug log

Updated the Git state and execution modules to no longer display HTTPS basic authentication credentials in log level debug output on the Salt master. These credentials are now replaced with REDACTED in the debug output. Thanks to Andreas Stieger <asteiger@suse.com> for bringing this to our attention.

Major Bug Fixes

- Fixed minion failover to next master on DNS errors (issue #21082)

Security Fixes

CVE-2015-6941 The Windows `user` module and `salt-cloud` display passwords in log when log level is set to debug or more verbose.

For the Windows `user` module, the password is now replaced with the string XXX-REDACTED-XXX.

For `salt-cloud`, debug logging no longer displays `win_password` and `sudo_password` authentication credentials.

CVE-2015-6918 Git state/execution modules log HTTPS auth credentials when log level is set to debug or more verbose.

These credentials are now replaced with REDACTED in the debug output. Thanks to Andreas Stieger <asteiger@suse.com> for bringing this to our attention.

Major Bug Fixes

- Add support for `spm.d/*.conf` configuration of SPM (issue #27010)
- Fix proxy grains breakage for non-proxy minions (issue #27039)
- Fix global key management for git state
- Fix passing http auth to `util.http` from `state.file` (issue #21917)
- Fix multiprocessing: `True` in windows (on by default)
- Add `pkg.info` to pkg modules
- Fix name of serial grain (this was accidentally renamed in 2015.8.0)
- Merge config values from `master.d/minion.d` conf files (rather than flat update)
- Clean grains cache on grains sync (issue #19853)
- Remove streamed response for fileclient to avoid HTTP redirection problems (issue #27093)
- Fixed incorrect warning about osrelease grain (issue #27065)
- Fix authentication via Salt-API with tokens (issue #27270)
- Fix winrepo downloads from https locations (issue #27081)
- Fix potential error with salt-call as non-root user (issue #26889)
- Fix global minion provider overrides (issue #27209)
- Fix backward compatibility issues for pecl modules
- Fix Windows uninstaller to only remove `.bin, salt*, nssm.exe, uninist.exe` (issue #27383)
- Fix misc issues with mongo returner.
- Add sudo option to cloud config files (issue #27398)
- Fix regression in RunnerClient argument handling (issue #25107)
- Fix dockerng.running replacing creation hostconfig with runtime hostconfig (issue #27265)
- Fix dockerng.running replacing creation hostconfig with runtime hostconfig (issue #27265)
- Increased performance on boto asg/elb states due to __states__ integration
- Windows minion no longer requires powershell to restart (issue #26629)
- Fix x509 module to support recent versions of OpenSSL (issue #27326)
• Some issues with proxy minions were corrected.

Known Issues

• Proxy minions currently cannot execute a highstate because of the way the proxymodule is being loaded internally. This will be fixed in a future release.

28.2.47 Salt 2015.8.10 Release Notes

Version 2015.8.10 is a bugfix release for 2015.8.0.

This release includes fixes for two issues discovered in 2015.8.9:

- Pip state broken in 2015.8.9 with pip <6.0 (issue #33376)
- Fix traceback in logging for config validation (PR #33386)

Final Release of Debian 7 Packages

Regular security support for Debian 7 ended on April 25th 2016. As a result, 2016.3.1 and 2015.8.10 will be the last Salt releases for which Debian 7 packages are created.

Important Post-Upgrade Instructions for Linux Mint

As a result of some upstream changes, the os grain on Mint Linux is now being detected as LinuxMint (issue #33295). Run the following command after you upgrade to 2015.8.10 to reset the os grain to Mint and the os_family grain to Debian:

```
salt -G 'os:LinuxMint' grains.setvals "{'os': 'Mint', 'os_family': 'Debian'}"
```

Ubuntu 16.04 Packages

SaltStack is now providing official Salt 2015.8 packages for Ubuntu 16.04.

Returner Changes

- Any returner which implements a `save_load` function is now required to accept a `minions` keyword argument. All returners which ship with Salt have been modified to do so.

New Master Configuration Parameter

- `rotate_aes_key`: if `True`, causes Salt to generate a new AES key whenever a minion key is deleted. This eliminates the chance that a deleted minion could continue to eavesdrop on communications with the master if it continues to run after its key is deleted.

28.2.50 Salt 2015.8.13 Release Notes

Version 2015.8.13 is a bugfix release for 2015.8.0.

Security Fixes

CVE-2017-5192 local_batch client external authentication not respected

The LocalClient.cmd_batch() method client does not accept external_auth credentials and so access to it from salt-api has been removed for now. This vulnerability allows code execution for already-authenticated users and is only in effect when running salt-api as the root user.

CVE-2017-5200 Salt-api allows arbitrary command execution on a salt-master via Salt’s ssh_client

Users of Salt-API and salt-ssh could execute a command on the salt master via a hole when both systems were enabled.

We recommend everyone on the 2015.8 branch upgrade to a patched release as soon as possible.

#### Security Fix

CVE-2015-8034 Saving `state.sls` cache data to disk with insecure permissions

This affects users of the `state.sls` function. The state run cache on the minion was being created with incorrect permissions. This file could potentially contain sensitive data that was inserted via jinja into the state SLS files. The permissions for this file are now being set correctly. Thanks to zmalone for bringing this issue to our attention.

Known Issues

- `_in` requisites (issue #30820)

  This issue affects all users targeting an explicit `- name: <name>` with a `_in` requisite (such as `watch_in` or `require_in`). If you are not using explicit `- name: <name>` arguments, are targeting with the state ID instead of the name, or are not using `_in` requisites, then you should be safe to upgrade to 2015.8.4.

  This issue is resolved in the 2015.8.5 release.

Security Fix

CVE-2016-1866 Improper handling of clear messages on the minion, which could result in executing commands not sent by the master.

This issue affects only the 2015.8.x releases of Salt. In order for an attacker to use this attack vector, they would have to execute a successful attack on an existing TCP connection between minion and master on the pub port. It does not allow an external attacker to obtain the shared secret or decrypt any encrypted traffic between minion and master. Thank you to Sebastian Krahmer <krahmer@suse.com> for bringing this issue to our attention.

We recommend everyone upgrade to 2015.8.4 as soon as possible.

Core Changes

- Support for IAM roles added to S3 module

- Added option `mock=True` for `state.sls` and `state.highstate`. This allows the state compiler to process sls data in a state run without actually calling the state functions, thus providing feedback on the validity of the arguments used for the functions beyond the preprocessing validation provided by `state.show_sls` (issue #30118 and issue #30189).

```bash
salt '*' state.sls core,edit.vim mock=True
salt '*' state.highstate mock=True
salt '*' state.apply edit.vim mock=True
```

### 28.2.54 Salt 2015.8.5 Release Notes

Version 2015.8.5 is a bugfix release for 2015.8.0.

**Important:** About this Release Salt 2015.8.5 is identical to the 2015.8.4 release with the addition of a fix for issue #30820, fixed by PR #30833. See [here](#) for the 2015.8.4 release notes.

#### Known Issue in boto_* execution modules

This release contains an issue that causes the boto_* execution modules to display a __salt__ not defined error (issue #30300). This issue will be fixed in an upcoming release, but can be manually resolved by completing the following:

1. Download the boto_* execution modules that you would like to update from the 2015.8 branch of Salt. A complete list of affected modules with the specific changes is available in `pull'30867`. A simple way to get the updated modules is to download a zip file of the 2015.8 branch from GitHub. The updated modules are in the `salt\modules` directory.
2. Place the boto_* modules into `salt://_modules`.
3. Run the following command to sync these modules to all Salt minions:

   ```bash
   salt '*' saltutil.sync_modules
   ```

### 28.2.55 Salt 2015.8.7 Release Notes

Version 2015.8.7 is a bugfix release for 2015.8.0.

**Note:** Salt 2015.8.4, 2015.8.5, and 2015.8.7 were all released within a short period due to regressions found soon after the releases of 2015.8.4 and 2015.8.5. See [here](#) for the 2015.8.4 release notes, and [here](#) for the 2015.8.5 release notes.

Change to Epoch Support for YUM/DNF

For `pkg.installed` states, on Linux distributions which use yum/dnf, packages which have a non-zero epoch in the version number now require this epoch to be included when specifying an exact version for a package. For example:

```yaml
vim-enhanced:
  pkg.installed:
    - version: 2:7.4.160-1.el7
```

The `pkg.latest_version` and `pkg.list_repo_pkgs` functions can be used to get the correct version string to use, as they will now contain the epoch when it is non-zero.

28.2.56 Salt 2015.8.8 Release Notes

Version 2015.8.8 is a bugfix release for 2015.8.0.

Important: Version 2015.8.8.2 was released shortly after 2015.8.8 to fix several known issues. If you installed 2015.8.8 before 03/30/2016, you likely have installed 2015.8.8 and can optionally upgrade (find out which version you have installed using salt --version).

Security Fix

CVE-2016-3176 Insecure configuration of PAM external authentication service

This issue affects all Salt versions prior to 2015.8.8/2015.5.10 when PAM external authentication is enabled. This issue involves passing an alternative PAM authentication service with a command that is sent to LocalClient, enabling the attacker to bypass the configured authentication service. Thank you to Dylan Frese <dmfrese@gmail.com> for bringing this issue to our attention.

This update defines the PAM eAuth service that users authenticate against in the Salt Master configuration.

Read Before Upgrading Debian 7 (Wheezy) from 2015.8.7 to 2015.8.8

Before you upgrade from 2015.8.7 on Debian 7, you must run the following commands to remove previous packages:
Note that `python-pycrypto` will likely remove `python-apache-libcloud`, so the second command might not be necessary. These have been replaced by `python-crypto` and `python-libcloud` with ~bpo70+1 moniker.

**Read Before Upgrading Debian 8 (Jessie) from Salt Versions Earlier than 2015.8.4**

Salt `systemd` service files are missing the following statement in these versions:

```
[Service]
KillMode=process
```

This statement must be added to successfully upgrade on these earlier versions of Salt.
